IBM API Connect 10.0.6.0

Tables of Contents

API Connect overview

IBM® API Connect is an integrated API management offering, with capabilities and tooling for all phases of the API lifecycle. IBM API Connect 10.0.6.0 is the latest Continuous Delivery (CD) release, following-on from the IBM API Connect 10.0.5.3 Long Term Support (LTS) release. If you're looking for a different version of API Connect, use the Change version list in the navigation pane to select the version that you require.

Key steps of the API lifecycle include create, secure, manage, socialize, monetize, and analyze. IBM API Connect Version 10 delivers enhanced capabilities for the market-leading IBM API management solution. In addition to the ability to deploy in complex, multi-cloud topologies, this version provides enhanced experiences for developers and cloud administrators in your organization.

IBM API Connect has two main focuses: the first is providing best in class API Management tooling, and the second is having a cloud native solution. This allows users to create, manage, and secure applications that are deployed across a variety of on-premises and cloud environments.

The following table explains the key phases in the API lifecycle in more detail.

Table 1. Key phases of the API lifecycle

Lifecycle Phase	Description
Create	Develop and write API definitions from an API development environment, eventually bundling these APIs into consumable products, and deploying them to production environments. For tutorials, walk-throughs, and in-depth guides for building, testing, and deploying APIs and Products in API Connect, see Tutorials, and Developing your APIs and applications.
Secure	Leverage the best-in-class API Gateway, gateway policies, and more, to manage access to your APIs and back-end systems. To learn more about adding security to your API, see *Enforcing security requirements on an API* for the OpenAPI version that you are working with: • OpenAPI 2.0: Enforcing security requirements on an API • OpenAPI 3.0: Enforcing security requirements on an API To learn more about how to add API Gateway policies to your API, see API policies and logic constructs.
Manage	Governance structures are built in to the entire API lifecycle, from managing the view/edit permissions of APIs and Products being deployed, to managing what application developers can view and subscribe to when APIs are deployed. To understand and leverage API Connect management and governance controls along the API lifecycle, see Managing your APIs.
Socialize	API Connect comes with an advanced Developer Portal that streamlines the onboarding process of application developers, and can be completely customized to an organization's marketing standards. To understand more about using the Developer Portal, see Developer Portal: Socialize your APIs.
Monetize	Bundle APIs into Products and Plans with monetization schemes that are built into those Plans, thereby opening up digital revenue streams. To understand more about how to leverage monetization strategies in API Connect, see Monetizing your Products.
Analyze	Developers and Product Managers alike are given the tooling in API Connect to understand their API traffic patterns, latency, consumption, and more to make data driven insights into their API initiatives. To learn more about how to leverage API Connect analytics tooling, see API Analytics.

API Connect has four major components: API Manager, Analytics, Developer Portal, and Gateway. These four components can be deployed in a variety of hybrid and multi-cloud topologies. The API Connect infrastructure can either be deployed and managed by an IBM team in an IBM Cloud environment, or it can be deployed and managed by the customers in their own dedicated environment or third-party cloud. There is also the option for having hybrid scenarios, for example, with the API Connect Reserved Instance Offering, users are able to have their API Manager and Developer Portal running in the IBM Cloud, but then place remote gateways next to their back-end services.

Configuration of customer deployed API Connect clouds is done through the Cloud Manager. For in-depth guides and instructions see Configuring and managing your server environment.

For information about the API Connect components that provide these capabilities, and details about the strategy for packaging and publishing APIs for use by API consumers, see:

- Packaging strategy and terminology in API Connect
- API Connect components

Note: For a comprehensive technical guide to best practices, considerations, and deployment options for API Connect, see the API Connect v10.x Whitepaper.

What's new in the latest release (Version 10.0.6.0)

Find out about the newest features and the latest updates in API Connect.

IBM® API Connect 10.0.6.0 is the latest Continuous Delivery (CD) release, following-on from the IBM API Connect 10.0.5.3 Long Term Support (LTS) release. IBM API Connect 10.0.6.0 CD includes the features that were previously delivered in the releases of 10.0.2.0 CD through 10.0.5.3 LTS, along with the following enhancements.

Product files and release notes

- Access the latest files from IBM Fix Central by searching for the API Connect product and your installed version. Full installation files for IBM API Connect can be downloaded from Passport Advantage.
- For details on the specific APARs that are included in this release, links to downloads, and additional blogs and conference notices, see the IBM API Connect 10.0.6.0 Support Announcement.

For full details of the enhancements, see the following sections.

What's new for Developers

New API governance add-on service
: API governance is an optional add-on to IBM API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process. For more information, see Validating an API document by using API governance.

Updated schema editor design for API definitions
: The Definitions section of the API editor in the API Manager and API Designer UIs is updated to improve the user experience when creating and editing schema definitions. For more information, see Defining schemas for an API.

What's new for API product managers

New API governance add-on service
: API governance is an optional add-on to IBM API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process. For more information, see Configuring API governance in the Cloud Manager, and Configuring API governance in the API Manager.

Analytics long-term data
: By default analytics event data is retained for up to 30 or 90 days, dependent on the deployment profile. With the new long-term data feature, event data is summarized and added to a new summary data index that has a 1 year default retention period. The summary data allows the product manager to view long-term trends. To view the summary data, the UIs have a new Reports tab, see Analytics dashboards. New REST API and toolkit CLI operations are also provided to access the summary data shown in the UI Reports tab.
: Note: If you are upgrading from v10.0.5, the summary data is gathered for all new API events after upgrade to 10.0.6 is complete. Existing API event data from 10.0.5 is not added to the summary data index.

Gateway policy titles, names, and types included in assembly latency visualization
: DataPower® v10.5.1.x only: To help identify where delays in API processing occur, when you click an API event in the analytics UI Discover view, the title, name, and type of gateway policies are included.

What's new for Developer Portal site administrators

New Developer Portal CLI product commands
: The new **product** commands allow you to update the images, attachments, tags and categories for products on your Developer Portal. In IBM API Connect 10.0.6.0 the newly added **product** commands are:

  - `product:add-attachment`
  - `product:set-icon`
  - `product:add-tag`

  For more information about the **product** commands and how to use them, see Using the product commands.

New Developer Portal CLI api commands
: The new **api** commands allow you to update the images, attachments, tags, and categories for products on your Developer Portal. In IBM API Connect 10.0.6.0 the newly added **api** commands are:

  - `api:add-attachment`
  - `api:set-icon`
  - `api:add-tag`

  For more information about the **api** commands and how to use them, see Using the api commands.

New Developer Portal CLI site command
: The new `site:login-link` command is now available for use through the IBM API Connect toolkit CLI. By running this command, you receive a one-time login link for the Developer Portal site admin account.

  For more information about the **site** commands and how to use them, see Using the site commands.

New flag for the modules and themes commands in Developer Portal CLI
: The new `--custom` flag added to your `modules:list` and `themes:list` commands helps you find what modules and themes have been installed on your Developer Portal site after an install.

  For more information about the `--custom` flag, see Using the themes commands and Using the modules commands.

What's new for DevOps

Migrate v5-compatible APIs to the DataPower API Gateway
: If your deployment includes v5-compatible APIs, they can only be used with the DataPower v5-compatible Gateway (also known as the v5c gateway). To use the v5-compatible APIs with the DataPower API Gateway, you must migrate the APIs to the newer format. For more information, see Migrating v5-compatible APIs to API Gateway.

Direct upgrades are only supported from API Connect 10.0.5.x
: API Connect 10.0.6.0 supports a direct upgrade only from versions of 10.0.5.x. If your deployment is using an older release of API Connect, you must upgrade to a 10.0.5.x release before attempting to upgrade to 10.0.6.0. For more information about upgrading, see:

  - Upgrading on Kubernetes
  - Upgrading on OpenShift and Cloud Pak for Integration
  - Upgrading on VMware

Cert-manager upgraded to version 1.9.1
: API Connect 10.0.6.0 uses cert-manager 1.9.1. If your environment requires a manual installation or upgrade of cert-manager, the instructions are included as part of the API Connect installation and upgrade procedures.

(Kubernetes, Red Hat OpenShift) Improved platform health status monitoring using Kubernetes events
: A new feature is enabled in the IBM `APIConnect` operator on Kubernetes and Red Hat OpenShift to generate CR events whenever there is a change in the top-level CR (APIConnectCluster) or subsystem CRs (`ManagementCluster`, `GatewayCluster`, `AnalyticsCluster`, `PortalCluster`) status conditions. Along with CR status conditions, you can monitor these events by using any third-party alerting system.
  For more information, see Monitoring platform health using Kubernetes events or Monitoring platform health on Red Hat OpenShift using Kubernetes events.

Red Hat OpenShift-based deployments now manage foundational services through the API Connect operands
: In previous releases of API Connect, a deployment on Red Hat OpenShift (including as a capability in Cloud Pak for Integration) managed the use of IBM Cloud Pak foundational services through dependencies that are enforced by OLM at the operator level. In API Connect 10.0.6.0, the dependency on foundational services is no longer managed at the operator level by OLM, but is instead handled at the operand level by the API Connect operator. This change provides more flexibility going forward by allowing the APIC operator to enforce the dependency only on the operands that actually require it.
  This change applies only to new installations and upgrades from 10.0.5.3 (or later). For more information, see the appropriate installation instructions for your Red Hat OpenShift environment.

Upgrade checks for Postgres leader
: The upgrade process on all platforms now includes checks for the condition where the original Postgres leader pod is no longer the leader, or if there is no Postgres leader pod. In both cases extra steps are required to complete the management subsystem upgrade: Postgres failover steps.

JWT security between gateway and analytics
: Network communication between the gateway and analytics subsystems can now be secured with JWT instead of mTLS. For more information, see Enable JWT security instead of mTLS.

What's new for security practitioners

New API governance optional add-on service
: API governance is an optional add-on to IBM API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process. For information about how to enable this add-on, see Enabling API governance on Kubernetes, and Enabling API governance on VMware.

Language versions offered by API Connect

API Connect is offered in several languages, as enabled by the operating platform on which the product is installed.

Note: When API Connect is deployed as a Cloud Pak for Integration capability, it is translated to the same set of languages as the Cloud Pak for Integration product.

Known limitations

This page describes the known limitations for API Connect 10.0.6.0 and later.

Note: The limitations that are documented on this page will be removed as they are addressed in the IBM® API Connect product. For the most up-to-date list of product limitations, visit the English version of this page.

Limitations to the updated schema editor for API definitions

The Definitions section of the API editor for the API Manager and API Designer UIs was updated in API Connect 10.0.6.0. However, the following limitations apply:

- You cannot rename the top level schema.
- The top level schema doesn't display the `minProperties`, `maxProperties`, and `enum` properties for the definition.
- The `OneOf`, `AllOf`, and `Enum` schema structures aren't handled properly by the UI.

You can work around these issues by editing the source YAML of your API document.

API Designer with Local Test Environment (LTE) fails to log in using https://localhost with the error message "Incorrect username, password, or credentials"

If you use the API Designer with the Local Test Environment and attempt to log in using the localhost, the login fails. You can work around the issue by configuring API Designer credentials to with the local host. Complete the following steps:

1. Download and extract API Designer, then install the credentials file as explained in steps 1, 2, and 6 in Installing the toolkit.
2. Edit the designer_credentials.json file and configure the following settings:
   - `"endpoint": "https://localhost"`
   - `"manager_endpoint": "https://localhost/manager"`
   - `"client_id": Client Id`
     The client ID displays on the console when you start the LTE platform-apic-lte. For more information, see Testing an API with the Local Test Environment.
   - `"client_secret": Client Secret`
     The client secret displays on the console when you start the LTE platform-apic-lte. For more information, see Testing an API with the Local Test Environment.
3. Start API Designer and log in with the LTE using https://localhost as the Host URL (the management endpoint).

Gateway timeout when validating very large API documents with the API governance service

If you are validating very large API documents (5 MB, or 100,000 lines, or more), with all of the rulesets selected by default, the API governance service is likely to take longer than 60 seconds to run, and this can result in an HTTP 504 gateway timeout. To workaround this issue, you can take the following actions:

- Validate the API document by using only one ruleset at a time.
- Increase your component deployment profile, for example to a three replica profile. For more information, see Planning your deployment topology on Kubernetes, OpenShift, and IBM Cloud Pak for Integration, and Planning your deployment topology and profiles on VMware.

New ibm-apiconnect-operator pod fails to start due existing terminating ibm-apiconnect-operator pod holding lock

The IBM APIConnect operator uses leader election (leader-for-life) to ensure that only one operator/controller pod is running/active at a time. This relies on Kubernetes garbage collection to clean up the lock when the old operator pod is deleted. The new ibm-apiconnect operator pod fails to start if an existing terminating ibm-apiconnect operator pod is still holding the lock.

If you suspect you are encountering this issue, verify it by running the following command:

```
kubectl -n <namespace> logs <new-ibm-apiconnect-pod-name> | grep "LockOwner"
```

If the lock is the problem, the log contains a message similar to the following example:

```
existing lock","LockOwner":"ibm-apiconnect-xxxxxx held by
terminating pod
```

Resolve the issue by completing one of the following options:

- Force delete the terminating pod by running the following command:

  ```
  kubectl -n <namespace> delete pod <terminating-ibm-apiconnect-pod-name> --force --grace-period=0
  ```

  Kubernetes deletes the lock when the pod is deleted.

- Remove the lock manually by running the following command:

  ```
  kubectl delete cm ibm-apiconnect-lock
  ```

API Designer might hang while activating a large imported API

When you import a large API using API Designer and attempt to activate the API in the import wizard, the process might hang. If you encounter this issue, you can work around the problem by completing the following steps:

1. On your local file system, locate the autoproduct file called API-NAME-auto-product_API-VERSION.yaml.
2. Delete the file.
3. In API Designer, edit the newly imported API and activate it by clicking the Online toggle.

In general, it is best practice to activate an API using the Online toggle or by publishing the API with the Publish option.

API Designer on Windows: APIs that use WSDL might encounter errors, or fail to activate, publish, or update.

If you activate, publish, or update a REST or SOAP API that uses a WSDL file, the operation might fail and never complete. Work around the issue by using the autopublish API feature in the API editor.

Permission restrictions in the API Designer UI

The API Designer UI currently has the following permission restrictions:

- Developers that have been given only View permissions cannot see the Test tab in the API editor. For developers to be able to see the Test tab, they must be given a different permission level. For information about the default permission levels available, see API Connect user roles.
- Users with API-Drafts permissions, but who don't have any Sandbox Catalog permissions, cannot see the Test preferences in the Sandbox Catalog. For these users to be able to see the Test preferences, they must be given the Developer or Administrator role on the Sandbox Catalog.

Deleted security requirements might remain in the API source

Security requirements that are deleted from APIs in the API Designer and API Manager UIs, might still remain in the source. To work around this issue, click the Source icon </> in the API editor, and manually remove the security requirements.

Sometimes the completion of an SFTP restore on the Management subsystem does not restore the actual data.

There is a known issue where sometimes a restore from the Management subsystem's SFTP backup succeeds but the data is not restored. If this happens, run the restore again.

Customized application view is reset to the default after upgrade if forums are also disabled

When upgrading API Connect version 10.0.5.0 or earlier to version 10.0.5.1 or later, if you have disabled forums on your Developer Portal site, and you have customized the application view, the customized application view will be reset to the default after the upgrade. To work around this issue, you can save the customized application view before running the upgrade, and then import the view into the upgraded Developer Portal.

To save the customized application view, run the following commands:

```
mkdir /tmp/tmp_config_<site-alias>
drush @<site-alias> config-get views.view.applications > /tmp/tmp_config_<site-alias>/views.view.applications.yaml
```

Where ***<site-alias>*** is the alias of your Developer Portal site.

To import the saved view after the upgrade, put the views.view.applications.yaml file inside a directory where it's the only file, and then run the following command:

```
drush @<site-alias> config-import --partial --source=/tmp/tmp_config_<site-alias>/
```

Cannot add comments to APIs by using the Source view in the API Designer and API Manager UIs

Comments cannot be added to APIs in the API Designer and API Manager UIs by clicking the Source icon </>, and using the hashtag symbol.

Changing Product visibility from Custom to Public doesn't automatically remove the Consumer organizations and groups

In the API Designer and API Manager UIs, changing Product visibility from Custom to Public doesn't automatically remove the consumer organizations and groups, so the Product publish will fail. To work around this issue, manually remove all of the consumer organizations and groups.

Stale cache can result in unexpected behavior in the Cloud Manager and API Manager UI

Having a stale cache in your browser can result in unexpected behavior in the Cloud Manager and API Manager UI, such as fetch errors, incorrect data being displayed, and blank pages. To work around this issue, particularly if you have just upgraded your deployment, complete the following actions:

- Reload the browser window.
- If there is still an issue, clear the browser cache and then log back in to the UI.
- Try using a private browser window.
- If possible, try a different browser type.

If issues persist, contact IBM Support.

The "Select compatible gateway services" option in Test Preferences causes a "404 POST undefined" error while testing the API

In the Test Preferences > Target gateway services setting, selecting Select compatible gateway services and choosing a specific gateway results in a "404 POST undefined" error when you test the API in the API Explorer or the Test tab.

Workaround: To avoid this problem, select the Use all compatible gateway services target gateway option instead.

Analytics command restrictions

The following **`--mode analytics`** commands work only when the flag **`--return_format`** is set to either **`json`** or **`yaml`**:

- **`clustermgmt:catAllocation`**
- **`clustermgmt:catIndices`**
- **`clustermgmt:catNodes`**
- **`clustermgmt:catRecovery`**
- **`clustermgmt:catShards`**
- **`clustermgmt:catAliases`**

The following commands don't currently work on the Toolkit CLI, as they return only **`text/plain`**:

- **`clustermgmt:getNodesHotThreads`**
- **`clustermgmt:getNodesHotThreadsById`**

Scale limits are used by default for the plan, collection, and operation rate and burst limits

Scale limits are used by default for the plan, collection, and operation rate and burst limits. Therefore, the following burst limit response headers are not used for the converted burst limits:

- **`"X-BurstLimit-Limit"`**
- **`"X-BurstLimit-Remaining"`**

Instead, the former burst limits are reported as the following rate limits in the headers:

- **`"X-RateLimit-Limit"`**
- **`"X-RateLimit-Remaining"`**

Note that this limitation does not apply to assembly burst limits.

Options menus in the Catalog might be hidden

In a Catalog, in any of the different tabs such as Consumers, or Subscriptions, when clicking on the options icon ⋮ the menu items might be hidden. To work around the issue, reload the page and the menu items will appear.

Override plan rate limits are not displayed in the Endpoint tab

Any override plan rate limits that have been added to your API for individual operations are not displayed in the API Endpoint tab in the UI. Only the plan rate limit is displayed.

You cannot install a "standalone" API Connect deployment on an OpenShift cluster where Cloud Pak for Integration is present

If an OpenShift cluster has Cloud Pak for Integration installed, then all API Connect deployments on that cluster are considered to be part of the Cloud Pak for Integration deployment, which will attempt to integrate with the standalone API Connect deployments.

Consumer rate limit notifications are not available in Version 10

The ability to configure notifications for applications so that API consumers are alerted when the usage of an API is nearing its rate limit is not available.

Cannot log in to API Manager using a Twitter OIDC if email is required

When the Email required option is enabled in the Twitter user registry as explained in Configuring an OIDC user registry, then invited pOrg members and owners are unable to log in. The workaround is to leave this optional setting unselected.

Configuration update mistakes cause admission webhook errors in OpenShift and Cloud Pak for Integration

In OpenShift and Cloud Pak for Integration, configuration update errors can cause the **APIConnectCluster** instance to go into the Pending state with an underlying component throwing an admission webhook error.

```
oc get apiconnectcluster -n APIC_namespace
```

```
NAME   READY  STATUS    VERSION             RECONCILED VERSION   AGE
m1     admission webhook "vmanagementcluster.kb.io" denied the request:
ManagementCluster.management.apiconnect.example.com "m1-mgmt" is invalid: [spec.databaseBackup.restartDB.accept: Invalid
value: false: databaseBackup protocol has changed (from '' to 'objstore') and requires database restart. accept restartDB
to restart database, spec.databaseBackup.restartDB.accept: Invalid value: false: databaseBackup configuration has changed
and requires database restart. accept restartDB to restart database]   Pending   10.0.1.5-3388-eus   10.0.1.5-3388-eus
2d6h
```

The 'strict' SameSite cookie causes incorrect invitations to consumer organizations

Using the 'strict' SameSite cookie might cause invitation links from emails to send users to a registration page where they are asked to create a new consumer organization instead of joining the organization they were invited to.
The workaround is to using the 'Lax' SameSite Cookie attribute.

Performance impact when publishing products from API Designer

When you publish a product from API Designer and have 10 or more catalogs available, you might experience a performance degradation.

Limitations to the OpenAPI 3.0 support

IBM API Connect supports the OpenAPI 3.0 specification, with some limitations. For information about what is supported, see OpenAPI 3.0 support.

A GraphQL API that contains a **graphql-input-type-cost** rate limit fails to publish

A GraphQL API created in releases earlier than IBM API Connect Version 10.0.3.0 might contain a **graphql-input-type-cost** rate limit, which is no longer supported. If you attempt to use the automatic activation mechanism to publish the API, or manually add the API to a Product and attempt to publish that Product, the publish operation will fail. You can resolve this problem in either of the following ways:

- Remove the rate limit definition from the OpenAPI source for the API. For example, if the source is in YAML format, remove the following lines:

  ```
  - name: graphql-input-type-cost
    operation: consume
  ```

- Edit the source for the Product and define a **graphql-input-type-cost** rate limit in all of the Plans that include the API.
  Note: You can edit only a manually created Product, not a Product that is generated by the automatic activation mechanism.

Analytics restore on OpenShift with **enableOverride: false** gets stuck in pending state

If you set **enableOverride: false** to avoid overwriting indices during a restore, the restore operation should fail when existing indices are encountered. However, the operation does not fail, it instead gets stuck in the pending state.
When you configure the restore operation, set **enableOverride: true** but be aware that existing indices will be overwritten.

If you attempted a restore using **enableOverride: false** and the operation is stuck, then remove that job and start a new restore operation.

Options menu is missing from items on the Product list pages

If, in the API Manager user interface, you open the Product list page in either a Catalog or a Space, the options menu icon ⋮ might be missing from alongside all of the listed Products. To resolve this problem. reload the page.

Testing an API with the Policies editor doesn't work in the API Designer UI

The API Designer UI doesn't support testing an API with the Policies editor in the Gateway tab. Instead, you can test your API by using the Test tab or the Explorer tab.

Update WSDL option is not supported in the API Designer UI

The Update WSDL option to update the configuration of an existing SOAP API from a WSDL file or a .zip archive, is supported only in the API Manager UI, or by using the developer toolkit. This option is not supported in the API Designer UI.

Upgrading a 3 node profile to IBM API Connect 10.0.3.0 might result in some **portal-db/www** pods being stuck in the **Pending** state

IBM API Connect 10.0.3.0 introduces the pod anti-affinity required rule, meaning that in a 3 node profile deployment, all 3 **db** and **www** pods can run only if there are at least 3 running worker nodes. This rule can cause some upgrades to version 10.0.3.0 to become stuck in the **Pending** state. To resolve this issue, see one of the following workarounds:

- On a Kubernetes deployment: Troubleshooting upgrades on Kubernetes
- On an OpenShift deployment: Troubleshooting installation and upgrade on OpenShift
- On a VMware deployment: Troubleshooting upgrades on VMware

A unique email address is required for all Developer Portal accounts

Remember that every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a Developer Portal user account (and associated consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in to the Developer Portal: **A user already exists with this email address**.
For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries.

Configured user registries incorrectly allow the unsupported **external_group_mapping_enabled: true** option

API Connect does not support a configured user registry that is based on a registry where **external_group_mapping_enabled** is set to **true**. Under certain conditions you can create a configured user registry based on a user registry with the unsupported option; if this happens you will encounter errors while onboarding users.
You can create and update user registries with the **apic user-registries:create** and **apic user-registries:update** commands. Both commands accept the **external_group_mapping_enabled** option. If you then create a configured user registry with the **configured_catalog_user_registries:create** command, the results depend on how you set the **external_group_mapping_enabled** option in the user registry.

Suppose you create a user registry (for example, call it UR) and you want to create a configured user registry (call it CUR) based on UR. Consider the following scenarios:

1. You create UR with the `external_group_mapping_enabled: false`. In this case, you can create your CUR based on that registry.
2. You create UR with `external_group_mapping_enabled: true`. In this case, you cannot base a configured user registry on it, so the creation of CUR fails.
3. You create UR with `external_group_mapping_enabled: false` and create CUR based on it, as in scenario 1. However, you then update UR and set `external_group_mapping_enabled: true`. In this case, you have a problem.
   The operation described in scenario 3 is not currently blocked, so you will successfully create an unsupported CUR and then run into errors when you attempt to onboard users. To resolve the issue, complete one of the following workarounds:
   - Update UR (the base user registry) and set `external_group_mapping_enabled: false`.
   - Leave UR with `external_group_mapping_enabled: true` but delete the configured registry (CUR) that is based on it.

A Product republish, with the Preserve Subscriptions option, fails after a consumer organization group has been removed from the visibility settings

If you remove a consumer organization group from the custom visibility settings for a Product, and that group contains a consumer organization with an application that is subscribed to the Product, an attempt to republish the Product with the Preserve Subscriptions option will fail even if that consumer organization is then added to the custom visibility settings individually.

For a secured GraphQL API, GraphQL subscriptions cannot be tested by using the Test tab in the user interfaces

For a GraphQL API that is secured by client ID, GraphQL subscriptions cannot be tested by using the Test tab in the API Designer or API Manager user interfaces. The API can still be published and used in production.
You can test GraphQL subscriptions in either of the following alternative ways:

- Remove client ID security from the API, for testing purposes, then use the Test tab.
- Use an external test tool.

A published API whose assembly contains a catch block with an invalid policy will now correctly fail to republish

Previously, policies in an assembly catch block were not validated, so if an incorrect policy configuration was coded in the OpenAPI source for an API, within an assembly catch block, the API would still publish successfully. Now, policies in an assembly catch block are validated, so such an API will fail to republish and will first need to be corrected.

An existing user cannot be added to a Space

If you attempt to add an existing user to a Space, the operation cannot be completed because the Create button is not enabled. Instead, use the invitation mechanism. For details, see Managing Space membership.
Note: The invited user must use the Sign in option on the activation form, rather than completing the registration details and using Sign up.

Adding an `operation-switch` policy to an API assembly produces an incorrect warning message

If you add a Version 2.0.0 `operation-switch` policy to an API whose gateway type is DataPower® API Gateway, the API Setup page on the Design tab displays an incorrect warning stating that the policy is not valid for the gateway type. This warning message can be ignored.

Simultaneous editing of the same API by multiple users might result in changes being overwritten

If one user saves changes to an OpenAPI 3.0 API, another user who has the same API open in the API editor might have their changes overwritten.

An API developed for IBM API Connect Version 2018.4.1 that uses an `apim.getvariable('message.body')` function call fails in IBM API Connect Version 10

With the DataPower API Gateway in IBM API Connect Version 2018.4.1, the type of object returned, for XML payloads, by an `apim.getvariable('context_name.body')` function call in a GatewayScript policy in an API assembly depends on how the variable is stored in the gateway context, as follows:

- If the variable is stored as a Buffer (because the variable data was written as an XML string), an XML Nodelist is returned provided that `contextname.headers.content-type` is an XML type.
- If the variable is stored as a parsed XML Document (because the variable data was written as parsed XML, either as an XML document or an XML Nodelist), an XML document is returned.

With the DataPower API Gateway in IBM API Connect Version 10 however, the same function call always returns an XML Nodelist provided that `contextname.headers.content-type` is an XML type. Therefore, such an API developed for Version 2018.4.1 will fail in Version 10 if it is configured to expect an XML document, and will need to be reconfigured appropriately.

The problem does not occur with such an API migrated from IBM API Connect Version 5 because, with that release, `apim.getvariable('context_name.body')` also returns an XML Nodelist for XML payloads, nor does it occur if you are using the DataPower Gateway (v5 compatible).

context_name could be `message`, `request`, or the name of the output from an `invoke` policy.

Validate policy limitations when GraphQL response contains a GraphQL server error

When a GraphQL response contains a GraphQL server error and no data, the assembly Validate policy generates an error on the missing data and overwrites the payload. When the response contains partial data and an error, the assembly Validate action validates the data and overwrites the payload. To work around this limitation, use the condition `$not($exists(message.body.errors))` in an assembly switch condition to skip the assembly Validate policy when the response contains errors.

S3 backup type must be specified when configuring S3 backups on CP4I Platform Navigator or OpenShift Form UI

When you configure S3 backups for the Management subsystem, you must specify an S3 backup type of `ibm` or `aws`. The graphical user interfaces for CloudPack for Integration and for OpenShift incorrectly state the specification of S3 backup type is optional. In the CP4I Platform Navigator, or the OpenShift Form UI, when you configure Management System > Database Backup, be sure to select the S3 provider type menu and specify a supported value. For more information see Configuring backup settings for fresh install of the Management subsystem and the Database Backup table in the Management subsystem section of IBM Cloud Pak for Integration.

A management backup remains in a `Pending` state

A management backup might remain in a `Pending` state for a long period of time, particularly after having upgraded the management subsystem. To resolve this problem, you must remove the pending backup and operation lock, and then re-run the backup CR. To remove the pending backup and operation lock, complete the following steps:

1. Verify the names of the pending backup and operation lock by running the following commands:

   ```
   kubectl -n get mgmtb | grep Pending
   ```

   ```
   kubectl -n get cm | grep oplock
   ```

2. Delete the pending backup by running the following command:

   ```
   kubectl -n <namespace> delete mgmtb <name-of-backup>
   ```

3. Delete the operation lock by running the following command:

   ```
   kubectl -n <namespace> delete cm <name-of-lock>
   ```

GraphQL API test fails when the generated example query contains variable definitions

If, when testing a GraphQL API in the Test tab, you use the Example dropdown menu to generate a Small, Medium, or Large query, and the generated query contains variable definitions, those variables are not added to the HTTP request, which then fails with the following error:

```
Parser failed with error: syntax error, variables type is neither a JSON object nor null.
```

To resolve this problem, modify the query to remove the variable definitions before re-sending the HTTP request.

Changes to parameters in an API definition aren't reflected on the Test tab

If you add or remove parameters in an API definition on the Design tab and then open the Test tab, the changes might not be reflected immediately. If you are using the API Manager user interface, either restart the browser or clear the browser cache and cookies, if you are using the API Designer user interface, restart the application. Then reopen the Test tab in the API definition.

An OpenAPI definition that contains regular expression syntax fails validation

IBM API Connect supports the GO regular expression syntax. When you import an OpenAPI definition into the API Designer or API Manager user interfaces, or validate one with the `apic validate`, the validation will fail if the OpenAPI source contains unsupported regular expression syntax, with errors that include `Does not match format 'regex'`; for example:

```
- Must validate at least one schema (anyOf) (context:
(root).paths./example/types.post.parameters.0.schema.properties.items, line: 0, col: 0)
- Must validate one and only one schema (oneOf) (context: (root).paths./example/types.post.parameters.0, line: 46164, col:
21)
- paths./example/types.post.parameters.0.schema.properties.items.properties.pattern Does not match format 'regex'
(context: (root).paths./example/types.post.parameters.0.schema.properties.items.properties.pattern, line: 0, col: 0)
```

During migration, the `archive:unpack` fails to find an OAuth provider

When migrating API Connect to Version 10, the `archive:unpack` command might generate a warning like the following:

```
WARN[2020-06-04T09:29:54-04:00] Leaving a placeholder OAuth Provider which must be replaced in draft API <api name>:
Unable to find an OAuth Provider to extract from Token URL or Authorization URL <api token/authorization URL> with
basePath /<base path> and scopes <scope list>.
```

A possible cause is that an OAuth provider matches the API path but is missing the necessary scopes. To resolve this problem, complete the following steps:

1. Update the API definition in the `cloud/provider-orgs/<provider_organization_name>/drafts` folder to replace the `x-ibm-oauth-provider` value 'placeholder' with `name://../<oauth_provider>`.
2. Update the API definition in the `cloud/provider-orgs/<provider_organization_name>/catalogs/<catalog_name>/products` folder to replace the `x-ibm-oauth-provider` value 'placeholder' with `name://../../../<oauth_provider>`.
3. Update the OAuth Provider definition in the `cloud/provider-orgs/<provider_organization_name>/oauth-providers` folder to add the extra scopes from the API definition.

In addition, if the OAuth Provider references a user-registry in a `user-security` section, and this user-registry is not specified in the `cloud/provider-orgs/<provider_organization_name>/catalogs/<catalog_name>/configured-api-user-registries` folder, then add an entry of the following form to ensure that the user-registry is pushed to the Catalog:

```
api_version: 2.0.0
name: name://../../../user-registries/<user_registry_name>/user-registry.yml
type: configured_api_user_registry
user_registry_url: file://../../../user-registries/<user_registry_name>/user-registry.yml
```

The migration of a user registry fails

When migrating API Connect to Version 10, a user registry might fail to be pushed to the API Manager with errors like the following:

```
ErrorLog2020-06-02T08:35:37-04:00.log:ERRO[2020-06-02T08:36:07-04:00] unable to create User registry <user registry name>
ErrorLog2020-06-02T08:35:37-04:00.log:ERRO[2020-06-02T08:36:07-04:00] orgldap: An error occurred communicating with the
ldap server at
'ldaps://<ldap-address>' (error: 'Error: self signed certificate in certificate chain').
```

To workaround this problem, for any artifacts, such as APIs or OAuth providers, that reference this user registry in their User Security section, replace the user registry with one that has been successfully migrated.

The migration of an OAuth provider push fails due to a missing TLS client profile ID

When migrating API Connect to Version 10, an OAuth Provider might fail to be pushed to the API Manager with an error like the following:

```
unable to create Oauth provider <provider name>
<provider name>: The expected path parameter 'tls-client-profile-id' is missing from the request URL.
```

and subsequently an error like the following:

```
unable to create Configured oauth provider <provider name>
<provider name>: The 'oauth_provider_url' property value '/api/orgs/<org>/oauth-providers/<provider name>' does not refer
to a known Oauth Provider.
```

This is caused by an OAuth provider containing a custom HTML form in one or more User Security sections that specifies an `ei-custom-form-tls-client-profile` or an `az-custom-form-tls-client-profile`.

To resolve this problem, use the default TLS client profile by specifying a value of `''`.

When scaling down a Kubernetes cluster of DataPower gateways, the cluster might enter an unrecoverable state if the peering primary instance is lost

If you are scaling down a Kubernetes cluster of DataPower gateways, you must first complete the following steps to ensure that the peering primary instance is not lost:

1. List the pods in the cluster; for example:

```
$ kubectl get pods -n apiconnect --selector
app.kubernetes.io/component=datapower,crd.apiconnect.ibm.com/instance=gwv6
NAME     READY   STATUS    RESTARTS   AGE
gwv6-0   1/1     Running   0          3h31m
gwv6-1   1/1     Running   0          3h32m
gwv6-2   1/1     Running   0          3h34m
```

2. Enter the DataPower admin CLI for gateway 0, by entering the following command and logging in at the prompt; for example:

```
$ kubectl attach -n apiconnect -it gwv6-0
```

3. Switch to the API Connect domain and enter config mode:

```
idg# switch apiconnect
idg[apiconnect]# config
Global mode
```

4. Show the gateway peering status; for example:

```
idg[apiconnect](config)# show gateway-peering-status
```

Address	Configuration name	Pending updates	Replication offset	Link status	Primary
1.2.3.1	gwd	0	18331896	ok	no
1.2.3.1	rate-limit	0	3091219	ok	no
1.2.3.1	subs	0	3150127	ok	no
1.2.3.1	tms	0	3063575	ok	no
1.2.3.2	gwd	0	18330948	ok	no
1.2.3.2	rate-limit	0	3091067	ok	no
1.2.3.2	subs	0	3149975	ok	no
1.2.3.2	tms	0	3063257	ok	no
1.2.3.3	gwd	0	18330948	ok	yes
1.2.3.3	rate-limit	0	3091067	ok	yes
1.2.3.3	subs	0	3149975	ok	yes
1.2.3.3	tms	0	3063257	ok	yes

5. For each of the configuration names, set gateway 0 to be the peering primary instance:

```
idg[apiconnect](config)# gateway-peering-switch-primary gwd
The instance is now the primary in the peer group.
idg[apiconnect](config)# gateway-peering-switch-primary rate-limit
The instance is now the primary in the peer group.
idg[apiconnect](config)# gateway-peering-switch-primary subs
The instance is now the primary in the peer group.
idg[apiconnect](config)# gateway-peering-switch-primary tms
The instance is now the primary in the peer group.
```

6. Show the gateway peering status to confirm the changes; for example:

```
idg[apiconnect](config)# show gateway-peering-status
```

Address	Configuration name	Pending updates	Replication offset	Link status	Primary
1.2.3.1	gwd	0	19067953	ok	yes
1.2.3.1	rate-limit	0	3218172	ok	yes
1.2.3.1	subs	0	3277032	ok	yes
1.2.3.1	tms	0	3189160	ok	yes
1.2.3.2	gwd	0	19067953	ok	no
1.2.3.2	rate-limit	0	3218172	ok	no
1.2.3.2	subs	0	3277200	ok	no
1.2.3.2	tms	0	3189160	ok	no
1.2.3.3	gwd	0	19069241	ok	no
1.2.3.3	rate-limit	0	3218172	ok	no
1.2.3.3	subs	0	3277508	ok	no
1.2.3.3	tms	0	3189312	ok	no

Incorrect UI behavior if API changes are not saved before creating a new API version

If you make changes to an API definition and then attempt to create a new API version without first saving your changes, you are not prompted to save your changes until after you have completed the new version creation operation. If you click OK in the prompt, your new version is created but your original changes are lost; to create your new version and retain your original changes, you should click Cancel in the prompt, then click Save to save your original changes.

Truststore and keystore settings in a shared TLS client profile are not reflected in API Manager

If you create a shared TLS client profile in the Cloud Manager user interface and assign a truststore and a keystore, these truststore and keystore settings are not reflected in that TLS client profile in the API Manager user interface and cannot be set there. Furthermore, the TLS client profile list views display the value shared for the truststore and keystore rather than the correct values. To workaround this problem, create the truststore, keystore, and TLS client profile separately for each provider organization in the API Manager user interface, then enable the TLS client profile in your Catalogs as required.

Login to the Cloud Manager or API Manager user interfaces might fail with error 431 if the browser has a large number of cookies

Attempts to login to the Cloud Manager or API Manager user interfaces might fail if the HTTP header or cookie size is larger than 16 KB, a limitation that is imposed for security reasons. To resolve this problem, either clear the browser cache and cookies, or open a private window, then retry.

The **`apic cloud-settings:topology`** command doesn't return a topology object

If you use the **`apic cloud-settings:topology`** command without a **`--format`** parameter, it returns only the string **`CloudTopology`** rather than the cloud topology. To retrieve the

topology object, include the `--format` parameter, with a value of either `yaml` or `json` as required.

The `apic cloud-settings:mail-server-configured` command response is incorrect

If you use the `apic cloud-settings:mail-server-configured` without a `--format` parameter, it returns only the string `MailServerConfigured` rather than a boolean value to indicate whether an email server has been configured in the cloud settings. To retrieve the correct response, include the `--format` parameter, with a value of either `yaml` or `json` as required.

API Designer user interface might not open correctly if there are badly formed OpenAPI YAML files in the startup directory

If, when launching the API Designer user interface, the startup directory that you select contains one or more badly formed OpenAPI YAML files, the interface might fail to load correctly, with an error such as the following:

```
Cannot read property 'type' of null
```

To resolve this problem, remove any invalid OpenAPI YAML files from the startup directory, then restart the API Designer user interface.

Pagination setting is global across the API Connect user interfaces

If you set the Items per page value on any page in the Cloud Manager or API Manager user interface, that setting is then applied to all pages in both user interfaces in the same browser session. If you want to set the value separately for a specific page, open it in a private browser window. Such a setting in a private browser window is specific to that window and is lost when the window is closed.

Refresh tokens are not supported in the API Manager or API Designer user interfaces with an OIDC registry

The use of refresh tokens is supported in API Manager, API Designer, the Developer Portal, and the toolkit CLI, provided that the user logs in with a non-OIDC Provider user registry. If the registry type used for user login is OIDC, then refresh tokens are not supported in API Manager or API Designer. For more information, see Specifying cloud settings for refresh tokens.

Setting resource limits in Kubernetes can cause containers to behave oddly at run time

In Kubernetes, you can set resource limits for each container. However, limiting CPU means that the container processes might slow down if they try to use too much. Limiting memory means that the Kubernetes code kills processes that try to allocate memory that would take the container over its limit. These limits can result in odd behavior such as the containers continually trying to start a daemon process, such as nginx or node, and exiting with success immediately.

Field validation for the Client security policy is incorrect

When configuring a Client Security policy in an API assembly in the API Designer or API Manager user interfaces, there is the following incorrect validation behavior:

- The ID Name field is required, but the API definition can be saved without entering a value in the field.
- The Secret Name field is required only when the Secret Required option is selected, but the user interface indicates that the Secret Name field is required regardless. Furthermore, when the field is required, the API definition can be save without entering a value.
- If the Authenticate Client Method is set to Third party, the User Registry Name field is required, but the API definition can be saved without entering a value in this field.

Requests that take longer than the value of the nginx timeout cause a 409 error

Requests that take longer than the value of the `nginx` timeout can cause a 409 error, such as:

```
Another request is operating on portal-subsystem-03729230-4df7-4419-94c9-e7691b616382 with the same name,
please try again.
```

The error occurs because the ingress controller is sending a repeat request when the previous one timed out. Your request will still continue processing in the background.

Adding members to a provider organization might fail

When adding members to a provider organization, the Cloud Manager user interface lists the current owner and members as well. If existing members are selected, the add action will fail.

Upgrading with new certificates breaks analytics ingestion

If the analytics subsystem certificates are modified after installation (by using the **apicup certs set** command , followed by the **apicup install** command to deploy the change to the cluster), the analytics ingestion ingress will no longer be recognized by the Gateway. The analytics service must be re-registered in the Cloud Manager interface so that the new certificates are recognized.

Users are not logged out of the user interfaces after tokens expire

If an API Manager or Cloud Manager user interface session times out, the user does not get redirected to the login page and might see an error. To redirect to the login page, refresh the browser window.

User interfaces are not supported in Microsoft Edge

The API Manager and Cloud Manager user interfaces are not supported in the Microsoft Edge web browser. To work in the user interfaces, use a different browser.

New gateways cannot connect to existing gateways after the gateway peering certificates are changed

Changing the gateway peering SSL certificates after gateway installation causes new gateways to be unable to connect to existing gateways, resulting in an outage. A full restart of the gateway StatefulSet (by deleting all the StatefulSet pods) is required for the gateways to come back online.

Changes to an OAuth provider are not reflected in the consuming APIs

If you modify the endpoints, scopes, or grants for an OAuth provider, the APIs that consume that OAuth provider will be affected. You might need to update the consuming APIs accordingly.

No option to bulk delete APIs or Products

In the API Designer and API Manager user interfaces, there is currently no option to delete multiple APIs or Products in a single operation; in the user interfaces, APIs and Products must be deleted individually. However, you can bulk delete APIs and Products by using the REST API or CLI interfaces.

Cannot publish an imported API that was generated with IBM API Connect Version 5.0 LoopBack®

If you import an API YAML file that was generated with IBM API Connect Version 5.0 LoopBack, attempts to publish the API fail. Before publishing, remove the catalogs section, and the invoke policy named `tls-invoke-profile`, from the YAML source of the API definition; for example:

```
catalogs:
    apic-dev:
      properties:
        runtime-url: $(TARGET_URL)
    sb:
```

```
      properties:
        runtime-url: 'http://localhost:4001
```

Cannot publish an API that has duplicate security definition entries
: The API Designer and API Manager user interfaces allow you to add duplicate security definitions to an API. However, attempts to publish the API will fail with OpenAPI validation errors. Ensure that the security definitions in an API are unique.

Kubernetes might excessively evict pods
: In Kubernetes, if insufficient memory, CPU, or storage resources are provided then pods are evicted randomly. To avoid this problem, allocate sufficient resources to the pods. In addition, there are known issues with log rotation in Kubernetes that are documented here: https://github.com/kubernetes/kubernetes/issues/59902. The lack of log rotation can cause logs to grow, limited only by the amount of storage on the node, eventually causing pods to restart. Therefore ensure that appropriate log levels are configured for all API Connect components.
You may also follow the instructions described here https://success.docker.com/article/how-to-setup-log-rotation-post-installation to set the maximum size of the log before it is rolled (max-size) and the maximum number of log files that can be present (max-files). More information about the Docker JSON File logging driver is available here: https://docs.docker.com/config/containers/logging/json-file/.

Logging in to the API Connect user interfaces fails when using the Safari web browser
: If you are using the Safari web browser and a Basic Authorization header exists for the same DNS domain in which API Connect is running, attempts to log in to the API Connect user interfaces, or to sign up by using an activation link, fail. To avoid this problem, use an alternative web browser.

Endpoints cannot be changed by using APICUP after they have been configured in Cloud Manager
: The changing of endpoints with APICUP after they have been configured in Cloud Manager is not supported. Any such endpoint changes will not be propagated to a running deployment.

An OAuth provider fails if the resources that it references aren't enabled in the Catalog
: If you enable an OAuth provider in a Catalog then any resources that it references, such as API user registries or TLS client profiles, must be enabled in the same Catalog; if not, then although the OAuth provider might publish successfully it will fail at run time. For information on enabling resources in a Catalog, see Creating and configuring Catalogs.

Redact conditions within `switch`, `operation-switch`, or `if` policies might not execute after converting to DataPower API Gateway
: If an API Connect v5-compatible `redact` policy is found within a `switch`, `operation-switch`, or `if` policy, the migration utility does not move the `redact` policy to the beginning or end of the assembly. The difference in the response between API Connect v5 and DataPower API Gateway may prevent data from being redacted in the DataPower API Gateway.
For example, if an assembly includes a `switch` policy containing four redact conditions followed by an `invoke` policy, each redact condition redacts the response data. After porting to the API Gateway, the redact conditions remain inside the `switch` policy and target the `message.body` property for redaction. These redactions fail to execute because the `message.body` property has not yet been retrieved by the `invoke` policy. To correct this problem, you must move the `invoke` policy before the `switch` policy in the assembly.

Redact on invalid XPath fails after converting to DataPower API Gateway
: A `redact` policy containing an XPath with a trailing slash is converted by the migration utility `apicm archive:port-to-apigw` command without removing the slash. This path is invalid. When the API containing this policy is called, an `assembly redact` error is generated.

"Test" tab's Trace feature displays blank policies list in Firefox
: When you create an API, you can invoke it and debug its execution using the Test tab. The Test tab shows the API's response and includes a subtab where you can run a trace on the API's translation flow. In Firefox, the Trace tab's list of policies is empty. Use Chrome to debug your API so you can see the policies list in the trace.

Analytics REST API support for multiple query parameters
: It is not possible to use multiple query parameters for the same nested API event record field when making calls to the analytics REST API. For example:

```
/cloud/events?response_http_headers[X-Client-IP]=not:10.51.11.183&response_http_headers[X-Client-IP]=not:10.51.11.184
```

Not possible to switch analytics from a three replica deployment to a one replica deployment
: An error is logged in the storage pods when this is attempted. For a workaround, see: https://www.ibm.com/support/pages/node/6845818.

Limitations to support for JSONata
: The DataPower API Gateway support for JSONata notation has the following limitations and restrictions.

- You cannot extract or redact content from the same source that is defined in the root. For example, if the root is defined as `message.body.a`, the action fails if the content to extract or redact is defined as the entire input.

  As a workaround, remove the last element of the root and define that element as the content to extract or redact. For the previous example, define root as `message.body` and the content as `a`.

- New JSON objects cannot be constructed from the capture field that is specified in an Extract policy. As a workaround, use the transform expression `$merge([])` to construct the empty object. You can then specify more extracts as needed for key-value pairs.
- If soft linked copies of a field exist in different locations, an Extract or Redaction policy can cause content from all of the linked fields to be extracted or redacted. As a workaround for the Extract policy, use the `$merge($spread($))` object function to construct new, unlinked objects and arrays. For example, the following transform expressions construct unlinked copies of the field `c`.

  ```
  \"a\": $merge($spread($.c)
  \"b\": $merge($spread($.c)
  ```

API Connect concepts

To help you get started, read about the API Connect concepts and obtain a high level understanding of the API management solution.

- **Who does what in API Connect?**
  Review the different functions that users can perform in API Connect, the typical set of tasks that is performed by each type of user, and the documentation most often used for each task.
- **Packaging strategy and terminology in API Connect**
  API Connect uses a proprietary packaging strategy for creating and publishing collections of APIs.

- **API Connect components**
  The API Connect components provide a unified user experience across the API lifecycle. Changes in one stage of the API lifecycle are automatically reflected in the other components of API Connect.
- **API Connect support**
  If you experience a problem with IBM API Connect that you cannot resolve, you can check the IBM Support website for the most recent technical bulletins and fixes. Otherwise, you can contact IBM Support.

Who does what in API Connect?

Review the different functions that users can perform in API Connect, the typical set of tasks that is performed by each type of user, and the documentation most often used for each task.

Systems administrators

If you deploy API Connect on premises, then your company manages the systems. Because API Connect comprises multiple servers even in an on-premises deployment, the collection of servers and services is referred to as a (local) cloud. This is unrelated to any servers and systems that are deployed in IBM® Cloud.

In an on-premises deployment, there are two roles for managing your deployment:

- Cloud owner: There is one cloud owner for a deployment, and that person adds other people to the server management team.
- Cloud administrator: Your deployment needs at least one cloud administrator; your company will probably assign multiple people to perform this role. Cloud administrators manage the deployment and configuration of API Connect servers and software.

In the API Connect documentation, cloud owners and administrators are primarily interested in the following sections, which introduce concepts and explain how to deploy, maintain, and configure the components of an on-premises deployment.

Users

At the highest level, API Connect users belong to organizations, which are groups of people. A *provider organization* (often shortened as *p-org*) is a group of people who create, publish, and maintain APIs that are then used by people in a *consumer organization*. Consumers develop their own applications that call the APIs created by providers. A single customer can create multiple provider organizations and consumer organizations. For example, different divisions within a large company might work with different technologies and create entirely different sets of APIs, so it makes sense to group them into different p-orgs. Each provider organization publishes their APIs to a Developer Portal that uses consumer organizations to manage the customers who use those APIs.

At a minimum, you need one provider organization if you want to publish and manage APIs with API Connect, and one consumer organization for each customer.

Provider organization

A provider organization performs many tasks during the lifecycle of an API, from developing, publishing, and maintaining APIs to managing the membership of the organization itself. Each p-org can be as large or as small as needed. A large company might create a p-org for each product team, or for each department but a small company might use a single p-org.
A person can be a member of multiple provider organizations and receive a different set of permissions for each. When the user logs in to API Connect, they select the organization whose resources they will use, and receive the appropriate permissions for that organization for the duration of the session.

The following roles are commonly associated with a provider organization but are not necessarily represented by different people. In a small company, one person might perform all of the API maintenance tasks while in a larger company, several people might take on separate roles.

- Organization Owner: Every provider organization requires one owner to ensure that a user account is associated with the organization. The organization owner has full access to all of the p-org's resources (APIs, Products, Catalogs, and so on) and role cannot be deleted. The organization owner can add people to the organization manager role.
- Organization Manager: Maintaining the organization account is the job of the organization manager. In a large company, several people might share this role. Organization managers add *members* to provider organizations and assign them the permissions needed to perform their jobs. Organization owners and managers typically use the docs on administering provider orgs and administering members and roles.
- API Developer: In API Connect, an API developer creates new APIs and updates existing APIs as needed. The API developer can configure *policies* that define security restrictions, logging rules, and quotas that control access to your company's resources. The API developer might be assigned to work with a specific *Catalog* that manages a subset of APIs, or they might receive access to all of the p-org's Catalogs and the *Spaces* within each. API developers are usually most concerned with documentation related to developing APIs, managing API settings, and authoring policies for APIs.
- API Administrator: After an API developer creates a set of APIs, the API administrator manages the distribution. The API administrator defines *Plans* that determine access to the APIs, collects related APIs into *Products*, and publishes them to the consumer Developer Portals. To complete these tasks, the API administrator uses documentation focused on managing API syndication and working with Products.
- Product Manager: A product manager controls access to the Developer Portal where customers subscribe to APIs and then tracks API usage and performance. For each customer, the product manager creates a consumer organization, assigns a customer representative as the owner, and manages the relationship between the provider organization and each consumer organization. The product manager can customize the appearance of Developer Portal for their p-org as well as provide forums and blogs for their consumers. The product manager uses the API Connect Analytics service to track API usage and performance so that the p-org knows when APIs should be updated or retired. The product manager typically uses documentation on administering consumer organizations, using the Developer Portal, and reviewing API analytics.

Consumer organization

A consumer organization creates applications that use the APIs that are developed by provider organizations. Each provider's APIs are made available to each consumer organization in the API Connect Developer Portal. Members of a consumer organization typically perform two functions:

- Consumer Organization Owner: The consumer organization owner also manages the organization by inviting other members and assigning permissions to each. This role additionally has permissions to customize the Developer Portal where members access APIs that the organization is subscribed to.
- Application Developer: Create applications that invoke APIs shared through the Developer Portal.

The only API Connect feature that API consumers use is the Developer Portal, which is managed by the API provider. There is no need for consumers to read the API Connect documentation.

- **API Connect user roles**
  The IBM API Connect solution provides an infrastructure, tools, and facilities that allows users to create, manage, and stage APIs. The ability to perform tasks in the API Connect user interfaces is controlled through user roles, and the permissions that are assigned to those roles.

API Connect user roles

The IBM® API Connect solution provides an infrastructure, tools, and facilities that allows users to create, manage, and stage APIs. The ability to perform tasks in the API Connect user interfaces is controlled through user roles, and the permissions that are assigned to those roles.

The roles described here are the default API Connect roles. In the API Manager user interface, you can create custom roles; for more information, see: Creating custom roles. You can also create custom roles in the Developer Portal user interface.

The following sections describe the roles and permissions for each of the API Connect user interfaces:

- User roles in the Cloud Manager UI.
- User roles in the API Manager UI.
- User roles in the Developer Portal UI.

User roles and permissions in the Cloud Manager UI

The following table describes the Cloud Manager UI user permissions as configured in the base product. Certain roles can edited as indicated In Table 2, and custom roles can be created. For instructions on how to create custom roles for the Admin organization (Cloud Manager users), see Creating roles in the admin organization.

Table 1. Cloud Manager UI permissions

Permission	Action	Meaning
Cloud Settings	View	View all items on the Cloud Manager > Settings menu (except Roles)
	Manage	Add, update, and delete all items on the Cloud Manager > Settings menu (except Roles)
Member	View	View members on the members list located at Cloud Manager > Members
	Manage	Add and invite members from Cloud Manager > Members Note: By default, a user with Member > Manage permission can assign, to themselves or to another user, any role with any permission regardless of the permissions that they themselves have. However, you can apply a restriction such that, for a user to assign a role, they must themselves have at least all of the permissions that are applied to that role. To apply that restriction, complete the following steps: 1. Log in to your management server from the toolkit CLI as a member of the cloud administration organization; for details, see Logging in to management server. 2. Enter the following command (the terminating hyphen character means that the command takes input from the command line): `apic cloud-settings:update --server mgmt_endpoint_url -` where *mgmt_endpoint_url* is the platform API endpoint URL. 3. Enter the following data, followed by a new line: `restrict_member_manage_permission: true` 4. Press `CTRL D` to terminate the input.
Org	View	Org:View is a permission assigned to all Roles in Cloud Manager. It does not provide access to any functionality. It allows a user to activate their membership. It is the only permission in the Member role.
Provider-Org	View	View the list of provider organizations at Cloud Manager > Provider Organizations
	Manage	Add, edit, and delete provider organizations and invite owners from Cloud Manager > Provider Organizations
Settings	View	View the items on the Cloud Manager > Resources menu plus Roles located at Cloud Manager > Settings > Roles
	Manage	Add, edit, and delete the items on the Cloud Manager > Resources menu plus Roles located at Cloud Manager > Settings > Roles
Topology	View	View the items on the Cloud Manager > Topology menu
	Manage	Add, edit, and delete the items on the Cloud Manager > Topology menu
Analytics	View	View items on Cloud Manager > Analytics, and also create, update, duplicate, delete, share, and unshare saved queries.

The following table lists the various Cloud Manager UI roles and the permissions assigned to them.

Table 2. Cloud Manager UI roles

Role	Permissions	Actions	Default role provides access to	Notes
Owner	All permissions	All actions	All menus	Cannot be modified or deleted.
Administrator	All permissions	All actions	All menus	Includes analytics:view.
Member	Org	View	Membership activation only	Cannot be modified or deleted. Member role is automatically assigned to all users when they activate their membership from the invitation. It allows them to activate but does not provide access to any menus.
Organization Manager	Org	View	N/A	Can be modified and deleted.
	Provider-Org	View, Manage	Provider Organizations menu	
Topology Administrator	Org	View	N/A	Can be modified and deleted.
	Topology	View, Manage	Topology Menu	

Role	Permissions	Actions	Default role provides access to	Notes
	Settings	View, Manage	Resources menu plus Settings > Roles	
Viewer	All permissions	View	All menus, view only	Cannot be modified or deleted.

User roles and permissions in the API Manager UI

The following tables describe the API Manager UI user permissions.

A user with Roles permission can change the permission assignments, and can create custom roles; for more information, see Creating custom roles in the section, Managing your APIs.

Note: In API Manager, the Owner role has full access and cannot be edited or deleted. All other roles, including custom roles, can be deleted. If you delete a role, users lose that role. If a user loses that role, their account remains in API Manager, enabling you to add a role to the user at a future date.

Table 3. Organization permissions

Permissions	Action	Permits the member to
Member	View	View organization's members
	Manage	Manage organization's members Note: By default, a user with Member > Manage permission can assign, to themselves or to another user, any role with any permission regardless of the permissions that they themselves have. However, you can apply a restriction such that, for a user to assign a role, they must themselves have at least all of the permissions that are applied to that role. To apply that restriction, complete the following steps: 1. Log in to your management server from the toolkit CLI as a member of the cloud administration organization; for details, see Logging in to management server. 2. Enter the following command (the terminating hyphen character means that the command takes input from the command line): `apic cloud-settings:update --server mgmt_endpoint_url -` where *mgmt_endpoint_url* is the platform API endpoint URL. 3. Enter the following data, followed by a new line: `restrict_member_manage_permission: true` 4. Press `CTRL D` to terminate the input.
Settings	View	View an organization's configuration settings, including roles, TLS profiles, and user registries. View configuration settings for a Catalog or Space, including policies and OpenAPI extensions.
	Manage	Manage an organization's configuration settings, including roles, TLS profiles, and user registries. Manage configuration settings for a Catalog or Space, including policies and OpenAPI extensions.
Topology	View	Same permissions as `Settings: View`.
	Manage	Same permissions as `Settings: Manage`.
Org	View	View an organization
Product-Drafts	View	View draft APIs and Products
	Edit	View draft APIs and edit draft Products
Api-Drafts	View	View draft APIs
	Edit	Edit draft APIs and view draft Products
Product	View	View Products
	Stage	Stage Product
	Manage	Manage Product
Product-Approval	View	View Product lifecycle changes
	Stage	Approve the staging of a Product
	Publish	Approve the publishing of a Product
	Supersede	Approve the superseding of a Product
	Replace	Approve the replacement a Product
	Deprecate	Approve the deprecation of a Product
	Retire	Approve the retiring of a Product
Consumer-Org	View	View consumer organization and developers
	Manage	Manage consumer organization and developers
App	View	View both production and development applications.
	Manage	Manage both production and development applications. A member with this permission can also request the promotion of a development app to a production app. This request triggers a task that needs approval by a member with the App-approval Manage permission.
App-Dev	Manage	Same permissions as `Settings: Manage`.
App-Approval	View	View application approvals, for requests to promote a development app to a production app.
	Manage	Manage (Approve or Decline) requests for approval to promote a development app to a production app.
Subscription	View	View application Plan subscriptions that have been created by application developers in the Developer Portal.
	Manage	Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.

Permissions	Action	Permits the member to
Subscription-Approval	View	View application Plan subscription approvals.
	Manage	Manage (approve or decline) application Plan subscriptions.
Consumer-Onboard-Approval	View	View consumer onboard approvals.
	Manage	Manage (approve or decline) consumer onboard approvals.
Api-Analytics	View	View analytics data, as well as access and apply saved analytics queries.
	Manage	In addition to the view permissions, the user can create, update, duplicate, delete, share, and unshare saved analytics queries.
Child	View	At the provider organization level, view Catalogs in the provider organization. At the Catalog level, view Spaces in the Catalog.
	Create	At the provider organization level, create Catalogs in the provider organization. At the Catalog level, create Spaces in the Catalog.
	Manage	At the provider organization level, manage Catalogs in the provider organization. At the catalog level, manage Spaces in the Catalog. Management tasks including deleting a Catalog or Space, or transferring ownership of a Catalog or Space.

A user with Settings > Manage permission can change the permission assignments, and can create custom roles; for more information, see Creating custom roles in the section, Managing your APIs.

Table 4. Default API Manager UI roles and the default permissions assigned to those roles.

Role	Role description	Permissions	Actions
Organization Owner	A provider organization owner has the full set of access permissions to API Connect functions, and also commission APIs and tracks their business adoption.	All permissions	All actions.
Administrator	A provider organization administrator has, by default, the full set of access permissions to API Connect functions, and also commission APIs and tracks their business adoption.	All permissions	All actions.
API Administrator	API administrators manage the lifecycle of APIs and publish APIs for discovery and use.	All permissions	All actions except cannot manage the following permissions: Member, Settings, Topology, and Child.
Community Manager	A community manager manages the relationship between the provider organization and application developers, provides information about API usage, and provides support to application developers.	Member	View
		Settings	View
		Topology	View gateway services or portal services at the provider organization.
		Org	View
		Drafts	View, Edit
		Product	View
		Product-approval	View
		Consumer-org	View, Manage
		App	View, Manage
		App-dev	Manage
		App-approval	View, Manage
		Subscription	View, Manage
		Subscription-approval	View, Manage
		Consumer-onboard-approval	View, Manage
		Api-analytics	View, Manage
		Child	View
Developer	API developers design and develop APIs and applications for the provider organizations to which they belong. Note: The Developer role allows the creation of Products and APIs, and the staging and publishing of Products to a Catalog or Space, when assigned to a user at the provider organization level--but not when assigned to a user who is a member only of a Catalog or Space within a provider organization. A Developer in a Catalog or Space can manage Products that are staged or published to the Catalog or Space.	Member	View
		Settings	View
		Topology	View gateway services or portal services at the provider organization.
		Org	View
		Drafts	View, Edit
		Product	View, Stage, Manage

Role	Role description	Permissions	Actions
		Product-approval	View, Stage, Publish, Supersede, Replace, Deprecate, Retire
		Consumer-org	View
		App	View, Manage
		App-dev	Manage
		App-approval	View, Manage
		Subscription	View, Manage
		Subscription-approval	View, Manage
		Api-analytics	View, Manage
		Child	View, Create
Member	Member of a provider organization	Org	View
Viewer	Viewer of a provider organization	Member	View
		Topology	View gateway services or portal services at the provider organization.
		Org	View
		Drafts	View
		Product-approval	View
		Consumer-org	View
		App	View
		App-approval	View
		Subscription	View
		Subscription-approval	View
		Api-analytics	View
		Child	View

Note: In API Manager, the Organization Owner role has full access and cannot be edited or deleted. All other roles, including custom roles, can be deleted. If you delete a role, users lose that role. If a user loses that role, their account remains in API Manager, enabling you to add a role to the user at a future date.

User roles in the Developer Portal UI

The following table describes the various Developer Portal UI roles that relate to working with APIs and applications. In addition, you can create custom roles for the Developer Portal site itself.

Table 5. Developer Portal UI roles

Role	Role Description	Permission	Actions
Owner	Owns and administers the app developer organization	Organization member	View, Manage
		Organization settings	View, Manage
		Organization view	View
		Consumer product	View
		Consumer app	View or Manage production or development applications
		Consumer app-dev	Manage development applications
		Consumer subscription	View or Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.
		Consumer app-analytics	View application analytics
Administrator	Administers the app developer organization	Organization member	View, Manage
		Organization settings	View, Manage
		Organization	View
		Consumer product	View
		Consumer app	View, Manage production or development applications
		Consumer app-dev	Manage development applications

Role	Role Description	Permission	Actions
		Consumer subscription	View or Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.
		Consumer app-analytics	View application analytics
Developer	Builds and manages apps in the developer organization	Organization member	View
		Organization settings	View
		Organization	View
		Consumer product	View
		Consumer app	View, Manage production or development applications
		Consumer app-dev	Manage development applications
		Consumer subscription	View or Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.
		Consumer app-analytics	View
Member	Member of the app developer organization	Organization	View
Viewer	Viewer of the app developer organization	Organization member	View
		Organization settings	View
		Organization	View
		Consumer product	View
		Consumer app	View applications
		Consumer production-app	View production applications
		Consumer app-analytics	View application analytics

Note: A user called admin is created automatically, with full administrator access to the Developer Portal site. The admin user can view Products and APIs but has no access to use APIs. The admin user assumes the email address of the owner of the provider organization associated with the Developer Portal.

Packaging strategy and terminology in API Connect

API Connect uses a proprietary packaging strategy for creating and publishing collections of APIs.

The packaging strategy supports API providers in meeting the requirements of the API consumers. An understanding of the concepts and terminology behind the packaging strategy is required before developing and deploying APIs using IBM® API Connect.

The following sections describe the concepts and terminology behind the packaging strategy for IBM API Connect:

- APIs
- Plans and Products
- Catalog and Spaces
- Organizations and users
- LoopBack® applications
- Sample provider organization with two Catalogs

APIs

An Application Programming Interface (API) is an industry-standard software technology. An API is a set of routines, protocols, and tools for building software applications. An API specifies how software components interact and provides quick access to common assets and processes. APIs can be public (such as offered on GitHub), can require client credentials, or can be kept private within an application. Thus, APIs are classified as external (public), partner (protected), or internal (private), based on how they are consumed.

An API is composed of operations, called methods, which are offered in one of the following styles in API Connect:

- A REST API is structured according to the principles of Representational State Transfer. REST APIs use HTTP or HTTPS requests to PUT, GET, POST, and DELETE data (also referred to as CRUD operations). REST identifies resources using URIs. Data can be described in a variety formats (XML, HTML, JSON, TXT, etc.), with JSON being the popular choice. REST APIs specify MIME (Multipurpose Internet Mail Extensions) types. REST is platform- and language-independent and works across firewalls using HTTPS. REST APIs leverage HTTP standards for security, caching, and status codes. HTTP clients and servers are available for all major programming languages and operating system/hardware platforms. REST implementations are easily scaled due to use of HTTP and browsers as a uniform interface.
- A SOAP (Simple Object Access Protocol) API is a web service that is exposed as an API. SOAP interfaces are described in WSDL (Web Services Description Language) format. The WSDL is an XML document describing the structure for headers, messages, URL endpoints, and datatypes used to access a web service. SOAP is considered more secure than REST as it supports WS-Security as well as SSL. SOAP also contains WS-Reliable Messaging for reliability, rather than relying on retrying the operation (as does REST). SOAP requires a client application and is better suited for enterprise applications that require secure transactions.

APIs can be versioned and packaged into multiple Products for distribution to API consumers on the Developer Portal. For information about creating and managing APIs, see Developing your APIs and applications and Managing your APIs.

Plans and Products

Plans and Products are proprietary packaging constructs that are unique to API Connect. API providers use Products to offer one or more APIs to the application developers who will consume the APIs (API consumers). The providers use Plans to control access to APIs and to manage API usage. Products are packages that contain both the APIs and the accompanying Plans. See Working with Products.

To make an API available to an application developer, it must be included in at least one Product and at least one Plan.

Plans perform the following functions:

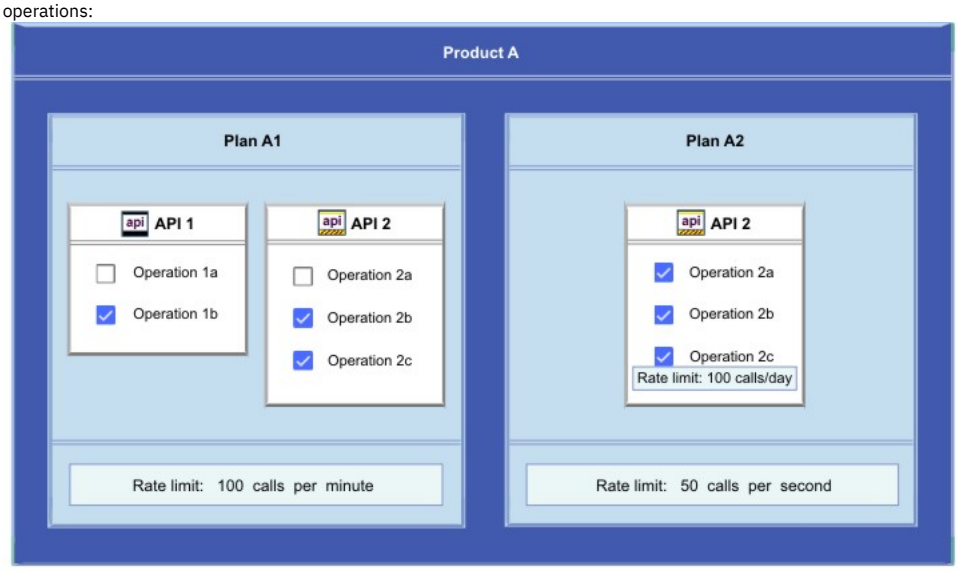
- Control which APIs an application developer can use
- Make available a collection of operations from one or more APIs
- Apply rate limits to APIs to differentiate between offerings
- Implement different rate limits to specify how many requests a consuming application is allowed to make during a specified time interval

A rate limit can be implemented as a default rate that is shared across all operations in a Plan, or can be set for specific operations of an API. Plans can use differing rate limits to provide different levels of service to API consumers. For example, a "Demo Plan" might enforce a rate limit of ten calls per minute, while a "Full Plan" might permit up to 1000 calls per second.

A Product in API Connect bundles a set of APIs and Plans into one offering that is intended for a particular use. You can create Plans only within Products, and these Products are then published in a Catalog. The following rules apply for the relationship between Products and Plans:

- A Plan can belong to only one Product.
- A Product can have multiple Plans that each contain a different set of APIs.
- A Plan in one Product can share APIs with Plans from any other Product.

Multiple Plans within a single Product provide different levels of performance for the same offering. For example, a Product can include a "Demo Plan" that makes a single API available, and a "Full Plan" that makes several APIs available.
The following diagram illustrates how Plans can be used to make operations from one or more APIs available, and to set rate limits on both Plans and individual operations:

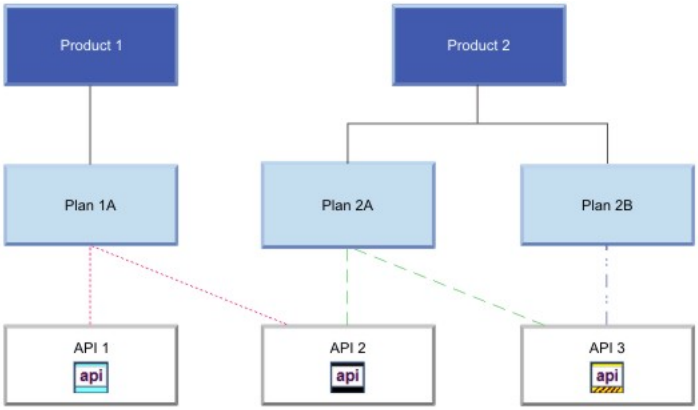


The diagram illustrates the following concepts:

- Product A contains two APIs and two Plans.
- Both APIs are included in Plan A1.
- Plan A2 includes only API 2, which is also included in Plan A1. Operation 2a for API 2 is excluded from Plan A1. All operations in API 2 are included in Plan A2.
- Different rate limits are set for the two Plans at the Plan level. For API 2 in Plan A2, a rate limit is also set specifically for Operation 2c to override the rate limit set at the Plan level.

Products are used to manage the lifecycle of the APIs they contain. The states in the Product lifecycle include draft, staged, published, deprecated, and retired. A Product in draft state is moved to the staged state when it is staged to a *Catalog*. A Product moves to the published state when the Product is published. The APIs in a Product become accessible to API consumers when the Product is in the published state and they then become visible on a *Developer Portal*. After a Product is published, application developers can use the Developer Portal to gain access to its APIs by registering applications to one or more Plans in the Product.

The following diagram illustrates the hierarchy of Products, Plans, and APIs.



For more information about managing the lifecycle of Products, see Working with Products in the API Manager.

Catalogs and Spaces

A Catalog contains a collection of Products. Catalogs are staging targets through which Products (together with the accompanying Plans and APIs) are published on a Developer Portal. Catalogs are used to separate Products and APIs for testing before publishing them on a Developer Portal. In a typical workflow, an API provider uses a development Catalog when developing and testing APIs, and uses a production Catalog for publishing APIs that are ready for external use. Each Catalog has an associated Developer Portal for exposing the published Products. A Catalog includes runtime capability through an associated gateway service that handles any API requests for the APIs in that Catalog.

API Connect includes a syndication feature that enables API providers to partition a Catalog into multiple staging targets (or *Spaces*) for API development purposes. Each API provider development team can use its own dedicated Space to manage its Products independently of other teams. A Space has its own set of capabilities relating specifically to the Products and APIs that are created and published to that Space. Products and APIs in all Spaces in a given Catalog are published to the same Developer Portal. Spaces are not visible on the Developer Portal. Application developers who consume the APIs on the Developer Portal are unaware of the Space configuration used by the API Developers. On the Developer Portal, the APIs are seen as a coordinated offering within a Catalog.

For more information about Catalogs and Spaces, see Working with Catalogs and Using syndication to partition Catalogs into Spaces.

Organizations and users

In the context of API Connect, there are two types of organizations: provider and consumer. An organization can encompass a project team, department, or division.

A provider organization owns APIs, and associated Plans and Products, and can additionally own *provider* applications that are called by APIs. To complete the various functions in the API lifecycle, a provider organization assigns responsibilities for certain tasks. Some standard responsibilities within a provider organization include:

- A provider organization owner who has the full set of access permissions to API Connect functions, and can also commission APIs and track their business adoption.
- API developers who design and develop APIs and applications for the provider organizations to which they belong.
- An administrator who manages the lifecycles of APIs and publishes APIs for discovery and use.
- A "community" manager who manages the relationship between the provider organization and application developers, provides information about API usage, and provides support to application developers.

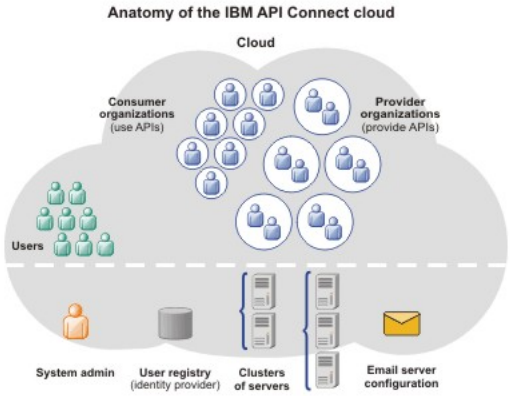
A consumer organization owns only *developer* applications, and consumes the APIs and applications produced by the provider organization. Standard responsibilities within a consumer organization include:

- A consumer organization owner who adds application developers to the consumer organization, views the Products and APIs that the provider organization has made available on the Developer Portal, and subscribes to APIs to use them in applications.
- Application developers who view the Products and APIs that the provider organization has made available on the Developer Portal, and subscribe to use these APIs in applications.

The provider and consumer organization responsibilities map to *roles* within API Connect. Some roles are independent of an organization; for example, an administrator who manages the cloud infrastructure and keeps the system running. For information about the full set of defined roles and access permissions, see API Connect user roles.

Users have an existence in the API Connect ecosystem that is independent of an organization. A user can be a member of more than one provider or consumer organization.

There can be multiple provider organizations in one API Connect cloud, to provide an API development environment for each line of business of an enterprise. The API Connect cloud is a collection of servers that comprise an API Connect installation, including the configuration information and metadata that they contain. The cloud infrastructure is shared by all organizations, and managed independently of them (by a cloud or system administrator). The following diagram shows the relationship between the provider organizations, consumer organizations, and users. The clusters shown are logical groupings of servers with the same capability.



For more information about organizations, see Administering provider organizations and Administering consumer organizations.

LoopBack applications

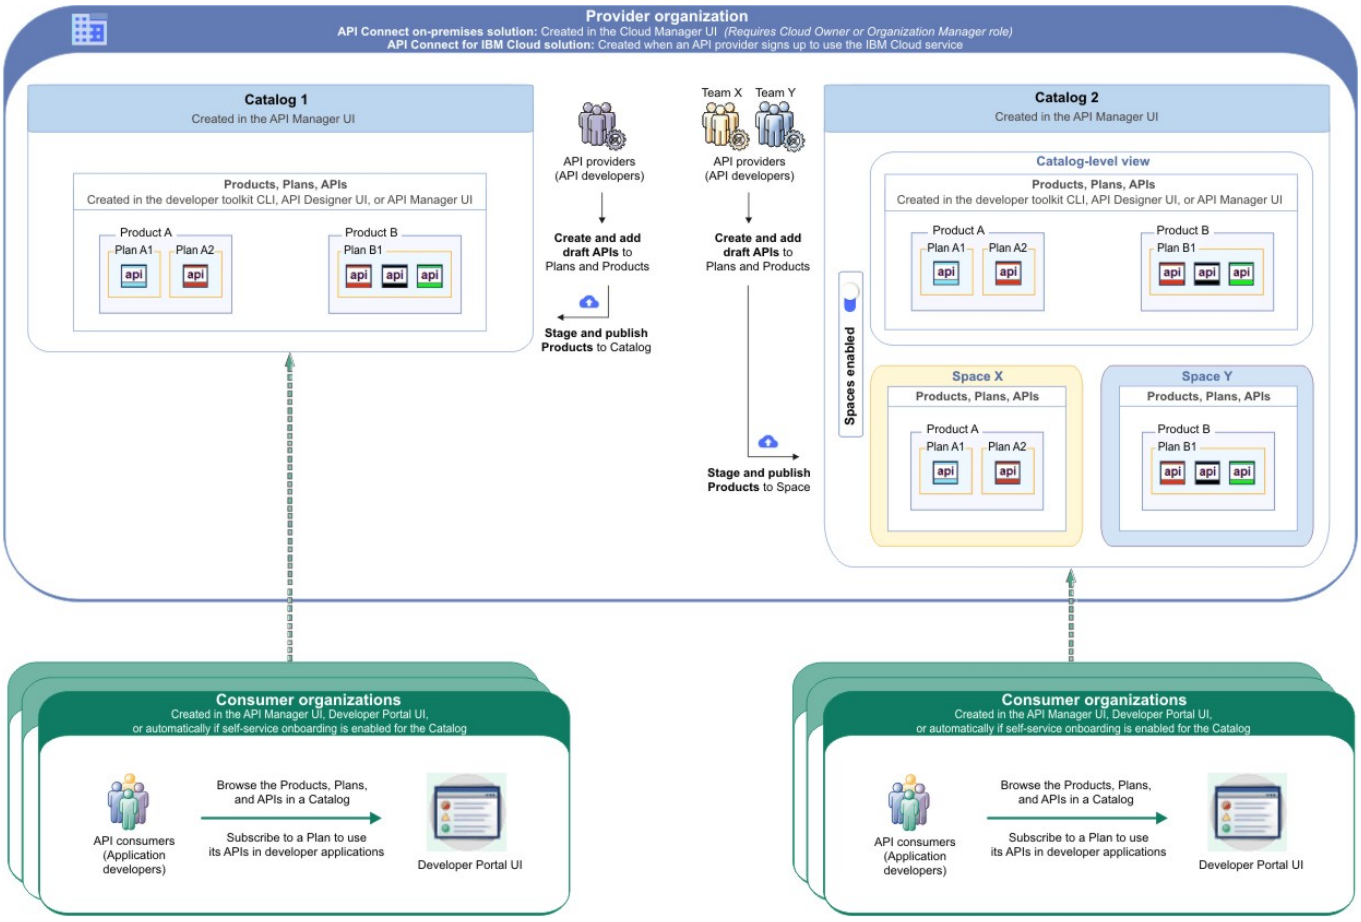
In addition to APIs, provider organizations can also create applications (with associated APIs), which are built using Node.js and Java technology. When published, these APIs and applications are called by developer applications. The developer applications contain client code that accesses APIs to interact with a service, system, or content. The developer applications are typically mobile or web applications that use the HTTP protocol.

For information about creating LoopBack applications, see Creating APIs and applications.

Sample provider organization with two Catalogs

The following diagram shows an example for how APIs, Plans, Products, Catalogs, and Spaces fit within provider and consumer organizations. In this example, two Catalogs are created in the provider organization to act as staging targets for different sets of requirements.

- Catalog 1 does not require separation of the Products for use by individual provider development teams, and so does not have Spaces enabled. API developers with access to this Catalog create draft APIs, and stage and publish them as Products to the Catalog. Several consumer organizations are granted permission to explore, discover, and use the published Products and APIs. In each of the consumer organizations, the published Products and APIs from Catalog 1 are exposed on a single Developer Portal.
- Catalog 2 is partitioned into two Spaces (X and Y) so that two provider development teams can manage their Products independently. These teams stage and publish their APIs (as Products) separately to the individual Spaces, to make them accessible to application developers in multiple consumer organizations. In each of the developer organizations, the published Products and APIs from both Spaces are exposed in the same Developer Portal, and application developers who access this portal will see the APIs from both Spaces as a coordinated offering.



- **Understanding rate limits for APIs and Plans**
  In API Connect, you can configure rate limiting on APIs and Plans to manage network traffic and API usage.

Understanding rate limits for APIs and Plans

In API Connect, you can configure rate limiting on APIs and Plans to manage network traffic and API usage.

What are rate limits and burst limits?

A rate limit is the maximum number of calls you want to allow in a particular time interval. Setting rate limits enables you to manage the network traffic for your APIs and for specific operations within your APIs. API Connect supports two types of rate limiting:

Rate limit
: A specified number of calls to be accepted within a defined time period; for example, 100 calls per minute. In API Connect, rate limits can be defined as unlimited, or with a specified number of calls per second, minute, hour, day, or week.

  Rate limits can be "hard" (enforced) or "soft". If the rate limit is hard and a call exceeds the limit, then the call is aborted and an error is returned. A soft rate limit allows the call to complete but logs a warning message. When a hard rate limit is reached, no more calls are accepted from that customer until the beginning of the next time period. For example, you might want to permit a total of 1000 calls per hour (rate limit). If a customer makes 1000 calls in the first 10 minutes, they cannot complete any more calls until the hour has expired.

Burst limit
: A rate limit that is applied to a very small time period. In API Connect, burst limits are defined for multiples of seconds or minutes. Burst limits are always hard. When a burst limit is reached, calls are not accepted until the time period has expired. Once that pause is over, calls continue to be accepted until a hard rate limit is reached. Configuring a burst limit prevents usage spikes and ensures that the rate limit is evenly spread across its overall time period. For example, you might want to permit a total of 1000 calls per hour (rate limit) and a maximum spike of 50 calls per second (burst limit).

Where can you apply rate limits?

You can configure rate limiting at several levels of an API and the Plan containing it. Each of the rate limits is tracked separately and when a hard limit is exceeded, calls at that point are no longer accepted until the start of the next time period.

The following list explains where you can configure rate limits:

Plan: all APIs
: You can define a general rate limit at the Plan level, and it affects all of the consumer orgs that use that Plan. When a rate limit is enforced for a Plan, the limit is checked before every call that involves any API contained in that Plan. If the rate limit is exceeded, APIs are not even called. For information on setting a rate limit for a Plan, see Editing a draft Product.

Note: If the subscriber changes to a different Plan, only the Plan-level rates limit are reset. If there is a hard rate limit specified in the API's definition or assembly, that rate limit is still enforced under the new Plan.

Plan: API path and operation

You can define a rate limit for a specific path and operation of an API within a Plan; for example, you might allow unlimited calls to a GET operation but enforce a limit on PUT operations for the same API. You can even define multiple rate limits on the same path and operation. If the rate limit is enforced, then the limit is checked before every call that involves the API's path and operation. For more information on configuring rate limits on API paths and operations within a plan, see the following topics:

- Defining rate limits for an API operation
- Describing Plans in your Product

API definition

You can define a rate limit on an API in the API definition (the Design page in the user interface). This rate limit applies to all calls involving the API, from all consumer orgs. If the containing Plan allows the call but the API definition has a hard limit set, the call is aborted. For more information on setting a rate limit on an API definition, see Changing an API rate limit.

API assembly

When you apply a rate limit to an API assembly, the limit only affects calls at that point in the assembly. This allows you to define a more granular rate limit than if you set it on the API definition. If the Plan and the API definition allow a call to proceed but a hard limit that is set on the assembly is exceeded, the call is aborted at the point in the process flow where the rate limit is set. Any actions that appear in the assembly's process flow before the rate limit policy are executed. Only the actions that appear in the flow after the rate limit policy are aborted. For more information on configuring assembly-level rate limits, see the following topics:

- Rate Limit policy
- GatewayScript policy
- Using context variables in a GatewayScript policy

How can you test rate limits?

When you're ready to test rate limits on an API or Plan, make sure you deploy it in a test Catalog where automatic subscriptions are not enabled. Execute a larger number of calls than specified by your rate limit, within a shorter period of time. If you set soft rate limits, check for warning messages that indicate when each limit is exceeded. If you set hard limits, you can tell it was enforced when the API call fails. You can also check the error messages to verify which calls exceeded the limits.

The built-in test application that is used by the API Manager and API Designer Test tool is not subject to rate limits if you enabled automatic subscriptions for the Catalog where you are testing. To ensure that your rate limits are applied as intended, create a new test Catalog that requires manual subscriptions and test your API and Plan there. For more information on creating and configuring Catalogs, see Working with Catalogs.

API Connect components

The API Connect components provide a unified user experience across the API lifecycle. Changes in one stage of the API lifecycle are automatically reflected in the other components of API Connect.

- Cloud Manager
- The developer toolkit
- API Manager
- API Gateways
- Runtime
- Developer Portal
- API Analytics
- Typical tasks per interface component
- API Connect server requirements

Cloud Manager

The API Connect Cloud Manager component is used to manage the API Connect on-premises cloud. The Cloud Administrator uses this UI to:

- Define the cluster of *Management servers*, *Gateway servers*, and *containers* that are required in the cloud, and configure the topology. For information about Management servers and Gateway servers, see API Connect server requirements. For information about containers, see Runtime.
- Manage (modify, move, remove, restart, reboot) the servers in the cloud.
- Monitor the health of the cloud.
- Define and manage the provider organizations that develop APIs. (Assigned managers or owners of provider organizations can also complete this task.)
- Define additional cloud administrators, or set up users with roles that enable access to specific capabilities.
- Add user registries for authenticating users and securing APIs, and configure the secure transmission of data (for example, through websites).

For more information about the Cloud Manager, see Managing your cloud.

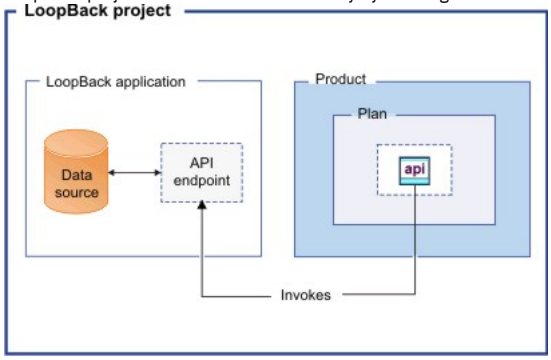
The developer toolkit

The developer toolkit provides the tools for modeling, developing, and testing APIs and LoopBack® applications. The developer toolkit includes a command-line interface (CLI). It also incorporates LoopBack, an open source Node.js framework.

API developers use the API management functions in the API Designer or the CLI to create draft API definitions for REST and SOAP APIs, or for OAuth provider endpoints that are used for OAuth 2.0 authentication. The API definitions can be configured to add the API to a Product, add a policy assembly flow (to manipulate requests/responses), and to define security options and other settings. APIs can then be tested locally prior to publishing, to ensure they are defined and implemented correctly.

Using LoopBack, an API developer can create a Node.js application, connect to a data source such as a back-end database or a REST API to be consumed, and then expose the application as a REST API by creating a model definition. A LoopBack model defines the application data, validation rules, data access capabilities, and business logic for an API, and provides a REST API by default. This REST API can then be used by a REST API definition that was created using the API Designer or CLI and

exposed to your users. The API and its associated application, which are implemented as a LoopBack project, must both be published to enable the project to be run. LoopBack projects can also be tested locally by creating a local runtime environment. The following diagram illustrates the LoopBack project architecture:



Draft APIs (in their containing Products) that are created by using the API Designer, CLI, or LoopBack are published to Catalogs. Applications created using LoopBack are published to containers, from where they run when called. (For information about containers, see Runtime.)

The developer toolkit is installed locally, for offline API and application development. For more information about the developer toolkit, see Developing your APIs and applications. For more information about LoopBack, see LoopBack: The Node.js API Framework.

API Manager

The API Manager provides a user interface that facilitates promotion and tracking of APIs that are packaged within Products and Plans. API providers can move the Products through their lifecycle, and manage the availability and visibility of APIs and Plans.

Catalogs and Spaces are created in the API Manager to act as staging targets through which APIs, Plans, and Products are published to consumer organizations. API providers can stage their Products to Catalogs or Spaces, and then publish them to make the APIs in those Products visible on a *Developer Portal* for external discovery.

To control access to the available API management functions, users in the provider organization can be set up in the API Manager UI with assigned roles and permissions. API providers can also use the UI to manage the consumer organizations that sign up to access their APIs and Plans. Developer *communities* can additionally be created as a way of grouping together a collection of consumer organizations to whom a particular set of Products and Plans can be made available.

The API Manager UI also includes functions to manage the security of the API environment, and provides access to analytics information about API invocation metrics within customizable dashboard views.

For more information about the API Manager, see Managing your APIs.

API Gateways

Gateways enforce runtime policies to secure and control API traffic, provide the endpoints that expose APIs to the calling applications, and provide assembly functions that enable APIs to integrate with various endpoints. They also log and report all API interactions to the API Connect analytics engine, for real-time and historical analytics and reporting. API Connect supports the following types of API gateways:

- DataPower Gateway (v5-compatible)

  The DataPower® Gateway is an enterprise API Gateway that is built for departments and cross-enterprise usage. In V10 API Connect, the DataPower Gateway is compatible with the V5 DataPower Gateway, so it is referred to in documentation as the "v5-compatible" (or "v5c") gateway. The v5-compatible gateway provides a comprehensive set of API policies for security, traffic management, mediation, acceleration, and non-HTTP protocol support.
- DataPower API Gateway

  The DataPower API Gateway was designed with the same security focus as the DataPower Gateway (v5-compatible). Where DataPower Gateway (v5 compatible) is built for flexibility, DataPower API Gateway is built specifically for the API use case, with resulting performance benefits. DataPower API Gateway is optimized for the cloud. Use this gateway if you are running applications in a public or private cloud and want to expose them as APIs.

Your API Connect deployment can include a virtual DataPower Gateway. Support for a physical DataPower Gateway is also available, subject to certain conditions.

For more information about the gateways, and a comparison of their features, see Gateway types.

Runtime

You can run applications and API implementations in API Connect in a containerized runtime.

Containerized runtime
: A containerized runtime environment provides a lightweight deployment location for APIs and applications. A container wraps an application in a complete file system that includes everything it needs to run, such as code, runtime, system tools, and system libraries. You can use Docker Swarm or Kubernetes containers to run your APIs and applications being managed by API Connect.

Developer Portal

The Developer Portal provides a customizable self-service web-based portal to application developers to explore, discover, and subscribe to APIs.

When API providers publish APIs in the API Manager, those APIs are exposed in the Developer Portal for discovery and usage by application developers in consumer organizations. Application developers can access the Developer Portal UI to register their applications, discover APIs, use the required APIs in their applications (with access approval where necessary), and subsequently deploy those applications.

The Developer Portal provides additional features, such as forums, blogs, comments, and ratings, for socialization and collaboration. API consumers can also view analytics information about the APIs that are used by an application, or used within a consumer organization. For more information, see Developer Portal: Socialize your APIs.

API Analytics

API Connect provides the capability to filter, sort, and aggregate your API event data. This data is then presented within correlated charts, tables, and maps, to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends. API analytics is built on the OpenSearch open source real-time distributed search and analytics engine. For more information, see Analytics: understand your API usage.

API Connect server requirements

From an on-premises cloud, you can create, promote, use, and track APIs. An on-premises cloud is composed of various appliances, where each appliance is a server of a specific type. The collection of servers defines your cloud and determines how to distribute the work of managing, analyzing, routing, and storing data.

Your on-premises cloud can be a combination of new and existing physical appliances and virtual appliances, or can be entirely composed of virtual appliances. The type and quantity of servers in an API Connect environment are determined by the individual needs of each enterprise, but the minimum requirement is one Management server, one Analytics server, one Gateway server, and one server to host the Developer Portal.

The API Connect on-premises cloud includes the following server types:

- Management server. Stores all of the cloud configuration, and controls communication between the other servers within API Connect. Manages the operations of the various servers in the API Connect cloud and provides the tools to interface with the various servers. The Cloud Manager and API Manager user interfaces run on the Management server.
- Analytics server. Provides analytic functions that collect and store information about APIs and API users.
- Gateway server. Processes and manages security protocols and stores relevant user and appliance authentication data. The Gateway server also provides assembly functions that enable APIs to integrate with various endpoints, such as databases or HTTP-based endpoints.
- **Developer Portal server**. Provides a customizable social developer portal with a full-featured content management system, and includes clustering capability. Enables API providers to build portals for their application developers, and provides the interface for application developers to discover APIs and subscribe to usage Plans contained in the published Products for use in their applications.

Note: All Management appliances in an API Connect cloud must run at the same firmware level as each other. Gateway appliances can run on different firmware levels to each other, but it is recommended that all of the Gateway appliances run on the same level as each other.

Typical tasks per interface component

API Connect offers both command line and graphical user interfaces. Provider and consumer organizations use different interfaces for completing typical tasks. Refer to the following table to locate the interface that corresponds to a specific task.

Table 1. API Connect Tasks per interface component

Organization Type	Interface Component	Tasks
API Provider	Command Line Interface (CLI)	Create APIs, Plans, and Products
	API Designer UI	Create APIs, Plans, and Products
	API Manager UI	Create Catalogs and Spaces; Create Consumer Organizations
	Cloud Manager UI	Create Provider Organizations
API Consumer (application developer)	Developer Portal	Access APIs to create and run applications; Create Consumer Organizations

If self-service onboarding is enabled for a Catalog, a consumer organization is automatically created when an application developer signs up or is invited by the API provider to a Developer Portal, and the application developer then becomes the owner of that consumer organization.

- **Gateway types**
  IBM API Connect provides the different types of gateways for use with your deployment.

Related concepts

- Packaging strategy and terminology in API Connect

Gateway types

IBM® API Connect provides the different types of gateways for use with your deployment.

DataPower API Gateway

The DataPower® API Gateway has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible). Where DataPower Gateway (v5 compatible) was built for flexibility, DataPower API Gateway is built specifically for the API use case, with resulting performance benefits.

DataPower API Gateway was built and optimized for the cloud. Use this gateway if you are running applications in a public or private cloud and want to expose them as APIs.

DataPower Gateway (v5 compatible)

DataPower Gateway (v5 compatible) provides compatibility with the IBM DataPower Gateway that was provided with IBM API Connect Version 5 and earlier releases.

Consider using DataPower Gateway (v5 compatible) if you are an existing DataPower user and want to utilize your DataPower resources and knowledge.

Gateway comparison

The following table compares support for features between the gateway types. For v5-compatible features and policies that are not supported in DataPower API Gateway, you can use the API Connect Migration Utility (AMU) to migrate them to an API Gateway-compatible format. For more information, see Migrating a Version 5 deployment .

Table 1. Comparison of the DataPower Gateway (v5 compatible) and DataPower API Gateway

Feature	DataPower Gateway (v5 compatible)	DataPower API Gateway
Native policies	No	Yes
OAuth provider	Full OAuth 2.0 Support	Full OAuth 2.0 Support
OAuth policy	No	Yes
OpenID Connect	Supported through a template	Supported natively
Invoke policy	Yes	Yes
Custom policies	Yes	Yes
Conditional policies	if, operation-switch, switch	switch
Activity logging	Implicitly executed at the end of API assembly	Configured in the API design, outside of the API assembly.
Parse policy (threat detection)	No	Yes
Gateway extensions	Yes	Yes
Support for mutual TLS (mTLS)	Yes	Yes

Attention: Version 5-compatible gateways and DataPower API Gateways have different mechanisms for interacting with the API context for GatewayScript and XSLT policies, or if you are authoring user-defined policies. Ensure that you are using the correct mechanisms for your gateway type:

- For v5-compatible gateways and v5 compatibility for APIs created for the API Gateway, see GatewayScript code examples and XSLT policy examples.
- For DataPower API Gateway, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

API Connect support

If you experience a problem with IBM® API Connect that you cannot resolve, you can check the IBM Support website for the most recent technical bulletins and fixes. Otherwise, you can contact IBM Support.

For the most recent API Connect technical information, see the IBM Support Community.

If you cannot find a resolution, before you contact IBM Support, you must gather information about the problem. For details of the information you must gather before contacting IBM Support, see MustGather - Collecting data: API Connect problem determination.

Providing IBM Support with a good description of the problem together with the details of your API Connect configuration, helps to expedite the problem resolution.

API Connect glossary

The IBM® API Connect and Cloud Manager glossary of terms and definitions.

API Administrator (role)
: Manages the API product lifecycle for the Provider Organizations for which they are a member.

API Event
: An event captured for use by API Connect Analytics or third-party analytics, such as response time, HTTP response code, payload of the request and response body, and so on. An API event is logged each time an API operation is invoked via the Gateway server.

API Gateway
: Service that acts as a single entry point or “front door” for provider APIs and back-end services. An API Gateway accepts and processes concurrent API calls, and performs traffic management, authorization and access control, monitoring, and API version management. See also IBM DataPower Gateway.

API Manager
: Graphical tool in API Connect that enables you to manage Catalogs, Spaces, and APIs, users and roles in the Provider organization, consumer organizations and communities, publish Products to the Developer Portal, and analyze API usage.

API Designer
: Graphical tool that runs locally on a laptop or desktop system that enables you to create and modify APIs and LoopBack® apps, and publish them to IBM Cloud or container runtimes.

API operation
: REST API call consisting of an HTTP verb and a URL path (endpoint). For example, `GET http://myserver.com/api/users` that returns a list of users.

Application
: Software that consumes (calls) an API. One or more Applications are registered by a consumer organization to subscribe to APIs. The application is allocated client ID and client secret credentials that it supplies when invoking API calls.

assembly
: Makes side calls to external services and then transforms and aggregates the response before a response is relayed to the calling application.

Availability zones
: In API Connect these are logical groupings of API Connect services that will typically reflect the deployment environment. For example, you could have availability zones named `internal` and `external` to reflect the APIs published in each. Or they could be defined by the geographic location the services are running in.

Catalog
: A staging target that behaves as a logical partition of the gateway and the Developer Portal. The URLs for API calls and for the Developer Portal are specific to a particular Catalog.

client ID
: A piece of information that identifies an individual application. An application can invoke an API only if it passes an application key that is recognized by the IBM API Connect system and is granted access to the API. The application key is passed by the client by using an HTTP query parameter.

client secret
: A piece of information used together with the application key to verify the identity of an application. An API can be configured to require that client applications supply their client secret with their client ID. The client secret functions effectively as a password known only to the application. The client secret is passed by the client by using an HTTP query parameter.

Cloud Manager (tool)

Graphical tool in API Connect on-premises installation that enables you to define servers, administer and scale system resources, monitor runtime health and create Provider organizations. The Cloud Administrator is the primary user of the Cloud Manager.

Cloud Administrator (role)
: Manages the configuration of resources, regions, and availability zones for the Admin Organization of an on-premises installation.

cluster
: A collection of one or more servers that provide a specific function.

Cold standby
: A deployment configuration in which failover servers are in a stopped state until a failover is required, resulting in a longer time window to restore the normal operation of the solution.

community
: A collection of consumer organizations. It is used as a grouping construct when publishing APIs. Communities are used to restrict the visibility and accessibility of APIs. An API can be published to selected communities, which means that only application developers within those organizations can see the API.

Community Manager (role)
: Manages application developer communities for the Provider Organizations for which they are a member.

Consumer organization
: Within a catalog, representation of a business entity that wishes to consume APIs exposed by the Catalog. For example, a third-party application development company would register themselves as a consumer organization (via the Developer Portal). Each developer in their company can then be registered as a user inside that consumer organization.

IBM DataPower® Gateway
: API Gateway service component of API Connect that helps provide security, control, integration and optimized access to APIs. Due to its security and hardening, it is well-suited for a deployment in the demilitarized zone (DMZ) for externally-facing production scenarios. Available in physical, virtual, cloud, Linux and Docker form factors. There are two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway; for details, see Gateway types.

Developer (role)
: Creates and configures APIs, Products, and policies for the Provider Organizations for which they are a member. An API Developer can be a member of one or more Provider Organizations. The API Developer focuses on the technical implementation of APIs more than they do on the business relationship with application developers.

Development Catalog
: Catalog used for testing APIs that are under development and in which approvals are bypassed for publishing and lifecycle actions. Pending approvals are canceled when a non-Development Catalog is converted to a Development Catalog.

Developer Portal
: Component of API Connect that provides a customizable graphical web portal for developers to discover APIs, register applications that consume APIs, subscribe to usage plans, and test and use APIs.

Developer Toolkit
: Locally-installed package that includes API Designer and the `apic` command-line tool that enables you to create, edit, manage, and publish APIs and apps.

Gateway
: See API Gateway.

Gateway service
: API Connect service that provides API gateway functionality, such as microgateway or IBM DataPower.

Hot standby
: A deployment configuration in which a set of servers are actively running ready to instantaneously take over in the event of a failure, but not actively serving traffic until that failover.

Identity provider
: Provides identifiers for users looking to interact with a system, assert to such a system that such an identifier presented by a user is known to the provider, and possibly provide other information about the user that is known to the provider. API Connect supports LDAP, AuthURL, and Local User Registries.

Integrations
: Third-party tools to build on and improve your API Connect workflow; for example, Slack, Auth0, etc.

Integration profile
: Standard API that you can use to integrate with management services for things like identity, notifications, API analytics, and so on.

Keystore
: A repository of security certificates, either authorization certificates or public key certificates, and corresponding private keys, used in SSL encryption. The Keystore file has a `.jks` extension.

LoopBack model
: A JavaScript object that represents application data and includes validation rules, data access capabilities, and business logic. LoopBack models provide a REST API by default, and connect to data sources for access to back-end data

LoopBack data source
: A JavaScript object that represents a back-end service such as a database, REST API (to be consumed), or SOAP web service. Data sources are backed by connectors that communicate directly with the database or other back-end service.

Management server
: Stores all of the cloud configuration, and controls communication between the other servers within API Connect.

Management service
: Consists of one or more Management servers.

Member (role)
: The default role for all users in both the Admin and Provider Organization. All users are assigned the Member role in addition to other roles they may require.

microservice
: Modular, independently-deployable application service that communicates with other microservices through a REST API. Microservices are typically organized around capabilities, for example, recommendation, inventory, shipping, or billing.

Mutual authentication
: Process in which both entities on a network authenticate each other. In a network environment, the client authenticates the server and vice-versa. It is optional for TLS. Also called two-way authentication.

Notification settings
: How you configure notifications for API Connect users (API providers and consumers).

Notification services
: Integrations that provide notification capabilities, such as email.

Notification templates
: The configuration of the message format and wording for a notification service.

OAuth provider
: The OAuth provider supplies the OAuth authentication for logins. API Connect supports both Native and Third Party OAuth providers. Some common third-party OAuth providers are Google and Facebook.

OpenAPI Components

Part of API specification that contains a set of reusable objects for aspects of an API specification, such as schemas, responses, reqeustBodies, and headers. For more information, see [OpenAPI v3 specification](https://github.com/OAI/OpenAPI-Specification/blob/OpenAPI.next/versions/3.0.md#components-object).

organization
: The entity that owns APIs or applications that use APIs. A provider organization owns APIs and associated Plans, and can additionally own applications. A consumer organization owns only applications. An organization has at least one owner. An organization can be a project team, department, or division.

Organization Manager (role)
: The Organization Manager manages Provider Organizations for the Admin Organization.

Path
: Defines the route through which users access REST APIs. A path consists of one or more HTTP operations such as GET or POST.

Plan
: The packaging construct by which APIs are made available to developers. A Plan makes a collection of operations from one or more APIs available, and is published to communities of application developers. Application developers gain access to APIs by registering applications to access Plans. A Plan carries with it a collection of policy settings. In the simplest form, a Plan defines a single quota policy that applies to all the API operations that are accessed through the Plan. In more advanced cases, additional policies can be associated with a Plan.

policy
: A configuration that controls a specific aspect of processing in the Gateway server during the handling of an API invocation at run time. Policies are the building blocks of assembly flows. Policies provide the means to configure capability, such as security, logging, routing of requests to target services, and transformation of data from one format to another. Policies can be configured in the context of an API or in the context of a Plan.

Product
: Provide a method by which you can group APIs into a package that is intended for a particular use. Additionally, they contain Plans, which can be used to differentiate between different offerings. You can create Plans only within Products, and these Products are then published in a Catalog.

Provider Organization Owner
: Owns and administers API provider organizations, manages application developer communities, authors APIs and defines products, manages the API product lifecycle. Owners are invited by the Cloud Administrator to join API Connect as an owner of a provider organization.

proxy
: Application programming interface that forwards requests to a user-defined back-end resource and relays responses back to the calling application.

Region
: A physical location (site or data center) hosting infrastructure isolated from other locations, with independent power and networking connectivity. A region may or may not have further sub-isolation characteristics such as semi-independent pods or availability zones.

Resources (User registries, TLS Profiles, Notifications)
: Resources supply necessary functions for the API Connect cloud, such as user authentication, SSL security, and sending system-generated emails.

role
: Defines permissions that can enable functionality for users. Each role has a different set of permissions.

security definition
: Specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

server
: A single appliance, such as an IBM WebSphere IBM DataPower appliance.

service
: A user-configurable element implemented through one or more server processes in the API Connect runtime, such as microgateway, Analytics, IBM DataPower, and Developer Portal.

SNMP
: Simple Network Management Protocol (SNMP) is a popular protocol for network management. It is used for collecting information from, and configuring, network devices, such as servers, printers, hubs, switches, and routers on an Internet Protocol (IP) network. The SNMP hosts are configured in the API Connect Cloud Manager.

Space
: A subdivision of a Catalog. Each Space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that Space, enabling each team to manage their APIs independently.

SSL (TLS) Profile
: An SSL/TLS profile is used to secure the transmission of data through web sites. SSL certificates guarantee that information you submit to web sites will not be stolen or tampered with.

subscription
: The means by which an application developer gains access to the resources provided by an API. An application developer uses the Developer Portal to subscribe to the plan in which the API is published.

TLS
: Transport Layer Security - a cryptographic protocol that provides secure communication over a network to prevent eavesdropping and tampering. It is a successor to SSL and runs over TCP.

TLS Profiles
: The Cloud Manager and API Manager use TLS profiles to secure transmission of data through web sites. TLS certificates guarantee that information you submit to web sites will not be stolen or tampered with. A TLS Profile consists of Server name, Protocol used (SSL or TLS), and whether Mutual Authentication is required.

Toolkit
: See Developer Toolkit.

Topology administrator (role)
: Configures gateway services for the Admin Organization.

Truststore
: Stores certificates from trusted Certificate authorities(CA) which are used to verify certificate presented by Server in SSL/TSL Connection. While a keystore stores a server's credentials, the truststore stores certificates from a third-party CA.

User registry
: A database or other collection containing credentials for users such as provider organization members, consumer organization members, and API Connect administrators. The users are authenticated by an identity provider such as LDAP. User registries authenticate users at login time when accessing the Cloud Manager or API Manager applications. User registries are also be used to protect APIs so that user credentials must be supplied when an API is called.

vendor extension
: An extension to OpenAPI (Swagger) specification required by a particular use case.

Visibility
: Setting visibility determines whether a Provider Organization has access to an Availability Zone, or other service.

Accessibility features for IBM API Connect

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

Accessibility features

The following list includes the major accessibility features in IBM® App Connect Enterprise. You can use screen-reader software to hear what is displayed on the screen.

- Supports keyboard-only operation.
- Supports interfaces commonly used by screen readers.

Tip: This product documentation, and its related publications, are accessibility-enabled for the IBM Home Page Reader. You can operate all features by using the keyboard instead of the mouse.
If you are reading a PDF file with a screen reader, the default reading option typically returns the best results. In some cases, how the PDF file is generated might require you to select one of the other reading options. For example, Use reading order in raw print stream.

Keyboard navigation

This product uses standard Linux® and Microsoft Windows navigation keys.

For more information about the commitments that IBM makes towards accessibility, see the IBM Accessibility Center.

Legal information

Notices, and terms and conditions for information centers.

- **Tracking API volume for auditing and compliance**
  For client security reasons, IBM entrusts its clients with monitoring their own API volume and ensuring that it is within the limits of the contract.
- **Notices**
  This information was developed for products and services offered in the U.S.A.
- **Terms and conditions for information centers**
  Permissions for the use of these publications are granted subject to the following terms and conditions.

Tracking API volume for auditing and compliance

For client security reasons, IBM entrusts its clients with monitoring their own API volume and ensuring that it is within the limits of the contract.

If you purchased IBM API Connect with a license metric of "API Calls", the count of total API Calls must be collected and archived by the client for audit and compliance. This includes, but is not limited to, licensed programs: "IBM API Connect Hybrid Entitlement" and "IBM Cloud Pak for Integration - API Calls".

Usage archiving

You **are required to regularly** record the number of your API calls from the Analytics **system** to maintain a record of **monthly** usage. To ensure the most accurate results, capture the counts of API Calls daily. For information about viewing API call counts and creating a query that counts API calls for **all** response status codes and for a specified time range, see Counting total API calls for your analytics service.

Overage charging

If you exceed your allotted usage, it is your responsibility to report this to IBM in the form of a CSV file so that the correct overage charge can be applied. IBM has the right to audit customer usage data at any time. If unreported overages are found, there are severe penalties.

Overage is based on the measurement period. For example, overage for a contract might be measured by the year. If your API volume exceeds the entitlement after 6 months, you must either pay overages for the remaining period or purchase additional volume.

Notices

This information was developed for products and services offered in the U.S.A.

IBM® may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Privacy Policy Considerations

IBM Software products, including software as a service solutions, (*Software Offerings*) may use cookies or other technologies to collect product usage information, to help improve the user experience, to tailor interactions with the user or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth in the following paragraphs.

Depending upon the configurations deployed, this Software Offering may use session and persistent cookies that collect each user's session ID for purposes of session management, or functional purposes. These cookies can be disabled, but disabling them will also eliminate the functionality they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, See IBM's Privacy Policy at https://www.ibm.com/privacy and IBM's Online Privacy Statement at https://www.ibm.com/privacy/details the section entitled *Cookies, Web Beacons and Other Technologies* and the *IBM Software Products and Software-as-a-Service Privacy Statement* at https://www.ibm.com/software/info/product-privacy.

Terms and conditions for information centers

Permissions for the use of these publications are granted subject to the following terms and conditions.

Applicability

These terms and conditions are in addition to any terms of use for the IBM® website.

Personal use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

Commercial use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the aforementioned instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

IBM API Connect Considerations for GDPR Readiness

Information about features of IBM® API Connect that you can configure, and aspects of the product's use, that you should consider to help your organization with GDPR readiness.

For PID(s): 5725-Z22 5725-Z63

Notice:

This document is intended to help you in your preparations for GDPR readiness. It provides information about features of API Connect that you can configure, and aspects of the product's use, that you should consider to help your organization with GDPR readiness. This information is not an exhaustive list, due to the many ways that clients can choose and configure features, and the large variety of ways that the product can be used in itself and with third-party applications and systems.

Clients are responsible for ensuring their own compliance with various laws and regulations, including the European Union General Data Protection Regulation. Clients are solely responsible for obtaining advice of competent legal counsel as to the identification and interpretation of any relevant laws and regulations that may affect the clients' business and any actions the clients may need to take to comply with such laws and regulations.

The products, services, and other capabilities described herein are not suitable for all client situations and may have restricted availability. IBM does not provide legal, accounting, or auditing advice or represent or warrant that its services or products will ensure that clients are in compliance with any law or regulation.

Table of Contents

GDPR

General Data Protection Regulation (GDPR) has been adopted by the European Union ("EU") and applies from May 25, 2018.

Why is GDPR important?

GDPR establishes a stronger data protection regulatory framework for processing of personal data of individuals. GDPR brings:

- New and enhanced rights for individuals
- Widened definition of personal data
- New obligations for processors
- Potential for significant financial penalties for non-compliance
- Compulsory data breach notification

- IBM GDPR website

Product Configuration - considerations for GDPR Readiness

The following sections provide considerations for configuring API Connect to help your organization with GDPR readiness.

Configuration to support data handling requirements

The GDPR legislation requires that personal data is strictly controlled and that the integrity of the data is maintained. This requires the data to be secured against loss through system failure and also through unauthorized access or via theft of computer equipment or storage media.
IBM API Connect stores identity data in a local database. This encompasses both clients' employee identity data and end users' identity data. Direct access to this database is not available. Identity information collected is protected in transit; refer to Creating a TLS Server Profile for details on configuring TLS profiles.

API Connect supports a variety of user registry types for authenticating users. Refer to Authenticating by using your enterprise user directory for details. When using a local user registry, passwords are stored in encrypted form in the local API Connect database. If you want alternative password management, leverage a non-user registry option to manage passwords.

Administrators, that you define, can view identity information. Administrators can take backups that include identity information. It is your responsibility to protect these backups.

A core component for an API Connect deployment is the gateway. Refer to the section on API Gateways (in the *API Connect components* topic) for details about gateways. DataPower® Gateways are commonly leveraged; refer to the DataPower Gateway documentation for details. Refer to the DataPower Gateway deployment guidelines document for considerations for configuring DataPower Gateways to help your organization with GDPR readiness.

Configuration to support Data Privacy

For Developer Portal, you can customize the privacy policy statement. Refer to Customizing the privacy policy statement for details.

Configuration to support Data Security

To learn about securing your solution, use this API Connect product documentation and search for "security".

Data Life Cycle

GDPR requires that personal data is:

- Processed lawfully, fairly and in a transparent manner in relation to individuals.
- Collected for specified, explicit and legitimate purposes.
- Adequate, relevant and limited to what is necessary.
- Accurate and, where necessary, kept up to date. Every reasonable step must be taken to ensure that inaccurate personal data are erased or rectified without delay.
- Kept in a form which permits identification of the data subject for no longer than necessary.

API Connect manages the life cycle of user-related data in the following ways:

User account information

API Connect collects and stores identity information, including first and last name, and email address, for the purposes of user registration. Cloud Manager and API Manager accounts are for your employees (or designated actors). Developer Portal accounts are for your consumers of your APIs. Identity information can be collected directly from users or can be copied from LDAP registries. In situations where non-local user registries are used, only the email address is copied from the LDAP registry. Developer Portal user accounts can be deleted; refer to Deleting your Developer account for details. Cloud Manager and API Manager user accounts' identity information can be anonymized by users.
Users of the API Manager UI can publish Products and APIs to the Developer Portal for Application Developers to access and use. Refer to Developer Portal: socialize your APIs to learn about Developer Portal. Developer Portal accounts are for consumers of your APIs. You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal; refer to Customizing the terms of use statement for details.

API analytics

API Connect optionally logs information related to API invocations. This capability in API Connect is known as API Analytics. Refer to Analytics: understand your API usage for details.
The API Analytics log information can optionally include unknown / unclassified information such as query headers and request and response information related to API calls -- you control defining the APIs and data associated with API invocations.

The retention period for storing Analytics data in API Connect is configurable; refer to Retention and rollover for details. Backup capability for this information is not available.

To disable API Analytics, disassociate it from the gateway that collects event data. For information, refer to Associating an analytics service with a gateway service.

System logs

Event-logging preferences can be configured at the API level, refer to Activity Log for details.

API Connect logs collect technical information related to service use including tracing of service execution and sequences of operation use. Other technical data related to service use includes data values that define the mechanisms used to connect to the service, for example, IP address. This data is collected for debugging and service improvement. Service diagnostics are collected during unexpected or error situations to allow the offering team to correct the situation and hopefully prevent it from occurring in the future. There is no direct access available to these logs.You can configure log settings and download the logs as explained in Logging.

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization; for example, publishing a product or creating an organization triggers this event. Refer to Configuring audit logging to monitor user operations for details.

Data Collection

Developer Portal accounts are for consumers of your APIs. You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal; refer to Customizing the terms of use statement for details. You can also customize the privacy policy statement for Developer Portal; refer to Customizing the privacy policy statement for details.

Types of Data Collected

API Connect collects and stores identity information (including first name, last name, and email address) for the purposes of user registration. Cloud Manager and API Manager accounts are for your employees (or designated actors). Developer Portal accounts are for your consumers of your APIs. Identity information can be collected directly from users or can be copied from LDAP registries. In situations where non-local user registries are used, only the email address is copied from LDAP registry. Developer Portal user accounts can be deleted; refer to Deleting your Developer account for details. Cloud Manager and API Manager user accounts' identity information can be anonymized by users.

Data Storage

Identity data is stored in API Connect local data store. There is no direct access available to this data store.

API Analytics leverages the OpenSearch real-time distributed search and analytics engine for storage of logged data. There is no direct access available to this data store.

Identity data is included in backups; refer to Backing up and restoring for details on taking backups. It is your responsibility to protect and discard backups.

Data Access

Identity information can be viewed by administrators that you define.

Analytics information can be accessed through a variety of means. Refer to Access your analytics data for details.

Analytics information can be offloaded to third-party systems. Refer to Offloading to third-party systems for details. It is your responsibility to protect off-loaded data.

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization; for example, publishing a product or creating an organization triggers this event. Refer to Configuring audit logging to monitor user operations for details.

API Connect logs collect technical information related to service use including tracing of service execution and sequences of operation use. Other technical data related to service use includes data values that define the mechanisms used to connect to the service, for example, IP address. This data is collected for debugging and service improvement. Service diagnostics are collected during unexpected or error situations to allow the offering team to correct the situation and hopefully prevent it from occurring in the future. There is no direct access available to these logs.You can configure log settings and download the logs as explained in Logging.

Data Processing

Data collected by API Connect or to gateways via API invocations is protected by TLS in transit. Refer to Creating a TLS Server Profile for details.

Data is stored in API Connect local database on the API Connect appliances. There is no direct access available to this data.

Cloud Manager and API Manager administrators (defined by you) have read access to identity data.

Data Deletion

Right to Erasure

Article 17 of the GDPR states that data subjects have the right to have their personal data removed from the systems of controllers and processors -- without undue delay -- under a set of circumstances.

Data Deletion characteristics

Users can delete their own Developer Portal user accounts -- refer to Deleting your Developer account for details. Cloud Manager and API Manager user account identity data can be anonymized by the users to remove association with the account data.
Technical information related to service use collected in logs is rolled over based on size and time criteria.

To disable API Analytics, disassociate it from the gateway that collects event data. For information, refer to Associating an analytics service with a gateway service.

The retention period for storing Analytics data in API Connect is configurable; refer to Retention and rollover for details. Backup capability for this information is not available.

Analytics information can be offloaded to third-party systems. Refer to Offloading to third-party systems for details. You are responsible for the security of off-loaded data.

Identity information for accounts is included in system backups. You manage the deletion of system backups.

Data Monitoring

Customers should regularly test, assess, and evaluate the effectiveness of their technical and organizational measures to comply with GDPR. These measures should include ongoing privacy assessments, threat modeling, centralized security logging, and monitoring

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization; for example, publishing a product or creating an organization triggers this event. Refer to Configuring audit logging to monitor user operations for details.

Capability for Restricting Use of Personal Data

Users of the API Manager UI can publish Products and APIs to the Developer Portal for Application Developers to access and use. Refer to Developer Portal: socialize your APIs to learn about Developer Portal. Developer Portal accounts are for consumers of your APIs.

You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal; refer to Customizing the terms of use statement for details. You can also customize the privacy policy statement for Developer Portal; refer to Customizing the privacy policy statement for details.

Developer Portal users can modify their own account information, and can delete their account.

Essential reading

These articles by IBM® API Connect product specialists provide a wealth of supporting information on APIs and the API economy.

Why Become a Digital Business?
: Executing a Digital Transformation to become a Digital Business is among the hottest initiatives now – crossing both business and IT. But, is this just the latest buzzword or is there something to this that is different? Do you know **why** you should become a “Digital Business”?

Creating A Digital Ecosystem – Past, Present, and Future
: The ability to create a digital ecosystem is critical to digital transformation success. Your success is your network reach.

Agile integration
: Your business needs a modern, agile approach to integration. It should empower extended teams to create integrations, leverages a complete set of integration styles and capabilities, and increases overall productivity.

What is an API? and What is the API Economy?
: Businesses start to consider APIs and the API Economy at various times. Many are long down their API journeys, while others are still considering whether to start. This article looks at some of the basics that companies considering APIs might want to know.

What is API Management?
: APIs are not new. Software and hardware have had APIs (Application Programming Interfaces) for decades. However, *having* an API and *managing* an API are not the same thing.

Providing APIs or Managing APIs – There is a Big Difference
: A discussion of the potential for confusion between APIs that are provided and APIs that are managed.

Recommendations for an API Economy Center of Excellence
: What roles are required to drive a successful API initiative, how should this fit in the current organization, and how do these roles relate to existing roles in the company?

Focus on the API Developer
: A productive developer is a happy developer. One of the most frequently discussed topics in the API economy is focusing on the needs of the Application developer – the consumer target for your APIs.

Agile API development
: Agile API Development Customer expectations and behavior are continuously changing. To deliver exceptional customer experience, a business must be nimble to adapt to these changing needs.

API Products – Who, What, Where, When, Why and How”
: An API Product is an API offering made available for consumer use that is offered to a target market to satisfy a customer’s needs.

Changing Culture – How Committed Are You?
: How do we change the culture in our organization to create an API culture?

Plan Ahead! Don’t Build an API Superhighway into a Cul-de-sac
: Without proper planning, a business can start their API initiatives, build incredible excitement quickly, but find that the path they have taken leads them into a cul-de-sac (or dead end) that cannot handle the demand they have created.

IBM API Connect v10.x Deployment WhitePaper
: A technical deep dive on the deployment options for IBM API Connect.

Principles for API Security - White Paper
: API security is of paramount importance in gaining the promised benefits without exposure to negative consequences.

Can you trust your APIs?
: As enterprises are continuously expanding their digital footprint, they must ensure the API behavior is intact, as it has a far-reaching effect on an application's execution and end-user experience.

Istio Service Mesh and APIConnect/DataPower Gateway integration
: What is Istio, and how can DataPower API Gateway integrate in an Istio Service Mesh.

Best Practice – Monetizing API Products
: Ultimately the goal for almost all API initiatives is Monetization in the broad sense that crosses multiple modes from Free - to Indirect - to Direct. Most businesses using APIs successfully are monetizing APIs by speeding offerings to market, reaching new markets and new customers, innovating, and sharing assets better inside their enterprise.

Tutorials

These tutorials guide you through the steps typically required to set up, configure and run an API Connect cloud.

Introduction

These tutorials are arranged according to the desired goal, such as creating and publishing an API, or managing catalogs of products, or consuming published API products. These goals can be grouped into categories as follows.

Table 1. Tutorial Categories

Category	Description
Cloud Administration	Setting up and configuring the API Connect cloud, including the creation of Provider Organizations.
API Provider Administration	Setting up and managing catalogs, inviting organization members (such as developers), creating Developer Portals, managing resources.
API Product Promotion and Usage	Managing the Developer Portal presentation and user administration, as well as consuming published API products as an external developer.

Time required

Each tutorial should take approximately 20 - 30 minutes to finish. If you explore other concepts that are related to this tutorial, it might take longer.

Use the links in the following sections to access the tutorials that fit your goals.

Cloud Administration

Table 2. Cloud Administration Tasks. Setting up and configuring the API Connect cloud, including the creation of Provider Organizations.

Category	Tutorials
Initial Configuration	• Initial Cloud Configuration
Provider Organization	• Creating a Provider Organization

API Provider Administration

Table 3. API Provider Tasks. Setting up and managing catalogs, inviting organization members (such as developers), creating Developer Portals, managing resources.

Category	Tutorials
Developer Portal Set Up	• Creating the Portal • Register a Consumer Application

API Product Promotion and Usage through the Developer Portal

There are many tutorials available for the Developer Portal from getting started to advanced customization. For more information, see Developer Portal tutorials.

Prerequisites

- You must have a web browser available, whether you are working online or offline.
- When publishing Products in any of the tutorials you must have the permissions of an Organization Manager or Administrator. However, you can complete several of the tutorials with fewer permissions. For more information about user roles, see Administering user access.

Installing and maintaining IBM API Connect

To ensure that your IBM® API Connect cloud functions, your cloud must have the necessary system requirements to support the installation. During the installation process, the components of IBM API Connect can be configured to satisfy your requirements.

Note: For a comprehensive technical guide to best practices, considerations, and deployment options for API Connect, see the IBM API Connect v10.x Deployment WhitePaper .

- **Kubernetes, OpenShift, and Cloud Pak for Integration**
  Use the instructions in this section to install, upgrade, and maintain API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.
- **VMware**
  Use the instructions in this section to install, upgrade, and maintain API Connect on VMware.
- **Migrating from IBM API Connect v5 Public Cloud to v10.0.6x**
  You cannot migrate direct to IBM API Connect 10.0.6.0 or later from API Connect v5 Public Cloud. You must migrate to version 10.0.5.x or later, and then upgrade to 10.0.6.0 or later.
- **Migrating a version 5 deployment to version 10.0.6x**
  You cannot migrate direct to IBM API Connect 10.0.6.0 or later from API Connect 5.0.x. You must migrate to version 10.0.5.x or later, and then upgrade to 10.0.6.0 or later.

- **Migrating v5-compatible APIs to API Gateway**
  Use the migration utility to automate the migration of v5-compatible APIs to DataPower API Gateway APIs.
- **Migrating from v10 to v10 on a different form factor**
  Migrate an API Connect v10 deployment from one form factor to a different form factor.
- **Replacing passwords, keys, and certificates**
  Ensure the security of your API Connect deployment by replacing compromised passwords, keys, and certificates.
- **The API Connect operations tool: apicops**
  Use the apicops operations tool to check the health, troubleshoot, and run maintenance operations on your API Connect installation.

Kubernetes, OpenShift, and Cloud Pak for Integration

Use the instructions in this section to install, upgrade, and maintain API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.

- **Planning your deployment**
  Review the following topics to plan your API Connect deployment.
- **Installing API Connect**
  Use these instructions to install a deployment of API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.
- **Upgrading API Connect**
  You can upgrade a v10 deployment of API Connect to a newer version.
- **Maintaining API Connect**
  You can use utilities to complete maintenance tasks such as backup, restore, and certificate management on Kubernetes.
- **Uninstalling API Connect**
  You can uninstall a Kubernetes deployment of API Connect.

Planning your deployment

Review the following topics to plan your API Connect deployment.

- **Key concepts: Custom Resources, Operators, and Operands**
  API Connect uses Custom Resources (CRs) and the Kubernetes Operator pattern.
- **Kubernetes ingress controller prerequisites**
  Describes the prerequisite settings for the ingress controller for a Kubernetes runtime environment.
- **Persistent Volume (PV) requirements**
  Review the persistent volumes (PVs) required by your API Connect installation.
- **Load balancer configuration in a Kubernetes deployment**
  When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect Kubernetes deployment.
- **Firewall requirements on Kubernetes**
  Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on Kubernetes.
- **Planning your analytics deployment**
  Plan your API Connect analytics deployment by reviewing options for deployment profile and estimating required persistent storage space.
- **Two data center deployment strategy on Kubernetes and OpenShift**
  An overview of the two data center disaster recovery deployment strategy in API Connect.
- **Key Concepts: Cert-manager, Issuers, and Secrets**
  By default API Connect uses an open source product that is called cert-manager to handle the issuing and renewal of the certificates that are used by API Connect. The cert-manager has its own Kubernetes pods and runs in its own namespace. The cert-manager adds some additional resources to the Kubernetes environment. The API Connect administrator needs to be familiar with these additional resources:
- **Certificates in a Kubernetes environment**
  Use of cert-manager is recommended for managing certificates in a Kubernetes environment.
- **Webhooks deployed and managed by the API Connect Operator**
  The API Connect Operator deploys and manages various Kubernetes API webhooks in the cluster to assist in management of its custom resources.

Key concepts: Custom Resources, Operators, and Operands

API Connect uses Custom Resources (CRs) and the Kubernetes Operator pattern.

- Kubernetes: https://kubernetes.io/docs/concepts/extend-kubernetes/operator/
- OpenShift: https://developers.redhat.com/articles/2021/06/11/kubernetes-operators-101-part-1-overview-and-key-features.

Below are some key points to understand about how API Connect implements this pattern:

- An API Connect instance is composed of two main operators and the API Connect subsystems that they manage, which in Kubernetes terminology are known as the Operands.
- The operator is responsible for monitoring the API Connect operands, ensuring that they are running as expected.
- API Connect operands can continue running without their operator, in an unmanaged state.
- The API Connect operator manages the Management Server, Portal, and Analytics subsystems. On Kubernetes each of these subsystems has its own Custom Resource, so each of these is an Operand. On Openshift and Cloud Pak for Integration there is also the option of having a top-level Custom Resource which manages all subsystems as a single Operand.
- The DataPower operator manages the Gateway operand.

- A single API Connect operator can manage multiple API Connect instances if the operator is installed globally and the API Connect operands are in individual namespaces. This is the recommended configuration where multiple API Connect instances are required, as opposed to a separate operator in each namespace.
- There can be only one instance of the API Connect operator in your Kubernetes or OpenShift environment. You cannot have multiple namespaces each with their own API Connect operator.
- In a single OpenShift/K8S environment all API Connect instances, operands, and operators, in all namespaces must be at the same version. The only exception is during upgrade where the operators are upgraded first.

Planning your deployment topology

On Kubernetes, OpenShift, and Cloud Pak for Integration, API Connect provides a choice of deployment options for capacity, High Availability (HA), and Disaster Recovery (DR).

High availability versus disaster recovery

High availability focuses on minimizing the loss of service that is experienced by users during a hardware or software failure. Disaster recovery (DR) focuses on the procedures for recovering a system after a catastrophic hardware, software, or operator failure. Consider the following two metrics:

Recovery Time Objective (RTO)
: The RTO is the time that it is acceptable for a system to be unavailable after a disaster.

Recovery Point Objective (RPO)
: DR solutions are usually based on restoring from a backup. This means that the system can only be recovered to the state it was in when the last backup was taken, and not to the state it was in at the instant the disaster occurred. The RPO measures how far back in time the recovery point is, and therefore how much new data is lost. An RPO of zero would assert that no data is lost, but such a solution is often a compromise against the cost and performance of the system.

To achieve high availability in your API Connect deployment, the three replica deployment profiles should be used, where each API Connect component consists of clusters of three replicas that are distributed across three worker nodes. However, this topology requires that all cluster members are running in the same Kubernetes environment, which requires a low network latency between worker nodes that is often unachievable between geographically separated data centers. To overcome this limitation, API Connect provides a two data center deployment solution that has both a low Recovery Time Objective (RTO), and a low Recovery Point Objective (RPO).

Deployment options

API Connect is composed of three components: Management, Portal, and Analytics, and a supporting program: the DataPower Gateway, see API Connect components.
Note: Throughout this document, the DataPower Gateway supporting program is also referred to as a "component" or a "subsystem". The Management, Portal, and Analytics components are also referred to as "subsystems".
The Management, Portal, Analytics, and Gateway each have a set of capacity and HA profiles, called component profiles. OpenShift and Cloud Pak for Integration also have API Connect deployment profiles that define the component profiles that are used by each component of a complete API Connect deployment.

The naming convention of the profiles is `nAxcB.mC` where:

- **nA** indicates the number (A) of replicas of each pod, where each replica must run on a different worker node.
- **cB** indicates the minimum number of virtual cores (B) required on the worker node to deploy the profile.
- **mC** indicates the minimum amount of memory (C) in GB required by the profile on the worker node.

Component profiles

Each API Connect component has a defined set of profiles that it can be deployed with. For information on the resource settings defined for each component profile, see Component profiles, CPU limits, memory limits, and licensing.

Key points of component profiles:

- One replica profiles are denoted by `n1`, and provide a single replica of each pod. The one replica profiles can be deployed on a single worker node.
- Three replica profiles are denoted by `n3`, and provide three replicas of each pod. At least three worker nodes must be available to deploy a three replica profile. If one replica pod fails, then the other two replicas continue serving requests, providing high availability.
- Component profiles do not have to be the same for each component. For example, you can have a three replica deployment of the Management component that is configured with a one replica deployment of the Portal component.
- It is possible to change component profile after installation see Advanced configuration.
- Multiple Portal, Analytics, and Gateway component instances can be added with either configuration. For example, you can have a three replica Management component that is configured with two Portal services: a one replica Portal component, and a three replica Portal component.

OpenShift and Cloud Pak for Integration API Connect deployment profiles

API Connect deployment profiles define a complete API Connect deployment, specifying the component profiles for the Management, Portal, Analytics, and Gateway components to be used in that deployment.

Key points of API Connect deployment profiles:

- The API Connect deployment profile is selected by the user in the installation steps on OpenShift and Cloud Pak for Integration.
- API Connect deployment profiles provide one instance of the Portal, Analytics, and Gateway components.
- For details of each API Connect deployment profile, see: API Connect deployment profiles for OpenShift and Cloud Pak for Integration

Two data center disaster recovery

API Connect deployments can operate across two data centers in an active/warm-standby configuration. Each data center has a complete API Connect installation. The active data center processes all user operations. The warm-standby data center does not process user operations but maintains its management and portal databases in

synchronization with the active data center. If a failure occurs at the active data center, the warm-standby data center can become active with a manual failover operation. For more information on the two data center disaster recovery configuration, see: Two data center deployment strategy on Kubernetes and OpenShift

API Connect deployment profiles for OpenShift and Cloud Pak for Integration

Details of the API Connect deployment profiles that are provided for OpenShift and Cloud Pak for Integration.

API Connect provides various profiles to suit your capacity and availability requirements.

The API Connect deployment profiles provide one Management component instance, and one instance of the Portal, Analytics, and Gateway components.

On Cloud Pak for Integration:

- The available deployment profiles are presented as tiles in the Platform UI.
- The Portal, Analytics, and Gateway components are automatically registered with the Management component during installation.

n1xc7.m48: Small - Single replica

Best suited for light, noncritical workloads such as small team development and testing. Deploys 1 replica of the Management, Developer Portal, Analytics, and Gateway components with a minimal footprint.

Table 1. n1xc7.m48

Component name	Component profile
Management	n1xc2.m16
Portal	n1xc2.m8
Analytics	n1xc2.m16
Gateway	n1xc1.m8

n1xc16.m72: Medium - Single replica

Ideal for medium workloads such as organizational development, testing, and production when in alignment with business availability requirements. Deploys 1 replica of the Management, Developer Portal, Analytics, and Gateway components.

Table 2. n1xc16.m72

Component name	Component profile
APIM	n1xc4.m16
Portal	n1xc4.m16
Analytics	n1xc4.m32
Gateway	n1xc4.m8

n3xc16.m48: Large - Three replicas

Ideal for heavy workloads when business requires redundancy for greater availability & capacity. Deploys 3 replicas of the Management, Developer Portal, Analytics, and Gateway components.

Table 3. n3xc16.m48

Component name	Component profile
APIM	n3xc4.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16
Gateway	n3xc4.m8

n1xc12.m64: Medium - Single replica - Remote Gateway

Ideal for medium workloads such as organizational development, testing, and production when in alignment with business availability requirements. Must be configured for use with existing or independently deployed Gateways. Deploys 1 replica of the Management, Developer Portal, and Analytics components.

Table 4. n1xc12.m64

Component name	Component profile
APIM	n1xc4.m16
Portal	n1xc4.m16
Analytics	n1xc4.m32

n3xc12.m40: Large - Three replicas - Remote Gateway

Ideal for heavy workloads when business requires redundancy for greater availability & capacity. Must be configured for use with existing or independently deployed Gateways. Deploys 3 replicas the Management, Developer Portal, and Analytics components.

Table 5. n3xc12.m40

Component name	Component profile
APIM	n3xc4.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16

Deprecated profiles

The API Connect deployment profiles presented here existed in previous releases, but are now in a deprecated state and should not be used for new installations.

Table 6. n3xc11.m48

Component name	Component profile
APIM	n3xc2.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16
Gateway	n3xc1.m8

Table 7. n3xc14.m48

Component name	Component profile
APIM	n3xc2.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16
Gateway	n3xc4.m8

Table 8. n1xc10.m48

Component name	Component profile
APIM	n1xc2.m16
Portal	n1xc2.m8
Analytics	n1xc2.m16
Gateway	n1xc4.m8

Component profiles, CPU limits, memory limits, and licensing

Available component profiles, their CPU and memory limits, and how the CPU-based licensing works.

API Connect is licensed based on the CPU usage of your deployment. Each component profile sets specific CPU and memory limits on each of the containers that comprise API Connect.

API Connect operator

The API Connect operator container uses the same CPU and memory requests and limits for all profiles, and is not a container that requires license entitlement.

Table 1. Operator container CPU and memory requirements

Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits	PVC Size	Number of replicas	License entitlement required
ibm-apiconnect	ibm-apiconnect	75	1000	128	1Gi		1	No

The CPU and memory usage tables for each API Connect component profile are shown in the following pages.

- **Management component deployment profile limits**
  The CPU, memory limits, and PVC space that are required for each Management profile.
- **Portal component deployment profile limits**
  The CPU and memory limits that are defined for each Portal deployment profile.
- **Analytics component deployment profile limits**
  The CPU and memory limits that are defined for each Analytics deployment profile.
- **DataPower gateway deployment profile limits**
  The CPU and memory limits that are defined for each Gateway deployment profile.

Management component deployment profile limits

The CPU, memory limits, and PVC space that are required for each Management profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: `<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>`. For example, for the `n3xc2.m16` profile:

- The three licensed containers are `apim`, `postgres`, and `taskmanager`.
- These three containers have CPU limits of 625, 750, and 625.
- This profile is a three replica (n3) profile.

The total CPU limit of the licensed containers then is: (625 + 750 + 625) * 3 = 6000

All Management component deployment profiles have job pods that complete tasks during startup, upgrade, backup, and restore operations. The job pods do not have any licensed containers, and their CPU/memory requests and limits are the same for all profiles.

Table 1. Management job pods CPU and memory requirements

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
management-up-apim-schema	management-up-apim-schema-0-to-<nnn>-<xx>-<yy>	apim-schema	50 m	500 m	128 Mi	256 Mi

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
management-up-apim-data-populate	management-up-apim-data-populate-0-to-<nnn>-<xx>-<yy>	apim-data-populate	50 m	600 m	256 Mi	4096 Mi
management-up-lur-schema	management-up-lur-schema-0-to-<nnn>-<xx>-<yy>	lur-schema	50 m	500 m	128 Mi	256 Mi
management-up-lur-data-populate	management-up-lur-data-populate-0-to-<nnn>-<xx>-<yy>	lur-data-populate	50 m	500 m	128 Mi	256 Mi
backrest-backup-management-<xx>-postgres	backrest-backup-management-<xx>-postgres-<yy>	backrest	not set	not set	not set	not set
management-apim-restore-<xxx>	management-apim-restore-<xxx>-<yyy>	apim-restore	50 m	500 m	128 Mi	256 Mi
management-<xxx>-postgres-rmdata	management-<xxx>-postgres-rmdata-<yyy>	rmdata	not set	not set	not set	not set
management-<xxx>-postgres-bootstrap	management-<xxx>-postgres-bootstrap-<yyy>	database	600 m	750 m	512 Mi	8192 Mi
management-<xxx>-postgres-stanza-create	management-<xxx>-postgres-stanza-create-<yyy>	backrest	50 m	500 m	128 Mi	256 Mi
management-up-compliance-schema	management-up-compliance-schema-0-to-<nnn>-<xx>-<yy>	compliance-schema	50 m	500 m	128 Mi	256 Mi
management-up-compliance-data-populate	management-up-compliance-data-populate-0-to-<nnn>-<xx>-<yy>	compliance-data-populate	50 m	500 m	128 Mi	256 Mi

The following tables show the pod resource and license requirement for each Management component deployment profile. A separate table shows the requirements for optional features.
Important: The tables for the three replica profiles show the usage for a single replica in the three replica deployment. Except for containers that are indicated to be single replica, multiply by three to get the total usage.

n1xc2.m16

Table 2. n1xc2.m16 profile resource and licensing requirements

Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits	PVC Size	Number of replicas	License entitlement required

Portal component deployment profile limits

The CPU and memory limits that are defined for each Portal deployment profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: **`<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>`**

All Portal component deployment profiles have a **`sync-backup`** job pod that completes tasks that are related to scheduled portal backups. The **`sync-backup`** job pod does not have any licensed containers, and its CPU/memory requests and limits are the same for all profiles.

Table 1. Portal job pods resource and licensing requirements

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
<portal-instance-name>-sync-backup	*<portal-instance-name>*-sync-backup-*<jobuuid>*	sync-ptl-backup-schedule	1m	1m	100Mi	100Mi

n1xc2.m8

Analytics component deployment profile limits

The CPU and memory limits that are defined for each Analytics deployment profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: **<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>**

All Analytics component deployment profiles have an **osinit** job pod that is run on startup and completes tasks that are related to initialization. The **osinit** job pod does not have any licensed containers, and its CPU/memory requests and limits are the same for all profiles.

You can choose different storage types with the three replica profiles, and so the pods deployed differ depending on the storage option chosen: Analytics storage type. If you choose storage type **shared**, then your analytics deployment has 1 storage pod, called **storage**. If you choose storage type **dedicated**, then your analytics deployment has 2 storage pods, called **storage** and **storage-os-master**. The tables for the three replica profiles indicate in parentheses after the pod name which storage type the pod applies to, for example "storage (shared)".

Table 1. Analytics job pods

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
<analytics-instance-name>-osinit	*<analytics-instance-name>*-osinit-*<podid>*	osinit	8 m	100 m	128 Mi	256 Mi
<analytics-instance-name>-oscron	*<analytics-instance-name>*-oscron-*<jobid>*-*<podid>*	oscron	8 m	100 m	128 Mi	256 Mi

The PVC sizes that are specified in the tables are the defaults. Review the planning and installation documentation to decide on the sizes to allocate for your deployment: Planning your analytics deployment.

Network requirements for inter-subsystem communication

Plan how to secure the network communications between your API Connect subsystems.

API Connect provides various configuration options that are related to inter-subsystem communication.

Support load-balancer TLS termination by disabling mTLS and enabling JWT security

If your network infrastructure requires that load-balancers implement TLS termination, then mTLS between API Connect subsystems can be disabled and JSON Web Token (JWT) security can be used instead.
Note: Although mTLS is disabled, the network communication is still secured with standard TLS, which does not require passthrough to be enabled on load-balancers.
The following communication flows can be secured with JWT:

- Management initiated communication to portal, analytics, and gateway subsystems.
- Analytics ingestion: The flow of API event records from the gateway to the analytics subsystem.
  Note: If the gateway is under a high transaction load and sending many API events to the analytics subsystem, the enablement of JWT might impact the performance of your analytics subsystem. It is recommended to run performance tests under your expected analytics load before you decide to use JWT for the analytics ingestion path.

With JWT enabled, the portal, gateway, and analytics subsystems verify the JSON Web Token (JWT) sent from the management subsystem when it initiates communication with them. The analytics subsystem verifies the JWT sent from the gateway with incoming API event data. The subsystems that receive the token contact a JSON Web Key Set (JWKS) URL to verify it. The JWKS URL is hosted by the management subsystem, in a subpath of the management subsystem's platform REST API.
For more information about this feature, see Enable JWT security instead of mTLS.

Use services instead of routes (OpenShift) or ingresses (Kubernetes)

Note: This feature is available on Kubernetes and OpenShift deployments where the API Connect subsystems are within the same cluster. It is not available on two data center disaster recovery deployments: Two data center deployment strategy on Kubernetes and OpenShift.
For inter-subsystem communication, API Connect uses routes on OpenShift and Ingresses on Kubernetes. Both routes and ingresses require the exposure of external HTTPS endpoints. On API Connect deployments where all subsystems are in the same cluster, you can use services instead of routes or ingresses for inter-subsystem communication. When API Connect is configured to use services, all inter-subsystem communications are kept within the cluster, providing greater security and reduced load on external network infrastructure such as load-balancers.

In the context of inter-subsystem communication, the use of routes or ingresses is referred to as **external** communication, and the use of services is referred to as **in-cluster** communication.

You select whether to use **external** or **in-cluster** communication when you register your portal, gateway, or analytics subsystems with the management subsystem.

For more information about this feature, see In-cluster service communication between subsystems.

Enabling mTLS on management to gateway communication

On Kubernetes and on OpenShift installations where the top-level CR is not used, mTLS can be enabled for management to gateway communication. To enable mutual TLS between the Management client and the Gateway service's manager endpoint, add **mtlsValidateClient** to the **spec** section:

```
spec:
  mtlsValidateClient: true
```

This ensures that the gateway service authenticates incoming requests from the API Manager, such as gateway service registration, and publishing APIs to the gateway service. Specifically, the gateway service requires that incoming requests present a certificate that was signed by the same CA that was used to sign the gateway service management endpoint. The gateway service management endpoint secret is specified under **gatewayManagerEndpoint.hosts.secretName**. The API Manager's gateway client's TLS credentials are specified in the ManagementCluster CR under **gateway.client.secretName**.
Note: In releases previous to 10.0.5.3, this property is called **validateApimClient**.
Note: On Cloud Pak for Integration and OpenShift where the top-level CR is used, mTLS enablement for management to gateway communication is not supported.

Management REST API CA certificate validation

The portal, gateway, and analytics subsystems make requests to the management subsystem through the REST API that is hosted by the management subsystem. This communication is standard TLS, where each REST API endpoint has a server certificate that is presented to the client during TLS handshaking. For extra security, validation of the management server certificate CA is enabled on all subsystems for new installations of API Connect v10.0.5.3 and later. If you are upgrading from an earlier release, the steps to enable this feature are

Certificates used to secure inter-subsystem communication

For information about the management of the certificates that are used in the TLS and mTLS communications between subsystems, see Key Concepts: Cert-manager, Issuers, and Secrets.

Enable JWT security instead of mTLS

When and how to use JWT security instead of mTLS.

Most of the network interactions between API Connect subsystems use mTLS. The communication flows in API Connect that are secured with mTLS are as follows:

- Management to portal. mTLS set by default.
- Management to analytics. mTLS set by default.
- Management to API gateway. TLS set by default, mTLS can be enabled following Enabling mTLS on management to gateway communication.
- Management to v5 compatible gateway. TLS set by default, mTLS can be enabled following Enabling mTLS on management to gateway communication.
- Management to Event gateway. mTLS set by default. Cloud Pak for Integration only.
- API gateway to analytics. mTLS set by default.
- V5 compatible gateway to analytics. mTLS is set and cannot be disabled.
- Event gateway to analytics. mTLS set and cannot be disabled. Cloud Pak for Integration only.

All other inter-subsystem communication uses TLS. For the communication routes that use mTLS, it is a requirement that all network infrastructure such as load-balancers that are located between API Connect subsystems implement TLS passthrough (and not TLS termination).

Use of JSON Web Token (JWT) security instead of mTLS allows for the deployment of API Connect in network infrastructures where TLS termination is enabled on load-balancers that are located between subsystems. JWT provides application layer security between API Connect subsystems. The typical use-case for this feature is when payload inspection of all network communications is required at network boundaries. The communication flows that support JWT security are:

- Management to portal.
- Management to analytics.
- Management to API gateway.
- Management to v5 compatible gateway.
- API gateway to analytics.
  Note: It is not possible to use JWT and disable mTLS on the V5 compatible gateway to analytics message flow.

The management subsystem always sends a JWT when it initiates communication with the other subsystems, but by default the subsystems do not verify this JWT. When JWT security is enabled, the subsystems verify the JWT by making a REST call to the JSON Web Key Set (JWKS) URL. The JWKS URL is hosted on the management subsystem's platform REST API.

To enable JWT verification on management initiated communication, update the subsystem CRs to specify the JWKS URL. To disable JWT verification, update the subsystem CRs and delete the value of the JWKS URL (leave it unset).

To enable JWT verification on gateway to analytics communication, enable the Use JWT switch when you register the gateway in the Cloud Manager UI.
Note: For OpenShift users: The example steps in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place. If you are using a top-level CR you must edit the **APIConnectCluster** CR (the top-level CR), instead of directly in the subsystem CRs. If the subsystem section is not included in the top-level CR, copy and paste the section from the subsystem CR to the **APIConnectCluster** CR.

Disabling mTLS and enabling JSON Web Token (JWT) security

If you disable mTLS, you must enable JWT. It is not possible to configure API Connect with both mTLS and JWT disabled.

You disable mTLS on the portal, gateway (for management to gateway communication), and analytics subsystems by setting the `mtlsValidateClient` property to false in the Custom Resources (CRs) of each subsystem.
Note: By default, `mtlsValidateClient` is set to false on the gateway subsystem.
When `mtlsValidateClient` is set to false, the subsystem does not verify the client's TLS credentials, but it does check for a valid JWT configuration. For example, to disable mTLS and enable JWT for management to portal communication, edit the portal CR and set:

```
spec:
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the `jwksUrl` specified in the management subsystem CR `status.endpoints` section.
Using registration of the portal service in the Cloud Manager UI as an example, JWT works as follows:

1. Management subsystem establishes a TLS connection to the portal subsystem on the portal director admin endpoint, and sends a JWT to the portal.
2. Before the portal trusts the management subsystem, it first verifies the JWT it received. The JWT is verified by a call to a JSON Web Key Set (JWKS) URL.
3. The management subsystem receives the JWT verification request from the portal on its platform REST API, and responds that the JWT is valid.
4. The portal receives confirmation that the JWT is valid, and so it can trust the management subsystem and continue the registration process.

To disable JWT security for management initiated communication, either remove the `jwksUrl` property from the CR, or leave its value empty. If you disable JWT, you must enable mTLS by setting `mtlsValidateClient` to true.

To disable JWT security for gateway to analytics communication, disable the Use JWT switch for the registered gateway in the Topology page of the Cloud Manager UI.

Configuring the JWKS URL

The JWKS URL is defined as the platform API hostname with the following subpath appended: `api/cloud/oauth2/certs`. You can see what the JWKS URL is from the `status.endpoints` section of the management CR, for example:

```
status:
...
  endpoints:
...
    - name: jwksUrl
      secretName: api-endpoint
      type: API
      uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

Note: The JWT feature is intended for environments where the are load-balancers located between subsystems. If you are using the in-cluster communications feature Use services instead of routes (OpenShift) or ingresses (Kubernetes), then you cannot have load-balancers between subsystems, and so disabling mTLS and enabling JWT is not necessary. However, if you do want to use the JWT feature with in-cluster communications then the JWKS URL can be obtained following these steps:

1. Describe any API Connect pod:

   ```
   kubectl describe pod <apic-pod>
   ```

2. In the pod describe output, search for `APIC_PLATFORM_API_SVC_ENDPOINT`:

   ```
   Containers:
     apim:
       Environment:
         APIC_PLATFORM_API_SVC_ENDPOINT:  https://management-juhu.acme-v1005-020323.svc:2000/api
   ```

3. The JWKS URL is the value of `APIC_PLATFORM_API_SVC_ENDPOINT` with `/cloud/oauth2/certs` appended to it. If the APIC_PLATFORM_API_SVC_ENDPOINT is missing the `/api` at the end, add `api/cloud/oauth2/certs` instead. The path of the JWKS URL must always be `api/cloud/oauth2/certs`.

Key points and limitations of JWT security

- For API Connect deployments upgraded from a pre-v10.0.5.3 release, the behavior of each subsystem remains the same as it was before upgrade.
- Changing the JWKS URL on portal, and analytics subsystems causes pods to restart, and so a short subsystem outage. The gateway pod does not restart when the JWKS URL is changed.
- On new installs of Cloud Pak for Integration and top-level CR OpenShift deployments, the JWKS URL is set automatically for the portal, gateway, and analytics subsystems.
- You can have both mTLS and JWT enabled, although the analytics subsystem does not verify the JWT if mTLS is enabled.
- The v5c gateway does not send a JWT to the analytics subsystem. This flow is secured by mTLS, which cannot be disabled.
- If you enable JWT for gateway to analytics communication, the ingestion of analytics data becomes dependent on the availability of the management subsystem (so that the JWT can be verified). For more information about this limitation, see: JWT usage between gateway and analytics subsystems.
- Under high analytics ingestion loads, JWT enablement might impact the performance of the analytics subsystem. It is recommended to complete a performance test under your expected analytics load before you decide to use JWT for gateway to analytics communication.

JWT usage between gateway and analytics subsystems

Because the analytics subsystem makes a REST call to the management subsystems to verify the JWT it receives from the gateway, analytics ingestion depends on the management subsystem when JWT is enabled. The analytics subsystem caches the response from the JWKS URL so that it does not need to make a REST call to the management subsystem every time API event data is received from the gateway. But the JWT verification cache does expire after 24 hours, and a new REST call to the management subsystem is made to refresh the cache. The JWT dependency on the platform REST API means that an outage of the management subsystem does eventually prevent the analytics subsystem from accepting new analytics API event records.

In-cluster service communication between subsystems

Key points and limitations of `in-cluster` inter-subsystem communication.

- In-cluster communication is only possible between subsystems that are in the same cluster.
- In-cluster communication cannot be used in two data center disaster recovery deployments, Two data center deployment strategy on Kubernetes and OpenShift.
- If you are upgrading from a pre-10.0.5.3 release, all existing subsystems continue to use `external` communication. If you want to change upgraded subsystems to use `in-cluster`, then you must reregister them.
- If you are adding new subsystems to an upgraded deployment you can set the subsystems to use `in-cluster` communication, but you must use different certificates and secrets for the subsystem endpoints. The default certificate and secret names for the subsystem endpoints are:
  - Analytics: `ai-endpoint`.
  - Portal: `portal-admin`.
  - Gateway: `gwv6-manager-endpoint` or `gw-gateway-manager`

  Do not use these same certificate and secret names if your additional subsystems are in the same namespace.
- After a portal, gateway, or analytics subsystem is registered with the management subsystem, to change the communication mechanism you must reregister the subsystem. For more information on this procedure, see:
  - Kubernetes: Change inter-subsystem communication type.
  - OpenShift: Change inter-subsystem communication type.

  Important: Backups of the management subsystem cannot be restored if the communication type of any registered subsystem is changed after the backup was taken. Do not change the communication type of any of your subsystems if you might want to restore your management subsystem from a previous backup.
- If you customize any TLS certificates used for inter-subsystem communication, then to use `in-cluster` communication the TLS certificates must include the service hostname in the DNS section of the SAN, for example:

```
X509v3 Subject Alternative Name: critical
                DNS: ptladmin.mydomain.com, DNS: portal.apic.svc, DNS: portal.apic.svc.cluster.local
```

- On Cloud Pak for Integration, all subsystems are registered automatically during deployment with `external` communication specified.

Kubernetes ingress controller prerequisites

Describes the prerequisite settings for the ingress controller for a Kubernetes runtime environment.

Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software may change and this information may become outdated.
These instructions assume you have a working Kubernetes environment and understand how to manage Kubernetes. Kubernetes is a platform for automated deployment, scaling, and operation of application containers across clusters of hosts, providing container-centric infrastructure. For more information, see https://kubernetes.io.

Kubernetes/ingress-nginx ingress controller `ingress-config.yml` settings

A Kubernetes deployment for IBM® API Connect requires the **kubernetes/ingress-nginx** ingress controller implementation (see https://github.com/kubernetes/ingress-nginx) with SSL passthrough enabled.

API Connect v10 does not require Helm, so it is recommended to use Helm3 for the installation of the ingress controller. Follow these steps:

1. Create a file `ingress-config.yaml` where the following values are required:
   Specify at least one SSL protocol; separate multiple protocols with a comma as shown in the example.

```
controller:
  watchIngressWithoutClass: true
  admissionWebhooks:
    enabled: false
  config:
    ssl-protocols: "TLSv1.2 TLSv1.3"
  extraArgs:
    annotations-prefix: ingress.kubernetes.io
    enable-ssl-passthrough: true
```

   You may use the following sample ingress-config.yml file to configure the ingress controller:

```
controller:
  watchIngressWithoutClass: true
  admissionWebhooks:
    enabled: false
  config:
    hsts-max-age: "31536000"
    keepalive: "32"
    log-format: '{ "@timestamp": "$time_iso8601", "@version": "1", "clientip": "$remote_addr",
      "tag": "ingress", "remote_user": "$remote_user", "bytes": $bytes_sent, "duration":
      $request_time, "status": $status, "request": "$request_uri", "urlpath": "$uri",
      "urlquery": "$args", "method": "$request_method", "referer": "$http_referer",
      "useragent": "$http_user_agent", "software": "nginx", "version": "$nginx_version",
      "host": "$host", "upstream": "$upstream_addr", "upstream-status": "$upstream_status"
      }'
    main-snippets: load_module "modules/ngx_stream_module.so"
    proxy-body-size: "0"
    proxy-buffering: "off"
    server-name-hash-bucket-size: "128"
    server-name-hash-max-size: "1024"
    server-tokens: "False"
    ssl-ciphers: HIGH:!aNULL:!MD5
    ssl-prefer-server-ciphers: "True"
    ssl-protocols: "TLSv1.2 TLSv1.3"
    use-http2: "true"
    worker-connections: "10240"
    worker-cpu-affinity: auto
    worker-processes: "1"
    worker-rlimit-nofile: "65536"
    worker-shutdown-timeout: 5m
  daemonset:
```

```
    useHostPort: false
  extraArgs:
    annotations-prefix: ingress.kubernetes.io
    enable-ssl-passthrough: true
  hostNetwork: true
  kind: DaemonSet
  name: controller
rbac:
  create: "true"
```

2. Run the commands:

```
helm3 repo add ingress-nginx https://kubernetes.github.io/ingress-nginx
helm3 repo update
helm3 install ingress-controller ingress-nginx/ingress-nginx --namespace kube-system --values ingress-config.yaml
```

Kubernetes/ingress-nginx ingress controller **config.map** settings

To ensure that the IBM API Connect services have time to start, increase the *proxy-read-timeout* and *proxy-send-timeout* values, which are in seconds, in the **kubernetes/ingress-nginx** ingress controller *config.map* to at least the following:

- proxy-read-timeout: "240"
- proxy-send-timeout: "240"

Depending on your environment, you might need to increase these further if the IBM API Connect services do not start. If there is a load balancer in front of the worker nodes, then the load balancer configuration might also need to have extended timeouts.

System and Software Requirements

The system and software requirements are described in the Software Product Compatibility Reports. See Detailed system requirements for a specific product

Persistent Volume (PV) requirements

Review the persistent volumes (PVs) required by your API Connect installation.

The PV requirements for API Connect subsystems vary according to the number of subsystem nodes that are deployed, whether you are using two datacenter disaster recovery (2DCDR) Two data center deployment strategy on Kubernetes and OpenShift, and other subsystem specific options.

Management subsystem

Table 1. Management PV requirements

Deployment profile	Number of PVs required
Single node (n1)	4
Three node (n3)	10

Note: An additional 4 PVs are required for upgrade of the n3 deployment profile. Replaced PVs can be deleted after successful upgrade.

Gateway subsystem

Only required where **tokenManagementService** is enabled:

```
tokenManagementService:
  enabled: true
  storage:
    storageClassName: $STORAGE_CLASS
    volumeSize: 30Gi
```

Portal subsystem

Table 2. Portal PV requirements

Deployment profile	Number of PVs required
Single node (n1), one datacenter	6
Three nodes (n3), one datacenter	18
Single node (n1), two datacenter	9 per datacenter
Three nodes (n3), two datacenter	27 per datacenter
Single node (n1), two datacenter, where other datacenter is three node (n3)	13 in n1 datacenter, 23 in n3 datacenter
Three node (n3), two datacenter, where other datacenter is single node (n1)	30 in n3 datacenter, 15 in n1 datacenter

Analytics subsystem

The number of PVs needed varies according to whether the persistent queue feature is used, and if internal storage is enabled, see: Disable local storage.

Table 3. Analytics PV requirements

Deployment profile	Storage enabled	Storage disabled (ingestion only)	Extra PVs if persistent queue enabled
Single node (n1)	1	0	1
Three node (n3)	3	0	3

Note: The last column shows the PVs that must be added to those specified in the storage columns. For example, if you have an n1 profile with storage and persistent queue enabled, then you need 2 PVs.

Load balancer configuration in a Kubernetes deployment

When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect Kubernetes deployment.

About this task

API Connect can be deployed on a single node cluster. In this case the ingress endpoints are host names for which the DNS resolution points to the single IP address of the corresponding node hosting a particular subsystem, and no load balancer is required. For high availability, it is recommended to have at least a three node cluster. With three nodes, the ingress endpoints cannot resolve to a single IP address. A load balancer should be placed in front of an API Connect subsystem to route traffic.

Because it is difficult to add nodes once endpoints are configured, a good practice is to configure a load balancer even for single node deployments. With the load balancer in place, you can easily add nodes when needed. Add the node to the list of servers pointed to by the load balancer and the ingress endpoints defined during installation of API Connect can remain unchanged.

To support Mutual TLS communication between the API Connect subsystems, configure the load balancer with **SSL Passthrough** and **Layer 4** load balancing. In order for Mutual TLS to be performed directly by the API Connect subsystems, the load balancer should leave the packets unmodified, as is accomplished by Layer 4. Following is a description of the communication between the endpoints that are configured with Mutual TLS:

- API Manager (with the client certificate portal-client) communicates with the Portal Admin endpoint portal-admin (with the server certificate portal-admin-ingress)
- API Manager (with the client certificate analytics-ingestion-client) communicates with the Analytics Ingestion endpoint analytics-ingestion (with the server certificate analytics-ingestion-ingress)

Note: From v10.0.5.3, it is possible to disable mTLS and use JWT instead, which allows the load-balancers to do TLS termination. For more information, see Enable JWT security instead of mTLS.

Set endpoints to resolve to the load balancer
: When configuring a load balancer in front of the API Connect subsystems, the ingress endpoints are set to host names that resolve to a load balancer, rather than to the host name of any specific node. For an overview of endpoints, see Deployment overview for endpoints and certificates.

Use these example topologies as a guideline to determine the best way to configure the load balancer for your deployment.

Procedure

- **Kubernetes cluster with wildcard DNS**
  In this example, API Connect is deployed to a Kubernetes cluster with three master and six worker nodes. The master nodes have the Kubernetes API server listening on port 6443. The Kubernetes API Server is used for communicating with the kubectl command line interface. Note that it is generally not necessary for the Kubernetes API server (on port 6443 in this example) to be exposed outside the cluster through the load balancer, this is just one possible setup shown here.

  The kubernetes/ingress-nginx ingress controller is deployed as a daemonset, so that every worker node in the cluster has an ingress controller pod listening on port 443. The API Connect subsystems (API Manager, Developer Portal, Analytics and Gateway) are all deployed on this same cluster.

  Note:
  - When you configure a load balancer in front of a Management subsystem, specify timeouts of at least 240 seconds. Note that large deployments might need larger values.

    The default timeout is typically 50 or 60 seconds, which is not long enough to avoid **`409 Conflict`** or **`504 Gateway Timeout`** errors. The **`409 Conflict`** error can occur when the time needed to complete an operation is sufficiently long that a second request gets issued.

    For example, to specify 240 seconds when using HAProxy as a load balancer, set **`timeout client`** and **`timeout server`** to **`240000`**.

    Best practice is to ensure that the same values are specified for the timeout settings for the load balancer and for the Kubernetes ingress controller. The ingress controller timeout settings are set in the ingress controller config.map. For more information, see the **`proxy-read-timeout`** and **`proxy-send-timeout`** settings in Kubernetes ingress controller prerequisites .

  - Ensure that the load balancer is configured to support the cipher **`TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)`**.
    When the Developer Portal, as a client, calls back to platform-api-endpoint or consumer-api-endpoint of the management subsystem, it sends only a single cipher in the Client Hello. The cipher is **`TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)`**. The SSL Handshake will fail if this cipher is not configured (supported) on the client's load balancer.

  A host running HAProxy acts as the load balancer, with a configuration for proxies in the HAProxy configuration file such as:

```
defaults
        log     global
        mode    http
        option  httplog
        option  dontlognull
        timeout connect 5000
        timeout client  240000
        timeout server  240000
        errorfile 400 /etc/haproxy/errors/400.http
        errorfile 403 /etc/haproxy/errors/403.http
        errorfile 408 /etc/haproxy/errors/408.http
        errorfile 500 /etc/haproxy/errors/500.http
        errorfile 502 /etc/haproxy/errors/502.http
        errorfile 503 /etc/haproxy/errors/503.http
        errorfile 504 /etc/haproxy/errors/504.http

frontend apiservers
        bind *:6443
        mode tcp
```

```
        option  tcplog
        option forwardfor
        default_backend k8s_apiservers

frontend ingress
        bind *:443
        mode tcp
        option  tcplog
        option forwardfor
        default_backend k8s_ingress

backend k8s_apiservers
        mode tcp
        option  tcplog
        option ssl-hello-chk
        option log-health-checks
        default-server inter 10s fall 2
        server cluster1-master-1 10.169.241.226:6443 check
        server cluster1-master-2 10.169.241.163:6443 check
        server cluster1-master-3 10.169.241.153:6443 check

backend k8s_ingress
        mode tcp
        option  tcplog
        option ssl-hello-chk
        option log-health-checks
        default-server inter 10s fall 2
        server cluster1-worker-1 10.169.241.142:443 check
        server cluster1-worker-2 10.169.241.150:443 check
        server cluster1-worker-3 10.169.241.188:443 check
        server cluster1-worker-4 10.169.241.196:443 check
        server cluster1-worker-5 10.169.241.168:443 check
        server cluster1-worker-6 10.169.241.156:443 check
```

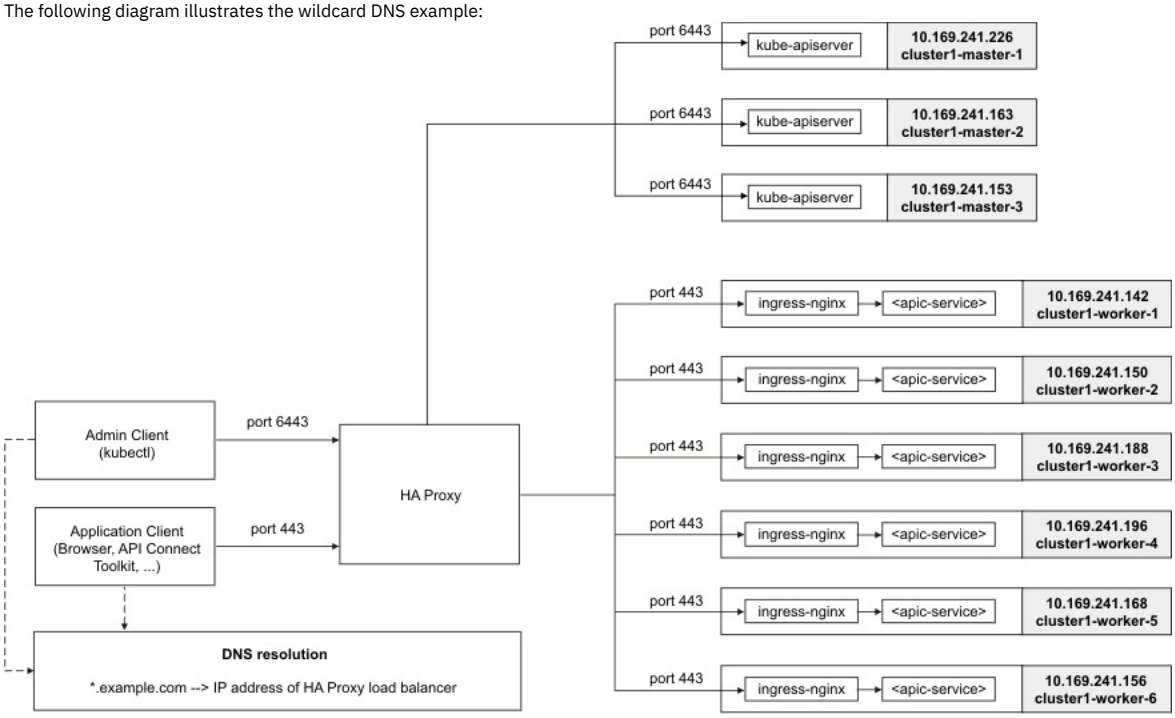
A wildcard DNS record allows the resolution of **`*.example.com`** to the IP address of the HAProxy host.

The ingress endpoints are defined in the CRs (custom resources) for each API Connect subsystem. During configuration of each subsystem, you define the endpoint by specifying a host name **`$STACK_HOST`** in the CR. For configuration instructions, see Installing the API Connect subsystems.

You can view the endpoint definitions in sample CRs:

- Installing the Management subsystem cluster
- Installing the Developer Portal subsystem
- Installing the Analytics subsystem
- Installing the DataPower Gateway subsystem

The following diagram illustrates the wildcard DNS example:



- **Kubernetes cluster without wildcard DNS**
  This example uses the same topology as the previous one, except that there is no wildcard DNS resolution. Instead, individual DNS records are added, all pointing to the IP address of the load balancer. For example: **`portal.example.com`** and **`admin.portal.example.com`** resolve to the IP address of the load balancer.
- **Kubernetes cluster with `xip.io` or `nip.io`**
  This example uses the same topology as the first one, except that there is no specific DNS resolution configured and instead a service such as **`xip.io`** or **`nip.io`** provides wildcard DNS resolution. It is not recommended to use this approach for a production setup, as the ingress endpoints configured during installation of API Connect would be tied to the IP address of the load balancer. This approach can be useful when configuring a test deployment in situations where access to DNS records is not practical or would introduce delay in the deployment.

Firewall requirements on Kubernetes

Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on Kubernetes.

Required Ports between zones

The following network diagram example helps to explain which ports must be configured in an API Connect network. Specific ports must be configured to enable the communication between the various zones, both public and private, in a network.

The ports specified in the diagram are default ports. Check your deployment to understand which communication, if any, is configured to use non-default ports.

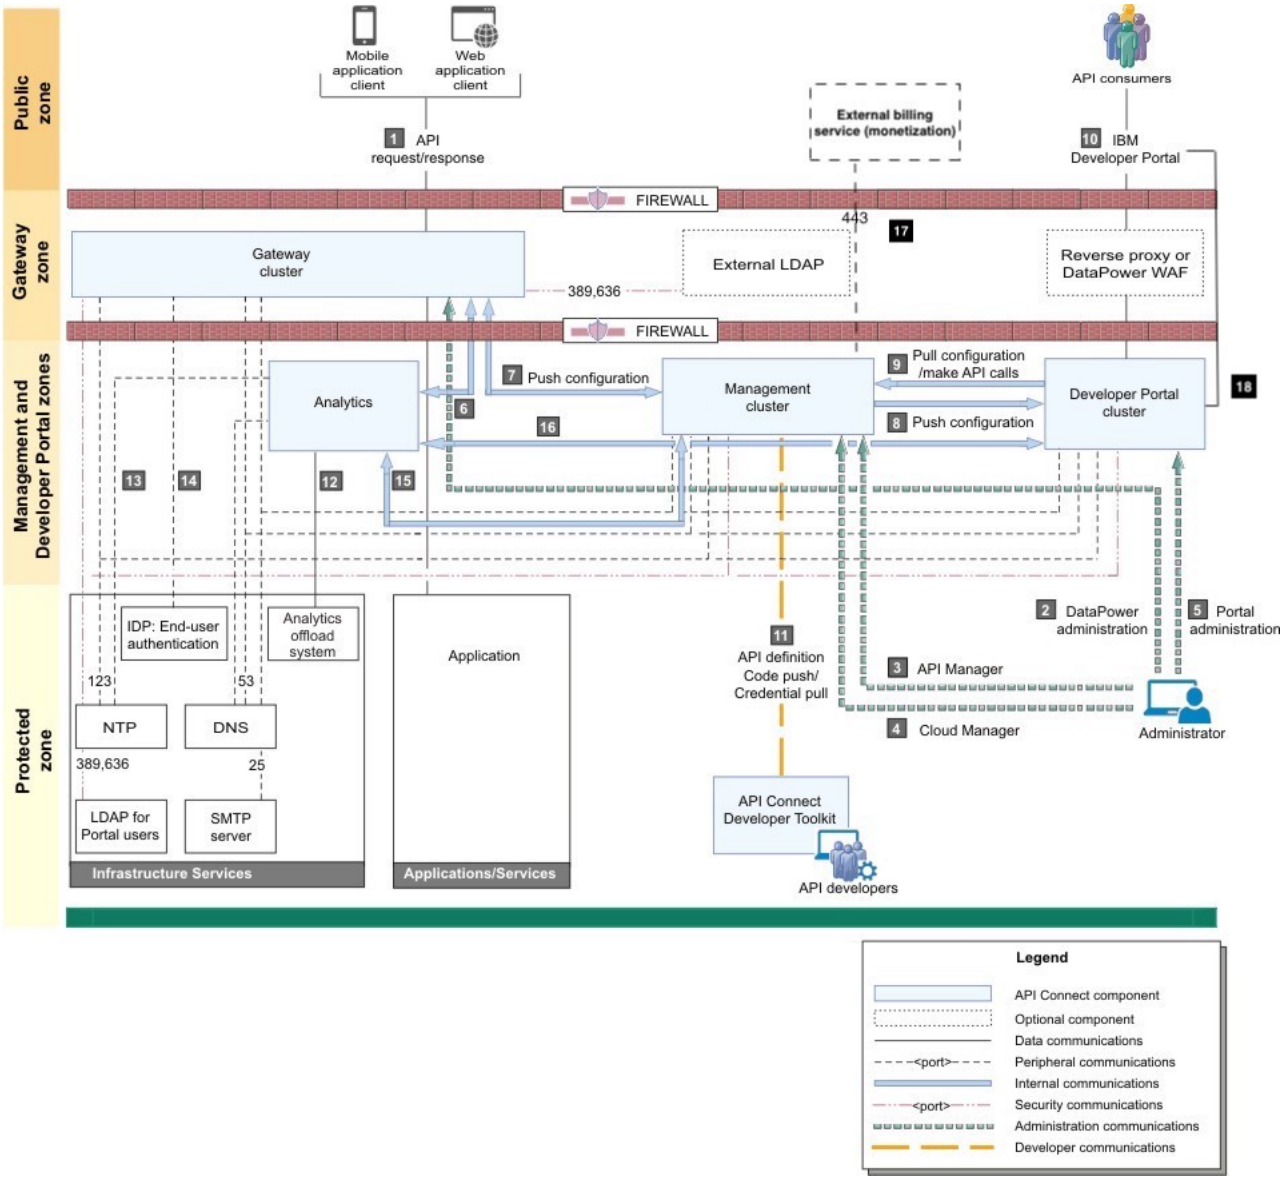


Table 1. Key for the network diagram example.
The following table lists the port numbers with a usage description.

	Usage description	Default port number
1	API request/response – Users invoking the provided APIs.	443 HTTPS from Public zone to Gateway zone
2	DataPower® administration – Internal operators who are managing the Gateway servers.	22 SSH, 9090 HTTPS from Protected zone to Gateway zone
3	API Manager – Internal business users who are defining and monitoring APIs.	443 HTTPS from Protected zone to Management zone
4	Cloud Manager – Internal operators who are administering the Cloud.	22 SSH, 443 HTTPS from Protected zone to Management zone
5	Developer Portal administration – Internal operators who are managing the Portal servers.	22 SSH, 443 HTTPS from Protected zone to Management zone
6	Gateway servers post traffic to Analytics service.	443 HTTPS from Gateway servers to Analytics service

	Usage description	Default port number
7	Push configuration – Management servers communicate bi-directionally with Gateway servers.	3000 and 443 HTTPS Management servers to and from Gateway servers for webhook delivery. Port 3000 is the default port for apic-gw-service, and this is the port Management uses to communicate with Gateway. Port 443 is the default port for the platform-api endpoint, which apic-gw-service uses to communicate with Management.
8	Push configuration/webhooks – Management servers push configuration and webhooks to the Developer Portal.	443 HTTPS Management servers to Developer Portal servers for webhook delivery
9	Pull configuration/make API calls – Developer Portal servers pull configuration and call REST APIs.	443 HTTPS from Developer Portal servers to Management servers within Management zone
10	Developer Portal – External developers who are accessing the Developer Portal.	443 HTTPS from Public zone to Developer Portal management zone. The reverse proxy/DataPower WAF for incoming web traffic to the Developer Portal cluster must be a transparent proxy - no modification of the portal URL, port, host name or path is allowed.
11	Push API definition to Management server. Pick up credential for microservice code push.	443 HTTPS from Protected zone to Management zone
12	Analytics offload	Port will depend on type of plugin and protocol used for the offload. Some possible protocols are: HTTP, HTTPS, TCP, UDP, KAFKA
13	Analytics accesses NTP	Standard NTP
14	Analytics access DNS	Standard DNS
15	Management service queries Analytics service	443 HTTPS within Management zone
16	The Portal service invokes an API (GET) on the Analytics service to retrieve data.	443 HTTPS within Management zone
17	External billing service – Management cluster connecting to external billing service (when configured for billing). If you are using Stripe as your external billing service, you must enable connections with the Stripe API at: https://stripe.com/files/ips/ips_api.json. You can also view the Stripe IP addresses at the following URL: https://stripe.com/docs/ips.	443 HTTPS from Management zone to Public zone
18	Developer Portal cluster must be able to access its own site endpoints.	443 HTTPS from Portal zone to Public zone

Firewall port requirements on Kubernetes

The following tables lists ports that must be open in both cluster and non-clustered deployments.

Table 2. Firewall port requirements common to all subsystems

Subsystem	Ports and description
Ports that must be open on all API Connect subsystems	The following ports must be open on the Management Server, Analytics, and Developer Portal subsystems, whether in a cluster or not. • 22 (outbound) Used for SFTP backups on Management and Portal subsystems • 53 (outbound) DNS • 123 (outbound) NTP • 443 (inbound and outbound) Used by all subsystems for communication with other subsystems • 44135 (inbound and outbound)

Each subsystem uses ports in addition to the ports in Table 2. See the following table.

Table 3. Additional firewall port requirements for each subsystem

Subsystem	Ports and description
Management Service	Management Service uses the ports in Table 2 plus: • 22 remote backup server port (configurable) If backups are configured to use another port, ensure that the port is open. • 161 (inbound) SNMP • LDAP server port (if using LDAP user registry), typically 389 (outbound) • 3007 (outbound) LDAP The Automated test behavior application must be able to invoke (outbound) any port that a test system might present an API on. It can be bound to a particular port (if it is the same in all environments) or to a range of ports (to cover all of the ports it might invoke).
Developer Portal	The Developer Portal uses the ports listed in Table 2, plus: • 22 - A remote backup server port (configurable) If backups are configured to use another port, ensure that the port is open. See Backing up and restoring the Developer Portal in a Kubernetes environment.
Analytics	The Analytics subsystem uses the ports listed in Table 2. Analytics port usage considerations: • 161 for SNMP is required for both non-clustered and clustered deployments • In a non-clustered deployment, no additional ports are required. • Analytics supports an optional configuration for offload of data. This configuration might require additional outbound ports to be open.

Subsystem	Ports and description
Gateway Server	The Gateway Server uses these ports in both non-clustered and clustered deployments: • 161 (inbound and outbound) SNMP • 162 (outbound) SNMP traps • 3000 (inbound) Gateway Service local port (configurable) • 5550 (inbound) XML management port (configurable) • 5554 (inbound) REST management port (if enabled; configurable) • 9022 (inbound) Gateway SSH (if enabled; configurable) • 9090 (inbound) Web GUI console (if enabled; configurable) • 9443 (inbound) Gateway local port (configurable)

Communications inside the Gateway cluster

There are a number of important points to note regarding the communications within the Gateway cluster.

- We advise that you use the same port for all Gateway servers within a cluster.
- Gateway servers communicate with each other to synchronize invocation counts.
- All Gateway servers in a Gateway cluster must be able to reach all of the other Gateway servers in the same Gateway cluster.
- Gateway servers in a Gateway cluster do not directly communicate with Gateway servers in a different Gateway cluster.
- All Gateway servers must be able to reach the management subsystem platform API endpoint, which was configured during the installation of your API Connect environment.

Ethernet interface usage

To separate network traffic, you can use two or more Ethernet interfaces on the DataPower appliance on which a Gateway server is installed. For example, you can use one interface for internal IBM API Connect communications, and another for processing incoming API calls.

Port requirement for Stripe billing service

All Management servers and Developer Portal servers must be able to communicate HTTPS content with the external billing service when billing is configured. If you are using Stripe as your external billing service, you must enable HTTPS communication on port 443 with the Stripe API: https://stripe.com/files/ips/ips_api.json.
Note: API Connect does not support using webhooks with Stripe. You can see a list of the Stripe IP addresses at: https://stripe.com/docs/ips.

Planning your analytics deployment

Plan your API Connect analytics deployment by reviewing options for deployment profile and estimating required persistent storage space.

Deployment profile

Decide which deployment **`profile`** you want to use, the available profiles are:

- For Kubernetes and OpenShift (individual subsystem) installations: Analytics deployment profiles.
- For Cloud Pak for Integration and OpenShift top-level CR installations: API Connect deployment profiles.

For a scalable analytics deployment, choose a three replica profile. If you do not expect a high API transaction rate and plan to keep a limited amount of analytics data, then a one replica profile is sufficient.

Storage class

Before you install analytics, you must choose a storage class. **`Ceph`**, **`Block`**, and **`Local Volume`** are all supported; however, **`Local Volume`** is the most suitable for analytics. The analytics subsystem provides internal data replication and HA support, so the additional HA capabilities that **`Ceph`** or **`Block`** storage might give you are not needed. In addition, analytics requires a high throughput of disk I/O operations to successfully handle the analytics data load from the gateway. **`Local Volume`** is the best-performing storage class for disk I/O.

Note: GlusterFS and NFS storage are not supported for analytics. If you use either of these storage classes, you might encounter severe performance degradation, and possibly loss of data.

Storage type

Note: Storage type selection is available on three replica deployments only.
To make an informed choice on which storage type is best for you, first read and understand the OpenSearch concepts that are described in OpenSearch nodes, indices, shards, and replicas.
API Connect provides two OpenSearch storage types:

- **Shared storage**
  A single pod provides data storage and OpenSearch cluster management. Shared storage is the default option, and the only option on a one replica deployment.
- **Dedicated storage**
  OpenSearch data storage and cluster management functions are split, and run in separate pods on each worker node:
  - The `storage-os-master` pod runs an OpenSearch "manager eligible" node that manages the OpenSearch cluster, but does not store any API event data.
  - The `storage` pod runs an OpenSearch "data" node that stores API event data.

Dedicated storage facilitates horizontal scaling to support greater analytics data storage and throughput. Add worker nodes and increase the number of `storage` pod replicas to scale horizontally (you do not need to increase the number of `storage-os-master` replicas). Dedicated storage also provides greater stability and allows some OpenSearch configuration changes to be made without downtime.
You can change storage type after installation, see Dedicated storage and scaling up.

Disabling internal storage

The analytics subsystem provides a complete solution for routing, storing, and viewing the analytics data. However, you might not need the internal storage and viewing solution if you are using a third-party system for data offloading. In this scenario, you can greatly reduce your CPU and memory costs by disabling the internal storage and viewing components.

When you disable internal storage for analytics data, the following microservices are disabled:

- `osinit`
- `storage`

Important:
If you disable local storage, the analytics views in your API Connect UIs remain accessible, but are empty.

Configure local storage disablement before installation. It is not possible to disable or re-enable internal storage after installation.

You can enable offload of analytics data to third-party systems after installation.

For the steps to disable internal storage, see Disable local storage.

Persistent storage space

Based on your expected API transaction rate, you can estimate how much storage space your analytics subsystem requires. See Estimating storage requirements.

Inter-subsystem communication security

By default the network communication from the management and gateway subsystems, to the analytics subsystem uses Kubernetes ingresses or OpenShift routes, and is secured with mTLS. You can configure alternative network communication options if your environment requires. For more information, see Network requirements for inter-subsystem communication.

Kubernetes operating map counts

When the analytics service is configured to store data, it uses OpenSearch, which requires map counts higher than the operating system defaults. The minimum recommended value is `262144`. Unless you plan to disable local storage, increase the default map count on every Kubernetes worker node:

1. To change the map counts on the live system, run the following command on every Kubernetes node:

   ```
   sudo sysctl -w vm.max_map_count=262144
   ```

2. To persist this change when node restarts occur, add the following setting to the /etc/sysctl.conf file:

   ```
   vm.max_map_count = 262144
   ```

For more information, see Important settings in the OpenSearch documentation.

PV requirements

The number of PVs needed depends on whether the persistent queue feature is enabled, and if you disable local storage.

Table 1. Analytics PV requirements

Deployment profile	Local storage enabled	Local storage disabled (ingestion only)	Extra PVs if persistent queue enabled
Single node (n1)	1	0	1
Three node (n3)	3	0	3

Note: The "Extra PVs if persistent queue enabled" column shows the number of PVs that must be added to the PVs specified in the storage columns. For example, if you have an n1 profile with local storage and persistent queue enabled, then you need 2 PVs.

Firewall requirements

The analytics firewall requirements are documented here: Firewall requirements

Two data center deployment strategy on Kubernetes and OpenShift

An overview of the two data center disaster recovery deployment strategy in API Connect.

Key points of the two data center disaster recovery (DR) solution

- Two data center DR is an active/warm-standby deployment for the API Manager and Developer Portal services, and must use manual failover.
- Two DataPower® Gateway subsystems must be deployed to provide high availability for the gateway service. However, this scenario doesn't provide high availability for the analytics service.
- If high availability is required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration Developer Portal analytics isn't possible.
- Data consistency is prioritized over data availability.
- Each data center must be setup within its own Kubernetes or OpenShift cluster.
- Latency between the two data centers must be less than 80 ms.
- Replication of the API Manager is asynchronous, so it is possible that the most recent updates do not transfer to the warm-standby data center if there is an active data center failure.
- Replication of the Developer Portal is synchronous, and therefore the latency is limited to 80 ms or less.
- The API Manager and the Developer Portal services in the two data centers must use the same deployment profile.
- The deployment in each data center is effectively an instance of the same API Connect deployment - therefore, the endpoints, certificates, and Kubernetes secrets must all be the same.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a two data center disaster recovery configuration.

Deployment architecture

A two data center deployment model is optimized for data consistency ahead of data availability, and must use manual failover when a fault occurs. For high availability of Management and Portal subsystems ensure that you use a three replica deployment profile. For more information on deployment profiles, see: Planning your deployment topology.

For a single Kubernetes cluster to span multiple data centers the network latency must be no more than a few milliseconds, typically less than 10 ms. This low latency is often unachievable between geographically separated data centers. For this reason, the two data center disaster recovery solution requires that each data center is set up with its own Kubernetes cluster. The Management and Portal subsystem databases are continually replicated from the active datacenter to the warm-standby datacenter, this requires a network latency between the two data centers of less than 80 ms.

To achieve high availability for the DataPower Gateway, you must deploy two gateway subsystems. One subsystem in the active data center, and a separate subsystem in the warm-standby data center. Publish all Products and APIs to both gateway subsystems. The gateway subsystems are independent, and so are insulated if an issue occurs in one of them. A global dynamic router can then be used to route traffic to one gateway subsystem or the other. If high availability is also required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration Developer Portal analytics isn't possible.

There can be multiple Developer Portal services in an API Connect deployment (although still only one Developer Portal site per Catalog).

The deployment in each data center is effectively an instance of the same API Connect deployment – as the database is replicated, all of the configuration is also shared. Therefore, the endpoints, certificates, and Kubernetes secrets all need to be the same.

Dynamic routing

Note: A dynamic routing device, such as a load balancer, is required to route traffic to either data center. However, neither this device nor its configuration is part of the API Connect offering. Contact IBM Services if you require assistance with configuring a dynamic router.
The dynamic router configuration must handle the traffic between the subsystems and between the data centers. For example, the consumer API calls from the Developer Portal to API Manager must transfer through a dynamic router so that the Developer Portal can use a single endpoint regardless of which data center API Manager is active in. The same is needed for calls to the Platform and Admin APIs from the other subsystems, as well as for incoming UI traffic for the Developer Portal UI, Cloud Manager UI, and API Manager UI.

The dynamic router must support SSL passthrough, so that it routes the Mutual TLS (mTLS) connections between API Manager and the Developer Portal, and between API Manager and the DataPower Gateway. The router should not do TLS termination, it should do layer 4 based routing by using SNI.
Note: From v10.0.5.3, it is possible to disable mTLS and use JWT instead, which allows the load-balancers to do TLS termination. For more information, see Enable JWT security instead of mTLS.

Service status

When a failure occurs, it is common practice to display an interstitial system outage web page. The dynamic router can be configured to display this web page when there is a failure, while the manual failover to the warm-standby data center is taking place.

Deployment-profiles

Both one replica and three replica deployment profiles can be used with two data center DR, but they must be the same at each data center. For more information about the deployment-profiles, see Planning your deployment topology on Kubernetes, and Requirements for initial deployment on VMware.

For more information about a two data center DR deployment, see the following topics:

  - Backup and restore requirements for a two data center deployment
  - Upgrading a two data center deployment on Kubernetes and OpenShift
  - Removing a two data center deployment

Key Concepts: Cert-manager, Issuers, and Secrets

By default API Connect uses an open source product that is called cert-manager to handle the issuing and renewal of the certificates that are used by API Connect. The cert-manager has its own Kubernetes pods and runs in its own namespace. The cert-manager adds some additional resources to the Kubernetes environment. The API Connect administrator needs to be familiar with these additional resources:

Issuers

Issuers play the part of certificate authorities (CAs) in the local environment and issue the certificates. Issuers reside in the API Connect namespace. There are two types of Issuers:

- Self-Signed - This issuer provides the self-signed certificates, for example a root CA.
- CA - This issuer can be either the root certificate authority or an intermediate certificate authority.

Here is an example of the issuers that can be found on the management subsystem:

```
kubectl get issuers -n <management namespace>
NAME                 READY   AGE
abc-management-ca    True    96d
selfsigning-issuer   True    96d
```

- **selfsigning-issuer** This is a SelfSigned Issuer that provides the root certificate for all default certificates that are used in API Connect.
- **abc-management-ca** This is a CA Issuer that signs all the end-entity certificates that are used for communication between the management subsystem pods. It is in effect an intermediate CA between the root (**selfsigning-issuer**) and the end-entity certificates.

Certificates

A certificate is a Kubernetes resource that contains a pointer to a Kubernetes secret. The Kubernetes secret contains the actual TLS certificate. Certificate objects contain other information such as the issuer, expiry date, and status. Run **kubectl get certificate** to see the certificates on an API Connect subsystem:

```
kubectl get certificate -n <management namespace>
NAME                                    READY   SECRET                                  AGE
abc-management-ca                       True    abc-management-ca                       96d
abc-management-client                   True    abc-management-client                   96d
abc-management-natscluster-mgmt         True    abc-management-natscluster-mgmt         96d
abc-management-server                   True    abc-management-server                   96d
...
```

The first certificate in the list **abc-management-ca** is the intermediate CA certificate that is used for signing the other certificates that are shown in the output. If you describe this certificate you can see that the **selfsigning-issuer** is its issuer:

```
kubectl describe certificate abc-management-ca -n <management namespace>
...
Spec:
  ...
  Issuer Ref:
    Kind:  Issuer
    Name:  selfsigning-issuer
```

Describing the other management subsystem certificates, observe that the **abc-management-ca** certificate is the issuer:

```
kubectl describe certificates abc-management-client -n <management namespace>
...
Spec:
  ...
  Issuer Ref:
    Kind:  Issuer
    Name:  abc-management-ca
```

Key points:

- The certificates with '-ca' on the end are all CA Certificates, and they sign all the other subsystem certificates whose names do not end with '-ca'.
- The CA certificates are also known as Issuer certificates.
- Certificates that CA certificates sign are known as end-entity certificates.
- When a CA certificate is updated, all end-entity certificates that it signs must also be updated.

For a complete list of the certificates in an API Connect installation, see API Connect certificates reference.

Secrets

Secrets are the Kubernetes resource for storing credentials. In API Connect, secrets are where the TLS certificates are stored. Every Kubernetes certificate object has a corresponding secret of the same name. The Kubernetes certificate contains a property that refers to its corresponding secret:

```
kubectl describe certificates abc-management-client -n <management namespace>
...
Spec:
  ...
  Secret Name:        abc-management-client
```

The default output of **kubectl get certificate** includes a column that is labeled **SECRET**, which shows the secret name.

```
kubectl get certificate -n <management namespace>
NAME                                    READY   SECRET                                  AGE
abc-management-ca                       True    abc-management-ca                       96d
abc-management-client                   True    abc-management-client                   96d
abc-management-natscluster-mgmt         True    abc-management-natscluster-mgmt         96d
abc-management-server                   True    abc-management-server                   96d
...
```

The **kubectl describe** output of a secret shows that it contains the TLS certificates:

```
kubectl describe secret abc-management-client -n <management namespace>
...
Name:         abc-management-client
Namespace:    default
```

```
Labels:       app.kubernetes.io/instance=abc-management
              app.kubernetes.io/managed-by=ibm-apiconnect
              app.kubernetes.io/name=abc-management-client
Annotations:  cert-manager.io/alt-names:
              cert-manager.io/certificate-name: abc-management-client
              cert-manager.io/common-name: abc-management-client
              cert-manager.io/ip-sans:
              cert-manager.io/issuer-group:
              cert-manager.io/issuer-kind: Issuer
              cert-manager.io/issuer-name: abc-management-ca
              cert-manager.io/uri-sans:

Type:  kubernetes.io/tls

Data
====
ca.crt:   1107 bytes
tls.crt:  1139 bytes
tls.key:  1675 bytes
```

The full TLS certificate strings can be seen with:

```
kubectl get -o yaml secret <secret name> -n <namespace>
```

For more details about cert-manager, and a full list of all the certificates that are created and used in an API Connect deployment, see API Connect certificate reference.

Certificates in a Kubernetes environment

Use of cert-manager is recommended for managing certificates in a Kubernetes environment.

When deploying on Kubernetes, choose one of the following methods for creating internal certificates:

- Do not specify any internal certificates. In this case, the operator generates all of the internal certificates without using a certificate manager. The CR definition to enable this option is:

  ```
  microServiceSecurity: custom
  ```

- Specify some, or all, of the internal certificates yourself without using a certificate manager. In this case, any certificates that you do not create are created by the operator. You retain control over the certificates that you create. The CR definition to enable this option is:

  ```
  microServiceSecurity: custom
  ```

- Configure cert-manager to generate the internal certificates. In this case, cert-manager creates and manages the certificates. The CR definition to enable this option is:

  ```
  microServiceSecurity: certManager
  ```

  To use cert-manager for generating the certificates, download and install cert-manager v1.9.1 from https://github.com/cert-manager/cert-manager/releases/tag/v1.9.1 and create an Issuer CR in the same namespace where you will install API Connect; for example:

  ```
  apiVersion: cert-manager.io/v1
  kind: Issuer
  metadata:
    name: selfsigning-issuer
  spec:
    selfSigned: {}
  ```

  In the CR for the API Connect Management subsystem, specify a **certManagerIssuer**. The **certManagerIssuer** can be configured to be a self-signing issuer, as in the following example:

  ```
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  ```

  API Connect supports any other kind of Issuer supported by cert-manager, in addition to the self signed type.

In all the CRs, certs are expected at the level of any endpoint. For example, for the cloud admin endpoint of the Management subsystem you could have:

```
cloudManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: admin.example.com
      secretName: cm-endpoint
```

The previous entry lets cert-manager automatically generate a **cm-endpoint** TLS secret using the **ingress-issuer**. One way to define the **ingress-issuer** is as follows:

```
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
```

```
kind: Certificate
metadata:
  name: ingress-ca
spec:
  secretName: ingress-ca
  commonName: "ingress-ca"
  usages:
  - digital signature
  - key encipherment
  - cert sign
  isCA: true
  duration: 87600h # 10 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
  issuerRef:
    name: selfsigning-issuer
    kind: Issuer
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
spec:
  ca:
    secretName: ingress-ca
```

Another way to configure the cloud admin endpoint would be with:

```
 cloudManagerEndpoint:
    hosts:
    - name: admin.example.com
      secretName: my-cm-endpoint
```

Where **my-cm-endpoint** is the name of a secret that you previously created, and is present in the same namespace as the subsystem, and contains TLS certificate files for termination of the endpoint.

Creating secrets and generating certificates

There is a number of "secrets" for which you can provide a name in the CRs:

- Portal admin secret.

  ```
  portal:
    admin:
      secretName:
  ```

- Analytics ingestion secret.

  ```
  analytics:
    ingestion:
      secretName: analytics-ingestion-client
  ```

- APIC Gateway Service TLS secret. Template entry from gateway_cr_v6.yaml (in the file name, "v6" refers to the API Gateway service):

  ```
    apicGatewayServiceTLS:
      secretName:
  ```

- APIC Gateway Peering TLS secret. Template entry from gateway_cr_v6.yaml (in the file name, "v6" refers to the API Gateway service):

  ```
    apicGatewayPeeringTLS:
      secretName:
  ```

You can create manually create secrets that contain the tls.crt, tls.key, and tls.ca files for a certificate. You can then refer to them by name in their subsystem CR. However, a simpler way to have those secrets created is by using cert-manager. The following example shows how to generate those certificates with cert-manager:

```
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ingress-ca
spec:
  secretName: ingress-ca
  commonName: "ingress-ca"
  usages:
  - digital signature
  - key encipherment
  - cert sign
  isCA: true
  duration: 87600h # 10 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
  issuerRef:
    name: selfsigning-issuer
```

```
    kind: Issuer
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
spec:
  ca:
    secretName: ingress-ca
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: portal-admin-client
spec:
  commonName: portal-admin-client
  secretName: portal-admin-client
  issuerRef:
    name: ingress-issuer
  usages:
  - "client auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: analytics-ingestion-client
spec:
  commonName: analytics-ingestion-client
  secretName: analytics-ingestion-client
  issuerRef:
    name: ingress-issuer
  usages:
  - "client auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: gateway-service
spec:
  commonName: gateway-service
  secretName: gateway-service
  issuerRef:
    name: ingress-issuer
  usages:
  - "client auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: gateway-peering
spec:
  commonName: gateway-peering
  secretName: gateway-peering
  issuerRef:
    name: ingress-issuer
  usages:
  - "client auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
```

So with the previous example, in the subsystem CRs (for Management and Gateway) the following values could be set:

-
```
portal:
  admin:
    secretName: portal-admin-client
```

-
```
analytics:
  ingestion:
    secretName: analytics-ingestion-client
```

-
```
apicGatewayServiceTLS:
  secretName: gateway-service
```

- `apicGatewayPeeringTLS:`
  `secretName: gateway-peering`

Also, the Client certificate should be signed by same CA as the one for the endpoint certificates, and the server side should be configured with the expected Subject DN for the client. For example:

- The `portalAdminSecret` certificate and the certificate used to terminate `portalAdminEndpoint` must have the same CA (in the example the CA is `ingress-ca` for both). Also, the `adminClientSubjectDN` in the Portal subsystem CR should be set to the Subject DN of `portal.admin.secretName`. For example:

  ```
  adminClientSubjectDN: CN=portal-admin-client,O=cert-manager
  ```

- Similarly, the `analyticsIngestionSecret` and the Analytics ingestion endpoint certificate should share the same CA. The `ingestion.clientSubjectDN` should be set to the Subject DN of the `analytics.ingestion.secretName` certificate.

  ```
  ingestion:
    endpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: ai.example.com
        secretName: analytics-ai-endpoint
    clientSubjectDN: CN=analytics-ingestion-client,O=cert-manager
  ```

Important: When installing more than one Analytics subsystem in the same Kubernetes namespace, all secret names must be unique.

Creating TLS secret using openssl

Use of the cert-manager is recommended for managing certificates. However, you can choose not to use cert-manager, and instead create certificates manually. Requirements for manually created certificates:

- Extended Key Usage (EKU), either serverAuth or clientAuth depending upon the type of certificate. Certificates of type *Server* must have an Extended Key Usage with serverAuth purpose. Certificates of type *Client* must have an Extended Key Usage with clientAuth purpose.
- Subject Alternative Name (SAN) for the required hosts
- If a certificate is signed by an internal or custom CA, include the full chain in the end certificate. If you omit the full chain, then a user who uses openSSL to access the endpoint will see the following error: `error:num=20:unable to get local issuer certificate`
  The following example shows the full chain for an end certificate (signed by a custom CA):

  ```
  -------BEGIN CERTIFICATE -----
  Cert contents for end-cert
  --------END CERTIFICATE ----------
  -------BEGIN CERTIFICATE -----
  Cert contents for Intermediate-CA
  --------END CERTIFICATE ----------
  -------BEGIN CERTIFICATE -----
  Cert contents for Root CA
  --------END CERTIFICATE ----------
  ```

The following steps can be used as an alternative to using cert-manager. If you choose to create your certificates this way, you lose some of the management features of cert-manager. For example, you must manually update your certificates when their expiration date gets near.

1. Generate the custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (platform-api-example) with an EKU serverAuth and SAN using openssl:

   ```
   openssl x509 -req -days 360 -in platform-api-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
   platform-api-cert -sha256
   -extfile <(cat /etc/ssl/openssl.cnf <(printf
   "\n[SAN]\nsubjectAltName=DNS:fqdn.myserver.com\nextendedKeyUsage=serverAuth"))
   -extensions SAN
   ```

   where
   - `DNS:fqdn.myserver.com` is the fully qualified domain name of the endpoint the certificate applies to.
   - `platform-api-example.csr` is the file name for the certificate signing request

   Following is an example for how to generate a certificate (portal-client) with an EKU clientAuth and SAN using openssl:

   ```
   openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
   portal-client-cert
   -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,
   digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,
   CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
   ```

2. Create a Kubernetes secret containing tls.cert, tls.key, and ca.cert.

Setting an encryption-secret for the management database using openssl

You can optionally set the encryption-secret for the management database. If you do not set one, one is automatically generated for you.

1. The encryption-secret is a secure random bytes password used for field level encryption in the management database. You can generate 128 random bytes using the following command in openssl:

   ```
   openssl rand -out /path/to/secret/encryption-secret.bin 128
   ```

2. Use kubectl to put the generated secret into `management-encryption-key`:

   ```
   kubectl create secret generic management-encryption-key -n <namespace>
         --from-file=/path/to/secret/encryption_secret.bin
   ```

   where `<namespace>` is the namespace where the Management CR is going to be created)

3. Make sure that in management_cr.yaml, encryptionSecret.secretName points to the name of the secret created in the previous step.

Important: Back up the encryption-secret.bin file to a safe location. If this file lost it will not be possible to access the management database or its backups.

- **Custom certificates on Kubernetes**
  You can use custom certificates in your Kubernetes deployment. You can optionally generate your own custom certificates.

Custom certificates on Kubernetes

You can use custom certificates in your Kubernetes deployment. You can optionally generate your own custom certificates.

To deploy API Connect with Custom Certificates, some additional preparation and steps are required before any subsystem CRs are applied into the Cluster.

You can provide existing custom certificates that you already own, for example DigiCert certificates, or generate new custom certificates using a package such as Cert-Manager.

- If you have your own custom certificates, see Configuring custom certificates before installation.
- If you do not already have your own custom certificates, and would like to use Cert-Manager to generate custom certificates, see Generating custom certificates
- To view a list of certificates used by API Connect, see Custom certificates reference

- **Custom certificates reference**
  API Connect supports custom certificates for each subsystem, and for internal communications.
- **Generating custom certificates**
  You can generate custom certificates.
- **Generating custom certificates using cert-manager in a two data center deployment**
  You can generate custom certificates in a two data center disaster recovery deployment on Kubernetes.
- **Configuring custom certificates before installation**
  Configure custom certificates for your API Connect deployment before you begin the installation procedures.
- **Converting to custom front-end/ingress certificates after deployment**
  Convert a front-end certificate generated by cert-manager to a custom certificate for an existing IBM® API Connect deployment.

Custom certificates reference

API Connect supports custom certificates for each subsystem, and for internal communications.

Table 1. Certificates for Management Subsystem:

Certificate	Type	Notes
`analytics-ingestion-client`	Common Subsystem Communication	Must be signed by the same CA as `analytics-ai-endpoint` Certificate of Analytics Subsystem. For a two data center deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=a7s-ingestion-client`, or they could both be `CN=a7s-ingestion-client, O=cert-manager`, but they must be identical.
`portal-admin-client`	Common Subsystem Communication	Must be signed by the same CA as `portal-admin` Certificate of Portal Subsystem. For a two data center deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=portal-admin-client`, or they could both be `CN=ptl-adm-client, O=cert-manager`, but they must be identical.
`gateway-client-client`	Common Subsystem Communication	Must be signed by the same CA as `gwv5-management-endpoint` and/or `gwv6-management-endpoint` of Gateway Subsystem
`cm-endpoint`	External Frontend/Ingress	
`apim-endpoint`	External Frontend/Ingress	
`api-endpoint`	External Frontend/Ingress	
`consumer-endpoint`	External Frontend/Ingress	
`hub-endpoint`	External Frontend/Ingress	
`turnstile-endpoint`	External Frontend/Ingress	

Note:
To generate the certificates for the endpoints used by the Automated testing behavior endpoints (`hub-endpoint` and `turnstile-endpoint`), add the following statements to the `custom-certs-external.yaml`:

```
apiVersion: cert-manager.io/v1alpha2
kind: Certificate
metadata:
  name: hub-endpoint
  labels: {

Table 2. Certificates for Analytics Subsystem

Certificate	Type	Notes
`analytics-ai-endpoint`	External Frontend/Ingress	Must be signed by the same CA as `analytics-ingestion-client` Certificate of Management Subsystem

Table 3. Certificates for Gateway Subsystem

Certificate	Type	Notes
`gwv5-endpoint`	External Frontend/Ingress	
`gwv5-management-endpoint`	External Frontend/Ingress	Must be signed by the same CA as `gateway-client-client` Certificate of Management Subsystem
`gwv6-endpoint`	External Frontend/Ingress	
`gwv6-management-endpoint`	External Frontend/Ingress	Must be signed by the same CA as `gateway-client-client` Certificate of Management Subsystem

Table 4. Certificates for Portal Subsystem

Certificate	Type	Notes
`portal-admin`	External Frontend/Ingress	Must be signed by the same CA as `portal-admin-client` Certificate of Management Subsystem
`portal-web`	External Frontend/Ingress	

Table 5. Internal Certificates

Certificate	Type (CA/Server/Client)	Subsystem	Notes
`caCertificate`	CA	Management, Analytics, Portal	
`clientCertificate`	Client	Management, Analytics, Portal	
`serverCertificate`	Server	Management, Analytics, Portal	Portal DNS names required `*.<namespace>` `*.<namespace>.svc` `*.<instance name>-server.<namespace>.svc` `<instance name>-server` `*.<instance name>-<site name>-db-all.<namespace>.svc` `*.<instance name>-<site name>-www-all.<namespace>.svc` `*.<instance name>-<site name>-db-all.<namespace>.svc.cluster.local` `*.<instance name>-<site name>-www-all.<namespace>.svc.cluster.local` `*.<namespace>.svc.cluster.local` `<instance name>-db`
`dbServerCertificate`	Server	Management	
`pgBouncerServerCertificate`	Server	Management	
`PGOTLSCertificate`	Server	Management	
`NATSTLSCertificate`	Server	Management	
`dbClientPostgres`	Client	Management	

Certificate	Type (CA/Server/Client)	Subsystem	Notes
`dbClientReplicator`	Client	Management	
`dbClientPgbouncer`	Client	Management	
`dbClientApicuser`	Client	Management	
`dbClientPrimaryuser`	Client	Management	

Several certificates as noted above are required to be signed by the same CA as another certificate. For example, **`portal-admin-client`**, and **`portal-admin`**. This means that if the **`portal-admin-client`** certificate were to be customized, then the **`portal-admin`** certificate must also be customized, and signed by the same CA as **`portal-admin-client`**. To ensure that pairs of certificates like these are signed by the same CA, the Issuer for each certificate must be the same.

Generating custom certificates

You can generate custom certificates.

About this task

If you do not already have your own custom certificates that you can provide for the installation, you can manually prepare Certificate definitions for Cert-Manager to generate the required Certificates for you.

Note: If a certificate is signed by an internal or custom CA, include the full chain in the end certificate. If you omit the full chain, then a user who uses openSSL to access the endpoint will see the following error: **`error:num=20:unable to get local issuer certificate`**
The following example shows the full chain for an end certificate (signed by a custom CA):

```
-------BEGIN CERTIFICATE -----
Cert contents for end-cert
--------END CERTIFICATE ----------
-------BEGIN CERTIFICATE -----
Cert contents for Intermediate-CA
--------END CERTIFICATE ----------
-------BEGIN CERTIFICATE -----
Cert contents for Root CA
--------END CERTIFICATE ----------
```

Procedure

1. Create a Certificate Authority (CA) and an Issuer for Signing
   a. Use the following YAML definition to generate a CA named **`ingress-ca`**, and an Issuer named **`ingress-issuer`** using that CA. Place the following definition into a file such as **`ingress-ca.yaml`**:

```
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
name: ingress-ca
spec:
    secretName: ingress-ca
    commonName: "ingress-ca"
    usages:
    - digital signature
    - key encipherment
    - cert sign
    isCA: true
    issuerRef:
        name: selfsigning-issuer
        kind: Issuer
    duration: 87600h # 10 years
    renewBefore: 720h # 30 days
    privateKey:
      rotationPolicy: Always
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
name: ingress-issuer
spec:
    ca:
        secretName: ingress-ca
```

   b. Apply this file into the cluster:

```
kubectl apply -f ingress-ca.yaml -n <namespace>
```

   This will create a CA Certificate named **`ingress-ca`**, and also a Secret named **`ingress-ca`**. This CA will be used to sign the rest of the custom certificates.

   c. Verify the presence of both:

```
kubectl get certificate -n <namespace>
kubectl get secret -n <namespace>
```

2. Generating common subsystem communication certificates with Cert-Manager for management CR.
   a. Use the following YAML definition to generate the following Common Certificates and Secrets: **`analytics-ingestion-client`**, and **`portal-admin-client`**. Place it into a file, for example, **`common-certs.yaml`**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
name: analytics-ingestion-client
spec:
    commonName: analytics-ingestion-client
    secretName: analytics-ingestion-client
    issuerRef:
        name: ingress-issuer
    usages:
    - "client auth"
    - "signing"
    - "key encipherment"
    duration: 17520h # 2 years
    renewBefore: 720h # 30 days
    privateKey:
      rotationPolicy: Always
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
name: portal-admin-client
spec:
    commonName: portal-admin-client
    secretName: portal-admin-client
    issuerRef:
        name: ingress-issuer
    usages:
    - "client auth"
    - "signing"
    - "key encipherment"
    duration: 17520h # 2 years
    renewBefore: 720h # 30 days
    privateKey:
      rotationPolicy: Always
---
```

Note that the **issuerRef** uses the Issuer created in Step 1. These certificates must be signed by the CA associated with that Issuer, **ingress-ca**.

b. Apply **common-certs.yaml** into the cluster:

```
kubectl apply -f common-certs.yaml -n <namespace>
```

This will create Client Certificates and Secrets named **analytics-ingestion-client**, and **portal-admin-client**.

c. Verify the presence of all of these certificates and secrets:

```
kubectl get certificate -n <namespace>
kubectl get secret -n <namespace>
```

3. Generating Front-end/Endpoint Certificates with Cert-Manager
   a. Generate server certificates.
   For each Endpoint in a subsystem CR, you can use the following YAML definition to generate a Server Certificate:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
name: <endpoint-host.secretName>
spec:
    commonName: <endpoint.host.secretName>
    secretName: <endpoint.host.secretName>
    dnsNames:
    - <endpoint.host.Name>
    issuerRef:
        name: ingress-issuer
    usages:
    - "server auth"
    - "signing"
    - "key encipherment"
    duration: 17520h # 2 years
    renewBefore: 720h # 30 days
    privateKey:
      rotationPolicy: Always
```

Replace **<endpoint.host.secretName>** with the **secretName** in the **host** block of the **Endpoint** in the CR. For example, if the **Endpoint** in the CR is:

```
cloudManagerEndpoint:
    hosts:
    - name: admin.example.com
      secretName: cm-endpoint
```

The Certificate YAML should be updated as follows:

```
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
name: cm-endpoint
spec:
    commonName: cm-endpoint
    secretName: cm-endpoint
    dnsNames:
    - admin.example.com
    issuerRef:
```

```
      name: ingress-issuer
  usages:
  - "server auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
```

Note that the **issuerRef** uses the Issuer created in Step 1. This certificate will be signed by the CA associated with that Issuer, **ingress-ca**.

Place the edited yaml into a file, e.g. **<*subsystem*>-server.yaml**.

b. Apply this file into the cluster:

```
kubectl apply -f <subsystem>-server.yaml.
```

This will create a Server Certificate named **<*subsystem*>-server**, and also a Secret named **<*subsystem*>-server**.

c. Check for the presence of both with:

```
kubectl get certificate -n <namespace>
kubectl get secret -n <namespace>
```

d. Repeat Step 3.a, step 3.b and step 3.c for each subsystem.
In each case, the Certificates must use the same Issuer created in Step 1. This ensures that all custom certificates are signed by the same CA Certificate.

Note that the **issuerRef** uses the Issuer created in Step 1. These certificates must be signed by the CA associated with that Issuer, **ingress-ca**.

e. Place the YAML definitions for each Certificate into a YAML file, for example, **endpoint-certs.yaml**. Apply this file into the cluster:

```
kubectl apply -f endpoint-certs.yaml -n <namespace>
```

This will create Client Certificates and Secrets for each Endpoint named **<endpoint.host.secretName>**.

f. Check for the presence of all of these with:

```
kubectl get certificate -n <namespace>
kubectl get secret -n <namespace>
```

4. Choose one of the following actions, based on whether or not you are customizing internal API certificates:
   - If you do not plan to customize internal certificates, continue with Configuring custom certificates before installation.
   - If you want to generate some, or all, of the internal certificates, continue with the next step.

   Note: It is not recommended to customize Internal certificates unless you have a specific requirement to do so.
5. Generate custom internal certificates using custom-certs-internal.yaml.
   Each of the Internal certificates listed in Custom certificates reference have differing strict requirements for Common Names and DNS Names (i.e. Subject Alternative Names).

   To generate custom certificates that meet these requirements, use the provided custom-certs-internal.yaml file, which can be found in the **helper_files** installation archive. For more information, see Obtaining product files.

   This file contains Certificate YAML definitions for all Internal certificates, CA, and Issuer that can be customized for each subsystem of IBM API Connect. The Certificate definitions file is already populated with the recommended default values.

   a. When using custom internal certificates, you are required to specify a site name. The site name is used as the identifier for the PostgreSQL database Cluster used by API Connect. The site name chosen is added to the Management Subsystem CR YAML file before installing the Management Subsystem.
   In addition, this name is also required for use with the custom internal certificates, so a site name should be chosen now before proceeding.

   b. Open custom-certs-internal.yaml in a text-editor, and make the following changes:
      i. Search for the **pg-bouncer-server-certificate** certificate definition. Replace **commonName** and **dns-names** with the following values:

      - ```
        commonName: management-pgo_cluster_id-postgres-pgbouncer
        ```
      - ```
        dnsNames:
          - "*.<namespace>"
          - "*.<namespace>.svc"
          - "management-pgo_cluster_id-postgres-pgbouncer.<namespace>.svc"
          - "management-pgo_cluster_id-postgres-pgbouncer"
        ```

      ii. Find and replace each occurrence of **<*namespace*>** with the desired namespace for the deployment. This must be done even if the **default** namespace is to be used.
      iii. Also in custom-certs-internal.yaml, replace each occurrence of **pgo_cluster_id** with the chosen site name described in Step 5.a.

   c. Apply the file to the Cluster:

   ```
   kubectl apply -f custom-certs-internal.yaml -n <namespace>
   ```

6. When all desired custom certificates are created and applied into the Kubernetes Cluster as **Certificates** and **Secrets**, update the Subsystem CR YAML files to use the custom certificates. See Configuring custom certificates before installation.

Generating custom certificates using cert-manager in a two data center deployment

You can generate custom certificates in a two data center disaster recovery deployment on Kubernetes.

About this task

You can provide your own custom certificates when you deploy IBM API Connect, if required, instead of having the application generate and manage them for you. In most deployment cases to use the built in default Cert-Manager integration is the preferred method.

When you use the custom option, the use of Cert-Manager is the recommended method for generating custom certificates if that fits your business needs. However, use of Cert-Manager is not required, and custom certificates can be generated in any way that suit your needs.

The following example of providing custom certificates uses Cert-Manager as a model for generating them. For generating custom certificates, the minimum supported version of cert-manager is v1.5.1.

Procedure

1. Set **KUBECONFIG** for the target cluster:

   ```
   export KUBECONFIG=<path_to_cluster_config_YAML_file>
   ```

   Example path:

   ```
   /Users/user/.kube/clusters/<cluster_name>/kube-config-<cluster_name>.yaml
   ```

2. Install cert-manager version 1.5.1 or later :
   a. Download v1.9.1 from https://github.com/cert-manager/cert-manager/releases/tag/v1.9.1.
   b. Install cert-manager. Do not specify a namespace:

   ```
   kubectl apply -f cert-manager.yaml
   ```

   c. Check the status of the **cert-manager** pods:

   ```
   kubectl -n cert-manager get po
   ```

   Wait for **cert-manager** pods to enter **Running 1/1** status before proceeding. There are 3 **cert-manager** pods in total.

3. Set up the customized external certificates:
   For quick setup, you can use the provided yaml files that are included in the **helper_files** that you expanded in Deploying operators and cert-manager. The yaml for the active data center (DC1) is called **custom-certs-external-dc1.yaml** and the yaml for the warm-standby data center (DC2) is called **custom-certs-external-dc2.yaml**.

   a. Open **custom-certs-external-dc1.yaml** and **custom-certs-external-dc2.yaml** in a text-editor. Find and replace each occurrence of **example.com** with the desired ingress subdomain for the API Connect stack.
   b. Ensure that the management CR for DC1 is ready for applying but not yet applied, make a note of the **hostname** of the site.
   c. In **custom-certs-external-dc1.yaml** find **spec.dnsNames**
   For example, in DC1:

   ```
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: dc1-mgmt-replication
   spec:
     commonName: dc1-mgmt-replication
     secretName: dc1-mgmt-replication
     dnsNames:
     - <INSERT SITE HOSTNAME HERE. THIS WILL BE THE SAME VALUE AS IN THE MANAGEMENT CR spec.multiSiteHA.hosts.name for
   site 1>
     issuerRef:
       name: ingress-issuer
     usages:
     - "signing"
     - "key encipherment"
     duration: 17520h # 2 years
     renewBefore: 720h # 30 days
     privateKey:
       rotationPolicy: Always
   ```

   d. Replace the line that begins **- <INSERT SITE HOSTNAME HERE** with *- hostname of the site*.
   e. Ensure that the management CR for DC2 is ready for applying but not yet applied, make a note of the **hostname** of the site.
   f. In **custom-certs-external-dc2.yaml** find **spec.dnsNames** and replace the line that begins **- <INSERT SITE HOSTNAME HERE** with *- hostname of the site*.
   g. Ensure that the portal CR for DC1 is ready for applying but not yet applied, make a note of the **hostname** of the site.
   h. In **custom-certs-external-dc1.yaml** find **spec.dnsNames**
   For example, in DC1:

   ```
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: dc1-ptl-replication
   spec:
     commonName: dc1-ptl-replication
     secretName: dc1-ptl-replication
     dnsNames:
     - <INSERT SITE HOSTNAME HERE. THIS WILL BE THE SAME VALUE AS IN THE PORTAL CR spec.multiSiteHA.hosts.name for site
   1>
       issuerRef:
       name: ingress-issuer
     usages:
     - "signing"
     - "key encipherment"
     duration: 17520h # 2 years
     renewBefore: 720h # 30 days
     privateKey:
       rotationPolicy: Always
   ```

i. Replace the line that begins `- <INSERT SITE HOSTNAME HERE>` with `- hostname of the site`.
j. Ensure that the portal CR for DC2 is ready for applying but not yet applied, make a note of the `hostname` of the site.
k. In `custom-certs-external-dc2.yaml` find `spec.dnsNames` and replace the line that begins `- <INSERT SITE HOSTNAME HERE>` with `- hostname of the site`.

4. Use the following steps to allow `ingress-ca` secrets to be the same on both data centers.
   a. On DC1 apply the file `custom-certs-external-dc1.yaml`:

   ```
   kubectl -n <namespace> apply -f custom-certs-external-dc1.yaml
   ```

   b. Validate that the command succeeded:

   ```
   kubectl get certificates -n <namespace>
   ```

   c. Export `ingress-ca` secret as a yaml from DC1:

   ```
   kubectl -n <namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
   ```

   d. Edit the `ingress-ca.yaml` file to remove all labels, annotations, `creationTimestamp`, `resourceVersion`, `uid`, and `selfLink`.
   e. Copy the `ingress-ca.yaml` from DC1 to DC2 and apply that file on DC2:

   ```
   kubectl -n <namespace> apply -f ingress-ca.yaml
   ```

   f. On DC2 apply the file `custom-certs-external-dc2.yaml`:

   ```
   kubectl -n <namespace> apply -f custom-certs-external-dc2.yaml
   ```

   g. Use the following commands to test that they are the same, on DC1 run:

   ```
   kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
   /tmp/ingress.pem.dc1
   ```

   h. On DC2 run:

   ```
   kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
   /tmp/ingress.pem.dc2
   ```

   i. To see the differences run:

   ```
   diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
   ```

   The files should be the same.
   j. To ensure that the certificates are working correctly and that they are using the `ingress-ca` secret. First, get the `portal-admin-client crt` file:

   ```
   kubectl -n <namespace> get secrets portal-admin-client -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
   /tmp/admin-client.crt
   ```

   k. Test that it is working by using OpenSSL:

   ```
   openssl verify -verbose -CAfile /tmp/ingress.pem.dc1 /tmp/admin-client.crt
   ```

   If it is working, you should see:

   ```
   /tmp/admin-client.crt: OK
   ```

5. Update the API Connect subsystem CR .yaml files to use the custom certificates. To do this, continue with Configuring custom certificates before installation.

Configuring custom certificates before installation

Configure custom certificates for your API Connect deployment before you begin the installation procedures.

About this task

To deploy API Connect with custom certificates, complete the following steps to configure your custom certificates before applying any subsystem installation CRs to the cluster.

Procedure

1. Determine which certificates you want to customize.
   For a list of certificates that can be customized, see Custom certificates reference.

   You can customize the following types of certificates:

   - Endpoint (External Frontend/Ingress) certificates:
     These are the certificates for external, public-facing endpoints where users interact with API Connect. You can customize none, some, or all of the endpoint certificates.

     If you initially deploy APIC using default certificates for endpoints, you can convert them to custom certificates later as explained in Converting to custom front-end/ingress certificates after deployment.

   - Internal (CA, Client, Server, and Common Subsystem Communication) cerificates:
     These are the certificates used within API Connect, so that subsystems can communicate. If you want to customize any of the internal certificates, then you must customize all of them; however you don't have to create them all yourself. Any custom certs that are not specifically named in your deployment CR will be generated automatically during installation.

     If you initially deploy API Connect using default certificates for internal certificates, you cannot convert them to custom certificates later.

2. Prepare your custom certificates.
   If you don't have a set of custom certificates already, you can use Kubernetes Cert-manager to generate them as explained in Generating custom certificates.

   When preparing your custom certificates, remember that certain pairs of certificates must by signed by the same Certificate Authority, as noted in Custom certificates reference.

   If you're installing a two data center disaster recovery configuration, and are using custom certificates, then the subject names of any client certificates must be the same in both data centers, as noted in Custom certificates reference. For example, both data centers subject name could be **CN=portal-admin-client**, or they could both be **CN=ptl-adm-client, O=cert-manager**, but they must be identical.

3. If needed, create a Kubernetes secret for each custom certificate.
   Each custom certificate that you use must be captured in a TLS secret. To create a secret, use the following commnad:

   ```
   kubectl create secret generic my-tls-secret --from-file=tls.crt=<path_to_cert_file> --from-file=tls.key=<path_to_key_file>
   --from-file=ca.crt=<path_to_cacert_file>
   ```

   When you create each secret, it's helpful to reference its purpose or its corresponding certificate in the secret name, to ensure you specify the correct secret for each custom certificate.

4. Edit the ingress-issuer-v1.yaml file and delete the default definitions for the certificates that you will customize.
   The ingress-issuer-v1.yaml file is provided as part of the installation **helper_files** archive.

   This file is used for generating the default certificates. To use a custom certificate, you must delete the default definition to ensure that API Connect uses your certificate instead of the default certificate. If you customize all of the default certificates and delete those definitions from the file, then you don't need to use the file during installation.

5. Customize endpoint (External Frontend/Ingress) certificates in the corresponding subsystem CRs.
   For each custom endpoint certificate, delete the annotation that specifies the default issuer, and replace the secret name with your own custom secret name.

   a. Open the subsystem CR for editing and locate the endpoint definition.
      For example, the following snippet shows the definition for the **cloudManagerEndpoint** in the Management CR:

      ```
      cloudManagerEndpoint:
        annotations:
          cert-manager.io/issuer: ingress-issuer
        hosts:
        - name: admin.example.com
          secretName: cm-endpoint
      ```

   b. Delete the annotation for the **cert-manager.io/issuer**.
      Delete the field name as well as the value; you can leave the **annotations:** label in place.

   c. Replace the default secret name with the name of the Kubernetes secret that you created for that endpoint's custom certificate.
      In the following example, **cm-endpoint** is the default secret name, which must be replaced. Make sure to reference the correct secret for the custom certificate.

      ```
      cloudManagerEndpoint:
        annotations:
        hosts:
        - name: admin.example.com
          secretName: my_cm-endpoint
      ```

6. Customize internal (CA, Client, Server, and Common Subsystem Communication) certificates.
   a. Open the subsystem CR for editing.
   b. Set the **microServiceSecurity** setting to **custom**.
      By default, the setting is configured for **certManager** as shown in the following example:

      ```
      microServiceSecurity: certManager
      certManagerIssuer:
          name: selfsigning-issuer
          kind: Issuer
      ```

   c. Delete (or comment-out) the **certManagerIssuer** block.
      In the following example, **microServiceSecurity** is set to **custom** and the **certManagerIssuer** block is commented out:

      ```
      microServiceSecurity: custom
      #certManagerIssuer:
      #    name: selfsigning-issuer
      #    kind: Issuer
      ```

7. Add the **customCertificates** block and list the secret name for each internal custom certificate that you created for the subsystem.
   Each subsystem supports a different set of Common Subsystem Communication and External Frontend/Ingress certificates. You do not have to provide a custom version of every certificate supported by the subsystem. Just list the custom certificates that you created; any certificates that you omit from the list will be generated automatically during installation.

   For example, your **customCertificates** list for the Management subsystem might look like the following example:

   ```
   customCertificates:
     - name: caCertificate
       secretName: my_ingress-ca
     - name: clientCertificate
       secretName: my_management-client
     - name: serverCertificate
       secretName: my_management-server
     - name: dbServerCertificate
       secretName: my_db-server-certificate
     - name: pgBouncerServerCertificate
       secretName: my_pg-bouncer-server-certificate
     - name: PGOTLSCertificate
       secretName: my_pgo.tls
     - name: NATSTLSCertificate
   ```

```
    secretName: my_management-natscluster-mgmt
  - name: dbClientPostgres
    secretName: my_db-client-postgres
  - name: dbClientReplicator
    secretName: my_db-client-replicator
  - name: dbClientPgbouncer
    secretName: my_db-client-pgbouncer
  - name: dbClientApicuser
    secretName: my_db-client-apicuser
  - name: dbClientPrimaryuser
    secretName: my_db-client-primaryuser
```

What to do next

Deploy API Connect:

- If you did not deploy the API Connect operator yet, proceed to Deploying operators in a single-namespace API Connect cluster or Deploying operators in a multi-namespace API Connect cluster.
- If you already deployed the operator, proceed to Installing the API Connect subsystems.

Converting to custom front-end/ingress certificates after deployment

Convert a front-end certificate generated by cert-manager to a custom certificate for an existing IBM® API Connect deployment.

About this task

If you deploy IBM API Connect using certificates that were generated by cert-manager, you can later convert front-end (ingress) certificates to use custom certificates instead. For a list of the certificates that are generated and managed by cert-manager, see Custom certificates reference.

Restriction: This task applies only to front-end certificates and is not supported for the "Common Subsystem Communication" and "Internal" type certificates.

Procedure

1. Create the secrets you want to use with the **`kubectl create secret`** command.
2. Edit the subsystem CR, and make the following changes for the endpoint secret you want to change:
   - In the **`annotations`** section, remove the following line:

     ```
     cert-manager.io/issuer: ingress-issuer
     ```

   - In the **`hosts`** section, update the **`secretName`** to the new secret that you created in step 1.

   The following example shows where the updates should be made:

```
spec:
  <endpoint>
    annotations:
      cert-manager.io/issuer: ingress-issuer  REMOVE THIS LINE
    hosts:
    - name: <api endpoint hostname>
      secretName:  CHANGE THIS TO THE NEW SECRET
```

Webhooks deployed and managed by the API Connect Operator

The API Connect Operator deploys and manages various Kubernetes API webhooks in the cluster to assist in management of its custom resources.

The webhooks included admission controllers and conversion webhooks.

Defaulting webhook

- Purpose
  The defaulting webhook is a type of Mutating Admission Webhook which runs against Custom Resources (CRs) at **`CREATE`** or **`UPDATE`** time to populate default values in the CR's **`spec`**.

- Creation
  Currently the defaulting webhook runtime is part of the API Connect Operator runtime, that is it exists within the API Connect Operator pod and container. When the operator boots, it creates **`MutatingWebhookConfiguration`** resources for each CRD (listed below). This **`MutatingWebhookConfiguration`** is a cluster-scope resource, but the configuration within will be specific to the namespace and operator instance which created it. If more than one instance of the API Connect Operator is deployed across a cluster (in different namespaces) there will be a set of webhook configurations for each API Connect Operator instance and namespace.

  The name for the **`MutatingWebhookConfiguration`** resource for each CRD will take the following form:

  ```
  <namespace>.<crd-name>.defaulter[.<component>].apiconnect.ibm.com
  ```

  The following CustomResourceDefinitions utilize a defaulting webhook:

  ```
  AnalyticsCluster
  ApiconnectCluster
  GatewayCluster
  ```

```
ManagementBackup
ManagementCluster
ManagementDBUpgrade
ManagementRestore
PortalCluster
```

- Lifecycle
  While the defaulting webhook runtime itself lives within the API Connect Operator pod, the **MutatingWebhookConfiguration** is a cluster-scope resource and is stand-alone. When it is created, an **ownerReference** is set on it that references the API Connect Operator's **ClusterRole**. Thus, the lifecycle of the **MutatingWebhookConfiguration** resources will be linked with the **ClusterRole**, which is linked with the installation of the operator itself.

  When the operator is uninstalled, the **MutatingWebhookConfiguration** resources for that operator instance are also removed.

- Example
  The below output shows the defaulting webhook configurations created for an operator deployed in the **apiconnect-operator** namespace. One can be seen for each CRD.

```
$ oc get mutatingwebhookconfiguration
NAME                                                                WEBHOOKS   AGE
apiconnect-operator.analyticsclusters.defaulter.analytics.apiconnect.ibm.com       1          4d4h
apiconnect-operator.apiconnectclusters.defaulter.apiconnect.ibm.com                1          4d4h
apiconnect-operator.gatewayclusters.defaulter.gateway.apiconnect.ibm.com           1          4d4h
apiconnect-operator.managementbackups.defaulter.management.apiconnect.ibm.com     1          4d4h
apiconnect-operator.managementclusters.defaulter.management.apiconnect.ibm.com    1          4d4h
apiconnect-operator.managementdbupgrades.defaulter.management.apiconnect.ibm.com  1          4d4h
apiconnect-operator.managementrestores.defaulter.management.apiconnect.ibm.com    1          4d4h
apiconnect-operator.portalclusters.defaulter.portal.apiconnect.ibm.com             1          4d4h
```

Validating webhook

- Purpose
  The validating webhook is a type of ValidatingAdmissionWebhook which runs against Custom Resources (CRs) at **CREATE** or **UPDATE** time to validate the CR contains a configuration which will yield an operable cluster. The CustomResourceDefinitions use OpenAPI schema validation for basic property checks (such as integer bounds and non-empty strings), but more complex validation of the configuration is done via the webhook.

- Creation
  Currently the validating webhook runtime is part of the API Connect Operator runtime, i.e. it exists within the API Connect Operator pod and container. When the operator boots, it creates **ValidatingWebhookConfiguration** resources for each CRD (listed below). This **ValidatingWebhookConfiguration** is a cluster-scope resource, but the configuration within will be specific to the namespace and operator instance which created it. If more than one instance of the API Connect Operator is deployed across a cluster (in different namespaces) there will be a set of webhook configurations for each API Connect Operator instance and namespace.

  The name for the **ValidatingWebhookConfiguration** resource for each CRD will take the following form:

  <namespace>.<crd-name>.validator[.<component>].apiconnect.ibm.com

  The following CustomResourceDefinitions utilize a validating webhook:

```
AnalyticsCluster
ApiconnectCluster
GatewayCluster
ManagementBackup
ManagementCluster
ManagementDBUpgrade
ManagementRestore
PortalCluster
```

- Lifecycle
  While the validating webhook runtime itself lives within the API Connect Operator pod, the **ValidatingWebhookConfiguration** is a cluster-scope resource and is stand-alone. When it is created, an **ownerReference** is set on it that references the API Connect Operator's **ClusterRole**. Thus, the lifecycle of the **ValidatingWebhookConfiguration** resources will be linked with the **ClusterRole**, which is linked with the installation of the operator itself.

  When the operator is uninstalled, the **ValidatingWebhookConfiguration** resources for that operator instance are also removed.

- Example
  The below output shows the validating webhook configurations created for an operator deployed in the **apiconnect-operator** namespace. One can be seen for each CRD.

```
validatingwebhookconfiguration
NAME                                                                WEBHOOKS   AGE
apiconnect-operator.analyticsclusters.validator.analytics.apiconnect.ibm.com       1          4d4h
apiconnect-operator.apiconnectclusters.validator.apiconnect.ibm.com                1          4d4h
apiconnect-operator.gatewayclusters.validator.gateway.apiconnect.ibm.com           1          4d4h
apiconnect-operator.managementbackups.validator.management.apiconnect.ibm.com     1          4d4h
apiconnect-operator.managementclusters.validator.management.apiconnect.ibm.com    1          4d4h
apiconnect-operator.managementdbupgrades.validator.management.apiconnect.ibm.com  1          4d4h
apiconnect-operator.managementrestores.validator.management.apiconnect.ibm.com    1          4d4h
apiconnect-operator.portalclusters.validator.portal.apiconnect.ibm.com             1          4d4h
```

Installing API Connect

Use these instructions to install a deployment of API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.

To deploy API Connect, complete the tasks in the order below.

- **Deployment requirements**
  Describes the system requirements for deploying into the Kubernetes, OpenShift, and Cloud Pak for Integration runtime environments.
- **Deployment procedures**
  You can use these procedures to deploy API Connect on either native Kubernetes or OpenShift.

Deployment requirements

Describes the system requirements for deploying into the Kubernetes, OpenShift, and Cloud Pak for Integration runtime environments.

Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software might change and this information might become outdated. Kubernetes is a platform for automated deployment, scaling, and operation of application containers across clusters of hosts, providing container-centric infrastructure. For more information, see https://kubernetes.io.

These instructions assume you have a working Kubernetes environment and understand how to manage Kubernetes.

About this task

Review all the requirements listed in the following steps before starting your API Connect deployment.

Note: If you plan to install the Automated API behavior testing application, review the *Before you begin* section in Installing the Automated API behavior testing application because the requirements might have an impact on your deployment choices for API Connect.

Procedure

1. Verify that you have supported software.
   - Refer to the IBM Software Product Compatibility Reports site for detailed requirements for operating systems, supporting software, and other prerequisites. See Detailed system requirements for a specific product
   - For new installations, the API Connect operators and operands must be from the same version of API Connect. This requirement applies to native Kubernetes and OpenShift installations.
     - Note that the API Connect operator version *number* does not match the API Connect release version *number*. You can view a mapping of API Connect release number to API Connect operator version numbers in Deploying operators and cert-manager.
     - For API Connect operands (Management, Portal, Analytics, and Gateway subsystems), the version number matches the API Connect release version number.

2. Verify that your Kubernetes environment is running and meets the configuration requirements for API Connect:
   - When using IBM Cloud Kubernetes Service, ingress-nginx is required.
   - Specify settings for the ingress controller for a Kubernetes runtime environment. See Kubernetes ingress controller prerequisites.
   - The timezone for API Connect pods is set to UTC. Do not change the timezone for the pods.
   - To ensure the API Connect services have time to start, we recommend increasing the *proxy-read-timeout* and *proxy-send-timeout* values in the *config.map* used to configure the kubernetes/ingress-nginx ingress controller. The following settings should be increased:
     - proxy-read-timeout: "240"
     - proxy-send-timeout: "240"

     240 seconds (4 minutes) is a recommended minimum; actual value will vary depending upon your environment. If there is a load balancer in front of the worker node(s), then the load balancer configuration may also need to have extended timeouts.
   - Storage type:
     When selecting storage type, review the following considerations:

     - Management subsystem requires block storage.
     - Developer Portal subsystem supports block storage or local volume storage.
     - Analytics subsystem supports block storage or local volume storage.

     Supported storage types
     - Block storage
       Select a block storage format of your choosing in order for API Connect components to be supported. Supported block storage types include, but are not limited to:

       - Rook Ceph
         Note: cephrbd (RADOS Block Device) is recommended over cephfs file system

       - OpenShift Container Storage
       - Portworx
       - IBM Cloud Block Storage
       - AWS: the gp2, gp3, io1, and io2 types of Elastic Block Storage (EBS) are supported.
       - IBM Spectrum Scale with Block Storage
       - Azure Premium Storage
       - GCE Persistent Disk

       See also the **API Connect v10 WhitePaper 1.5** for information on limitations observed with other block storage solutions:
       https://community.ibm.com/community/user/integration/viewdocument/api-connect-deplyoment-whitepaper-v?CommunityKey=2106cca0-a9f9-45c6-9b28-01a28f4ce947&tab=librarydocuments&LibraryFolderKey=&DefaultView=folder

     - Local volume storage

       Management subsystem and Developer Portal subsystem
       All subsystems will run on local volume storage but it is not recommended for the Management subsystem and Developer Portal subsystem because it has severe performance impacts for high availability deployments, and for pod allocation.

Note also that local volume storage is not available in most cloud environments, and might incur limitations in disaster recovery scenarios, since it is tied to the node on which the pod is run. This means that use of LVS might be adequate for deployments with a one replicaprofile, but inadequate for deployments with a three replica profile.

Analytics subsystem
: For Analytics subsystems, transactions per second (TPS) is three times faster with local volume storage than with Ceph block storage. In a production scenario, you will have multiple analytics-storage (OpenSearch) nodes forming a storage cluster. OpenSearch will manage data replication across its cluster and ensure high availability, thus mitigating possible local volume storage drawbacks with disaster recovery.

Non-supported storage
- NFS
  API Connect v10 cannot be deployed on NFS.
- GlusterFS
  GlusterFS is not recommended as a storage option due to severe performance degradation and in some cases, loss of data. There are known GlusterFS issues that affect OpenSearch (which is used in the API Connect analytics service), the Developer Portal and the Management subsystem

- Storage class configuration:
  In your Kubernetes cluster configuration, you must create storage classes with the setting:

  `volumeBindingMode: WaitForFirstConsumer`

  This setting is needed to avoid volume node **affinity** conflicts, such as those caused by **requiredPodAntiAffinity** restrictions. If **WaitForFirstConsumer** is the binding mode, PVCs (PersistentVolumeClaims) are only bound once the pod is actually created.

  By contrast, when the binding mode is immediate (**volumeBindingMode: Immediate**), the PVCs are bound to PVs (PersistentVolumes) as soon as the PV is created.

  - Example:
    The Postgres operator creates the PVC first and then deploys the deployments. In immediate mode, PVCs are bound to PVs as soon as the PV is created. The **pgbackrest** pod starts successfully, but because **requiredPodAntiAffinity** restrictions are set, and the **postgres** pod is **NOT ALLOWED** to schedule on the same node as **pgbackrest** pod, Kubernetes cannot schedule the pod in node **eu-west-1c**. Also, because the volume attached to the pod is at **eu-west-1c**, Kubernetes cannot move the pod to any other node, thus causing **volume node affinity** conflict.
  - Example:
    When deploying to a multi-zone cluster, you must use StorageClass with **WaitForFirstConsumer** because when binding mode is immediate, successful deployment is indeterminate because of interactions between pod/node affinity and the Kubernetes provisioning of the PV on the right node where the pod is being provisioned.

  For more information, see "Volume Binding Mode" on https://kubernetes.io/docs/concepts/storage/storage-classes/.

  Note: During deployment, you are required to specify the name of the storage class you created. You can either use the setting **storageClassName: $STORAGE_CLASS** in the applicable CR (such as apiconnect top-level CR or an individual subsystem CR), or you can use a configuration UI such as Platform Navigator UI or OpenShift Container Platform (OCP) UI.
- When the Analytics service is configured to store data, (that is, it is not configured for ingestion-only), the service depends on OpenSearch, which requires map counts higher than the operating system defaults. See: Installing the Analytics subsystem.
  If you are deploying on OpenShift, the map count is preconfigured (**vm.max_map_count = 1027580**) with a value that is sufficiently large for OpenSearch so you do not need to modify this setting.

- Ensure that your Kubernetes deployment addresses known security vulnerabilities with SSH to prevent the use of weak SSH Message Authentication Code (MAC) and Key exchange algorithms (KexAlgorithms) with TCP over port 22. Use of weak algorithms can allow an attacker to recover the plain text message from the encrypted text. If you have not yet addressed the security vulnerabilities with weak MACs and KexAlgorithms, update your configuration manually by adding the following lines to /etc/ssh/sshd_config:

  ```
  KexAlgorithms curve25519-sha256@libssh.org,diffie-hellman-group-exchange-sha256
  MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
  ```

- IBM API Connect requires a number of container registry repositories to be added to your container registry service if automatic repository creation is not supported. Follow the procedure in Step 4 of Obtaining product files.

- Logging:
  - Configure a remote server for logging. See Logging. Pods are terminated during an upgrade, and the logs will be lost if not stored remotely.
  - Configure the log rotation by setting the **max-size** and **max-files** values to a setting appropriate for your deployment. In a Kubernetes deployment, insufficient values for max-size and max-files can cause logs to grow too large and eventually force pods to restart.
    For more information, visit the Docker documentation and search for "JSON File logging driver".

3. Ensure your deployment meets the DNS requirements for API Connect domain names, host names, and endpoints.
   You specify endpoints when you edit the custom resource templates for each subsystem, and when you use the Cloud Manager UI to configure the services for your cloud. The domain names you use for the endpoints must be recognized by your DNS configuration. DNS entries must meet these requirements:

   Important: For API Connect on native Kubernetes and OpenShift, do not use coredns 1.8.1 through 1.8.3. These releases have a defect that can prevent pods for Developer Portal from starting. See https://coredns.io/.
   - Endpoints cannot contain the underscore character `"_"` or uppercase characters.
   - Host names that are used to create endpoints cannot contain the underscore character `"_"` or uppercase letters.
   - DNS must be configured with domain names that correspond to the endpoints configured at installation time for each subsystem.
   - Host names and DNS entries may not be changed on a cluster after the initial installation.
   - Kubernetes ingress limits the character set for DNS names to not support the underscore character `"_"`. This means you cannot specify underscores in domain names that are used as endpoints. For example, **my_domain.abc.com** and **my.domain_abc.com** are not supported for **<xxx>.<hostname>.<domainname>**, and will cause an error:

     ```
     Invalid value: "my_domain.abc.com": a DNS-1123 subdomain must consist of lowercase alphanumeric characters, '-' or '.',
     ```

`and must start and end with an alphanumeric character (e.g. 'example.com', regex used for validation is '[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*')`

- We recommend that you keep a record of the DNS entries and endpoint names, as you will need to map the DNS entries and use the same endpoints when restoring a backup of the management database. Note that endpoints are FQDNs, entered in all lowercase. For an overview on endpoints, review Deployment overview for endpoints and certificates
- Specifying domain names when deploying CRs (custom resources) for each subsystem:
  The custom resource templates provide endpoint settings that consist of a default endpoint prefix and a variable **$STACK_HOST** that you set to specify your domain name, as part of Installing the API Connect subsystems.

Table 1. Endpoints with domain names that must be configured in DNS

Default endpoint name	Description
`admin.$STACK_HOST`	Cloud Manager URL endpoint for the Management subsystem
`manager.$STACK_HOST`	API Manager URL endpoint for the Management subsystem
`api.$STACK_HOST`	Platform REST API Endpoint for admin and provider APIs
`consumer.$STACK_HOST`	Platform REST API Endpoint for consumer APIs for the Management subsystem.
`rgw.$STACK_HOST`	Gateway Endpoint for API invocation for DataPower API Gateway
`rgwd.$STACK_HOST`	Gateway Management Endpoint for DataPower API Gateway
`gw.$STACK_HOST`	Gateway Endpoint for API invocation for DataPower Multi-Protocol Gateway (v5-compatible)
`gwd.$STACK_HOST`	Gateway Management Endpoint for DataPower Multi-Protocol Gateway (v5-compatible)
`ai.$STACK_HOST`	Analytics ingestion endpoint for the Analytics subsystem
`api.portal.$STACK_HOST`	Developer Portal admin endpoint
`portal.$STACK_HOST`	Developer Portal UI endpoint

- Specifying endpoints using the Cloud Manager interface
  After initial deployment of the Kubernetes custom resource for each subystem, you will also enter the endpoints in the Cloud Manager user interface when defining each service as part of Defining your topology.

4. The Cloud Provider for the target Kubernetes platform must provide Ingress Controller support for SSL Passthrough.
   For example, if the Cloud Provider uses or suggests the use of the NGINX Community Ingress, then the **`--enable-ssl-passthrough`** flag would need to be provided at runtime, as described at https://kubernetes.github.io/ingress-nginx/user-guide/tls/#ssl-passthrough. For IBM Cloud Kubernetes Service, see https://cloud.ibm.com/docs/containers?topic=containers-ingress-user_managed..
5. Determine your strategy for using certificates and cert-manager with API Connect.
   If you haven't already, review the topics in the section Certificates in a Kubernetes environment.

   Consider the following:

   - Will you use a cert-manager (recommended) or manually manage your certificates?
     API Connect provides a cert-manager and default certificates. If you use these, you can follow default configuration steps. See Deploying operators and cert-manager.
   - Will you use custom certificates rather than default certificates? See Custom certificates on Kubernetes.
6. If you plan to deploy API Connect on Kubernetes with DataPower Gateway in a *non-Kubernetes* environment, such as a DataPower appliance, review the API Connect requirements for operation with DataPower Gateway:
   - When deploying with a DataPower appliance, configure a Gateway Service Management Endpoint and API invocation Endpoint in DataPower. See *Configuring the API Connect Gateway Service* in the appropriate version of the DataPower documentation.
   - Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.
     Note:
     You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

     Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.
7. If you plan to deploy the API Connect management subsystem and the DataPower Gateway subsystem on a Kubernetes deployment, managed by the DataPower and API Connect Operators, you can use any combination of API Connect 10.0.5.x with DataPower Gateway 10.5.0.x or DataPower API Gateway 10.5.0.x.
8. Observe namespace restrictions:
   - OpenShift
     Only one top level CR (APIConnectCluster) can be deployed in each namespace.

   - Cloud Pak for Integration
     In the Platform Navigator UI, only one APIConnect capability can be deployed in each namespace.

   - Native Kubernetes
     Only one instance of a subsystem can be deployed in each namespace. Deploying multiple similar subsystems in a single namespace is not supported. For example, there is no support for deploying two management subsystems, **`mgmt1`**, **`mgmt2`** in a single namespace where apiconnect operator is installed.
9. The following kernel or Kubernetes node limits for the Developer Portal subsystem must be set correctly:
   - Ensure that your kernel or Kubernetes node has the value of its **`inotify`** watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a **`non-ready`** state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of **`inotify`** watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take **`inotify`** watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.
   - Ensure that your kernel or Kubernetes node has a value of **`nproc`** (maximum number of processes) that applies to the user ID of the Portal pods that have been assigned, and that it is high enough to allow all of the Portal processes to execute. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls, you might need as many as 125205. If the number is too low, you will see errors like **`"fork: retry: Resource temporarily unavailable"`** in the Portal logs. Note that this value might need to be even higher if other, non-Portal, pods are sharing the same user ID.

- Ensure that your kernel or Kubernetes node has a value of `nofiles` (maximum number of open file descriptors) that applies to the user ID of the Portal pods that have been assigned, and that it is high enough to allow the Portal to open all of the files that it requires. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls and Portal web sites, you might need as many as 1048576. If the number is too low, you will see errors like `"too many open files"` in the Portal logs. Note that this value might need to be even higher if other, non-Portal, pods are sharing the same user ID.

- **IBM API Connect Version 10 software product compatibility requirements**
  Ensure that you install the minimum API Connect operating system requirements. Use the IBM Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.
- **API Connect licenses**
  When you install a new version of API Connect, you must accept a license for the API Connect program that you purchased.

IBM API Connect Version 10 software product compatibility requirements

Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.

Generating a Software Product Compatibility Report

To generate an API Connect requirements report, complete the following steps:

1. Open the Detailed system requirements for a specific product page on the IBM Software Product Compatibility Reports site.
2. Search for the IBM API Connect product.
3. In the Search results list, select IBM API Connect.
4. From the Version list, select the required version.
5. Use the Filters to refine the contents of the requirements report.
6. Click Submit to generate your requirements report.

Supported versions of Kubernetes

The following tables provide a quick reference of the supported Kubernetes versions for each API Connect release:

Table 1. API Connect and Kubernetes (K8S) compatibility matrix

API Connect version	K8S 1.22	K8S 1.23	K8S 1.24	K8S 1.25	K8S 1.26	K8S 1.27
10.0.5.0	✓	✓				
10.0.5.1	✓	✓				
10.0.5.2		✓	✓	✓		
10.0.5.3			✓	✓	✓	
10.0.6.0			✓	✓	✓	✓

Upgrading to an API Connect release that uses a newer version of Kubernetes

When you upgrade API Connect, both your current deployment and your target release must support the same version of Kubernetes. After the API Connect upgrade, you can optionally update Kubernetes to the highest version supported by the new release of API Connect.

It is possible you will need to upgrade both Kubernetes and API Connect more than once to complete the process. For example, suppose that your current deployment is running API Connect 10.0.5.0 on Kubernetes v1.22 and you want to upgrade to API Connect 10.0.6.0. The highest version of Kubernetes supported with API Connect 10.0.5.0 is v1.23, but the lowest version of Kubernetes supported by API Connect 10.0.6.0 is v1.24, so a direct upgrade of API Connect is not possible.

In this scenario, you must make multiple upgrades of both Kubernetes and API Connect to reach the target versions; for example:

1. On your API Connect 10.0.5.0 deployment, upgrade Kubernetes from v1.22 to v1.23.
2. Upgrade API Connect to 10.0.5.2 on Kubernetes v1.23.
3. On the API Connect 10.0.5.2 deployment, upgrade Kubernetes to v1.24.
4. Upgrade API Connect to 10.0.6.0 on Kubernetes v1.24.
5. On the API Connect 10.0.6.0 deployment, optionally upgrade Kubernetes from v1.24 to v1.25, v1.26, or v1.27 (the interim upgrades are required to reach each version).

Supported versions of OpenShift

The following tables provide a quick reference of the supported OpenShift versions for each API Connect release:

Table 2. API Connect and OpenShift Container Platform (OCP) compatibility matrix

API Connect version	OCP 4.10	OCP 4.12
10.0.5.0	✓	
10.0.5.1	✓	
10.0.5.2	✓	✓

API Connect version	OCP 4.10	OCP 4.12
10.0.5.3	✓	✓
10.0.6.0	✓	✓

Upgrading to an API Connect release that uses a newer version of OpenShift

When you upgrade API Connect, both your current deployment and your target release must support the same version of OpenShift. After the API Connect upgrade, you can optionally update OpenShift to the highest version supported by the new release of API Connect.

For example, suppose that your current deployment is running API Connect 10.0.5.0 on OpenShift 4.10 and you want to upgrade to API Connect 10.0.6.0 on OpenShift 4.12. The highest version of OpenShift supported with API Connect 10.0.5.0 is 4.10, but you can upgrade OpenShift after completing the API Connect upgrade to 10.0.6.0.

In this scenario, you would complete the following upgrades:

1. On your API Connect 10.0.5.0 deployment, upgrade API Connect to 10.0.6.0.
2. On the API Connect 10.0.6.0 deployment, upgrade OpenShift to version 4.11 and then 4.12 (interim upgrades are required by OpenShift).

API Connect licenses

When you install a new version of API Connect, you must accept a license for the API Connect program that you purchased.

When you install or upgrade API Connect, the procedures include instructions for specifying your license. Be sure to specify a License ID from the version of API Connect that your installing, or are upgrading to.

For API Connect 10.0.6.0 and later, the licenses in Table 1 will be used as the master mod-level license for all Fix Pack and security roll-up releases in this stream. There are no changes to license terms, only updates to open-source notices documented in the notes for each.

Table 1. API Connect 10.0.6 licenses

License ID	Program Name	URL
L-KZXM-S7SNCU	IBM API Connect Enterprise V10.0.6.0 If you are upgrading from 10.0.5.0 or 10.0.5.1, this ID replaces the ID for "IBM API Connect Enterprise PVU V10.0.5"	https://ibm.biz/BdPJsn
L-NRHE-WFD7EY	IBM Cloud Pak for Integration - API Calls 2023.2.1	https://ibm.biz/BdPJse
L-TBPQ-X87AGB	IBM API Connect Enterprise Add-on for IBM Products V10.0.6.0	https://ibm.biz/BdPJsb
L-FNPP-MXMAH5	IBM API Connect Professional V10.0.6.0	https://ibm.biz/BdPJsp

Deployment procedures

You can use these procedures to deploy API Connect on either native Kubernetes or OpenShift.

- **Deploying on Kubernetes**
  Use the procedures in this section to install API Connect on native Kubernetes distributions.
- **Deploying on OpenShift and Cloud Pak for Integration**
  You can install API Connect in an OpenShift environment or as the API Management capability in IBM Cloud Pak for Integration.

Deploying on Kubernetes

Use the procedures in this section to install API Connect on native Kubernetes distributions.

- **Obtaining product files**
  Obtain the product files, upload the images to a Docker registry, and decompress the operators and templates.
- **Deploying operators and cert-manager**
  Deploy the Kubernetes operator files and install cert-manager.
- **Installing the API Connect subsystems**
  Deploy the API Connect subsystem custom resources.
- **Installing a two data center deployment on Kubernetes**
  Additional installation instructions for a two data center disaster recovery (2DCDR) deployment on Kubernetes.
- **Troubleshooting installation on Kubernetes**
  Review the following known issues and troubleshooting tips if you encounter a problem while installing API Connect on Kubernetes

Obtaining product files

Obtain the product files, upload the images to a Docker registry, and decompress the operators and templates.

Before you begin

- Ensure you have supported hardware and software. See IBM API Connect Version 10 software product compatibility requirements.
- Complete the Deployment requirements

- Install and run Docker on the local machine being used for API Connect installation. Log in to your image registry.

About this task

From the IBM Fix Central site, download the Docker image-tool file of the API Connect subsystems. Next, you will upload the image-tool file to your Docker local registry. If necessary, you can populate a remote container registry with repositories. Then you can push the images from the local registry to the remote registry.

You will also download the Kubernetes operators, API Connect Custom Resource (CR) templates, and Certificate Manager, for use during deployment configuration.

Note:

- If you plan to migrate from Version 5 to Version 10, review Migrating a version 5 deployment to version 10.0.6x before you start the installation process.
- If you have API Connect installed and want to upgrade your release version, follow the upgrade instructions: Upgrading API Connect in a Kubernetes runtime environment

Procedure

1. Obtain the API Connect files:
   a. Go to the What's New in the latest version information page.
   b. Locate the Note: *You can access the latest files from <URL link>*. Select the *<URL link>* to go directly to the Announce page on Fix Central, where you can download files for the *latest version* of API Connect.

   The following files are used for initial deployment on native Kubernetes:

   IBM® API Connect *<version>* for Containers
   Docker images for all API Connect subsystems

   IBM® API Connect *<version>* Operator Release Files for Containers
   Kubernetes operators and API Connect Custom Resource (CR) templates

   IBM® API Connect *<version>* Toolkit for *<operating_system_type>*
   Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:
   - IBM® API Connect *<version>* Toolkit for *<operating_system_type>*
   - IBM® API Connect *<version>* Toolkit with Loopback for *<operating_system_type>*
   - IBM® API Connect *<version>* Toolkit Designer with Loopback for *<operating_system_type>*

   Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See Installing the toolkit.

   IBM® API Connect *<version>* Local Test Environment
   Optional test environment. See Testing an API with the Local Test Environment

   IBM® API Connect *<version>* Security Signature Bundle File
   Checksum files that you can use to verify the integrity of your downloads.

2. Optionally, you can verify the integrity of the downloaded files to ensure that they originated from IBM and are not modified. See Signature verification by using PGP.
3. Load the image-tool image in your Docker local registry. The image is contained in the IBM® API Connect *<version>* for Containers download file. For example:

   ```
   docker load < apiconnect-image-tool-<version>.tar.gz
   ```

   Ensure that the registry has sufficient disk space for the files.

4. If your Docker registry requires repositories to be created before images can be pushed, create the repositories for each of the images listed by the image tool. (If your Docker registry does not require creation of repositories, skip this step and go to Step 5.)
   a. Run the following command to get a list of the images from image-tool:

   ```
   docker run --rm apiconnect-image-tool-<version> version  --images
   ```

   b. From the output of each entry of the form `<image-name>:<image-tag>`, use your Docker registry repository creation command to create a repository for `<image-name>`.
   For example in the case of AWS ECR the command would be for each `<image-name>`:

   ```
   aws ecr create-repository --repository-name <image-name>
   ```

5. Upload the image:
   - If you do not need to authenticate with the docker registry, use:

     ```
     docker run --rm apiconnect-image-tool-<version> upload <registry-url>
     ```

   - Otherwise, if your docker registry accepts authentication with username and password arguments, use:

     ```
     docker run --rm apiconnect-image-tool-<version> upload <registry-url> --username <username> --password <password>
     ```

   - Otherwise, such as with IBM Container Registry, if you need the image-tool to use your local Docker credentials, first authenticate with your Docker registry, then upload images with the command:

     ```
     docker run --rm -v ~/.docker:/root/.docker --user 0 apiconnect-image-tool-<version> upload <registry-url>
     ```

     Note: The previous command does not work on macOS if Docker is configured to use the `osxkeychain` credential store. In this case, complete the following steps:
     - Disable **Docker > Preferences... > Securely store Docker logins in the macOS keychain**.
     - Inspect `~/.docker/config.json` to make sure that it does not contain `"credsStore": "osxkeychain"`, as some versions of Docker-for-mac may handle the setting correctly per https://github.com/docker/for-mac/issues/4192.
     - Authenticate with the Docker registry you intend to upload to.
     - Run the command:

       ```
       docker run --rm -v ~/.docker:/root/.docker --user 0 apiconnect-image-tool-<version> upload <registry-url>
       ```

     - Once the upload of images is successful you may enable **Docker > Preferences... > Securely store Docker logins in the macOS keychain**.

Docker authentication notes:

- Both HTTPS and HTTP are supported. Best practice for Docker registry security is to use HTTPS by utilizing standard Docker load tools, to ensure your images and platform are protected. However, when necessary you can use HTTP by specifying the `--tls-verify=false` flag.
- When using a Docker registry on `localhost`, you might encounter that the image-tool Docker container is on the Docker network and typically without access to `localhost`. You can workaround this issue by using the `--network host` argument to the Docker command. Note that `--network host` is a Docker argument, not an image-tool argument.
- Example of using `--network host` and `--tls-verify=false`:

```
$ docker run -d -p 5000:5000 --name registry registry:2
...
$ docker run --rm --network host apiconnect-image-tool-<version> upload localhost:5000 --tls-verify=false
...
```

Providing a certificate for verification, or disabling TLS verification

See the sample output of the tool usage for options to provide a certificate for verification or to disable TLS verification:

```
$ docker run --rm apiconnect-image-tool-<version> upload --help
upload docker images

Usage:
  image-tool upload REGISTRY [flags]

Flags:
      --cert-dir string   Directory with destination registry certificate tls.crt file
      --username string   User name
  -h, --help              help for upload
      --password          password for <username>
      --tls-verify        Verify TLS on destination registry (default true)

Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Notes:

- `--username=<username>` and `--password=<password>` can be used to specify credentials for authentication with the destination Docker registry.
- `--tls-verify=false` can be used to disable verification of the destination Docker registry certificate
- `--cert-dir <path>` can be used to provide a `tls.crt` file to be used for validation of the destination Docker registry certificate. For example:

```
docker run --rm -v <path-to-folder-with-tls.crt-file>:/cert apiconnect-image-tool-<version> upload <registry> --
cert-dir /cert
```

6. Download the file IBM® API Connect *<version>* Operator Release Files for Containers
   a. Decompress the downloaded Operator Release Files for Containers
   Contents:

   - API Connect Operator operator custom resource definition (CRDs).
   - API Connect Operator Deployment and required resources CRDs.
   - API Connect Operator Deployment and required resources CRDs, for multiple-namespace installations.
   - DataPower Gateway Operator operator custom CRDs.
   - API Connect custom resource templates, and Certificate Manager

   The Operator Release Files for Containers files will be used later in deployment instructions.

   Note: The Operator Release files may include catalog and operator source for OpenShift. These files are not used when deploying on native Kubernetes.

   b. To access the API Connect custom resource templates and Certificate Manager, decompress the archive `helper_files.zip`.
   The zip file contains custom resource templates for:

   - Deployment of each subsystem.
   - Backup and restore of each subsystem
   - Custom certificates, both external and internal, for either standard deployments or 2-site HA deployments
   - Certificate support for multi-namespace deployments
   - Multi-site secret generation in a two data center deployment on Kubernetes.
   - Ingress Issuer and Subsystem Certificates Resources, for either standard deployments or 2-site HA deployments
   - Setting an administrator secret for DataPower Gateway

   The templates will be used later in deployment instructions.

What to do next

Continue with Deploying operators and cert-manager.

- **Signature verification by using PGP**
  You can verify the integrity of files to ensure that they originated from IBM and are not modified.

Signature verification by using PGP

You can verify the integrity of files to ensure that they originated from IBM and are not modified.

About this task

You can use code signatures to verify that a downloaded file was created by IBM and that no bits in the file were changed. The signature files that are used are **`*.asc`**. The key/cert file is **`PRD0003216key.pub.pgp`**.

Procedure

1. Import the public key.

```
$ gpg --import PRD0003216key.pub.pgp
gpg: key 020ED6B5DBE65F3B: public key "APIConnect <psirt@us.ibm.com>" imported
gpg: Total number processed: 1
gpg:               imported: 1

$ gpg --list-key --fingerprint APIConnect
pub   rsa4096 2023-02-28 [SCE]
      39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
uid           [ unknown] APIConnect <psirt@us.ibm.com>
```

   When the key is imported, it does not need to be imported again. It is not signed, but you should make a note of the fingerprint so you can compare to make sure that the key is IBM's:

```
39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
```

2. Verify the files.

```
$ $ gpg --verify helper_files.zip.asc
gpg: assuming signed data in 'helper_files.zip'
gpg: Signature made Mon 28 Sep 17:35:17 2020 PDT
gpg:                using RSA key 39ED16345FCDEDB5D6EDE860020ED6B5DBE65F3B
gpg: Good signature from "APIConnect <psirt@us.ibm.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
```

   The verification shows that the key matches the signature and that shows the fingerprint of the key, which should match the import:

```
39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
```

Deploying operators and cert-manager

Deploy the Kubernetes operator files and install cert-manager.

Before you begin

You must have completed the following installation tasks before you deploy the operators:

1. Review the installation requirements. See Deployment requirements.
2. Obtain the API Connect product files. See Obtaining product files.

About this task

Table 1 lists the operator that applies to each release of API Connect.

Table 1. Operators and operands for API Connect

API Connect release	API Connect Operator version	DataPower Operator version
10.0.6.0	5.0.0	1.7.0
10.0.5.3	3.3.0	1.6.6
10.0.5.2	3.2.0	1.6.3
10.0.5.1	3.1.0	1.6.2
10.0.5.0	3.0.0	1.6.0

Note: There can be only one instance of the API Connect operator in your Kubernetes environment. You cannot have multiple namespaces each with their own API Connect operator.
The deployment procedures differ depending on whether your deployment cluster uses a single namespace or multiple namespaces. Follow the instructions that apply to your deployment cluster:

- **Deploying operators in a single-namespace API Connect cluster**
  Deploy the Kubernetes operator files in a single namespace cluster.
- **Deploying operators in a multi-namespace API Connect cluster**
  Deploy the Kubernetes operator files in multi-namespace cluster.
- **Installing cert-manager and certificates in a two data center deployment**
  Additional instructions explaining how to install a cert-manager and certificates in a two data center disaster recovery deployment on Kubernetes.

Deploying operators in a single-namespace API Connect cluster

Deploy the Kubernetes operator files in a single namespace cluster.

Before you begin

- Ensure you completed the prerequisite tasks for installing operators. See Deploying operators and cert-manager.
- Be sure to review your strategy for using certificates with API Connect. See Deployment requirements.

Note: If you are deploying a multi-namespace API Connect cluster, do not use these instructions. Instead, go to Deploying operators in a multi-namespace API Connect cluster.

Procedure

1. Ensure `KUBECONFIG` is set for the target cluster:

   ```
   export KUBECONFIG=<path_to_cluster_config_YAML_file>
   ```

   An example path is `/Users/user/.kube/clusters/<cluster_name>/kube-config-<cluster_name>.yaml`

2. Decide on a namespace to be used for installation.
   If not using the default namespace, create the namespace in the Kubernetes cluster where the API Connect deployment will take place. Use the following command, replacing `<namespace>` with the namespace for the deployment:

   ```
   kubectl create ns <namespace>
   ```

3. Install a cert-manager.
   Use of a certificate manager adds convenience to the generation and management of certificate, but is not required. Whenever a custom resource (CR) takes a certificate secret name as input, you can point to any secret name, as long as the secret exists before deploying the CR, and the secret contains relevant certificate data. Typically, this is the tls.crt, tls.key, and ca.crt files. See Certificates in a Kubernetes environment.

   Restriction: Do not use this step to install a cert-manager if:
   - You want to use custom certificates. See Custom certificates on Kubernetes
   - You are deploying a two data center disaster recovery deployment on Kubernetes, see Installing cert-manager and certificates in a two data center deployment.

   After you complete one of the alternate sets of instructions in the links in this Note, continue with Step 4.

   a. Obtain the certificate manager.
      API Connect uses cert-manager v1.9.1 of cert-manager, which is a native Kubernetes certificate management controller.

      You can obtain cert-manager v1.9.1 from the API Connect v10 distribution `helper_files.zip` archive, or download it from https://github.com/cert-manager/cert-manager/releases/tag/v1.9.1

      IBM Cloud Pak for Integration bundles the cert-manager with its foundational services.

   b. Apply the CR:

      ```
      kubectl apply -f cert-manager-1.9.1.yaml
      ```

      Do not specify a custom namespace.

      See https://cert-manager.io/docs/release-notes/release-notes-1.9/.

   c. Wait for `cert-manager` pods to enter `Running 1/1` status before proceeding. To check the status:

      ```
      kubectl get po -n cert-manager
      ```

      There are 3 `cert-manager` pods in total.

4. Create a registry secret with credentials to be used to pull down product images.
   Use the following command, replacing `<namespace>` with the namespace for your deployment, and replacing `<registry_server>` with the location of the Docker Registry where the installation product images were pushed:

   ```
   kubectl create secret docker-registry apic-registry-secret
   --docker-server=<registry_server>
   --docker-username=<username@example.com> --docker-password=<password> --docker-email=<username@example.com> -n <namespace>
   ```

5. Create a registry secret for the DataPower registry with the credentials to be used to pull down product images.
   Use the following command, replacing `<namespace>` with the desired namespace for the deployment:

   ```
   kubectl create secret docker-registry datapower-docker-local-cred
   --docker-server=<docker_server> --docker-username=<username@example.com> --docker-password=<password> --docker-email=
   <username@example.com> -n <namespace>
   ```

6. Create a DataPower admin secret.
   Use the following command, replacing `<namespace>` with the desired namespace for the deployment:

   ```
   kubectl create secret generic datapower-admin-credentials --from-literal=password=admin -n <namespace>
   ```

   The admin secret will be used for `$ADMIN_USER_SECRET` when deploying the gateway CR.

7. If you are using a namespace other than `default`, open `ibm-apiconnect.yaml` in a text editor. Replace each occurrence of `default` with the namespace for your deployment.
8. Open `ibm-apiconnect.yaml` in a text editor. Replace the value of each `image:` key with the location of the apiconnect operator images (from the ibm-apiconnect container and the ibm-apiconnect-init container), either uploaded to your own registry or pulled from a public registry.

   ```
     serviceAccountName: ibm-apiconnect
      imagePullSecrets:
      - name: apic-registry-secret
      initContainers:
      - name: ibm-apiconnect-init
        image: <My_registry_or_public_registry>/ibm-apiconnect-operator-
   init@sha256:0d3bbac7c67372ad013407a8049c69dbd08b1559b59a7606fcd87eb0f4519ce1
   ...
   ```

```
   containers:
    - name: ibm-apiconnect
    image: <My_registry_or_public registry>/ibm-apiconnect-
operator@sha256:a7473ee26c252fca4931b682cd95d73b4149e4b5b773834408f9f22d0246a76c
```

9. If DataPower Gateway is desired in this installation, and if you are using a namespace other than `default`, open `ibm-datapower.yaml` in a text editor. Replace each occurrence of `default` with the namespace for your deployment.
10. Open `ibm-datapower.yaml` in a text editor.
    a. Locate the `image:` key in the containers section of the deployment yaml immediately after `imagePullSecrets:`. Replace the value of the `image:` key with the location of the `datapower` operator image, either uploaded to your own registry or pulled from a public registry.
    b. Update the `IBM_DOCKER_HUB` and `IBM_ENTITLED_REGISTRY` value in the `env` section with the registry address where the images were uploaded with the image-tool in Obtaining product files.
    For example, the default entries are:

```
            - name: IBM_ENTITLED_REGISTRY
              value: "cp.icr.io/cp/datapower"
            - name: IBM_DOCKER_HUB
              value: "cp.icr.io/cp/datapower"
```

11. Install the ibm-apiconnect CRDs.

```
kubectl apply -f ibm-apiconnect-crds.yaml
```

12. Install the ibm-apiconnect Kubernetes deployment.

```
kubectl apply -f ibm-apiconnect.yaml
```

13. If DataPower Gateway is desired in this installation, install the ibm-datapower Kubernetes deployment for DataPower Gateway, with the following command, replacing `<namespace>` with the desired namespace for the deployment (`-n <namespace>` may be omitted if default namespace is being used for installation):

```
kubectl apply -f ibm-datapower.yaml -n <namespace>
```

    Troubleshooting: If your DataPower operator pod fails to start, see Troubleshooting install.

14. Install the `ingress-ca` Issuer to be used by `cert-manager`.
    Note:
    If you are installing a two data center disaster recovery deployment, skip this step, and follow the steps in: Installing cert-manager and certificates in a two data center deployment.

    a. Use the following command, replacing `<namespace>` with the desired namespace for the deployment:

```
kubectl apply -f ingress-issuer-v1.yaml -n <namespace>
```

    The file `ingress-issuer-v1.yaml` is included in the release files contained in `helper_files.zip`

    b. Validate that the command succeeded:

```
kubectl get certificates -n <namespace>
```

    Example output indicating success:

```
NAME                          READY   SECRET                        AGE
analytics-ingestion-client    True    analytics-ingestion-client    70s
gateway-peering               True    gateway-peering               69s
gateway-service               True    gateway-service               69s
ingress-ca                    True    ingress-ca                    71s
portal-admin-client           True    portal-admin-client           71s
portal-tunnel-client          True    portal-tunnel-client          70s
```

    The list of certificates might vary based on your deployment.

15. Continue with Installing the API Connect subsystems.

Deploying operators in a multi-namespace API Connect cluster

Deploy the Kubernetes operator files in multi-namespace cluster.

Before you begin

- Ensure you completed the prerequisite tasks for installing operators. See Deploying operators and cert-manager.
- Be sure to review your strategy for using certificates with API Connect. See Deployment requirements.

About this task

Note: If you are deploying a single-namespace API Connect cluster, do not use these instructions. Instead, go to Deploying operators in a single-namespace API Connect cluster.

- These instructions apply only to native k8s deployments. They do not apply to OpenShift deployments.
- The apiconnect operator is deployed as a cluster-scoped operator which watches every namespace in the cluster. The apiconnect operator can be installed in any namespace, although it is recommended that the API Connect operator is installed in its own dedicated namespace.
- The DataPower operator must be deployed in a namespace where gateway subsystem install is planned.
- Single ingress-ca certificate must be installed and used across the various namespaces where subsystems will be installed.

Procedure

1. Prepare your environment:
   a. Ensure **KUBECONFIG** is set for the target cluster:

      ```
      export KUBECONFIG=<path_to_cluster_config_YAML_file>
      ```

      An example path is **/Users/user/.kube/clusters/<cluster_name>/kube-config-<cluster_name>.yaml**

   b. Create namespaces on which subsystems are planned to be installed.
   The required namespaces are:

      - Apiconnect operator namespace
      - Gateway subsystem namespace
      - Management subsystem namespace
      - Portal subsystem namespace
      - Analytics subsystem namespace

   The following example values and deployment are used throughout these instructions:

      - An apiconnect operator is installed in **operator** namespace
      - A DataPower operator and gateway subsystem is installed in **gtw** namespace
      - The Management subsystem is installed in **mgmt** namespace
      - The Portal subsystem is installed in **portal** namespace
      - The Analytics subsystem is installed in **a7s** namespace

   c. Multi-namespace templates are provided in **helper_files.zip**, inside the **release_files.zip** you downloaded in Obtaining product files:

      ```
      helper_files_unpack/multi-ns-support/
      ```

2. Install cert-manager and configure certificates:
   Use of a certificate manager adds convenience to the generation and management of certificate, but is not required. Whenever a custom resource (CR) takes a certificate secret name as input, you can point to any secret name, as long as the secret exists before deploying the CR, and the secret contains relevant certificate data. Typically, this is the tls.crt, tls.key, and ca.crt files. See Certificates in a Kubernetes environment.

   You can obtain cert-manager v1.9.1 from the API Connect v10 distribution **helper_files.zip** archive, or download it from https://github.com/cert-manager/cert-manager/releases/tag/v1.9.1.

   a. Install cert-manager v1.9.1, do not specify a custom namespace as cert manager will be installed in its own namespace.
   Restriction: Do not use Step 2.a to install a cert-manager if:
      - You want to use custom certificates. See Custom certificates on Kubernetes
      - You are deploying a two data center disaster recovery deployment on Kubernetes, see Installing cert-manager and certificates in a two data center deployment

      i. **kubectl apply -f cert-manager-1.9.1.yaml**

      ii. Wait for cert-manager pods to enter **Running 1/1** status before proceeding. Use the following command to check:

      ```
      kubectl -n cert-manager get po
      ```

      There are 3 cert-manager pods in total.

   b. Install **ingress-ca** certificate:
      i. Locate **ingress-ca** certificate at **helper_files/multi-ns-support/ingress-ca-cert.yaml**
      ii. Create **ingress-ca** certificate in one of the subsystems. For example, if we choose **mgmt** namespace:

      ```
      kubectl -n mgmt apply -f ingress-ca-cert.yaml
      ```

   c. Install common issuers on all the namespaces:
      i. Locate **common-issuer.yaml** in **helper_files/multi-ns-support/**
      ii. Create **common-issuer.yaml** in all namespaces:

      ```
      kubectl create -f common-issuer.yaml -n mgmt
      kubectl create -f common-issuer.yaml -n gtw
      kubectl create -f common-issuer.yaml -n ptl
      kubectl create -f common-issuer.yaml -n a7s
      ```

   d. Obtain the ingress-ca secret created by cert manager and create the secret on all namespaces:
   Note: The instructions in this step result in having a **selfsigning-issuer** in every namespace. This issuer is typically referenced by an API Connect CR in the namespace with:

      ```
      ...
        microServiceSecurity: certManager
        certManagerIssuer:
          name: selfsigning-issuer
          kind: Issuer
      ...
      ```

      This issuer (and associated root certificate) does not need to be the same in every namespace, nor does it need to be the same for 2 CRs in the same namespace. Each subsystem can use its own **selfsigning-issuer**, because it is only used for certificates that are internal to the subsystem.

      To ensure that the ingress-issuer is in sync across namespaces, it should be backed by the same **ingress-ca** certificate. This enables, for example, APIM to use a client certificate that matches the CA of the portal-admin ingress endpoint. The sync is achieved by copying around the **ingress-ca** certificate in each namespace, as shown in the following steps. It does not matter that it is the same issuer, or whether it has a different name. However it is important is that the ingress-ca is the same for the all the "ingress-issuer" that are going to be used by the subsystems.

      i. Make sure ingress-ca certificate READY status is set to true:

      ```
      kubectl get certificate ingress-ca -n mgmt
      NAME         READY   SECRET       AGE
      ```

```
ingress-ca   True    ingress-ca   9m24s
```

ii. Cert-manager creates a secret called `ingress-ca` in `mgmt` namespace which represents the certificate we created in Step 2.c.
iii. Use the following command to obtain the yaml format of the secret:

```
kubectl get secret ingress-ca -n <namespace-where-ingress-ca-cert-is-created> -o yaml > ingress-ca-secret-in-cluster.yaml
```

iv. Remove unwanted content from the secret yaml:

```
cat ingress-ca-secret-in-cluster.yaml | grep -v 'creationTimestamp' | grep -v 'namespace' | grep -v 'uid' | grep -v 'resourceVersion' > ingress-ca-secret.yaml
```

v. Create the secret using the yaml we prepared in previous step on rest of the subsystem namespaces. In this example, in the `gtw`, `a7s` and `ptl` namespaces.

```
kubectl create -f ingress-ca-secret.yaml -n gtw
kubectl create -f ingress-ca-secret.yaml -n ptl
kubectl create -f ingress-ca-secret.yaml -n a7s
```

e. Install management certs in management namespace:
i. Locate `management-certs.yaml` in `helper_files/multi-ns-support/`
ii. Create `management-certs.yaml` in the `mgmt` namespace:

```
kubectl create -f management-certs.yaml -n mgmt
```

f. Install gateway certs in the gateway namespace:
i. Locate `gateway-certs.yaml` in `helper_files/multi-ns-support/`
ii. Create `gateway-certs.yaml` in the `gtw` namespace:

```
kubectl create -f gateway-certs.yaml -n gtw
```

3. Install the apiconnect operator:
a. Install the ibm-apiconnect CRDs with the following command. Do not specify a namespace:

```
kubectl apply -f ibm-apiconnect-crds.yaml
```

b. Create a registry secret with the credentials to be used to pull down product images with the following command, replacing `<namespace>` with the desired namespace for the apiconnect operator deployment.

```
kubectl -n <namespace> create secret docker-registry apic-registry-secret
              --docker-server=<registry_server>
              --docker-username=<username@example.com> --docker-password=<password>
              --docker-email=<username@example.com>
```

- For example, replace `<namespace>` with `operator`.
- `docker-password` can be your artifactory API key.
- `-n <namespace>` may be omitted if `default` namespace is being used for installation

c. Locate and open `ibm-apiconnect-distributed.yaml` in a text editor of choice. Then, find and replace each occurrence of `$OPERATOR_NAMESPACE` with `<namespace>`, replacing `<namespace>` with the desired namespace for the deployment. In this example, the namespace is `operator`.
d. Also in `ibm-apiconnect-distributed.yaml`, locate the `image:` keys in the containers sections of the deployment yaml right below `imagePullSecrets:`. Replace the placeholder values `REPLACE-DOCKER-REGISTRY` of the `image:` keys with the docker registry host location of the apiconnect operator image (either uploaded to own registry or pulled from public registry).
e. Install `ibm-apiconnect-distributed.yaml` with the following command

```
kubectl apply -f ibm-apiconnect-distributed.yaml
```

4. Install DataPower operator:
Deployment of the DataPower operator is only needed if you have at least one API Connect v10 Gateway subsystem (whether v5 compatible or not) to upgrade. If you are using DataPower in a different form factor such as an Appliance, you will not have an API Connect v10 Gateway subsystem to upgrade, and will not need the DataPower operator for your upgrade.

Note: The DataPower Operator supports multiple instances of DataPower in the same cluster, separated by namespace. When deploying into multiple namespaces, ensure that any cluster-scoped resources are created with unique names for separate installations, such that they are not overwritten by subsequent installations. For example, DataPower cluster-scoped resources include `ClusterRoleBindings`.

a. Create a registry secret for the DataPower registry with the credentials to be used to pull down product images with the following command, replacing `<namespace>` with the desired namespace for the deployment .(In this case `gtw`):

```
kubectl -n <namespace> create secret docker-registry datapower-docker-local-cred
              --docker-server=<registry_server>
              --docker-username=<username@example.com> --docker-password=<password>
              --docker-email=<username@example.com>
```

- For example, replace `<namespace>` with `gtw`.
- `docker-password` can be your artifactory API key.
- `-n <namespace>` may be omitted if `default` namespace is being used for installation

b. Create a DataPower admin secret, replacing `<namespace>` with the desired namespace for the deployment. For example, `gtw`. This secret will be used for `$ADMIN_USER_SECRET` later in the Gateway CR:

```
kubectl -n <namespace> create secret generic datapower-admin-credentials --from-literal=password=admin
```

`-n`
`<namespace>` may be omitted if `default` namespace is being used for installation.

c. Locate and open `ibm-datapower.yaml` in a text editor of choice. Then, find and replace each occurrence of `default` with `<namespace>`, replacing `<namespace>` with the desired namespace for the deployment. For example, `gtw`.
d. Install `ibm-datapower.yaml` with the following command:

```
kubectl -n <namespace> apply -f ibm-datapower.yaml
```

Troubleshooting: If your DataPower operator pod fails to start, see Troubleshooting install.

5. Next, install the subsystems. Continue with Installing the API Connect subsystems.
   Note: Unless otherwise stated, when performing the individual subsystem upgrades the **<*namespace*>** value of example **kubectl** commands for a given subsystem should be set to the namespace for the particular subsystem component they are acting on.

Installing cert-manager and certificates in a two data center deployment

Additional instructions explaining how to install a cert-manager and certificates in a two data center disaster recovery deployment on Kubernetes.

Before you begin

Before you install a cert-manager, you should know your strategy for using certificates with API Connect. Review the certificate requirements in Deployment requirements.

You should also have already completed Obtaining product files.

About this task

You must create certificates and keys for API Manager and the Developer Portal on both data centers, dc1 and dc2, and ensure that they match on both.

Use these instructions to install the supplied cert-manager and **ingress-issuer-v1.yaml**. Use these instructions if you are *not* using custom certificates.

Note that **ingress-issuer-v1.yaml** is supplied by cert-manager.

Note:
Do not use these instructions if you want to use custom certificates. See Custom certificates on Kubernetes.

Procedure

1. Install a cert-manager.
   Use of a certificate manager adds convenience to the generation and management of certificate, but is not required. Whenever a custom resource (CR) takes a certificate secret name as input, you can point to any secret name, on condition that the secret exists before you deploy the CR, and that the secret contains relevant certificate data. Typically, this is tls.crt, tls.key, and ca.crt files. See Certificates in a Kubernetes environment.

   a. Obtain the certificate manager.
      API Connect v10 uses cert-manager v1.9.1 of cert-manager, which is a native Kubernetes certificate management controller.

      You can obtain cert-manager v1.9.1 from the API Connect v10 distribution **helper_files.zip** archive, or download it from https://github.com/cert-manager/cert-manager/releases/tag/v1.9.1

      Note: cert-manager is bundled as a common service in IBM CloudPack for Integration.

   b. Apply the CR:

      ```
      kubectl apply -f cert-manager-1.9.1.yaml
      ```

      Do not specify a custom namespace.

      See https://cert-manager.io/docs/release-notes/release-notes-1.9/.

   c. Wait for **cert-manager** pods to enter **Running 1/1** status before proceeding. To check the status:

      ```
      kubectl get po -n cert-manager
      ```

      There are 3 **cert-manager** pods in total.
2. Use the following steps to allow **ingress-ca** secrets to be the same on both data centers.
   a. On DC1 apply the file **ingress-issuer-v1-dc1.yaml**:

      ```
      kubectl -n <namespace> apply -f ingress-issuer-v1-dc1.yaml
      ```

   b. Validate that the command succeeded:

      ```
      kubectl get certificates -n <namespace>
      ```

   c. Export **ingress-ca** secret as a yaml from DC1:

      ```
      kubectl -n <namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
      ```

   d. Edit the **ingress-ca.yaml** file to remove all **annotations**, **labels**, **creationTimestamp**, **managedFields**, **manager**, **operation**, **time**, **resourceVersion**, **selfLink**, and **uid**. Also, if you are using a different **namespace** in DC2, then update the **namespace** field.
   e. Copy the **ingress-ca.yaml** from DC1 to DC2 and apply that file on DC2:

      ```
      kubectl -n <namespace> apply -f ingress-ca.yaml
      ```

   f. On DC2 apply the file **ingress-issuer-v1-dc2.yaml**:

      ```
      kubectl -n <namespace> apply -f ingress-issuer-v1-dc2.yaml
      ```

   g. Use the following commands to test that they are the same, on DC1 run:

      ```
      kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' | base64 -d
      > /tmp/ingress.pem.dc1
      ```

h. On DC2 run:

```
kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' | base64 -d
> /tmp/ingress.pem.dc2
```

i. To see the differences run:

```
diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
```

The files should be the same.

j. On DC2, to ensure that the certificates are working correctly and that they are using the `ingress-ca` secret. First, get the `portal-admin-client crt` file:

```
kubectl -n <namespace> get secrets portal-admin-client -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/admin-client.crt
```

k. Test that it is working by using OpenSSL:

```
openssl verify -verbose -CAfile /tmp/ingress.pem.dc1 /tmp/admin-client.crt
```

If it is working, you should see:

```
/tmp/admin-client.crt: OK
```

3. Continue with Deploying operators and cert-manager.

Installing the API Connect subsystems

Deploy the API Connect subsystem custom resources.

Before you begin

Attention: API Connect is not supported on a FIPS-enabled environment.
Before you install the subsystems, verify that you completed the following prerequisite tasks:

1. Obtaining product files
2. Deploying operators and cert-manager

About this task

Use the CR (custom resource) files to install the Management, Gateway, Analytics, and Portal subsystems for your API Connect cloud. CRs are extensions of the Kubernetes API. API Connect installs its subsystems using individual CRs. One CR is deployed per one managed subsystem. The API Connect operator manages the lifecycle of the subsystem CRs and deploys and manages the microservice for each one.

CR templates are provided in the `helper_files` archive to install each API Connect subsystem. You uncompressed these files into an installation folder of your choosing in Obtaining product files.

- The API Connect operators and operands must be from the same version of API Connect. For example, the API Connect operator 10.0.4.0 does not successfully deploy the API Connect management subystem (operand) from Version 10.0.3.0.
- You can deploy multiple instances of API Connect into the same cluster by using different namespaces.
- Deploying multiple similar subsystems in a single namespace is not supported. For example, deploying two management subsystems, `mgmt1`, `mgmt2` in a single namespace where apiconnect operator is installed.
- For more information on Custom Resources in Kubernetes see https://kubernetes.io/docs/concepts/extend-kubernetes/api-extension/custom-resources/.
- For details on how the API Connect operator manages the CRs using the Kubernetes operator pattern, see https://kubernetes.io/docs/concepts/extend-kubernetes/operator/.
- For guidance on choosing object names and IDs in Kubernetes, see https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names.

Procedure

Complete each of the following instructions:

1. Installing the Management subsystem cluster.
2. Installing the DataPower Gateway subsystem.
3. Installing the Developer Portal subsystem.
4. Installing the Analytics subsystem.
5. When all subsystems are running, verify you can access the API Connect Cloud Manager. Enter the Cloud Manager endpoint URL in your browser.
   Tip:
   You can find your Cloud Manager endpoint URL as follows:

   The property `cloudManagerEndpoint` is specified in the management CR (`management_cr.yaml`). When you edited the template, you specified a value for *`$STACK_HOST`*:

   ```
   cloudManagerEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: admin.$STACK_HOST
         secret: cm-endpoint
   ```

   The template URL is `https://admin.<STACK_HOST>/admin`. The `/admin` suffix at the end is the name of the Cloud Manager administrator.

   For example, if *`$STACK_HOST`* is `myhost.subnet.example.com`, the Cloud Manager endpoint URL is:

`https://admin.myhost.subnet.example.com/admin`

The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See Accessing the Cloud Manager user interface.

What to do next

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

- **Installing the Management subsystem cluster**
  Install the Management subsystem cluster
- **Installing the DataPower Gateway subsystem**
  Install the DataPower Gateway subsystem
- **Installing the Developer Portal subsystem**
  Install the Developer Portal subsystem.
- **Installing the Analytics subsystem**
  Install the IBM API Connect analytics subsystem.

Installing the Management subsystem cluster

Install the Management subsystem cluster

Before you begin

Before you start this task, you should have already:

- Reviewed the Kubernetes requirements in Pre-installation requirements
- Completed Deploying operators and cert-manager

About this task

Edit the custom resource template for the Management system, apply the resource, verify that the pods are up and running, and verify that you can connect to the API Connect Cloud Manager.

Procedure

1. Edit the **`management_cr`** template CR, to replace the placeholders with values for your deployment.

   `$APP_PRODUCT_VERSION`
   API Connect application version for the subsystems.

   `version: <version_number>`

   Example version number: 10.0.6.0

   `$SECRET_NAME`
   Use for image pull.

   ```
   imagePullSecrets:
     - apic-registry-secret
   ```

   `$PROFILE`
   Specify your Management subsystem profile, where **`n`** indicates number of replicas, **`c`** number of cores, and **`m`** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

   `$DOCKER_REGISTRY`
   The host name of the Docker Registry to which you uploaded the installation images. For example:

   `my.docker.registry.domain.example.com.`

   $INGRESS_CLASS
   The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation **`ingressclass.kubernetes.io/is-default-class:`** **`true`** is used. If such an ingress class does not exist in the Kubernetes environment, then **`nginx`** is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system.
   Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

   `$STACK_HOST`
   The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:
   - Subdomain customization only
     Accept the prefixes predefined for the ingress hostnames to use and just replace all instances of **`STACK_HOST`** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **`myhost.subnet.example.com`**:

     ```
     cloudManagerEndpoint:
           < ... >
       hosts:
       - name: admin.myhost.subnet.example.com
         secret: cm-endpoint
     ```

```
  apiManagerEndpoint:
      < ... >
    hosts:
    - name: manager.myhost.subnet.example.com
      secret: apim-endpoint

  platformAPIEndpoint:
      < ... >
    hosts:
    - name: api.myhost.subnet.example.com
      secret: api-endpoint

  consumerAPIEndpoint:
      < ... >
    hosts:
    - name: consumer.myhost.subnet.example.com
      secret: consumer-endpoint
```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **cloudManagerEndpoint**, you can replace **admin.$STACK_HOST** with **my.cloudmgr.myhost.subnet.example.com**, where **my.cloudmgr** replaces **admin**, and **myhost.subnet.example.com** replaces **STACK_HOST**. For example:

  ```
  cloudManagerEndpoint:
      < ... >
    hosts:
    - name: my.cloudmgr.myhost.subnet.example.com
      secret: cm-endpoint
  ```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **kubectl get sc**.

```
storageClassName: local-storage
```

2. Edit the **license:** setting:
   a. Set **accept:** to **true** to accept the license. Note that the default value is **false**. If you do not accept the license, the Operator will not install the subsystem.
   b. Set **metric:** to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.
      - MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.

      For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.

   c. Set **use:** to either **production** or **nonproduction**, to match the license you purchased.
   d. Set **license:** to the License ID for the version of API Connect that you purchased. See API Connect licenses.

   Example entry to accept the license for a production system:

```
  license:
    accept: true
    metric: PROCESSOR_VALUE_UNIT
    use: production
    license: L-RJON-BZ5LSE
```

3. If installing with custom internal certificates, specify a site name.
   - The site name is used as the identifier for the PostgreSQL database cluster used by API Connect. This name should already have been decided upon and used to update the **custom-certs-internal.yaml** file as described in Generating custom certificates.
   - You must now add your chosen site name to **management_cr.yaml**, by creating a **siteName** property anywhere inside the **spec** block, set to the chosen site name:

     ```
       siteName: <site_name>
     ```

     Replace <*site_name*> with your chosen site name.

4. It is recommended to allocate 100Gi for write-ahead logging (WAL) storage.
   The default storage is:

   - One replica profile - 30Gi
   - Three replica profile - 47Gi

   For best performance, edit the CR to add the following entries, and set **volumeSize:** to 100Gi:

```
spec:
  dbArchiveVolumeClaimTemplate:
    storageClassName: <storage-class>
    volumeSize: <volume-size>
```

5. Configure backups for the management subsystem.
   Important: Note that in order to restore your deployment in the event of a disaster where you must redeploy a new cluster, you must take specific configuration actions **before** installing the Management subsystem. See Preparing the management subsystem for disaster recovery.
   You can review the backup and restore features here: Configuring backup settings for fresh install of the Management subsystem
6. Optional: If you are installing as part of a two data center disaster recovery set up, complete the steps in Installing a two data center deployment on Kubernetes before you apply the edited file.
7. Install the management Custom Resource, replacing **<*namespace*>** with the target installation namespace in the Kubernetes cluster.

```
kubectl apply -f management_cr.yaml -n <namespace>
```

8. Verify that the Management subsystem is fully installed:

```
kubectl get ManagementCluster -n <namespace>
```

The installation has completed when the **READY** status is **True**, and the **SUMMARY** reports that all services are online (e.g. **9/9**). For example:

```
NAME          READY   SUMMARY   VERSION    RECONCILED VERSION   AGE
management    True    16/16      <version>   <version-build>       7m17s
```

9. Retain the encryption secret and database credential secrets in a safe location, in case you need to restore during a disaster recovery scenario. Complete the steps in Preparing the management subsystem for disaster recovery.
   Important: If you do not complete the steps in Preparing the management subsystem for disaster recovery, you will not be able to restore your management subsystem to a new cluster during a disaster recovery scenario.
10. Check your connection to the Cloud Manager user interface on the Management subsystem on your Cloud Manager endpoint.
    For example, if you accepted the default prefix of **admin**, and you set ***$STACK_HOST*** to **myhost.subnet.example.com**, the Cloud Manager endpoint URL is:

    ```
    https://admin.myhost.subnet.example.com/admin
    ```

    The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. For further details, see Accessing the Cloud Manager user interface.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Installing the DataPower Gateway subsystem

Install the DataPower Gateway subsystem

Before you begin

If you plan to install the Gateway subsystem in a remote cluster, be sure to satisfy the following requirements:

- Install both the API Connect and the DataPower operators.
  The versions of the operators on the remote cluster and the version of the Gateway operand must exactly match the versions used in the main cluster.
- Make sure the remote cluster has the certificates:
  - If you are using certificate manager, ensure that the ingress-ca is synced between sites.
  - If you are not using certificate manager, copy the client gateway certificates to the remote cluster and reference them in the Gateway CR.

About this task

Note: An alternate deployment scenario is to use a physical DataPower appliance for the gateway. If you are using an appliance for the gateway, do not install using API Connect Kubernetes CRs, since you do not need to configure a gateway subsystem in your Kubernetes cluster when using an appliance. For an appliance-based gateway, you must configure two endpoints in DataPower to be used as the Gateway Service Management Endpoint and the API invocation Endpoint. Enter these endpoints in the Configure Gateway Service screen in Cloud Manager. See Configuring DataPower Gateway for API Connect for instructions for configuring a DataPower appliance.
The installation folder where the **helper_files.zip** was extracted contains two templates for Gateway service. The **v5cgateway_cr.yaml** template is for the v5 compatible Gateway, and the **apigateway_cr.yaml** template is for the API Gateway.

Procedure

1. Edit the template CR, either **apigateway_cr.yaml** or **v5cgateway_cr.yaml**, to replace the placeholders with values for your deployment.

   $APP_PRODUCT_VERSION
   API Connect application version for the subsystems.

   ```
   version: <version_number>
   ```

   Example version number: 10.0.6.0

   $PROFILE
   Specify your gateway profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

   $SECRET_NAME
   Use for image pull.

   ```
   imagePullSecrets:
     - apic-registry-secret
   ```

   $DOCKER_REGISTRY
   The host name of the Docker Registry to which you uploaded the installation images. For example:

   ```
   my.docker.registry.domain.example.com.
   ```

   $INGRESS_CLASS
   The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation **ingressclass.kubernetes.io/is-default-class:**

`true` is used. If such an ingress class does not exist in the Kubernetes environment, then `nginx` is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system.
Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

`$STACK_HOST`
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and just replace all instances of `STACK_HOST` to be the desired ingress subdomain for the API Connect stack. For example, if your host is `myhost.subnet.example.com`:

  ```
  gatewayEndpoint:
        < ... >
    hosts:
    - name: rgw.myhost.subnet.example.com
      secret: gwv6-endpoint

  gatewayManagerEndpoint:
        < ... >
    hosts:
    - name: rgwd.myhost.subnet.example.com
      secret: gwv6-manager-endpoint
  ```

- Complete hostname customization
  Change both the predefined prefixes and the `STACK_HOST` subdomain to match your desired hostnames.

  For example, for `gatewayEndpoint`, you can replace `rgw.$STACK_HOST` with `my.gateway.endpoint.myhost.subnet.example.com`, where `my.gateway.endpoint` replaces `rgw`, and `myhost.subnet.example.com` replaces `$STACK_HOST`:

  ```
  gatewayEndpoint:
        < ... >
    hosts:
    - name: my.gateway.endpoint.myhost.subnet.example.com
      secret: gwv6-endpoint
  ```

  You can do this for some or all of the hostnames, depending on your customization requirements.

`$STORAGE_CLASS`
The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: `kubectl get sc`.

```
storageClassName: local-storage
```

`$ADMIN_USER_SECRET`
Edit `$ADMIN_USER_SECRET` to set the value you created in Deploying operators and cert-manager.

```
adminUserSecret: $ADMIN_USER_SECRET
```

`$PLATFORM_CA_SECRET`
Set to `ingress-ca`. The `$PLATFORM_CA_SECRET` contains the CA certificate for the platform REST API endpoint. The gateway makes calls to the platform REST API and this property must be set so that the gateway can verify the server certificate.

```
mgmtPlatformEndpointCASecret:
  secretName: $PLATFORM_CA_SECRET
```

2. Edit the `license:` setting:
   a. Set `accept:` to `true` to accept the license. Note that the default value is `false`. If you do not accept the license, the Operator will not install the subsystem.
   b. Set `metric:` to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.
      - MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.

      For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.

   c. Set `use:` to either `production` or `nonproduction`, to match the license you purchased.
   d. Set `license:` to the License ID for the version of API Connect that you purchased. See API Connect licenses.

   Example entry to accept the license for a production system:

   ```
   license:
     accept: true
     metric: PROCESSOR_VALUE_UNIT
     use: production
     license: L-RJON-BZ5LSE
   ```

3. Optional: If applicable to your deployment, you can override the resource settings for CPU and memory.
   - CPU override
     When you specify `spec.license.use: nonproduction` and a one replica profile `profile: n1xc4.m8`, the default CPU request for the gateway pod is 1 CPU. You can manually override this setting. For example, to request 2 CPUs:

     ```
     template:
       - name: datapower
         containers:
         - name: gateway
           resources:
             requests:
               cpu: 2
     ```

     - When you specify `spec.license.use: production` and a one replica profile `profile: n1xc4.m8`, the default CPU request for the gateway pod is 4 CPUs.
     - The CPU limit cannot be specified separately from the CPU request. The value for the CPU request is used as both CPU request and CPU limit in the Gateway CR.

- Memory override
  The default memory limit and request is 8Gi. The memory limit should always be greater than or equal to the memory request.

  For example, to request 10Gi and set a limit of 12Gi:

```
template:
 - name: datapower
   containers:
   - name: gateway
     resources:
       limits:
         memory:  12Gi
       requests:
         cpu: 2
         memory: 10Gi
```

Note: The override mechanism is specific only to the CPU and memory values, and cannot be used for other resource requests in the DataPower Gateway CR.

4. For **apigateway_cr.yaml** only, you can optionally enable **openTracing**.
   a. Edit the CR to add the following properties, and supply values for each:

```
openTracing:
    enabled: false # if true provide below details
    odTracingRegistrationHostname: $OD_TRACING_REGISTRATION_HOSTNAME
    odTracingDataHostname: $OD_TRACING_HOSTNAME
    imageAgent: $AGENT_IMAGE
    imageCollector: $COLLECTOR_IMAGE
```

   Where:

   enabled

```
enabled: true
```

   $OD_TRACING_REGISTRATION_HOSTNAME
   odTracingRegistrationHostname: icp4i-od.tracing.svc
   The hostname of the registration server for OpenTracing.

   $OD_TRACING_HOSTNAME
   odTracingDataHostname: od-store-od.tracing.svc
   The hostname of the data server for OpenTracing.

   $AGENT_IMAGE
   imageAgent: icp4i_od_agent:1.0.0-amd64
   Image will be pulled from the **imageRegistry** of this CR.

   $COLLECTOR_IMAGE
   imageCollector: icp4i_od_collector:1.0.0-amd64
   Image will be pulled from the **imageRegistry** of this CR.

   b. During the OpenTracing registration process, name the secret that stores credentials **icp4i-od-store-cred**, and add it to the cluster and into the installation namespace.
5. Enable or disable **syslogConfig**.

```
syslogConfig:
    enabled: false # if true, provide below details
    # remoteHost: $DATAPOWER_SYSLOG_TCP_REMOTE_HOST # must be a string
    # remotePort: $DATAPOWER_SYSLOG_TCP_REMOTE_PORT # must be an int
    # secretName: $DATAPOWER_SYSLOG_TCP_TLS_SECRET # must be a string
```

- To disable syslog, remove the **syslogConfig** block from **apigateway_cr.yaml** and **v5cgateway_cr.yaml**. Alternatively, you can set **syslogConfig.enabled** to **false**.
- To enable **syslogConfig** in the Gateways, set the following values in **apigateway_cr.yaml** and **v5cgateway_cr.yaml**:

  enabled
  enabled: true
  $DATAPOWER_SYSLOG_TCP_REMOTE_HOST
  remoteHost: <*remote.host*>
  String. The hostname of the server for **syslogConfig**.

  $DATAPOWER_SYSLOG_TCP_REMOTE_PORT
  remotePort: <*remote_port_number*>
  Integer. The port number of the server for **syslogConfig**.

  $DATAPOWER_SYSLOG_TCP_TLS_SECRET
  secretName: <*secret*>
  String. The TLS secret name of the server for **syslogConfig**.

6. Optional: If applicable to your deployment, update the GatewayCluster CR to configure **DataPowerService** APIs to customize your DataPower deployment. See Customizing a DataPower deployment.
7. To enable mutual TLS between the Management client and the Gateway service's manager endpoint, add **mtlsValidateClient** to the **spec** section:

```
spec:
  mtlsValidateClient: true
```

   This ensures that the gateway service authenticates incoming requests from the API Manager, such as gateway service registration, and publishing APIs to the gateway service. Specifically, the gateway service requires that incoming requests present a certificate that was signed by the same CA that was used to sign the gateway service management endpoint. The gateway service management endpoint secret is specified under **gatewayManagerEndpoint.hosts.secretName**. The API Manager's gateway client's TLS credentials are specified in the ManagementCluster CR under **gateway.client.secretName**.
   Note: In releases previous to 10.0.5.3, this property is called **validateApimClient**.

8. Optional: If you want to enable JWT security for communications between the management and gateway, add and set the property **jwksUrl**.

   ```
   spec:
     ...
     jwksUrl: <JWKS URL>
   ```

   where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

   ```
   kubectl describe mgmt -n <namespace>
   ...
   status:
     - name: jwksUrl
       secretName: api-endpoint
       type: API
       uri: https://api.apic.acme.com/api/cloud/oauth2/certs
   ```

   For more information about JWT security, see Enable JWT security instead of mTLS.
9. Optional: If you want to use the In-cluster inter-subsystem communication feature, then uncomment the **mgmtPlatformEndpointSvcCASecret** section, and set the **secretName**:

   ```
     mgmtPlatformEndpointSvcCASecret:
       secretName: management-ca  # Usually management-ca
   ```

   Unless you customized your internal certificates, this is always **management-ca**.
10. Optional: Enable autoscaling of gateway pods to ensure high availability of DataPower pods. See Enabling autoscaling of gateway pods.
11. Install the Gateway Custom Resource by applying the Gateway template file:
    For a DataPower API Gateway, run the following command:

    ```
    kubectl apply -f apigateway_cr.yaml -n <namespace>
    ```

    For a DataPower Gateway (v5 compatible), run the following command:

    ```
    kubectl apply -f v5cgateway_cr.yaml -n <namespace>
    ```

12. To verify that the Gateway subsystem(s) are fully installed, run the following command:

    ```
    kubectl get GatewayCluster -n <namespace>
    ```

    The installation has completed when the **READY** status is **True**, and the **SUMMARY** reports that all services are online (**2/2**) for all the Gateway subsystems that were installed. Example:

    ```
    NAME   READY   SUMMARY   VERSION     RECONCILED VERSION    AGE
    gwv5   True    2/2       <version>   <version-build>       7m31s
    gwv6   True    2/2       <version>   <version-build>       7m32s
    ```

    There is no need to wait for the **READY** status to be **True** before moving on to the next Subsystem installation.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Installing the Developer Portal subsystem

Install the Developer Portal subsystem.

About this task

Important:

- To enable effective high availability for your Portal service, you need a latency that is less than 50 ms between all portal-db pods to avoid the risk of performance degradation. Servers with uniform specifications are required, as any write actions occur at the speed of the slowest portal-db pod, as the write actions are synchronous across the cluster of portal-db pods. It is recommended that there are three servers in each cluster of portal-db pods for the high availability configuration. The three servers can be situated in the same availability zone, or across three availability zones to ensure the best availability. However, you can configure high availability with two availability zones.
- The Portal does not do certain operations if the free space on certain volumes falls beneath predefined limits. In particular:
  The **databaseVolumeClaimTemplate** needs at least 4GB of free space to create new sites, restore site backups, or upgrade or change the URL of existing sites.

  The **webVolumeClaimTemplate** needs at least 256MB free space to create new sites, restore site backups, or upgrade or change the URL of existing sites.

- Ensure that your kernel or Kubernetes node has the value of its **inotify** watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a **non-ready** state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of **inotify** watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take **inotify** watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.
- Ensure that your kernel or Kubernetes node has a value of **nproc** (maximum number of processes) that applies to the user ID of the Portal pods that have been assigned, and that it is high enough to allow all of the Portal processes to execute. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls, you might need as many as 125205. If the number is too low, you will see errors like **"fork: retry: Resource temporarily unavailable"** in the Portal logs. Note that this value might need to be even higher if other, non-Portal, pods are sharing the same user ID.

- Ensure that your kernel or Kubernetes node has a value of `nofiles` (maximum number of open file descriptors) that applies to the user ID of the Portal pods that have been assigned, and that it is high enough to allow the Portal to open all of the files that it requires. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls and Portal web sites, you might need as many as 1048576. If the number is too low, you will see errors like `"too many open files"` in the Portal logs. Note that this value might need to be even higher if other, non-Portal, pods are sharing the same user ID.

The Portal endpoints values are used when you configure a Portal service in the Cloud Manager. See Registering a Portal service.

- `portalAdminEndpoint` - This is the Management Endpoint that is defined in Cloud Manager, which is used for communicating with API Manager.
- `portalUIEndpoint` - This is the Portal website URL defined in Cloud Manager. It determines the URL for the site that is created for each catalog. It is used for public access to the Portal from a browser.

Important: The endpoints defined here must be the ones used by the Management subsystem when registering the portal, and portal users when accessing portal sites. Do not attempt to proxy these endpoints. You will not be able to register the portal service nor access portal sites using any other endpoint URLs than those defined here.

Procedure

1. Edit the `portal_cr` template CR to replace the placeholders with values for your deployment.

   `$APP_PRODUCT_VERSION`
   API Connect application version for the subsystems.

   ```
   version: <version_number>
   ```

   Example version number: 10.0.6.0

   `$PROFILE`
   Specify your portal subsystem profile, where `n` indicates number of replicas, `c` number of cores, and `m` is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

   `$SECRET_NAME`
   Use for image pull.

   ```
   imagePullSecrets:
     - apic-registry-secret
   ```

   `$DOCKER_REGISTRY`
   The host name of the Docker Registry to which you uploaded the installation images. For example:

   ```
   my.docker.registry.domain.example.com.
   ```

   $INGRESS_CLASS
   The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation `ingressclass.kubernetes.io/is-default-class: true` is used. If such an ingress class does not exist in the Kubernetes environment, then `nginx` is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system.
   Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

   `$STACK_HOST`
   The desired ingress subdomain for the API Connect stack. Used when you specify endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

   - Subdomain customization only
     Accept the prefixes predefined for the ingress hostnames to use and replace all instances of `STACK_HOST` to be the desired ingress subdomain for the API Connect stack. For example, for a subdomain of `myhost.subnet.example.com`:

     ```
     portalAdminEndpoint:
         < ... >
         hosts:
         - name: api.portal.myhost.subnet.example.com
           secret: portal-admin

       portalUIEndpoint:
         < ... >
         hosts:
         - name: portal.myhost.subnet.example.com
           secret: portal-web
     ```

   - Complete hostname customization
     Change both the predefined prefixes and the `$STACK_HOST` subdomain to match your desired hostnames.

     For example, for `portalAdminEndpoint`, you can replace `api.portal.$STACK_HOST` with `my.api.portal.myhost.subnet.example.com`, where `my.api.portal` replaces `api.portal`, and `myhost.subnet.example.com` replaces `$STACK_HOST`:

     ```
     portalAdminEndpoint:
           < ... >
         hosts:
         - name: my.api.portal.myhost.subnet.example.com
           secret: cm-endpoint
     ```

     You can do this for some or all of the hostnames, depending on your customization requirements.

   `$STORAGE_CLASS`
   The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: `kubectl get sc`. For example, for local storage:

   ```
   databaseVolumeClaimTemplate:
       storageClassName: $STORAGE_CLASS
       volumeSize: 120Gi
   ```

```
    databaseLogsVolumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: 12Gi
    webVolumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: 200Gi
    backupVolumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: 300Gi
    adminVolumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: 20Gi
    certVolumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: 4Gi
```

$PLATFORM_CA_SECRET
Set to **ingress-ca**. The **$PLATFORM_CA_SECRET** contains the CA certificate for the platform REST API endpoint. The portal makes calls to the platform REST API and this property must be set so that the portal can verify the server certificate.

```
mgmtPlatformEndpointCASecret:
  secretName: $PLATFORM_CA_SECRET
```

$CONSUMER_CA_SECRET
Set to **ingress-ca**. The **$CONSUMER_CA_SECRET** contains the CA certificate for the consumer REST API endpoint. The portal makes calls to the consumer REST API and this property must be set so that the portal can verify the server certificate.

```
mgmtConsumerEndpointCASecret:
  secretName: $CONSUMER_CA_SECRET
```

Note:

- The **databaseVolumeClaimTemplate** has a minimum value of 30Gi. The **webVolumeClaimTemplate** has a minimum value of 20Gi. The **backupVolumeClaimTemplate** has a minimum value of 30Gi. However, all three need to be sized according to the installation.
- The **adminVolumeClaimTemplate** and **databaseLogsVolumeClaimTemplate** in this example have their minimum values and you do not need to change them.
- The **certVolumeClaimTemplate** is used by the nginx pod and in 2dcha (two data center high availability) mode it is also by the tunnel, db-remote and www-remote pods. It can be sized small, just like the **adminVolumeClaimTemplate**, and does not need to be increased based on the number of sites.

2. Edit the **license:** setting:
   a. Set **accept:** to **true** to accept the license. Note that the default value is **false**. If you do not accept the license, the Operator will not install the subsystem.
   b. Set **metric:** to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.
      - MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.

      For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.

   c. Set **use:** to either **production** or **nonproduction**, to match the license you purchased.
   d. Set **license:** to the License ID for the version of API Connect that you purchased. See API Connect licenses.

   Example entry to accept the license for a production system:

```
  license:
    accept: true
    metric: PROCESSOR_VALUE_UNIT
    use: production
    license: L-RJON-BZ5LSE
```

3. Optional: If you want to disable mTLS for communications between the management and portal, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

   where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

   For more information about JWT security, see Enable JWT security instead of mTLS.

4. Optional: If you want to use the In-cluster inter-subsystem communication feature, then uncomment the **mgmtPlatformEndpointSvcCASecret** and the **mgmtConsumerEndpointSvcCASecret** sections, and set the **secretName** for both:

```
  mgmtPlatformEndpointSvcCASecret:
    secretName: management-ca  # Usually management-ca
  mgmtConsumerEndpointSvcCASecret:
    secretName: management-ca  # Usually management-ca
```

   Unless you customized your internal certificates, these secrets are always **management-ca**.

5. Optional: If you are installing as part of a two data center disaster recovery set up, complete the steps in Installing a two data center deployment on Kubernetes before you apply the edited file.
6. Install the Portal Custom Resource, replacing **<namespace>** with the target installation namespace in the Kubernetes cluster:

```
kubectl apply -f portal_cr.yaml -n <namespace>
```

7. Verify that the Portal subsystem is fully installed:

```
kubectl get PortalCluster -n <namespace>
```

The installation is complete when **STATUS** reports **Running**, **Ready** reports that all services are online (**3/3**), and **MESSAGE** reports "Ready for API Cloud Manager service registration", for example:

```
NAME            READY   STATUS    VERSION     RECONCILED VERSION   MESSAGE                                    AGE
portal          3/3     Running   <version>   <version>            Ready for API Cloud Manager service registration   2h
```

You do not need to wait for the portal installation to complete before you move on to the next subsystem installation.

8. We highly recommend that you retain the Portal subsystem encryption secret in a safe location, in case you need to restore the Portal subsystem during a disaster recovery scenario.
   The encryption secret is created when the Portal subsystem is initially deployed. You can obtain the name of the encryption secret from the Portal subsystem custom resource once the installation is complete. For example:

   a. Obtain the name of the encryptionSecret:

   ```
   kubectl get ptl portal -o yaml | grep encryptionSecret
   encryptionSecret: portal-enc-key
   ```

   The name of encryption secret is **portal-enc-key**.

   b. Save the secret yaml in a safe location:

   ```
   kubectl get secret portal-enc-key -o yaml > portal-enc-key.yaml
   ```

9. Backup the Portal installation. See Backing up and restoring the Developer Portal in a Kubernetes environment.
   Note:
   When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the **portal-www** pod, admin container logs, if the endpoint cannot be reached:

   ```
   An error occurred contacting the provided portal web endpoint: example.com
   The provided Portal web endpoint example.com returned HTTP status code 504
   ```

   In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully.
   To disable the endpoint check, complete the following update:

   On Kubernetes, OpenShift, and IBM® Cloud Pak for Integration
   Add the following section to the Portal custom resource (CR) template:

   ```
   spec:
     template:
     - containers:
       - env:
         - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
           value: "true"
         name: admin
       name: www
   ```

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you completed the installation of all the required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

- **Defining multiple portal endpoints for a Kubernetes environment**
  Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

Defining multiple portal endpoints for a Kubernetes environment

Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

About this task

You can override the single endpoint definition for portal-WWW, and the associated portal-www-ingress TLS certificate, to support multiple portal-www endpoints.

For information about the endpoints for the Developer Portal, see Installing the Developer Portal subsystem.

Following are the example endpoints for configuring different sites served by the same Developer Portal service, as configured in this task:

- https://banking.example.com/loans
- https://insurance.example.com/vehicle

These unique endpoints allow Developer Portal sites to be defined on the Developer Portal service with different host names and domains. They replace endpoints that distinguish different sites by sub paths, as shown in the following examples:

- https://www.example.com/banking/loans
- https://www.example.com/insurance/vehicle

Procedure

Edit your **portal_cr** template. You can add multiple entries for your endpoints in the **hosts** element:

For example:

```
spec:
    portalUIEndpoint:
        annotations:
          cert-manager.io/issuer: ingress-issuer
        hosts:
        - name: ptl.host1.example.com
          secretName: portal-web-host1
        - name: ptl.host2.example.com
          secretName: portal-web-host2
        - name: ptl.host3.example.com
          secretName: portal-web-host3
```

Installing the Analytics subsystem

Install the IBM® API Connect analytics subsystem.

Review Planning your analytics deployment to ensure that you understand the choices for configuring the topology, disk space, and other elements of the analytics subsystem.

Note: When the analytics service is configured to store data, it uses OpenSearch, which requires map counts higher than the operating system defaults. The minimum recommended value is `262144`. If you plan to store analytics data locally (that is, do you not intend to disable local storage and offload all data), increase the default map count on every Kubernetes node:

1. To change the map counts on the live system, run the following command on every Kubernetes node:

   ```
   sudo sysctl -w vm.max_map_count=262144
   ```

2. To persist this change when node restarts occur, add the following setting to the /etc/sysctl.conf file:

   ```
   vm.max_map_count = 262144
   ```

For more information, see Important settings in the OpenSearch documentation.

- **Creating the analytics CR**
  Create the installation CR for API Connect analytics so that you can deploy the analytics subsystem.
- **Installing analytics**
  Deploy the analytics CR to install the analytics subsystem in your API Connect deployment.

Creating the analytics CR

Create the installation CR for API Connect analytics so that you can deploy the analytics subsystem.

Before you begin

Review Analytics preinstallation planning to decide on your deployment options.

About this task

To install the analytics subsystem, create a Custom Resource (CR) in a `.yaml` file. The file contains all of your configuration settings for the analytics deployment. Use the file to install, upgrade, and update the configuration of your analytics subsystem.
Note: The analytics_cr.yaml and analytics_dedicated_cr.yaml template files are stored in the directory where you extracted helper_files.zip.

Procedure

1. Create or copy the appropriate analytics CR file from the helper_files, depending on which deployment storage type you want, see: Analytics preinstallation planning.
   - If you want to use shared storage, use analytics_cr.yaml.
   - If you want to use dedicated storage, use analytics_dedicated_cr.yaml. Dedicated storage is only supported on three replica deployments.
2. Edit the CR file and update the following settings:
   You cannot install the analytics subsystem until the placeholders are replaced with real values for your environment.

   `$APP_PRODUCT_VERSION`
   API Connect application version for the subsystems.

   ```
   version: <version_number>
   ```

   Example version number: 10.0.6.0

   `$PROFILE`
   Specify your analytics subsystem profile, where **`n`** indicates number of replicas, **`c`** number of cores, and **`m`** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

   `$SECRET_NAME`
   The name of the secret used to pull images from the Docker registry.

   ```
   imagePullSecrets:
     - apic-registry-secret
   ```

$DOCKER_REGISTRY
The hostname of the Docker Registry to which you uploaded the installation images. For example:

```
my.docker.registry.domain.example.com.
```

$INGRESS_CLASS
The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation **ingressclass.kubernetes.io/is-default-class: true** is used. If such an ingress class does not exist in the Kubernetes environment, then **nginx** is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system.
Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

$STACK_HOST
The ingress subdomain for the API Connect stack. Used for the ingestion endpoint. Domain names that are used for endpoints cannot contain the underscore "_" character. You can customize the subdomain or the complete hostname:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** with the ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
ingestion:
  endpoint:
     < ... >
    hosts:
    - name: ai.myhost.subnet.example.com
      secretName: analytics-ai-endpoint
     < .... >
```

$STORAGE_CLASS
The Kubernetes storage class to be used for persistent volume claims. For more information, see Analytics preinstallation planning. Find the available storage classes in the target cluster by running the following command: **kubectl get sc**.

- For shared storage deployments:

```
storage:
  type: shared
  shared:
    volumeClaimTemplate:
      storageClassName: local_storage
```

- For dedicated storage deployments, set **$STORAGE_CLASS** in two places:

```
storage:
  type: dedicated
  shared:
    volumeClaimTemplate:
      storageClassName: local_storage
      ...
  master:
    volumeClaimTemplate:
      storageClassName: local_storage
      ...
```

$DATA_VOLUME_SIZE
Replace **$DATA_VOLUME_SIZE** with the value that you calculated in Estimating storage requirements. If you are unable to estimate your storage requirement then set it to 500Gi.

```
storage:
  ...
  shared:
    volumeClaimTemplate:
      ...
      volumeSize: 500Gi
```

3. Edit the **license** setting.
   a. Set **accept:** to **true** to accept the license. The default value is **false**. If you do not accept the license, the Operator does not install the subsystem.
   b. Set **metric:** to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.
      - MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.

      For information on tracking monthly call volume, see Counting total API calls.
   c. Set **use:** to either **production** or **nonproduction** to match the license you purchased.
   d. Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

Example entry to accept the license for a production system:

```
license:
  accept: true
  metric: PROCESSOR_VALUE_UNIT
  use: production
  license: L-RJON-CEBL97
```

4. Optional: If you want to disable mTLS for communications between the management and analytics subsystem, and between the gateway and analytics subsystem, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow.

5. Save the file.

What to do next

Install your analytics subsystem: Installing analytics.
Important: All analytics advanced configuration options can be added, changed, or removed after installation **except** for disablement or enablement of internal storage. If you want to disable internal storage, you must configure it in the analytics CR before installation: Disable local storage.

Installing analytics

Deploy the analytics CR to install the analytics subsystem in your API Connect deployment.

Before you begin

Now that you have a complete analytics CR file, double-check it for accuracy. In particular, verify that:

- No placeholder values remain in the analytics_cr.yaml file.
- You configured all the topology options that you plan to deploy.
- You configured appropriate volume size for storage.

Procedure

1. Run the following command to apply the analytics_cr.yaml:

   ```
   kubectl apply -f path/to/analytics-cr -n namespace
   ```

   where:
   - ***path/to/analytics-cr*** is the path to your saved analytics_cr.yaml file.
   - ***namespace*** is the name of your namespace.
2. Verify that the analytics subsystem is fully installed by running the following command:

   ```
   kubectl get AnalyticsCluster -n namespace
   ```

   where ***namespace*** is the name of your namespace.
   The installation is complete when the **READY** status is **True** and the **SUMMARY** reports that all services are online. Example:

   ```
   NAME         READY   SUMMARY   VERSION    RECONCILED VERSION   AGE
   analytics    True    5/5       <version>   <version-build>       7m39s
   ```

   The **SUMMARY** total count is based on your configured topology. Both numbers are equal when the installation is complete.

Results

Table 1 lists the pods that are expected in the three replica analytics deployment profile.

Table 1. Expected analytics subsystem pods

Expected	Pods	Note
3	director	Always expected.
3	ingestion	Always expected.
3	mtls-gw	Always expected.
3	storage	Not expected if you disabled internal storage.
3	storage-os-master	Not expected if you disabled internal storage. Not expected if shared storage is configured.
3	osinit	Expected to be in completed state.

The one replica profile has 1 replica (instead of 3) of each pod.

What to do next

Take a backup of your analytics subsystem and configure scheduled analytics database backups: Analytics backup and restore.

Installing a two data center deployment on Kubernetes

Additional installation instructions for a two data center disaster recovery (2DCDR) deployment on Kubernetes.

Before you begin

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center deployment strategy on Kubernetes and OpenShift.

Download the operator files and custom resource definitions for use during installation onto both of your data centers. Ensure that you complete the instructions for Deploying operators and cert-manager, and set the same ingress-ca certificate in both data centers: Installing cert-manager and certificates in a two data center deployment.

Familiarize yourself with the instructions in Installing the API Connect subsystems. Follow these instructions along with the 2DCDR specific steps in this topic.

Important: Each data center must use a different backup path for your Management backups. For portal backups each data center must use the same backup path. For more information, see Backup and restore requirements for a two data center deployment.
Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center deployment strategy on Kubernetes and OpenShift).

The following endpoints must be the same on both data centers:

Management subsystem endpoints

- `cloudManagerEndpoint`
- `apiManagerEndpoint`
- `platformAPIEndpoint`
- `consumerAPIEndpoint`

Portal subsystem endpoints

- `portalAdminEndpoint`
- `portalUIEndpoint`

For more information about how to set the endpoints, see Installing the Management subsystem cluster on Kubernetes, Installing the Developer Portal subsystem on Kubernetes.

About this task

A 2DCDR deployment differs from a standard API Connect deployment in that the custom resources (CRs) for both the management and portal in each data center include a `multiSiteHA` configuration section. The `multiSiteHA` section is used to define which data center is the active and which is the warm-standby.

The following examples show `multiSiteHA` sections in the `PortalCluster` CRs for the active and warm-standby data centers.

```
siteName: dallas
multiSiteHA:
  mode: active
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationdallas.cluster1.example.com
      secretName: dallas-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationraleigh.cluster2.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

```
siteName: raleigh
multiSiteHA:
  mode: passive
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationraleigh.cluster2.example.com
      secretName: raleigh-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

Table 1. `multiSiteHA` configuration properties

Configuration property	Description
`mode`	The state of the data center in the context of the 2DCDR deployment. Valid values are: • `active` - indicates the active data center. • `passive` - indicates the warm-standby data center.
`replicationEndpoint` `  annotations:` `  cert-manager.io/issuer:` `ingress-issuer` `  hosts:` `  - name:` `  secretName:`	Contains details of the external ingress name for the subsystem in the current data center in the 2DCDR deployment. The hosts `name` is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`replicationPeerFQDN`	The ingress hostname for the other data center in the 2DCDR deployment. This information is required so that the two data centers can communicate with each other.
`tlsClient:` `  secretName`	The TLS client secret for the subsystem.

The `siteName` property is a unique descriptive name for the portal and management subsystems, in each data center. For example, `dallas` in data center 1 (DC1), and `raleigh` in data center 2 (DC2).

- Set a different `siteName` on the active to the one set on the warm-standby data center.
- `siteName` is used in the hostnames, and so can contain only `a-z` and `0-9` characters.
- You can set a `siteName` in the `ManagementCluster` or `PortalCluster` CRs only on installation. You cannot change the name after deployment. If you don't set a `siteName` at first deployment, an automated `siteName` is created for you.

To install a 2DCDR deployment:

1. Set the placeholder properties in the CR file for management and portal subsystems as detailed in Installing the API Connect subsystems, but do not run the final `kubectl apply` operation. Complete the additional 2DCDR configuration steps before you run `kubectl apply`.
2. Set the properties in the `multiSiteHA` section, and synchronize encryption secrets between the data centers as described in the procedure below:

Procedure

- **Installing to an active data center**
  The following example shows how to set the multi-site HA CR values for deploying to the active data center. In this example, the initial active data center is called `dallas` (DC1) and the warm-standby data center is called `raleigh` (DC2).

  1. Set Dallas to be active for the API Manager service on DC1.
     Edit the `ManagementCluster` CR file management_cr for DC1, and set the `multiSiteHA` properties as shown:

     ```
     siteName: dallas
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: mgrreplicationdallas.cluster1.example.com
           secretName: dc1-mgmt-replication
       replicationPeerFQDN: mgrreplicationraleigh.cluster2.example.com
       tlsClient:
         secretName: dc1-mgmt-replication-client
     ```

  2. Set Dallas to be active for the Developer Portal service on DC1.
     Edit the `PortalCluster` CR file portal_cr for DC1, and set the `multiSiteHA` properties as shown:

     ```
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: ptlreplicationdallas.cluster1.example.com
           secretName: dallas-ptl-replication-worker-1
       replicationPeerFQDN: ptlreplicationraleigh.cluster2.example.com
       tlsClient:
         secretName: ptl-replication-client
     ...
     siteName: dallas
     ```

  3. Create a secret called `ptl-encryption-key` on the active and warm-standby data centers.
     The secret must use the same random string in both data centers. Run the following command:

     ```
     kubectl create secret generic ptl-encryption-key --from-literal=encryption_secret=<RANDOM STRING> -n <namespace>
     ```

     The string can consist of uppercase letters, lowercase letters, and numbers, and must be at least 64 characters and no more than 100 characters.

  4. When the secrets are created on both DC1 and DC2, update the portal CR on DC1 and DC2 and add the following under the `spec` section:

     ```
     encryptionSecret:
       secretName: ptl-encryption-key
     ```

     Warning: Ensure that you add the secret directly under the `spec` section and not inside the `multiSiteHA` section.
  5. Create a secret called `mgmt-encryption-key` on the active and warm-standby data centers.
     The secret must use the same random string in both data centers. Run the following command:
     Note: Do not use the same random string that you used to create the secret for `ptl-encryption-key`.

     ```
     kubectl create secret generic mgmt-encryption-key --from-literal=encryption_secret.bin=<RANDOM STRING> -n <namespace>
     ```

     The string can consist of uppercase letters, lowercase letters, and numbers, and must be at least 64 characters and no more than 100 characters.

  6. When the secrets are created on both DC1 and DC2, update the portal CR on DC1 and DC2 and add the following under the `spec` section:

     ```
     encryptionSecret:
       secretName: mgmt-encryption-key
     ```

     Warning: Ensure that you add the secret directly under the `spec` section and not inside the `multiSiteHA` section.
  7. Apply the CR files to the subsystems in DC1.
     For example, to apply the `ManagementCluster` CR file to the DC1 cluster, run the following command:

     ```
     kubectl apply -f management_cr.yaml -n <namespace>
     ```

     Where `<namespace>` is the target installation namespace in the Kubernetes cluster for DC1. Repeat this process to apply the updated `PortalCluster` CR file to DC1.
     You can verify that the installation process is running with the following command:

     ```
     kubectl get ManagementCluster -n <namespace>
     ```

     Change `ManagementCluster` to `PortalCluster` to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.
  8. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

     Management subsystem endpoints
     - `cloudManagerEndpoint`
     - `apiManagerEndpoint`
     - `platformAPIEndpoint`

- `consumerAPIEndpoint`

Portal subsystem endpoints

- `portalAdminEndpoint`
- `portalUIEndpoint`

- **Installing the warm-standby data center**
  The following example shows how to set the multi-site HA CR values for the remote data center called `raleigh` (DC2) to be the warm-standby. Use the same encryption key on both sites.

  Ensure that the installation of the active data center is complete before you start the installation of the warm-standby data center.

  1. Set Raleigh to be warm-standby for the API Manager service on DC2.
     Edit the `ManagementCluster` CR file management_cr for DC2, and set the `multiSiteHA` properties as shown:

     ```
     multiSiteHA:
       mode: passive
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: mgrreplicationraleigh.cluster2.example.com
           secretName: raleigh-mgr-replication-worker-1
       replicationPeerFQDN: mgrreplicationdallas.cluster1.example.com
       tlsClient:
         secretName: mgr-replication-client
     ...
     siteName: raleigh
     ```

  2. Set Raleigh to be warm-standby for the Developer Portal service on DC2.
     Edit the `PortalCluster` CR file portal_cr for DC2, and set the `multiSiteHA` properties as shown:

     ```
     multiSiteHA:
       mode: passive
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: ptlreplicationraleigh.cluster2.example.com
           secretName: raleigh-ptl-replication-worker-1
       replicationPeerFQDN: ptlreplicationdallas.cluster1.example.com
       tlsClient:
         secretName: ptl-replication-client
     ...
     siteName: raleigh
     ```

  3. Apply the CR files to the subsystems in DC2.
     For example, to apply the `ManagementCluster` CR file to the DC2 cluster, run the following command:

     ```
     kubectl apply -f management_cr.yaml -n <namespace>
     ```

     Where `<namespace>` is the target installation namespace in the Kubernetes cluster for DC2. Repeat this process to apply the updated `PortalCluster` CR file to DC2.
     You can verify that the installation process is running with the following command:

     ```
     kubectl get ManagementCluster -n <namespace>
     ```

     Change `ManagementCluster` to `PortalCluster` to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.

- **Validating your two data center deployment**
  While the management subsystems on the warm-standby and active data centers are synchronizing their databases, the management status reports `Warning`, and the `haStatus` reports `pending`:

  ```
  kubectl get mgmt -n <namespace>
  ```

  ```
  NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
  AGE
  management    n/n     Warning   10.0.5.3-0   10.0.5.3-0           Management is ready. HA Status Warning - see HAStatus in
  CR for details   8m59s
  ```

  ```
  status:
    haStatus
      {
        "lastTransitionTime": "2023-03-31T19:47:08Z",
        "message": "Replication not working, install or upgrade in progress.",
        "reason": "na",
        "status": "True",
        "type": "Pending"
     }
  ```

  When the management database replication between sites is complete, the management status reports `Running`, and `status.haStatus` reports `Ready`:

  ```
  NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
  AGE
  management    n/n     Running   10.0.5.3-0   10.0.5.3-0           Management is ready.              8m59s
  ```

  ```
  status:
    haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication is working",
      "reason": "na",
      "status": "True",
  ```

```
    "type": "Ready"
  }
```

If the management database replication between sites fails for any reason other than because an install or upgrade is in progress, the **haStatus** output shows:

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.5.3-0   10.0.5.3-0           Management is ready. HA Status Warning - see HAStatus in
CR for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "Warning"
   }
```

If the warning persists, see Troubleshooting a two data center deployment.
You can validate that your portal deployments are synchronizing by running **kubectl get pods** on both the active and warm-standby data centers, and confirming that the number and names of the pods all match (the UUIDs in the names might be different on each site), and that all are in the **Ready** state.

For additional replication verification checks, see Verifying replication between data centers. It is recommended to run a test failover, and confirm that all of the expected data is present and correct on the newly active site. See How to perform 2DCDR failover for details.

Converting a single data center to a two data center deployment on Kubernetes

Instructions on how to convert a single data center to a two data center disaster recovery (2DCDR) deployment on Kubernetes.

Before you begin

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center deployment strategy on Kubernetes and OpenShift.

Download the operator files and custom resource definitions for use during installation onto both of your data centers. Ensure that you complete the instructions for Deploying operators and cert-manager, and set the same ingress-ca certificate in both data centers: Installing cert-manager and certificates in a two data center deployment.

Familiarize yourself with the instructions in Installing the API Connect subsystems. Follow these instructions along with the 2DCDR specific steps in this topic.

Important: Each data center must use a different backup path for your Management backups. For portal backups each data center must use the same backup path. For more information, see Backup and restore requirements for a two data center deployment.
Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center deployment strategy on Kubernetes and OpenShift).

About this task

You can convert a single data center API Connect to a two data center disaster recovery deployment. Both data centers must have the same **portal-admin** and **portal-www** endpoints. The main difference is that the custom resource (CR) files for both the Management subsystem and the Developer Portal subsystem on each data center must include a **multiSiteHA** configuration section, and it's this section that determines the two data center DR deployment. It's also this section that's used to control the deployment in the future, for example in failover and recovery situations.

The following codeblocks show examples of completed **multiSiteHA** sections in the **PortalCluster** CR files for two data centers, one active and one warm-standby. Both the **ManagementCluster** and the **PortalCluster** CR templates have a **multiSiteHA** section containing the placeholder **$MULTI_SITE_HA**, and it is this placeholder that must be replaced with the values for your deployment.

```
siteName: dallas
multiSiteHA:
  mode: active
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationdallas.cluster1.example.com
      secretName: dallas-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationraleigh.cluster2.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

```
siteName: raleigh
multiSiteHA:
  mode: passive
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationraleigh.cluster2.example.com
      secretName: raleigh-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

The configuration properties are described in the following table.

Table 1. The configuration properties of the multi-site HA section in the CR file

Configuration property	Description
`mode`	The state of the data center in the context of the two data center deployment. Valid values are: • `active` - indicates the primary data center • `passive` - indicates the warm-standby data center
`replicationEndpoint` `annotations:` `cert-manager.io/issuer` `hosts:` `- name:` `secretName:`	Contains details of the external ingress name for the subsystem in the current data center in the two data center deployment. The hosts `name` is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`replicationPeerFQDN`	The ingress hostname for the other data center in the two data center deployment. This information is required so that the two data centers can communicate with each other.
`tlsClient:` `secretName`	The TLS client secret for the subsystem.
`siteName`	A descriptive name for the Portal subsystem, and the Management subsystem, in the current data center, for example `dallas`. This name is used in the hostnames, and so can contain only `a-z` and `0-9` characters. Note that you can set a `siteName` in the `ManagementCluster` or `PortalCluster` CR only when the subsystems are first deployed, and you cannot change the name after deployment. If you don't set a `siteName` at first deployment, an automated `siteName` is created for you. For example, if you are converting an existing single Management cluster to a two data center Management cluster by adding the multi-site HA values, you will not be able to configure a `siteName` for the existing Management cluster.

To install a two data center disaster recovery deployment, you must set all of the placeholder properties in the CR file for both the Management and the Developer Portal subsystems as detailed in the relevant topics in the Installing the API Connect subsystems section, as well as the properties in the multi-site HA section that are detailed here. Some examples of complete CR files are shown in the Example section.

Procedure

- **Converting a single data center deployment to two data centers**
  When converting a single data center deployment into a two data center deployment, it is best practice to use the existing data center as the active one, and add a new warm-standby data center elsewhere. This practice ensures that the data is retained.
  Remember:
  - Both data centers must have the same `portal-admin` and `portal-www` endpoints.
  - You cannot configure a `siteName` for the existing Management or Portal cluster because the `siteName` property can be configured only at first deployment.

  The following example shows how to update the multi-site HA CR values for making the local data center called `dallas` (DC1) active, and for setting the new remote data center called `raleigh` (DC2) as warm-standby.

- Install a cert-manager.
  Use of a certificate manager adds convenience to the generation and management of certificate, but is not required. Whenever a custom resource (CR) takes a certificate secret name as input, you can point to any secret name, on condition that the secret exists before you deploy the CR, and that the secret contains relevant certificate data. Typically, this is tls.crt, tls.key, and ca.crt files. See Certificates in a Kubernetes environment.
  Note: Run these steps on DC1 only if you don't already have cert-manager running.
  1. Obtain the certificate manager.
     API Connect v10 uses cert-manager v1.9.1 of cert-manager, which is a native Kubernetes certificate management controller.

     You can obtain cert-manager v1.9.1 from the API Connect v10 distribution `helper_files.zip` archive, or from https://github.com/cert-manager/cert-manager/releases/tag/v1.9.1.

     Note: Cert-manager is bundled as a common service in IBM CloudPack for Integration.

  2. Apply the CR:

     ```
     kubectl apply -f cert-manager-1.9.1.yaml
     ```

     Do not specify a custom namespace.

     See https://docs.cert-manager.io/en/release-0.10/getting-started/install/kubernetes.html.

  3. Wait for `cert-manager` pods to enter `Running 1/1` status before proceeding. To check the status:

     ```
     kubectl get po -n cert-manager
     ```

     There are 3 `cert-manager` pods in total.
- Use the following steps to allow `ingress-ca` secrets to be the same on both data centers.

1. On DC1 apply the file `ingress-issuer-v1-dc1.yaml`:

   ```
   kubectl -n <namespace> apply -f ingress-issuer-v1-dc1.yaml
   ```

2. Validate that the command succeeded:

   ```
   kubectl get certificates -n <namespace>
   ```

3. Export `ingress-ca` secret as a yaml from DC1:

   ```
   kubectl -n <namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
   ```

4. Edit the `ingress-ca.yaml` file to remove all labels, annotations, `creationTimestamp`, `resourceVersion`, `uid`, and `selfLink`.
5. Copy the `ingress-ca.yaml` from DC1 to DC2 and apply that file on DC2:

   ```
   kubectl -n <namespace> apply -f ingress-ca.yaml
   ```

6. On DC2 apply the file `ingress-issuer-v1-dc2.yaml`:

   ```
   kubectl -n <namespace> apply -f ingress-issuer-v1-dc2.yaml
   ```

7. Use the following commands to test that they are the same, on DC1 run:

   ```
   kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
   /tmp/ingress.pem.dc1
   ```

8. On DC2 run:

   ```
   kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
   /tmp/ingress.pem.dc2
   ```

9. To see the differences run:

   ```
   diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
   ```

   The files should be the same.
10. To ensure that the certificates are working correctly and that they are using the `ingress-ca` secret. First, get the `portal-admin-client crt` file:

    ```
    kubectl -n <namespace> get secrets portal-admin-client -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
    /tmp/admin-client.crt
    ```

11. Test that it is working by using OpenSSL:

    ```
    openssl verify -verbose -CAfile /tmp/ingress.pem.dc1 /tmp/admin-client.crt
    ```

    If it is working, you should see:

    ```
    /tmp/admin-client.crt: OK
    ```

- **Installing to an active data center**
  The following example shows how to set the multi-site HA CR values for deploying to an active data center (DC). In this instance, we are deploying to a local data center called `dallas` (DC1) that has a remote data center called `raleigh` (DC2).

  1. Set Dallas to be active for the API Manager service on DC1.
     As the API Manager service already exists, you cannot set the `siteName` property. Add the multi-site HA section properties to the existing `ManagementCluster` CR file for DC1. For example:

     ```
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: mgrreplicationdallas.cluster1.example.com
           secretName: dc1-mgmt-replication
       replicationPeerFQDN: mgrreplicationraleigh.cluster2.example.com
       tlsClient:
         secretName: dc1-mgmt-replication-client
     ```

  2. Set Dallas to be active for the Developer Portal service on DC1.
     As the Developer Portal service already exists, you cannot set the `siteName` property. Add the multi-site HA section properties to the existing `PortalCluster` CR file for DC1. For example:

     ```
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manage.io/issuer: ingress-issuer
         hosts:
         - name: ptlreplicationdallas.cluster1.example.com
           secretName: dallas-ptl-replication-worker-1
       replicationPeerFQDN: ptlreplicationraleigh.cluster2.example.com
       tlsClient:
         secretName: ptl-replication-client
     ```

  3. Create a secret called `ptl-encryption-key` on the active and warm-standby data centers.
     You must create a secret on the active and warm-standby sites that use the same random string, run the following command:

     ```
     kubectl create secret generic ptl-encryption-key --from-literal=encryption_secret=<RANDOM STRING> -n <namespace>
     ```

     The string can consist of uppercase letters, lowercase letters, and numbers, and must be at least 64 characters and no more than 100 characters.

  4. When the secrets are created on both DC1 and DC2, update the Portal CR on DC1 and DC2 to include in the `spec` object:

```
encryptionSecret:
   secretName: ptl-encryption-key
```

Warning: Ensure that you add the secret to the **spec** object and not to the **multiSiteHA** object.

5. Apply the CR files to the subsystems in DC1.
   For example, to apply the **ManagementCluster** CR file to the DC1 cluster, run the following command:

   ```
   kubectl apply -f management_cr.yaml -n <namespace>
   ```

   Where ***<namespace>*** is the target installation namespace in the Kubernetes cluster for DC1. Repeat this process to apply the updated **PortalCluster** CR file to DC1.
   You can verify that the updated CR files have been applied by running the following command:

   ```
   kubectl get ManagementCluster -n <namespace>
   ```

   Change ***ManagementCluster*** to ***PortalCluster*** to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.
6. Set your dynamic router to direct all traffic to DC1.
   This includes setting the four endpoints for the API Manager cluster, and the two endpoints for the Developer Portal cluster.

- **Installing to a warm-standby data center**
  The following example shows how to set the multi-site HA CR values for the remote data center called **raleigh** (DC2), which is being installed as the warm-standby, standby location. You must use the same encryption key on both sites.

1. Get the encryption key from Dallas the **active** (DC1) site:
   a. Run the command **kubectl get mgmt -o yaml|grep enc** to get the db encryption key on the **active** site, for example:

      ```
      $ kubectl -n <namespace> get mgmt -o yaml|grep enc
      ```

      An example of possible output:

      ```
      encryptionSecret: dallas-enc-key
      ```

      Make a note of the secret name. In this case, it's **dallas-enc-key**.
   b. Run **kubectl get secret dallas-enc-key -o yaml**, an example of possible output:

      ```
      apiVersion: v1
      data:
        encryption_secret.bin:
      VKBNFj7sAOizxvE1H6i+9P31oJHvWWsO+x**********************************EGe/K+x6b3D7FEWGgoyGlWBUJKB4+T21My2iR5rBTov
      pyLiY5g*****************************************tSiRcQKegMPNBPgL829SVBCxuv3I=
      kind: Secret
      metadata:
        creationTimestamp: "2020-08-28T12:53:41Z"
        labels:
          app.kubernetes.io/instance: m1
          app.kubernetes.io/managed-by: ibm-apiconnect
          app.kubernetes.io/name: dallas-enc-key
        name: dallas-enc-key
        namespace: default
        resourceVersion: "43039"
        selfLink: /api/v1/namespaces/default/secrets/m1-enc-key
        uid: 46c92395-9cc2-4421-b2c4-48e472c0cbb1
      type: Opaque
      ```

   c. Copy the output that you got and put it into a new file. Delete the contents of **metadata:** and add back in a **name:** attribute, in this case **dc1-enc-key**. An example of the format is here:

      ```
      apiVersion: v1
      data:
        encryption_secret.bin:
      VKBNFj7sAOizxvE1H6i+9P31oJHvWWsO+x**********************************EGe/K+x6b3D7FEWGgoyGlWBUJKB4+T21My2iR5rBTov
      pyLiY5g*****************************************tSiRcQKegMPNBPgL829SVBCxuv3I=
      kind: Secret
      metadata:
        name: dc1-enc-key
      type: Opaque
      ```

   d. Save the file. In this example, it's called **dc1-enc-key.yaml**.
2. On Raleigh the (DC2) site:
   a. Copy the yaml file that you just saved that contains the **encryption_secret.bin** from Dallas the **active** (DC1) site.
   b. Run **kubectl create -f dc1-enc-key.yaml** to create the same secret with the same key on the Raleigh (DC2) site. For example:

      ```
      $ kubectl  -n <namespace> create -f /tmp/dc1-enc-key.yaml
      ```

      An example of possible output:

      ```
      secret/dc1-enc-key created
      ```

   c. In the management CR for Raleigh the (DC2) site, add the following entry to the **spec**.

      ```
      encryptionSecret:
          secretName: dc1-enc-key
      ```

3. Set Raleigh to be warm-standby for the API Manager service on DC2.
   Edit the **ManagementCluster** CR file management_cr for DC2, and set the multi-site HA section properties, for example:

   ```
   multiSiteHA:
     mode: passive
     replicationEndpoint:
       annotations:
         cert-manage.io/issuer: ingress-issuer
       hosts:
   ```

```
    - name: mgrreplicationraleigh.cluster2.example.com
      secretName: raleigh-mgr-replication-worker-1
  replicationPeerFQDN: mgrreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: mgr-replication-client
...
siteName: raleigh
```

4. Set Raleigh to be warm-standby for the Developer Portal service on DC2.
   Edit the `PortalCluster` CR file portal_cr for DC2, and set the multi-site HA section properties, for example:

```
multiSiteHA:
  mode: passive
  replicationEndpoint:
    annotations:
      cert-manage.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationraleigh.cluster2.example.com
      secretName: raleigh-ptl-replication-worker-1
  replicationPeerFQDN: ptlreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: ptl-replication-client
...
siteName: raleigh
```

5. Ensure that you completed the steps that are in the **Installing to an active data center** section to create a secret called `ptl-encryption-key` on DC1 and DC2, and to update the Portal CR on DC1 and DC2 to include the `ptl-encryption-key` in the `spec` object.
6. Apply the CR files to the subsystems in DC2.
   For example, to apply the `ManagementCluster` CR file to the DC2 cluster, run the following command:

   ```
   kubectl apply -f management_cr.yaml -n <namespace>
   ```

   Where `<namespace>` is the target installation namespace in the Kubernetes cluster for DC2. Repeat this process to apply the updated `PortalCluster` CR file to DC2.
   You can verify that the updated CR files are applied by running the following command:

   ```
   kubectl get ManagementCluster -n <namespace>
   ```

   Change `ManagementCluster` to `PortalCluster` to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.

Troubleshooting installation on Kubernetes

Review the following known issues and troubleshooting tips if you encounter a problem while installing API Connect on Kubernetes

- DataPower operator fails to start

DataPower operator fails to start

There is a known issue on Kubernetes that can cause the DataPower operator to fail to start. In this case, the DataPower operator pods can fail to schedule, and will display the status message: `no nodes match pod topology spread constraints (missing required label)`. For example:

```
0/15 nodes are available: 12 node(s) didn't match pod topology spread constraints (missing required label),
3 node(s) had taint {node-role.kubernetes.io/master: }, that the pod didn't tolerate.
```

You can workaround the issue by editing the DataPower operator deployment and re-applying it, as follows:

1. Delete the DataPower operator deployment, if deployed already:

   ```
   kubectl delete -f ibm-datapower.yaml -n <namespace>
   ```

2. Open `ibm-datapower.yaml`, and locate the `topologySpreadConstraints:` section. For example:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
     topologyKey: zone
     whenUnsatisfiable: DoNotSchedule
   ```

3. Replace the values for `topologyKey:` and `whenUnsatisfiable:` with the corrected values shown in the example below:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
     topologyKey: topology.kubernetes.io/zone
     whenUnsatisfiable: ScheduleAnyway
   ```

4. Save `ibm-datapower.yaml` and deploy the file to the cluster:

   ```
   kubectl apply -f ibm-datapower.yaml -n <namespace>
   ```

Deploying on OpenShift and Cloud Pak for Integration

You can install API Connect in an OpenShift environment or as the API Management capability in IBM Cloud Pak for Integration.

If you are deploying multiple API Connect instances in the same OpenShift cluster, all of them should be at the same version. The recommended configuration is to have a single operator in the global namespace, managing multiple API Connect instances in separate namespaces.

Attention: If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.

- **Configuring FIPS support on OpenShift**
  Configure support for FIPS (Federal Information Processing Standards) on the cluster where you will install IBM API Connect.
- **Preparing for installation**
  Set up your OpenShift environment in preparation for deploying API Connect.
- **Installation procedures with IBM Cloud Pak for Integration**
  The API Management capability of IBM Cloud Pak for Integration uses IBM API Connect.
- **Installing with the top-level CR on OpenShift**
  Use the single, top-level `APIConnectCluster` CR to deploy API Connect on OpenShift.
- **Installing with subsystem CRs in a shared namespace on OpenShift**
  Use the individual subsystem CRs to install API Connect subsystems in a shared namespace on OpenShift.
- **Installing with subsystem CRs in different namespaces or environments on OpenShift**
  Install API Connect subsystems in different namespaces, for example Management subsystem in a namespace that is called `apicmgmt`, Gateway in a namespace called `apicgway`. These same steps can also be used for installing subsystems in different environments.

Configuring FIPS support on OpenShift

Configure support for FIPS (Federal Information Processing Standards) on the cluster where you will install IBM API Connect.

Before you begin

API Connect supports FIPS with the following limitations:

- API Connect must be installed on Red Hat OpenShift Container Platform 4.10 or 4.12
- Only FIPS version 140-2 is supported
- FIPS must be configured on the cluster before you install API Connect
- You must deploy API Connect 10.0.6.0 or later, with DataPower Gateway 10.5.2 or later

About this task

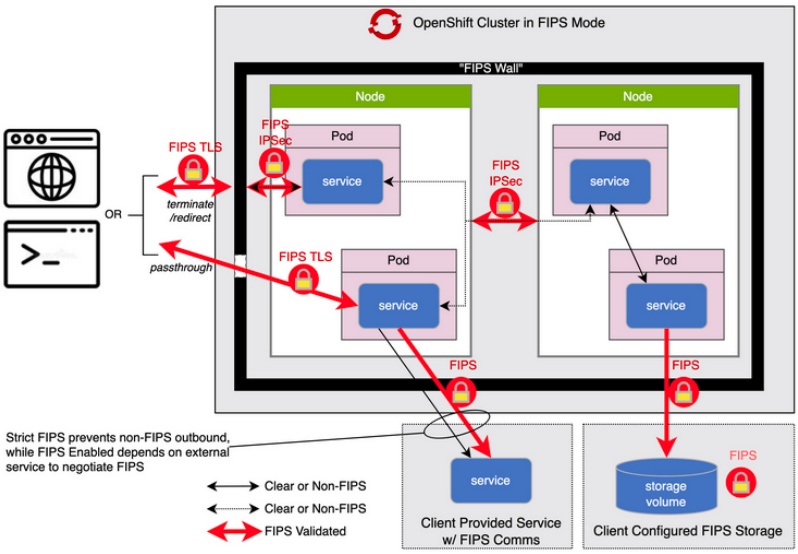
To be FIPS compliant, an organization must adhere to the various data security and computer system standards outlined in the FIPS requirements. FIPS compliance for API Connect is supported by implementing a "FIPS wall".

What is FIPS?

Federal Information Processing Standards (FIPS) are standards and guidelines issued by the National Institute of Standards and Technology (NIST) for federal government computer systems. The standards are developed when there are compelling federal government requirements for standards, such as for security and interoperability, but acceptable industry standards or solutions do not exist. Government agencies and financial institutions use these standards to ensure that products conform to specified security requirements.
API Connect supports version 140-2 of the FIPS requirements, implemented using the "FIPS wall" approach.

What is a FIPS wall?

The "FIPS wall" is a boundary approach to FIPS compliance that is used by IBM products. All pods in the cluster are FIPS-tolerant (the pods can run without issues on a FIPS-enabled OpenShift cluster), while creating a compliant "boundary" that is secured at external points of contact (known as "touch points").
Traffic inside the boundary is secure because the communication between nodes is automatically encrypted at the OpenShift Container Platform level using the IPSec protocol. Traffic within any node happens in-memory, so it never leaves the node. The following diagram illustrates a typical OpenShift cluster that is configured to support the FIPS wall. In the diagram, the "wall" is represented with a heavy black border. Communications between pods within the border are secured with IPSec encryption, and communications that cross the border to external devices are secured using other means for example, TLS encryption).



What are the cluster requirements to support a FIPS wall?

- FIPS is enabled on the cluster during installation (by setting `fips: true` in the install-config.yaml file)
- FIPS is enabled for node-to-node communication (using the OVN-Kubernetes Container Network Interface cluster network provider, and with IPSec enabled)
- The etcd key-value store is encrypted with `aescbc`
- Storage is encrypted with FIPS ciphers
- Runtimes are managed using Kubernetes CRI-O (all OCP deployments use CRI-O by default)

What are the Red Hat OpenShift Container Platform dependencies?

API Connect 10.0.6.0 can be deployed with the following versions of OpenShift Container Platform (OCP):

- version 4.10: based on Red Hat Enterprise Linux 8.4; certified for FIPS 140-2
- version 4.12: based on Red Hat Enterprise Linux 8.6; on-going certification for FIPS 140-2 and 140-3

For more information about OpenShift support for FIPS, see

- Current status on FIPS certification: Compliance Activities and Government Standards in the Red Hat Customer Portal

Install and configure OpenShift Container Platform

Configure settings for FIPS and IPSec, install the OpenShift cluster, and then configure the cluster to enable encryption and provide storage.

Procedure

1. Configure settings in the install-config.yaml file.
   Edit the install-config.yaml and make the following changes:
   - Set `fips: true`
   - Set the `networkType` to `OVNKubernetes`

   For example:

```
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  networkType: OVNKubernetes
  serviceNetwork:
  - 172.30.0.0/16
fips: true
```

   For an example of the install-config.yaml file, see Sample install-config.yaml file for bare metal in the Red Hat OpenShift documentation.

2. Create the IPSec installation manifests to allow IPSec tunneling for node-to-node communication in the OpenShift cluster.
   a. Generate the manifests from `install-config.yaml` by running the following command:

```
openshift-install create manifests
```

   b. Create a cluster-network-03-config.yaml file with the following content, and save it in the `manifests` directory:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    type: OVNKubernetes
    ovnKubernetesConfig:
      ipsecConfig: {}
      mtu: 1400
```

3. Deploy the OpenShift cluster.

Install the OpenShift cluster, and then install the OpenShift CLI.

a. Install the OpenShift cluster as explained in Chapter 2. Installing the system in FIPS mode in the Red Hat OpenShift "FIPS support" documentation.

b. Install the OpenShift CLI (oc) as explained in Installing the OpenShift CLI in the Red Hat OpenShift documentation.

4. Log in to the cluster as a user with `cluster-admin` privileges.

5. Validate the OpenShift cluster.

   a. Verify that FIPS is enabled on the OpenShift cluster.

      i. Run the following command to verify the `fips` setting:

      ```
      oc get cm cluster-config-v1 -n kube-system -o json | jq -r '.data."install-config"' | grep -i "fips"
      ```

      Review the results and verify that the `fips` setting is set to `true`:

      ```
      fips: true
        name: fips-apic
        root@fips-apic
      ```

      ii. Run the following command to get the names of the machine configurations:

      ```
      oc get mcp
      ```

      In the result, the configuration name appears in the `CONFIG` column; for example:

      ```
      NAME     CONFIG                                             UPDATED   UPDATING   DEGRADED   MACHINECOUNT
      READYMACHINECOUNT   UPDATEDMACHINECOUNT   DEGRADEDMACHINECOUNT   AGE
      master   rendered-master-41831cf684b6e570518728abd24b9006   True      False      False      3              3
      3                   0                     15h
      worker   rendered-worker-2a4937983238e94a74307abc3eed2080   True      False      False      7              7
      7                   0                     15h
      ```

      For each configuration listed in the result, run the following command to verify that `Fips` is set to `true`:

      ```
      oc describe mc <CONFIG> | grep Fips
      ```

      The previous example returned two configurations, so run the command on each configuration:

      - `oc describe mc rendered-master-41831cf684b6e570518728abd24b9006 | grep Fips`
        `Fips:  true`
      - `oc describe mc rendered-worker-2a4937983238e94a74307abc3eed2080 | grep Fips`
        `Fips:  true`

   b. Verify that IPSec is enabled on the OpenShift cluster.

      i. Check the `ovn-ipsec` daemonset that manages the daemons responsible for configuring IPSec:

      ```
      oc get ds -n openshift-ovn-kubernetes ovn-ipsec
      ```

      A successful result looks like the following example:

      ```
      NAME        DESIRED   CURRENT   READY   UP-TO-DATE   AVAILABLE   NODE SELECTOR                 AGE
      ovn-ipsec   66666           beta.kubernetes.io/os=linux   3d3h
      ```

      ii. Verify that IPSec pods are running in all of the nodes in your OpenShift cluster:

      ```
      oc get pod -n openshift-ovn-kubernetes -o wide | grep ipsec
      ```

      A successful result looks like the following example:

      ```
       ovn-ipsec-4qp86        1/1     Running   0          38m   192.168.7.23   master2.ocp4.rober.lab   <none>
      <none>
       ovn-ipsec-pk7vh        1/1     Running   0          38m   192.168.7.21   master0.ocp4.rober.lab   <none>
      <none>
       ovn-ipsec-q4mwj        1/1     Running   0          22m   192.168.7.11   worker0.ocp4.rober.lab   <none>
      <none>
       ovn-ipsec-trz5m        1/1     Running   0          22m   192.168.7.12   worker1.ocp4.rober.lab   <none>
      <none>
       ovn-ipsec-vjmw8        1/1     Running   0          38m   192.168.7.22   master1.ocp4.rober.lab   <none>
      <none>
      ```

6. Enable `etcd` encryption with `aescbc` as explained in Encrypting etcd data in the Red Hat OpenShift documentation.

7. For local storage, choose either RHEL-provided disk encryption or Container Native Storage that uses RHEL-provided disk encryption.
   By storing all data in volumes that use RHEL-provided disk encryption and enabling FIPS mode for your cluster, both data at rest and data in motion (network data) are protected by FIPS-validated or Modules In Process encryption. You can configure your cluster to encrypt the root filesystem of each node, as described in Customizing nodes in the Red Hat OpenShift documentation.

Install API Connect

Install API Connect on the OpenShift cluster, and ensure that server connections support FIPS.

Procedure

1. Replace the `openssh` algorithm used by the Postgres database (which is used by the Management subsystem).
   Before installing API Connect, prepare the Postgres database for use in a FIPS environment.

   a. Install `ssh-keygen` on your local machine.

   b. Create a name for the pgcluster as follows:

      i. Create a 4-letter name for the APIConnectCluster; for example: `apic`

      ii. Create a 4-letter `siteName` for the Management subsystem; for example: `fips`

iii. Construct the **pgclusterName** as follows:

***<APIConnectCluster_name>*-mgmt-*<siteName>*-postgres**

For example: **apic-mgmt-fips-postgres**

c. Create and execute the backrest-secret.sh.zip script to generate a relevant pgbackrest secret.

i. Create a file called backrest-secret.sh with the following content:

```
DIR="$( cd "$( dirname "${BASH_SOURCE[0]}" )" && pwd )"

if ! command -v ssh-keygen &> /dev/null
then
    echo "ssh-keygen could not be found"
    exit 1
fi

if ! command -v kubectl &> /dev/null
then
    echo "ssh-keygen could not be found"
    exit 1
fi

if [ $# -eq 0 ]; then
    printf "Please pass pgcluster name and namespace as 1st and 2nd arguments\n"
    printf "Usage: ./backrest-secret.sh <pgcluster-name> <namespace>\n"
    exit 1
fi

if [ -z "$1" ]; then
    printf "empty pgcluster cannot be passed as 1st argument\n"
    printf "Usage: ./backrest-secret.sh <pgcluster-name> <namespace>\n"
    exit 1
fi

if [ -z "$2" ]; then
    printf "empty namespace cannot be passed as 2nd argument\n"
    printf "Usage: ./backrest-secret.sh <pgcluster-name> <namespace>\n"
    exit 1
fi

# Generate an RSA SSH key pair for use by pgBackRest
ssh-keygen -t rsa -N '' -b 4096 -f $DIR/rsa-example

# base64 encode the key pair for the generation of the pgBackRest secret
export PUBLIC_KEY_TEMP=$(cat $DIR/rsa-example.pub | base64)
export PRIVATE_KEY_TEMP=$(cat $DIR/rsa-example | base64)

export PUBLIC_KEY="${PUBLIC_KEY_TEMP//[$'\n']}"
export PRIVATE_KEY="${PRIVATE_KEY_TEMP//[$'\n']}"

unset PUBLIC_KEY_TEMP
unset PRIVATE_KEY_TEMP

printf "namespace is $2\n"
printf "pgcluster name passed is $1\n"
printf "Creating pgbackrest secret $1-backrest-repo-config in namespace $2\n"

kubectl create -f - <<EOF
apiVersion: v1
data:
  id_ed25519: ${PRIVATE_KEY}
  ssh_host_ed25519_key: ${PRIVATE_KEY}
  authorized_keys: ${PUBLIC_KEY}
kind: Secret
metadata:
  name: $1-backrest-repo-config
  namespace: $2
type: generic
EOF
```

ii. Assign **777** permissions to the script with the following command:

```
chmod 777 backrest-secret.sh
```

iii. Run the script with the following command:

./backrest-secret.sh *<pgcluster-name>* *<namespace>*

In the command, replace ***<pgcluster-name>*** with the pgcluster name that you created in step 1; for example: **apic-mgmt-fips-postgres**, and replace ***<namespace>*** with the namespace where the Management subsystem is installed.

Attention: The script creates a simple secret with SSH RSA keys. Make sure that:

- The secret is created in the correct namespace
- You do not change the key values of the secret

If the script fails, correct it as needed for your environment and run it again.

2. Install API Connect, making sure to specify your custom **siteName** (from step 1) in the CR.
The location of the **siteName** property depends on the type of CR that you use for installing API Connect:

Installing with the top-level CR

If you deploy API Connect using the top-level CR, add the **siteName** property to the **spec.management** section of the **APIConnectCluster** CR as shown in the following example:

```
spec:
  management:
    siteName: fips
```

For instructions on installing API Connect with the top-level CR, see Installing with the top-level CR on OpenShift.

Installing with individual subsystem CRs

If you deploy API Connect using the individual subsystem CRs, add the `siteName` property to the `spec` section of the `ManagementCluster` CR as shown in the following example:

```
spec:
  siteName: fips
```

For instructions on installing API Connect with subsystem CRs, see Installing with subsystem CRs in a shared namespace on OpenShift or Installing with subsystem CRs in different namespaces or environments on OpenShift.

3. Ensure that all server connections support FIPS.

Inbound connections: ensure that the Gateway API invocation endpoint supports FIPS

The following list shows the inbound connections to an API Connect deployment:

```
$ oc get routes
NAME                          HOST/PORT                                                    PATH   SERVICES
PORT   TERMINATION          WILDCARD
apic-a7s-ai-endpoint          apic-a7s-ai-endpoint-apic.apps.fips-apic.cp.fyre.ibm.com             apic-a7s-mtls-gw
4443   passthrough           None
apic-gw-gateway               apic-gw-gateway-apic.apps.fips-apic.cp.fyre.ibm.com                  apic-gw-datapower
9443   passthrough           None
apic-gw-gateway-manager       apic-gw-gateway-manager-apic.apps.fips-apic.cp.fyre.ibm.com          apic-gw-datapower
3000   passthrough           None
apic-mgmt-admin               apic-mgmt-admin-apic.apps.fips-apic.cp.fyre.ibm.com                  apic-mgmt-juhu
2005   reencrypt/Redirect    None
apic-mgmt-api-manager         apic-mgmt-api-manager-apic.apps.fips-apic.cp.fyre.ibm.com            apic-mgmt-juhu
2006   reencrypt/Redirect    None
apic-mgmt-consumer-api        apic-mgmt-consumer-api-apic.apps.fips-apic.cp.fyre.ibm.com           apic-mgmt-juhu
2001   reencrypt/Redirect    None
apic-mgmt-platform-api        apic-mgmt-platform-api-apic.apps.fips-apic.cp.fyre.ibm.com           apic-mgmt-juhu
2000   reencrypt/Redirect    None
apic-ptl-portal-director      apic-ptl-portal-director-apic.apps.fips-apic.cp.fyre.ibm.com         apic-ptl-nginx
4443   passthrough           None
apic-ptl-portal-web           apic-ptl-portal-web-apic.apps.fips-apic.cp.fyre.ibm.com              apic-ptl-b1aab746-
www    4443    reencrypt/Redirect    None
```

All of the inbound connections support FIPS by default, except for the Gateway API invocation endpoint.

The TLS server profile used by the DataPower Gateway for API invocation is configured from the Cloud Manager when you create a gateway service. To be FIPS compliant, the TLS server profile used with a gateway service must be configured with FIPS-only ciphers to ensure that the server only accepts FIPS connections.

To configure the TLS server profile, use the Cloud Manager's Register Service > DataPower Gateway page, which you can access from the Topology menu. Locate the API invocation endpoint section and use the Server Name Indication (SNI) - TLS server profile setting to create the server profile. Use a TLS server profile that is FIPS-compliant (for example, do not use: `TLS_CHACHA20_POLY1305_SHA256`, which is not compliant). For information on configuring the TLS server profile, see Registering a gateway service in this documentation.

Outbound connections: Ensure that all of the outbound connections support FIPS

For outbound connections, it is your responsibility to ensure that the external servers configured with API Connect accept only FIPS connections. The following list shows the typical outbound connections for an API Connect deployment

- OIDC providers (Google, Facebook, Keycloak etc.)
- LDAP providers
- Authentication URLs
- External user registry
- Target URLs used in APIs
- Remote backups
- Auditing endpoints
- SMTP endpoints
- Analytics offloading
- Analytics backup to S3 storage
- Automated API behavior testing tool (ATM) - calls out to the APIs being tested
- Portal - Potential drupal extensions installed by customer
- Portal - SFTP and S3 backups
- 2-data-center deployments - Calls to other clusters

Preparing for installation

Set up your OpenShift environment in preparation for deploying API Connect.

About this task

Ensure that your environment meets all prerequisites, plan your deployment, and download files for installation.

Procedure

1. Ensure that your environment meets the following prerequisites:

- IBM API Connect Version 10 software product compatibility requirements
  Attention: API Connect is not supported on a FIPS-enabled environment.
- Deployment requirements

- If you want to use the OpenShift web console, Cluster admin access is required.

- API Connect requires `block storage` as the storage class for all subsystems.

- Set the default SCC (security context constraint) to `restricted`.
  API Connect supports only the `restricted` SCC on OpenShift.

- If your Openshift deployment uses a LimitRange and a CPU maxLimitRequestRatio is set, then its value must be at least 25; otherwise some API Connect pods might fail to start.

2. Plan your deployment as explained in Planning your deployment.
3. Review Operator, operand, and CASE versions to determine the operator, operand, and CASE versions that you need for your deployment.
4. Optional: Specify additional settings in each subsystem CR to define the deployment's configuration before beginning the installation.
   In particular, consider increasing the timeout value for Management endpoints as explained in Configuring timeouts for management endpoints.

   For information on other configuration settings, see API Connect configuration settings.

   Tip: If you choose not to specify configuration settings now, you can modify the installation CRs later and then re-apply them to update the deployment.

- **Operator, operand, and CASE versions**
  When you install API Connect on OpenShift, each release of API Connect supports a new combination of operator and operand, as well as a new CASE version for air-gapped installations.
- **API Connect configuration settings**
  Specify configuration settings for API Connect in the CR, or the Platform UI in Cloud Pak for Integration.
- **Configuring timeouts for management endpoints**
  Adjust the timeout settings for management endpoints by updating the CR.

Operator, operand, and CASE versions

When you install API Connect on OpenShift, each release of API Connect supports a new combination of operator and operand, as well as a new CASE version for air-gapped installations.

Table 1 lists the operator, operand, and CASE information that applies to each release of API Connect.

Table 1. Operators and operands for recent versions of API Connect

API Connect release	Operator channel	Operator version	CASE	DataPower Operator version
10.0.6.0	v5.0	5.0.0	5.0.0	1.7.0
10.0.5.5	v3.5	3.5.0	4.0.6	1.6.10
10.0.5.4	v3.4	3.4.0	4.0.5	1.6.8
10.0.5.3	v3.3	3.3.0	4.0.4	1.6.6
10.0.5.2	v3.2	3.2.0	4.0.2	1.6.3
10.0.5.1	v3.1	3.1.0	4.0.1	1.6.2
10.0.5.0	v3.0	3.0.0	4.0.0	1.6.0

API Connect configuration settings

Specify configuration settings for API Connect in the CR, or the Platform UI in Cloud Pak for Integration.

You can use the Platform UI on Cloud Pak for Integration, the OpenShift web console, or direct editing of the top-level or subsystem CR YAML files to specify advanced configuration options for API Connect. The following topics describe the available configuration options.

Attention: A mistake in a configuration update can result in an admission webhook error when `APIConnectCluster` is updated, or the `APIConnectCluster` can get stuck in a pending state with a webhook error message.

- Example of an admission webhook error when the `APIConnectCluster` update is rejected:
  In this example, the user attempted to change the deployment profile to `n12xc4.m12-incorrect` and the result looked like the following example:

  ```
  oc edit apiconnectcluster

  error: apiconnectclusters.apiconnect.ibm.com "production" could not be patched: admission webhook
  "vapiconnectcluster.kb.io" denied the request: APIConnectCluster.apiconnect.ibm.com "production" is invalid: spec.Profile:
  Invalid value: "n12xc4.m12-incorrect": invalid profile. Options are: [n3xc4.m16 n12xc4.m12]
  ```

- Example of when the `APIConnectCluster` update is allowed, but is the state changes pending due to an underlying webhook error:

  ```
  oc get apiconnectcluster -n apic

  NAME   READY  STATUS    VERSION             RECONCILED VERSION   AGE
  m1     admission webhook "vmanagementcluster.kb.io" denied the request: ManagementCluster.management.apiconnect.ibm.com
  "m1-mgmt" is invalid: [spec.databaseBackup.restartDB.accept: Invalid value: false: databaseBackup protocol has changed
  (from '' to 'objstore') and requires database restart. accept restartDB to restart database,
  spec.databaseBackup.restartDB.accept: Invalid value: false: databaseBackup configuration has changed and requires database
  restart. accept restartDB to restart database]   Pending   10.0.1.5-3388-eus   10.0.1.5-3388-eus    2d6h
  ```

Basic configuration

- Basic configuration settings

Advanced configuration
: To enable access to the advanced configuration settings with Platform UI, toggle the Advanced Options slider.

  - Analytics subsystem settings
  - Gateway subsystem settings
  - Management subsystem settings
  - Developer Portal subsystem settings
  - Additional Kubernetes settings

Additional configuration
: You must edit the yaml file to set additional properties.

- **Basic configuration settings**
  You can specify the API Connect basic configuration settings directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Management subsystem settings**
  You can specify advanced configuration settings for the Management subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Gateway subsystem settings**
  You can specify advanced configuration settings for the Gateway subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Developer Portal subsystem settings**
  You can specify advanced configuration options for the Developer Portal subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Analytics subsystem settings**
  Specify advanced configuration settings for the analytics subsystem directly in the analytics CR. If you are using Cloud Pak for Integration, you can configure many of the analytics settings in Platform UI.
- **Additional Kubernetes settings**
  For each API Connect subsystem, you can specify additional settings for annotations and pod management.

Basic configuration settings

You can specify the API Connect basic configuration settings directly in the CR or with the Platform UI in Cloud Pak for Integration.

Review the tables for information on configuration settings for the following areas:

- Details
- License
- Deployment profiles for installing with a single, top-level CR
- Product version
- Storage class

Details

Table 1. Details

Field	Type	Required	Description
Name	String	Yes	Name this instance using only lowercase alphanumeric characters plus the underscore "-". Maximum of 54 characters. Default: none

License

Table 2. License

Field	Type	Required	Description
License acceptance	Boolean	Yes	The license agreement https://ibm.biz/apictoolkitlic must be accepted before you can install the API Connect capability. Default value: **`false`** (off). In the UI, click the License acceptance toggle to enable it. In the CR, set the **`accept:`** field to **`true`** to accept the license.
License use	String	Yes	Select **`production`** or **`nonproduction`**, to match the license you purchased. Default: **`nonproduction`**
License metric	Enumerated	No	Enter the unit of measure that is used for your program license: OpenShift • PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used. • MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program. Cloud Pak for Integration • VIRTUAL_PROCESSOR_CORE - Default value. If you leave the field blank, this value is used. • MONTHLY_API_CALL - Applies only to the IBM Cloud Pak for Integration - API Calls add-on program. For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.
License ID	String	Yes	Select the license that you purchased for this instance of API Connect. Valid licenses are based on the selected value in the Product version field (see Table 4). When deploying the standalone IBM API Connect product, you must select the License ID for the API Connect program that you purchased. To view all License IDs, see API Connect licenses.

Deployment profiles for installing with a single, top-level CR

Select a deployment profile for the new installation. See API Connect deployment profiles for OpenShift and Cloud Pak for Integration for more information on the available profiles.

For information on switching to a different deployment profile after installation, see the following topics:

- Changing the deployment profile on Cloud Pak for Integration
- Changing deployment profiles on OpenShift

Product version

Table 3. Product version

Field	Type	Required	Description
Product version	Enumerated	No	Select the product version to be installed in the system. Warning: Do not select a channel here instead of the API Connect version. Selecting a channel will result in any API Connect interim fix updates being applied automatically and without warning.

Storage class

Table 4. Storage class

Field	Type	Required	Description
Default Storage Class	Enumerated	No	Specify the RWO block storage class to use for persistence storage. This will be used when creating a PVC. Specification of the storage class is optional, but is highly recommended. If not specified the default cluster storage class is used. See the IBM Cloud Pak documentation for guidance for Storage class selection. Go to the following page and select your Cloud Pack release level: https://www.ibm.com/support/knowledgecenter/SSGT7J. In the navigation panel, select System Requirements > Storage. To review API Connect storage support, see Storage classes.

Management subsystem settings

You can specify advanced configuration settings for the Management subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.

The IBM Cloud Pak Platform UI enables you to specify settings for the following areas:

- Database backup
- Database persistence
- Site name
- Test and Monitor
- Billing

For annotations, labels, node selectors, and tolerations, see Additional Kubernetes settings

Note: Optionally, you might want to increase the timeout settings for management endpoints, particularly for large deployments. See Configuring timeouts for management endpoints.

Database backup

Table 1. Database backup

Field	Type	Required	Description
Credentials	Drop down menu	No. Optional	• For `objstore` type backups, the name of the Kubernetes secret containing your S3 Access Key / Key Secret • For `SFTP` type backups, the name of the Kubernetes secret containing your SFTP Username/password Default: (Generated Value) See Configuring backup settings for fresh install of the Management subsystem.
Server hostname	String	No. Optional	The backups host: • For `objstore` type backup, specify S3 endpoint with the corresponding S3 region in the format `<S3endpoint>/<S3region>`. For example: `s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard` • For `sftp` type, the SFTP server hostname. For example: `203.0.113.0` or `example.com` • Not required for local storage backups Default: none See Configuring backup settings for fresh install of the Management subsystem.

Field	Type	Required	Description
Path	String	No. Optional	The path to the location of the backup: • For **objstore** backups, the name of your S3 bucket to store backup data. For example, **bucket-name/folder**. The use of subdirectories in the bucket name is not supported. Ensure that **bucket-name/folder** is empty. If the folder was previously used for backups, the folder will not be empty, and stanza create might encounter an error. • For **sftp** type, the folder name on the SFTP server. For example: **mgmt_backup**. • Not required for local storage backups Default: none See Configuring backup settings for fresh install of the Management subsystem.
Server port	String	No. Optional	Backup server port The port for the protocol to connect to the **host**. The backup port is not required for object storage. Default: **22** See Configuring backup settings for fresh install of the Management subsystem.
Protocol	String	No	The type of the backup. Supported types: • **objstore** • **sftp** The default value is **sftp**. • Local storage backups For local backups, do not specify this parameter. When the parameter is set to "", the backup type is set to local storage backup. See Configuring backup settings for fresh install of the Management subsystem.
Restart database	Toggle Switch	No. Optional	Flag to accept database reconfiguration. Restarting the database is required when changing the backup configuration. When marked true and the new backup configuration differs, the operator will stop the database and any dependent services, apply the change, and restart the stopped components. Defaults to Off. For more information on restarting the database, see Reconfiguring or adding backup settings after installation of the management subsystem
Retries	String	No. Optional	For **sftp** type backups only, the number of times the **ibm-apiconnect** Operator attempts backups in the event of a failed SFTP backup. Not used for **objstore** or local storage backup. Default value: **0**. See Configuring backup settings for fresh install of the Management subsystem.
S3 provider type	Drop down menu	Required when using s3 provider.	Name of the S3 provider to use. Not required for local backups or SFTP backups. If you are configuring backups with an **s3provider**, you must specify one of the supported values of **aws** or **ibm**. See Configuring backup settings for fresh install of the Management subsystem.
Schedule	String	No. Optional	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * • - - - - - • | | | | | • | | | | +----- day of week (0 - 6) (Sunday=0) • | | | +------- month (1 - 12) • | | +--------- day of month (1 - 31) • | +----------- hour (0 - 23) • +------------ min (0 - 59) The backup schedule defaults to **0 0 * * ***. This means a backup is run every day at midnight and minute zero UTC. When you configure a host, if you do not specify a value for **schedule**, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed. See Configuring backup settings for fresh install of the Management subsystem.

Database persistence

Table 2. Database persistence

Field	Type	Required	Description
Storage Class	Drop down menu	No. Optional	Specify the RWO block storage class to use for persistence storage. This will be used when creating a PVC. Specification of the storage class is highly recommended. If not specified the default cluster storage class is used. See the IBM Cloud Pak documentation for guidance for Storage class selection. Go to the following page and select your Cloud Pack release level: https://www.ibm.com/support/knowledgecenter/SSGT7J. In the navigation panel of the KC, select System Requirements > Storage. To review API Connect storage support, see Storage classes.

Field	Type	Required	Description
Volume size	Integer	No. Optional	Represents the size of the Database volume. Defaults to 120G for `n1xc4.m16` installation profile, 180G for `n3xc4.m16` installation profile.

Site name

Table 3. Site Name

Field	Type	Required	Description
Site name	string	No. Optional	Site name is the logical name of this failure domain. Typically site name is the name of your data center, such as Amazon AZ. Default: randomly generated name. This will be the site name of the management deployment. For example, given the site name of `test` your management deployment will look like `management-test-postgres`.

Test and Monitor

Table 4. Test and Monitor

Field	Type	Required	Description
Enable Test and Monitor	Boolean. Toggle off/on	No. Optional	Test and Monitor automatically generates API test assertions. It contains dashboards for monitoring API test assertions and getting alerts on the health of your APIs. Default: off See Installing the Automated API behavior testing application.

Billing

Table 5. Billing

Field	Type	Required	Description
Enable Billing	Boolean. Toggle off/on	No. Optional	To enable the monetization of your Product Plans, you must add a billing integration resource in your API Connect provider organization that defines the configuration data needed to synchronize with an external subscription billing system. Default: off See Adding a billing integration resource.

Gateway subsystem settings

You can specify advanced configuration settings for the Gateway subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.

The IBM Cloud Pak Platform UI enables you to specify settings for the following areas:

- v5 compatibility mode
- Operations Dashboard
- Token management service
- Autoscaling gateway pods

For annotations, labels, node selectors, and tolerances, see Additional Kubernetes settings

v5 compatibility mode

Table 1. v5 compatibility mode

Field	Type	Required	Description
V5 comparability mode	Toggle Switch off/on	No. Optional	Enabling this provides v5 compatibility (trading off some performance) with the IBM DataPower Gateway that was provided with IBM API Connect Version 5 and earlier releases. Consider using this DataPower Gateway (v5 compatible) if you are an existing DataPower user and want to utilize your DataPower resources and knowledge. Default: off To review v5 compatibility, see API Connect gateway types.

Operations Dashboard

Table 2. Operations Dashboard

Field	Type	Required	Description

Field	Type	Required	Description
Enable Operations Dashboard tracing	Toggle Switch off/on	No. Optional	Enable or disable cross-component transaction tracing to allow troubleshooting and investigating errors and latency issues. Default: disabled (off) To review the Operations Dashboard, see https://www.ibm.com/support/knowledgecenter/SSGT7J_20.3/tracing/operations_dashboard.html For information on configuring the Operations Dashboard, see https://ibm.github.io/datapower-operator-doc/apis/datapowerservice/v1beta2/#odtracing.
Operations Dashboard namespace	string	No. Optional	Namespace where the IBM Cloud Pak for Integration Operations Dashboard has been deployed. Default: none
Replica count	string	No. Optional	Specify the number of instances of the Gateway that should be deployed. For high-availability, a minimum of 3 replicas (one per node) is recommended. Default: none

Token management service

Table 3. Token management service

Field	Type	Required	Description
Advanced: Enable TMS	Toggle Switch	No. Optional	Enable or disable token management service (TMS) to use the DataPower to manage the token lifecycle.. Default: disabled (off) The Token Management Service uses the DataPower distributed cache to manage the token lifecycle which includes when to revoke access rights. For more information, see Token management with DataPower API Gateway.
Advanced: Storage Class	string	No. Optional	Specify the RWO block storage class to use for persistence storage. This will be used when creating a PVC. Specification of the storage class is highly recommended. If not specified the default cluster storage class is used. See the IBM Cloud Pak documentation for guidance for Storage class selection. Go to the following page and select your Cloud Pack release level: https://www.ibm.com/support/knowledgecenter/SSGT7J. In the navigation panel of the KC, select System Requirements > Storage. To review DataPower storage configuration, see https://ibm.github.io/datapower-operator-doc/apis/datapowerservice/v1beta2/#storage.
Advanced: Volume size	string	No. Optional	Resources represents the minimum resources the volume should have. For example, 10Gi.Default: none To review DataPower storage configuration, see **`storage`** API. in the DataPower documentation.

Autoscaling gateway pods

Autoscaling enables the gateway deployment to scale dynamically, either vertically or horizontally. It is not possible to use both horizontal and vertical pod scaling simultaneously. You must configure either **`HPA`** (for horizontal scaling) or **`VPA`** (for vertical scaling) as the scaling method.

Note: DataPower Gateway supports long-lived connections such as such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when pods are scaled down based on defined CPU or memory thresholds. Workloads with long-lived connections are more vulnerable to failed API transactions when auto-scaling is occurring.
To learn more about HPA and VPA autoscaling, see the following topics in the DataPower documentation:

- Autoscaling DataPower Pods
- **`podAutoScaling`** API

You can configure autoscaling for Gateway pods by inserting a new subsection in the **`spec`**
`gateway` section of the top-level CR, or by filling in the corresponding fields in the OpenShift or IBM Cloud Pak Platform UI. Settings are described in Table 4.

The following example configures HPA autoscaling in the gateway section of the top-level API Connect CR:

```
spec:
  gateway:
    podAutoScaling:
      hpa:
        maxReplicas: 5
        minReplicas: 3
        targetCPUUtilizationPercentage: 90
        targetMemoryUtilizationPercentage: 80
      method: HPA
```

Table 4. Autoscaling configuration settings

UI Field name / CR Setting	Autoscaling method	Required	Description
• Scaling method • **`method`**	All	Yes	Select the autoscaling method to be used: either **`HPA`** (Horizontal Pod Autoscaling) or **`VPA`** (Vertical Pod Autoscaling). To disable autoscaling, leave **`method`** blank, or omit the **`podAutoScaling:`** section from the CR.
• Minimum pods • **`minReplicas`**	HPA	Yes	Minimum number of pods that can be scaled down to by the horizontal pod autoscaler.
• Maximum pods • **`maxReplicas`**	HPA	Yes	Maximum number of pods that can be scaled up to by the horizontal pod autoscaler. Must be a value greater than **`minReplicas`**.

UI Field name / CR Setting	Autoscaling method	Required	Description
• Target CPU Utilization Percentage • `targetCPUUtilizationPercentage:`	HPA	No	Percent threshold on average CPU usage by pods for triggering horizontal scaling.
• Target Memory Utilization Percentage • `targetMemoryUtilizationPercentage`	HPA	No	Percent threshold on average memory usage by pods for triggering horizontal scaling.
• Maximum CPU • `maxAllowedCPU`	VPA	No	Maximum value for CPU resource that can be assigned to a DataPower container when scaling vertically. Minimum value is set from `DataPowerRequestsSpec.ResourceCPU`
• Maximum Memory • `maxAllowedMemory`	VPA	No	Maximum amount of memory that can be assigned to a DataPower container when scaling vertically. Minimum value is set from `DataPowerRequestsSpec.ResourceMemory`

Developer Portal subsystem settings

You can specify advanced configuration options for the Developer Portal subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.

The IBM Cloud Pak Platform UI enables you to specify settings for the following areas:

- Database backups
- Site name

For annotations, labels, node selectors, and tolerations, see Additional Kubernetes settings

Known limitation: When deployed on OpenShift or Cloud Pak for Integration, the API Connect Developer Portal subsystem does not support multiple hosts for the `portalUIEndpoint` endpoint, due to a limitation of Routes in OCP.

Database backups

Table 1. Database backup settings

Field	Type	Description
Credentials	String	For `objstore`, this is the name of your Kubernetes secret that was generated with your username and password for your backup database. For `sftp`, this is the secret that contains the credentials for your `sftp` username and password. Required if configuring backups. See also Backing up and restoring the Developer Portal in a Kubernetes environment.
Backup host	String	The S3 endpoint with the corresponding S3 region in the format `<S3endpoint>/<S3region>`. For example: `s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard` For sftp, this is the sftp server host name. Required if configuring backups. See also Backing up and restoring the Developer Portal in a Kubernetes environment.
Backup path	String	For `objstore`, the name of your S3 bucket to store backup data. For example: `test-bucket/restore-test`. For sftp, this is the path to the folder on the sftp server. Required if configuring backups. See also Backing up and restoring the Developer Portal in a Kubernetes environment.
Backup port	Integer	This is the port for the protocol to connect to the host. There is no default. See also Backing up and restoring the Developer Portal in a Kubernetes environment.
Backup protocol	String	Choose the protocol (sftp or objstore) you wish to use to communicate with your remote backup endpoint. Objstore is recommended for most reliability. There is no default. This field must be set to either `sftp` or `objstore` to configure backups. See also Backing up and restoring the Developer Portal in a Kubernetes environment.
Backup schedule	String	This is the schedule in cron string format for how often automatic Developer Portal backups are run. For example: `0 /3 * * *` means at minute 0 past every 3rd hour. There is no default. Required if configuring backups. See also Backing up and restoring the Developer Portal in a Kubernetes environment.

Site name

Table 2. Site name

Field	Type	Description
Site name	string	Site name is the logical name of the failure domain of this portal subsystem. Typically site name is the name of your data center, such as Amazon AZ. The default is a randomly generated name.

Analytics subsystem settings

Specify advanced configuration settings for the analytics subsystem directly in the analytics CR. If you are using Cloud Pak for Integration, you can configure many of the analytics settings in Platform UI.

Review Analytics preinstallation planning to decide on the deployment options for your analytics subsystem. If you want to offload your analytics data and disable local storage, you must configure local storage disablement before installation because it cannot be changed after installation.

For annotations, labels, node selectors, and tolerations, see Additional Kubernetes settings

Cloud Pak for Integration Platform UI

In the Cloud Pak for Integration Platform UI you can specify settings for:

- Analytics database backup
- Storage type, class, and size

All other analytics settings must be configured directly in the analytics section of the `APIConnectCluster` CR.

Table 1. Database backup

Field	Type	Required	Description
Backup chunk size in GB	Integer	No	`chunkSize` specifies how large files are stored. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB. Default value is 1 GB. See Configuring analytics backups.
Credentials	String	No	The backup credential is the name of the Kubernetes secret that you created for accessing your S3-compatible storage. No default. See Configuring analytics backups.
Compress	Boolean: off or on	No	Determines whether metadata files are stored in compressed format. Default value is false (off). See Configuring analytics backups.
Enable server-side encryption	Boolean: off or on	No	Determines whether files are encrypted. When set to true (on), files are encrypted on the server side by using AES256. Default is false (off). See Configuring analytics backups.
Analytics server hostname	String	No	The URL to your S3 storage. No default. See Configuring analytics backups.
Backup Path	String	No	The path to your S3 storage at the URL specified by analytics server hostname.host. No default. See Configuring analytics backups.
Schedule cron expression	String	No	The schedule that determines how often backups are run automatically. The format for the schedule is any valid `cron` string. Default: "*/20 * * * *" See Configuring analytics backups.

Table 2. Storage type, class, and size settings

Field	Type	Required	Description
Master storage class	String	Yes	If you specified dedicated storage, the master storage class is the storage class that is used by your `storage-os-master` pods. Select from the drop down. Local-volume storage is recommended for best performance. If none selected, the default storage class of your cluster is used. See Analytics preinstallation planning.
Shared storage class	String	Yes	The storage class used by your analytics `storage` pods. Select from the drop down. Local-volume storage is recommended for best performance. If none selected, the default storage class of your cluster is used. See Analytics preinstallation planning.
Master volume size	Integer > 0	No	If you specified dedicated storage, then master volume size specifies the disk storage that is allocated to your `storage-os-master` pods. The `storage-os-master` pods do not store your analytics data, and if left unset the value defaults to 5Gi.
Shared volume size	Integer > 0	Yes	How much persistent disk storage is allocated for analytics data (in Gi). See Estimating storage requirements. If you do not have the information to estimate your usage, set this to 500Gi. For an installation where you expect to store little or no analytics data, you can set the storage to 50Gi.
Type	Boolean: dedicated or shared	Yes	OpenSearch storage type to use for your analytics data. For more information about storage types, see Analytics preinstallation planning. The default storage type is shared.

Additional Kubernetes settings

For each API Connect subsystem, you can specify additional settings for annotations and pod management.

The additional settings are generic Kubernetes configuration settings. The Platform UI advanced configuration option for API Connect enables you to set them specifically for each subsystem.

Annotations

The annotations field serves as a pass-through for all the resources managed by the CR. You can add any annotation to this field. The annotations here overwrite the default annotations.

See https://kubernetes.io/docs/concepts/overview/working-with-objects/annotations/.

Labels

The labels field serves as a pass-through for Pod labels. You can add any label to this field and have it apply to the pod. The labels here overwrite the default labels provided. For example, if the label 'mylabel=1' was provided, it would apply to all kubernetes resources managed by this CR.

See https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/.

Node Selector

This field allows you to specify a set of key value pair that must be matched against the node labels to decide which API Connect pods can be scheduled on that node. Only nodes matching all of these key value pairs in their labels will be selected for scheduling API Connect pods.

See https://kubernetes.io/docs/concepts/scheduling-eviction/assign-pod-node/.

Tolerations

This field allows you to select which nodes API Connect pods can be scheduled or not scheduled. By specifying a set of matching tolerations, you can control whether specific nodes can be used for scheduling API Connect Pods.

Effect (optional)
: Effect indicates the taint effect to match. Empty means match all taint effects. When specified, allowed values are NoSchedule, PreferNoSchedule and NoExecute.

Key (optional)
: Key is the taint key that the toleration applies to. Empty means match all taint keys. If the key is empty, operator must be Exists; this combination means to match all values and all keys.

  Operator represents a key's relationship to the value. Valid operators are Exists and Equal. Defaults to Equal. Exists is equivalent to wildcard for value, so that a pod can tolerate all taints of a particular category.

Operator (optional)
: Operator represents a key's relationship to the value. Valid operators are Exists and Equal. Defaults to Equal. Exists is equivalent to wildcard for value, so that a pod can tolerate all taints of a particular category.

Toleration seconds (optional)
: TolerationSeconds represents the period of time the toleration (which must be of effect NoExecute, otherwise this field is ignored) tolerates the taint. By default, it is not set, which means tolerate the taint forever (do not evict). Zero and negative values will be treated as 0 (evict immediately) by the system.

Value (optional)
: Value is the taint value the toleration matches to. If the operator is Exists, the value should be empty, otherwise just a regular string.

See https://kubernetes.io/docs/concepts/scheduling-eviction/taint-and-toleration/.

Configuring timeouts for management endpoints

Adjust the timeout settings for management endpoints by updating the CR.

About this task

On large deployments, or with large API usage, you might encounter timeout issues when deployed with the default timeout setting of 30 seconds. To avoid timeout issues, increase the setting for the management endpoints used in routing.

You do not have to set these values on initial installation. You can set them or change them after installation and reapply the CR YAML files.

Procedure

Edit the CR to set the timeout to 240 seconds.
The instructions for editing depend on whether you install API Connect using subsystem CRs or a single top-level CR:

- If you are installing API Connect using subsystem CRs, edit **`management_CR.yaml`**:

```
  cloudManagerEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: admin.example.com
      secretName: cm-endpoint
  apiManagerEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: manager.example.com
      secretName: apim-endpoint
  platformAPIEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: api.example.com
```

```
      secretName: api-endpoint
  consumerAPIEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: consumer.example.com
      secretName: consumer-endpoint
```

- If you are installing API Connect using a top-level CR, the management subsystem settings are embedded in the top-level APIConnectCluster CR. Edit the endpoint settings under `spec:management:` as follows:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-minimum
  name: <name_of_your_instance>
  namespace: ${NAMESPACE}
spec:
...
  management:
    cloudManagerEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: admin.example.com
        secretName: cm-endpoint
    apiManagerEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: manager.example.com
        secretName: apim-endpoint
    platformAPIEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: api.example.com
        secretName: api-endpoint
    consumerAPIEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: consumer.example.com
        secretName: consumer-endpoint
...
```

Installation procedures with IBM Cloud Pak for Integration

The API Management capability of IBM Cloud Pak for Integration uses IBM API Connect.

There are several methods for installing API Connect with Cloud Pak for Integration:

- Use the Cloud Pak for Integration Platform UI to install API Connect with a top-level CR. The steps are documented in the installation section of the Cloud Pak for Integration documentation: https://www.ibm.com/docs/en/cloud-paks/cp-integration.
- If API Connect is already installed with the top-level CR and you want to migrate it to Cloud Pak for Integration, see Migrating from OpenShift to Cloud Pak for Integration on the same cluster.

Installing with the top-level CR on OpenShift

Use the single, top-level **`APIConnectCluster`** CR to deploy API Connect on OpenShift.

About this task

When you deploy API Connect with a top-level CR, all of the subsystems are deployed in the same namespace. The CR contains a section for each subsystem; configure deployment settings in the appropriate section for each subsystem.

If you want to install multiple API Connect instances (for example **`dev`**, **`uat`**, and **`prod`**), the recommended configuration is to have single API Connect and DataPower operators installed globally in the **`openshift-operators`** namespace, and then install each API Connect instance in its own namespace using a top-level CR.

Attention: If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.

- **Connected installation**
  Install API Connect on OpenShift using a single, top-level Custom Resource while connected to the internet.
- **Air-gapped installation**
  In a disconnected environment using Red Hat OpenShift Container Platform (OCP), install API Connect by mirroring product images to a bastion host or a portable device and then completing the installation.
- **Enable additional features post-install**
  After installing API Connect, you can enable additional features that are related to inter-subsystem communication.

Connected installation

Install API Connect on OpenShift using a single, top-level Custom Resource while connected to the internet.

About this task

Complete the following tasks in the sequence shown:

1. Installing operators
   Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect on Red Hat OpenShift.
2. Installing API Connect
   Use the top-level **APIConnectCluster** CR to install all the API Connect subsystems into a shared namespace on OpenShift while connected to the internet.

Installing operators

Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect on Red Hat OpenShift.

Before you begin

The API Connect operator and operand must be from the same release and fix pack level. Table 1 lists the current version of the operator and operand for API Connect.

Table 1. API Connect operator and operand versions

API Connect (operand)	Operator channel version	Highest operator version
10.0.6.0	v5.0	5.0.0

Note: There can be only one instance of the API Connect operator in your OpenShift environment. You cannot have multiple namespaces each with their own API Connect operator.
You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

Procedure

1. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
   The **ibm-pak** plug-in enables you to access hosted product images, and to run **oc ibm-pak** commands against the cluster. To confirm that **ibm-pak** is installed, run the following command and verify that the response lists the command usage:

   ```
   oc ibm-pak --help
   ```

2. Obtain an entitlement key for the Entitled Registry:
   a. Log in to the IBM Container Library.
   b. In the Container software library, select Get entitlement key.
   c. After the Access your container software heading, click Copy key.
   d. Copy the key to a safe location.
3. Create the namespace where API Connect will be installed, either by selecting Home > Projects > Create Project in the UI, or with the following command:

   ```
   oc create ns <APIC-namespace>
   ```

   The namespace where you install API Connect must meet the following requirements:
   - Red Hat OpenShift: Only one top-level CR (**APIConnectCluster**) can be deployed in each namespace.
   - Cloud Pak for Integration: Only one API Connect capability can be deployed in each namespace.
   - Red Hat OpenShift restricts the use of default namespaces for installing non-cluster services. The following namespaces cannot be used to install API Connect:
     - **default**
     - **kube-system**
     - **kube-public**
     - **openshift-node**
     - **openshift-infra**
     - **openshift**
4. If you are installing the operator into a single namespace, create an OperatorGroup object specifying that namespace.
   Attention: If you are installing the operator into all namespaces, skip this step because the **openshift-operators** namespace already has an appropriate Operator group in place.
   a. Create the apiconnect-operator-group.yaml file with an OperatorGroup object that identifies the namespace in which RBAC permissions for the IBM API Connect Operator will be generated, and where the CSV will be available:

      ```
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: <operator-group-name>
        namespace: <APIC-namespace>
      spec:
        targetNamespaces:
        - <APIC-namespace>
      ```

   b. Apply the OperatorGroup object with the following command:

      ```
      oc apply -f apiconnect-operator-group.yaml
      ```

5. Create a pull secret in the namespaces where you want to install API Connect.

a. Open the Red Hat OpenShift web console, click Workloads > Secrets.
b. Ensure that the Project is set to the namespace where you intend to install API Connect.
c. Click Create and select Image pull secret.
d. Set the following parameters for the secret:
- Set Secret name to `ibm-entitlement-key`.
- Set Authentication type to `Image registry credentials`.
- Set Registry server address to `cp.icr.io`.
- Set Username to `cp`.
- Set Password to the entitlement key generated in Step 1.
- Click Create to create the secret.

Note: If your Red Hat OpenShift platform is Red Hat OpenShift on IBM Cloud (ROKS), you might need to reload your worker nodes after the image pull secret is created. You can reload the worker nodes either from the Red Hat OpenShift web console or from the command line with: `ibmcloud oc worker reload`. For information on using the `reload` command, see the Red Hat OpenShift on IBM Cloud documentation.

6. Add the API Connect catalog sources to your cluster.
Adding catalog sources to your Red Hat OpenShift cluster adds the IBM operators to the list of operators you can install. For most connected and air-gapped clusters, applying individual catalog sources is the most effective way to fully control software versioning on the cluster.

a. Generate the catalog source files:
i. Log into your cluster using the `oc login` command and your user credentials:

```
oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
```

ii. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.0.0
export ARCH=amd64
```

For information on API Connect CASE versions and their corresponding operators and operands, see Operator, operand, and CASE versions.

iii. Download the files for the operators required by API Connect:

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

iv. Generate the catalog sources for API Connect:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
Get the catalog sources (run both commands):

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

b. Apply the catalog sources:
i. Apply the catalog sources (run both commands):

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

7. Add the IBM Cloud Pak foundational services (common services) catalog sources to your cluster.
a. Generate the catalog source files:
i. Log into your cluster using the `oc login` command and your user credentials:

```
oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
```

ii. Export the variables for the command line to use; substituting the appropriate version for the CASE:

```
export CASE_NAME=ibm-cp-common-services
export CASE_VERSION=1.15.10
export ARCH=amd64
```

For example, for IBM Cloud Pak foundational services 3.19.X (Long Term Service Release), use version 1.15.10; for foundational services 3.23.X (Continuous Delivery), use version 1.19.2.

For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

iii. Download the files for the operators required by IBM Cloud Pak foundational services (common services):

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

iv. Generate the catalog sources:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

This command might not return anything if there are no architecture-specific catalog sources.

b. Apply the catalog sources:

i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

8. Create the `apiconnect` subscription.
   a. Create the `apiconnect` subscription with the appropriate channel by creating a file called `apic-sub.yaml` and pasting in the following contents, updating the namespace as required:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-apiconnect
  namespace: <namespace>
spec:
  channel: v5.0
  name: ibm-apiconnect
  source: ibm-apiconnect-catalog
  sourceNamespace: openshift-marketplace
```

   Where *<namespace>* is one of the following values:
   - `openshift-operators` if you are installing the operator in all namespaces
   - The namespace created in step 3 if you are installing the operator in a single namespace

   b. Apply the subscription with the following command:

```
oc apply -f apic-sub.yaml
```

   c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
   If any operators such as `ibm-apiconnect` or `IBM DataPower Gateway` show the status of "Upgrade available", approve the upgrade by completing the following steps:

   i. Click Upgrade available.
   ii. Click Preview InstallPlan.
   iii. Click Approve.
   iv. Wait for the `IBM API Connect` and `IBM DataPower Gateway` operators to install.

   The `IBM DataPower Gateway` operator is a prerequisite to API Connect and must not be removed.

9. Create the `ibm-common-services-operator` subscription, if it does not already exist.
   a. Create a file called common-services-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-common-service-operator
  namespace: <namespace>
spec:
  channel: <channel>
  name: ibm-common-service-operator
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

   Where:

   - *<namespace>* is one of the following values:
     - `openshift-operators` if you are installing the operator in all namespaces
     - The namespace created in step 3 if you are installing the operator in a single namespace
   - *<channel>* is one of the following values:
     - `v3.23` if you are using IBM Cloud Pak foundational services CD (Continuous Delivery)
     - `v3` if you are using IBM Cloud Pak foundational services LTSR (Long Term Service Release)

   b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

   c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
   If any operators such as `ibm-apiconnect`, `IBM Cloud Pak foundational services`, or `Operand Deployment Lifecycle Manager` show the status of "Upgrade available", approve the upgrade by completing the following steps:

   i. Click Upgrade available.
   ii. Click Preview InstallPlan.
   iii. Click Approve.
   iv. Check the `ibm-common-services` namespace and ensure that all operators with a status of "Upgrade available" are approved.
   v. Wait for the `IBM Cloud Pak foundational services` and `Operand Deployment Lifecycle Manager` operators to install.

10. Install cert manager:
    a. Create a file called cert-manager-operand-request.yaml and paste in the following content:

```
apiVersion: operator.ibm.com/v1alpha1
kind: OperandRequest
metadata:
  name: ibm-apiconnect-cert-manager
  namespace: <namespace>
spec:
  requests:
  - operands:
    - name: ibm-cert-manager-operator
```

```
    registry: common-service
    registryNamespace: ibm-common-services
```

where *<namespace>* is the namespace you created for API Connect.

b. Create the **operandRequest** for cert-manager by running the following command:

```
oc apply -f cert-manager-operand-request.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
Wait for the **ibm-cert-manager-operator** to display and if it shows the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Wait for the **IBM Cert Manager** operator to install.

Next topic: Installing API Connect

Installing API Connect

Use the top-level **APIConnectCluster** CR to install all the API Connect subsystems into a shared namespace on OpenShift while connected to the internet.

Before you begin

Review installation considerations and complete and prerequisite tasks as explained in:

1. Preparing for installation
2. Installing operators

Procedure

1. Install the subsystems by using the OpenShift web console.
API Connect uses a single top-level **APIConnectCluster** CR to quickly deploy all of the subsystems. With the **APIConnectCluster** CR, you provide values for a few properties, and then the installation logic chooses sensible defaults for the other properties during subsystem deployment.

   a. Select Operators->Installed Operators.
   b. Click the IBM API Connect operator.
   c. Click Create Instance on the API Connect cluster tile to install the top-level Custom Resource.
   Selecting API Connect cluster installs all the API Connect subsystems with the default configuration. The API Connect subsystems are Management, Developer Portal, Gateway, and Analytics.

   d. Provide values for the following fields.

Table 1. Properties for the API Connect top-level CR

Input	Value
Name	The name to be used when deploying the **APIConnectCluster** CR.
License acceptance	Required. Click to accept the license. You must accept the license to install API Connect.
License use	Required. Select production or nonproduction to match the type of license that you purchased.
License metric	Optional. Enter the unit of measurement that is used for your program license: • PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used. • MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.
License ID	Required. Select the license ID for the API Connect program that you purchased. To view all license IDs, see API Connect licenses.
Deployment profile	The deployment profile defines the number of worker nodes, CPU, and memory that is available for API Connect. The available profiles are listed in API Connect deployment profiles for OpenShift and Cloud Pak for Integration.
Product version	Optional. The API Connect application version. Defaults to the latest version available.
Default storage class name	The name of the Storage class to be used. You can set a default to appear here with the command: `oc patch storageclass <storage class name> -p '{"metadata": {"annotations": {"storageclass.kubernetes.io/is-default-class":"true"}}}'`

   e. Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, click the YAMLtab and manually add the following annotation to the **metadata** section of the CR:

```
metadata:
  annotations:
    apiconnect-operator/cp4i: "false"
```

   This annotation disables all integration with the Cloud Pak.
   f. If you want to configure additional settings, click Advanced and see API Connect configuration settings for information on the advanced settings.
   Note: You cannot specify more than one host for the **portalUIEndpoint** endpoint, due to a limitation of the Routes in OpenShift. If you require multiple **portalUIEndpoint** hosts to provide public access to multiple catalogs, deploy a new Portal service for each hostname.
2. To verify your API Connect cluster is successfully installed, run **oc get apic -n *<APIC-namespace>***.
3. Verify that you can log in to the API Connect Cloud Manager UI:
   - To determine the location for logging in, view all the endpoints:

```
oc get routes -n <APIC-namespace>
```

- Locate the `mgmt-admin-apic` endpoint, and access the Cloud Manager UI.
- Login as `admin`. When you install with the top-level CR, the password is auto-generated. To get the password:

```
oc get secret -n <APIC-namespace> | grep mgmt-admin-pass

oc get secret -n <APIC-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d && echo ""
```

4. Optional: Configure additional features related to inter-subsystem communication security, such as CA verification and JWT security: Enable additional features post-install.
5. Optional: Increase the timeout settings for management endpoints, particularly for large deployments. See Configuring timeouts for management endpoints.
6. Optional tasks:
   - Download the API Connect toolkit from the Cloud Manager UI or API Manager UI after installation is completed. See Installing the toolkit.
   - Install a test environment. See Testing an API with the Local Test Environment.

   Note: You can also install the Toolkit and Local Test Environment from IBM Fix Central. For a link to the latest files on Fix Central, see What's new in the latest release.

What to do next

Configure backups for all your API Connect subsystems: prepare your deployment for disaster recovery.

Previous topic: Installing operators

Air-gapped installation

In a disconnected environment using Red Hat OpenShift Container Platform (OCP), install API Connect by mirroring product images to a bastion host or a portable device and then completing the installation.

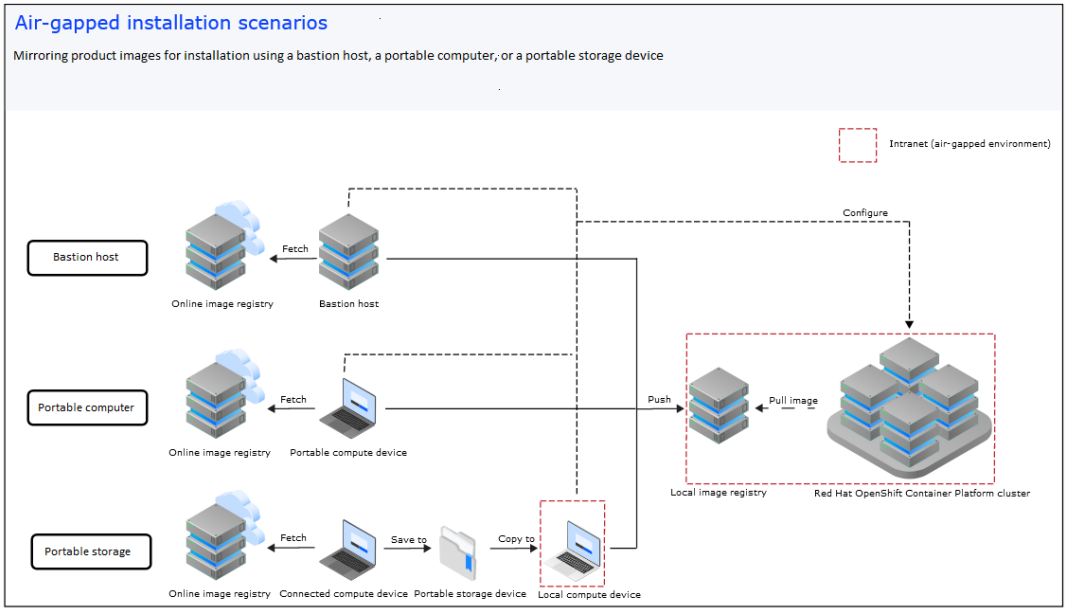
Before you begin

- Mirroring API Connect product images requires the use of IBM Catalog Management Plug-in for IBM Cloud Paks because IBM Cloud Pak CLI (cloudctl) is deprecated. If you still require the use of cloudctl for mirroring product images, see Deprecated: Air-gapped installation using cloudctl.
- An air-gapped installation is not possible in the following environments:
  - Red Hat OpenShift Service on AWS (ROSA)
  - Red Hat OpenShift Service Kubernetes Service on IBM Cloud (ROKS)

About this task

If your cluster is not connected to the internet (it is network-restricted, or air-gapped), you can install API Connect in your cluster by using either a bastion host, a portable computer, or a portable storage device.

The following diagram illustrates how you can mirror product images for an air-gapped installation with a bastion host, a portable computer, or a portable storage device.



All of the scenarios use Container Application Software for Enterprises (CASE) files to mirror content from a source (on the internet) to an intermediary target (a bastion host, a portable computer, or a portable storage device) before pushing them to a local server or device.

Then, you can transfer the files to the local air-gapped network and run the installation.

- **Installing with a bastion host**
  You can use a bastion host to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.

- **Installing with a portable computer or storage device**
  You can use a portable device, such as a portal computer or a USB storage device, to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.

Installing with a bastion host

You can use a bastion host to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.

Before you begin

This task must be performed by a Red Hat OpenShift administrator.

About this task

If your cluster is not connected to the internet, you can mirror product images to a registry in your network-restricted environment by using a bastion host. A bastion host has access to both the public internet and the network-restricted environment where the target clusters reside. You can fetch product images from the internet and push them to a local registry; then you can pull the images from the local registry to the target cluster for installation.

Note: In 10.0.5.3 and later, the API Connect operator is uncoupled from the IBM Cloud Pak foundational services operator. To accommodate the change, you will create environment variables and run commands to download and mirror two CASE files instead of one CASE file as in previous releases.

Procedure

1. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in IBM API Connect Version 10 software product compatibility requirements.
      - Configure storage on the cluster and make sure that it is available.

   b. Prepare the bastion host:
      You must be able to connect your bastion host to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry) at the same time. Your host must be on a Linux x86_64 or Mac platform with any operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

      i. Ensure that the sites and ports listed in Table 1 can be reached from the bastion host:

      Table 1. Sites that must be reached from the bastion host

Site	Description
`icr.io:443`	IBM entitled registry
`quay.io:443`	Local API Connect image repository
`github.com`	CASE files and tools
`redhat.com`	Red Hat OpenShift Container Platform (OCP) upgrades

      ii. On the bastion host, install either Docker or Podman (not both).
      Docker and Podman are used for managing containers; you only need to install one of these applications.

      - To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

        ```
        yum check-update
        yum install docker
        ```

      - To install Podman, see the Podman installation instructions.
        For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

        ```
        yum install podman
        ```

      iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
      The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

      iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
      The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

      ```
      oc ibm-pak --help
      ```

   c. Set up a local image registry and credentials.
      The local Docker registry stores the mirrored images in your network-restricted environment.

      i. Install a registry, or get access to an existing registry.
      You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

      The registry product that you use must meet the following requirements:
      - Supports multi-architecture images through Docker Manifest V2, Schema 2
        For details, see Docker Manifest V2, Schema 2.
      - Is accessible from the Red Hat OpenShift Container Platform cluster nodes
      - Allows path separators in the image name

Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.

ii. Configure the registry to meet the following requirements:
- Supports auto-repository creation
- Has sufficient storage to hold all of the software that is to be transferred
- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials)
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials)

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries during runtime, use an account that can read from the target local registry.

2. Set environment variables and download CASE files.
Because you will use values from two different CASE files, you must create environment variables for both; notice that the variables for the foundational services (common services) CASE file are prefixed with "CS_" to differentiate them.

a. Create the following environment variables with the installer image name and the image inventory on your host:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.0.0
export ARCH=amd64
```

For information on API Connect CASE versions and their corresponding operators and operands, see Operator, operand, and CASE versions.

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

For example, for IBM Cloud Pak foundational services 3.19.X (Long Term Service Release), use version 1.15.10; for foundational services 3.23.X (Continuous Delivery), use version 1.19.2.

For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

b. Connect your host to the internet (it does not need to be connected to the network-restricted environment at this time).

c. Download the CASE file to your host:
Be sure to download both CASE files as shown in the example:

```
oc ibm-pak get $CASE_NAME --version $CASE_VERSION
```

```
oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
```

If you omit the `--version` parameter, the command downloads the latest version.

3. Mirror the images.
The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before installing API Connect.

a. Generate mirror manifests.

i. Define the environment variable $TARGET_REGISTRY by running the following command:

```
export TARGET_REGISTRY=<target-registry>
```

Replace ***<target-registry>*** with the IP address (or host name) and port of the local registry; for example: `172.16.0.10:5000`. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: `172.16.0.10:5000/registry_ns`.

ii. Generate mirror manifests by running the following commands:

```
oc ibm-pak generate mirror-manifests $CASE_NAME --version $CASE_VERSION $TARGET_REGISTRY
```

```
oc ibm-pak generate mirror-manifests $CS_CASE_NAME --version $CS_CASE_VERSION $TARGET_REGISTRY
```

If you need to filter for a specific image group, add the parameter `--filter` ***<image_group>*** to the command.

The `generate` command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION and ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION:
- catalog-sources.yaml
- catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
- image-content-source-policy.yaml
- images-mapping.txt

The files are used when mirroring the images to the `TARGET_REGISTRY`.

b. Obtain an entitlement key for the entitled registry where the images are hosted:

i. Log in to the IBM Container Library.

ii. In the Container software library, select Get entitlement key.

iii. In the "Access your container software" section, click Copy key.

iv. Copy the key to a safe location; you will use it to log in to `cp.icr.io` in the next step.

c. Authenticate with the entitled registry where the images are hosted.
The image pull secret allows you to authenticate with the entitled registry and access product images.

i. Run the following command to export the path to the file that will store the authentication credentials that are generated on a Podman or Docker login:

```
export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
```

The authentication file is typically located at $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

ii. Log in to the `cp.icr.io` registry with Podman or Docker; for example:

```
podman login cp.icr.io
```

Use **cp** as the username and your entitlement key as the password.

d. Authenticate with the local registry.
Log in to the local registry using an account that can write images to that registry; for example:

```
podman login $TARGET_REGISTRY
```

If the registry is insecure, add the following flag to the command: **--tls-verify=false**.

e. Update the CASE manifest to correctly reference the DataPower Operator image.
Files for the DataPower Operator are now hosted on **icr.io**; however, the CASE manifest still refers to **docker.io** as the image host. To work around this issue, visit Airgap install failure due to 'unable to retrieve source image docker.io' in the DataPower documentation and update the manifest as instructed. After the manifest is updated, continue to the next step in this procedure.

f. Mirror the product images.
   i. Connect the bastion host to both the internet and the restricted-network environment that contains the local registry.
   ii. Run the following commands to copy the images to the local registry:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

Note: If the local registry is not secured by TLS, or the certificate presented by the local registry is not trusted by your device, add the **--insecure** option to the command.
There might be a slight delay before you see a response to the command.

g. Configure the target cluster.
Now that images have been mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

   i. Log in to your Red Hat OpenShift Container Platform cluster:

```
oc login <openshift_url> -u <username> -p <password> -n <namespace>
```

   ii. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
   Note: If you have an insecure registry, add the registry to the cluster's **insecureRegistries** list by running the following command:

```
oc edit image.config.openshift.io/cluster -o yaml
```

   and add the TARGET_REGISTRY to **spec.registrySources.insecureRegistries** as shown in the following example:

```
spec:
  registrySources:
    insecureRegistries:
    - insecure0.svc:5001
    - <TARGET_REGISTRY>
```

   If the **insecureRegistries** field does not exist, you can add it.
   iii. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry (run both commands):

```
oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml
```

```
oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
```

   iv. Verify that the ImageContentSourcePolicy resource was created:

```
oc get imageContentSourcePolicy
```

   v. Verify your cluster node status:

```
oc get MachineConfigPool -w
```

   Wait for all nodes to be updated before proceeding to the next step.

4. Apply the catalog sources.
Now that you have mirrored images to the target cluster, apply the catalog sources.

In the following steps, replace **<Architecture>** with either **amd64**, **s390x** or **ppc64le** as appropriate for your environment.

a. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.0.0
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

b. Generate the catalog sources and save them in another directory in case you need to replicate this installation in the future.
   i. Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Get any architecture-specific catalog sources that you need to back up as well:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

c. Apply the catalog sources to the cluster.

i. Apply the universal catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Apply any architecture-specific catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

iii. Confirm that the catalog sources were created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

5. Create the namespace where you will install API Connect.

a. Specify the namespace where you want to install the operator:

```
export NAMESPACE=<APIC-namespace>
```

The namespace where you install API Connect must meet the following requirements:

- Red Hat OpenShift Container Platform (OCP): Only one top-level CR (APIConnectCluster) can be deployed in each namespace.
- Cloud Pak for Integration: Only one API Connect capability can be deployed in each namespace.
- The following namespaces cannot be used to install API Connect because Red Hat OpenShift Container Platform (OCP) restricts the use of default namespaces for installing non-cluster services:
  - `default`
  - `kube-system`
  - `kube-public`
  - `openshift-node`
  - `openshift-infra`
  - `openshift`

b. Create a new namespace for installing the operator:

```
oc new-project $NAMESPACE
```

c. Create an `OperatorGroup`:

i. Create a YAML file called apiconnect-operator-group.yaml similar to the following example, replacing `<APIC-namespace>` with your new namespace:

```
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: ibm-apiconnect-operatorgroup
spec:
  targetNamespaces:
  - <APIC-namespace>
```

ii. Add the new operator group to your namespace:

```
oc apply -f apiconnect-operator-group.yaml -n ${NAMESPACE}
```

6. (10.0.5.3 and later) Create the `ibm-common-services-operator` subscription, if it does not already exist.
This step only applies when you install version 10.0.5.3 or later. If you are installing an older version of API Connect, skip this step.

The `ibm-common-services-operator` is provided by IBM Cloud Pak foundational services.

a. Create a file called common-services-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-common-service-operator
  namespace: <APIC-namespace>
spec:
  channel: <channel>
  installPlanApproval: Automatic
  name: ibm-common-service-operator
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

Where:

- `<APIC-namespace>` the namespace where you will install API Connect.
- `<channel>` is one of the following values:
  - `v3.23` if you are using IBM Cloud Pak foundational services for Continuous Delivery
  - `v3` if you are using IBM Cloud Pak foundational services for Long Term Service Release

b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.

If any operators such as **ibm-apiconnect** or **ibm-cert-manager-operator** show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the **ibm-common-services** namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the **IBM Cloud Pak foundational services**, **IBM NamespaceScope**, and **Operand Deployment Lifecycle Manager** operators to install.

7. (10.0.5.3 and later) Install cert manager:
This step only applies when you install version 10.0.5.3 or later. If you are installing an older version of API Connect, skip this step.

a. Create a file called cert-manager-operand-request.yaml and paste in the following content:

```
apiVersion: operator.ibm.com/v1alpha1
kind: OperandRequest
metadata:
  name: ibm-apiconnect-cert-manager
  namespace: <namespace>
spec:
  requests:
  - operands:
    - name: ibm-cert-manager-operator
    registry: common-service
    registryNamespace: ibm-common-services
```

where *<namespace>* is the namespace you created for API Connect.

b. Create the **operandRequest** for cert-manager by running the following command:

```
oc apply -f cert-manager-operand-request.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
Wait for the **ibm-cert-manager-operator** to display and if it shows the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Wait for the **IBM Cert Manager** operator to install.

8. Create a **Subscription** for the **IBM APIConnect** operator.

a. Create a YAML file called apic-sub.yaml similar to the following example:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-apiconnect
spec:
  channel: v5.0
  name: ibm-apiconnect
  source: ibm-apiconnect-catalog
  sourceNamespace: openshift-marketplace
```

b. Apply the new subscription to your namespace:

```
oc apply -f apic-sub.yaml -n ${NAMESPACE}
```

9. Install API Connect (the operand).
API Connect provides one top-level CR that includes all of the API Connect subsystems (Management, Developer Portal, Analytics, and Gateway).

a. Create a YAML file to use for deploying the top-level **APIConnectCluster** CR. Use the template that applies to your deployment (non-production or production).
Note: The values shown in the following examples might not be suitable for your deployment. For information on the license, profile, and version settings, as well as additional configuration settings, see API Connect configuration settings.

- Example CR settings for a one replica deployment:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-minimum
  name: <name_of_your_instance>
  namespace: <APIC-namespace>
spec:
  license:
    accept: true
    license: L-KZXM-S7SNCU
    metric: PROCESSOR_VALUE_UNIT
    use: nonproduction
  profile: n1xc17.m48
  version: 10.0.6.0
  storageClassName: <default-storage-class>
```

- Example CR settings for a three replica deployment:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
```

```
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-production
  name: <name_of_your_instance>
  namespace: <APIC-namespace>
spec:
  license:
    accept: true
    license: L-KZXM-S7SNCU
    metric: PROCESSOR_VALUE_UNIT
    use: production
  profile: n3xc16.m48
  version: 10.0.6.0
  storageClassName: <default-storage-class>
```

b. Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, add the following annotation to the **metadata** section of the CR:

```
metadata:
  annotations:
    apiconnect-operator/cp4i: "false"
```

This annotation disables all integration with the Cloud Pak.

c. Apply the YAML file:

```
oc apply -f <your_yaml_file>
```

d. To verify your API Connect cluster is successfully installed, run the following command:

```
oc get apic -n <APIC-namespace>
```

e. Verify that you can log in to the API Connect Cloud Manager UI:
To determine the location for logging in, view all the endpoints:

```
oc get routes -n <APIC-namespace>
```

f. Locate the **mgmt-admin-apic** endpoint, and access the Cloud Manager UI.
g. Login as the API Connect administrator.
When you install with the top-level CR, the password is auto-generated. To get the password:

```
oc get secret -n <APIC-namespace> | grep mgmt-admin-pass
oc get secret -n <APIC-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d &&
echo
```

10. Optional: Increase the timeout settings for the API Connect management endpoints, particularly for large deployments. See Configuring timeouts for management endpoints.

What to do next

When you finish installing API Connect, prepare your deployment for disaster recovery so that your data can be restored in the event of an emergency.

Installing with a portable computer or storage device

You can use a portable device, such as a portal computer or a USB storage device, to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.

Before you begin

This task must be performed by a Red Hat OpenShift administrator.

About this task

If your cluster is not connected to the internet, you can mirror product images to a registry in your network-restricted environment by using a portable device. You can download images from the public registries on the internet to the portable device; then you can bring that portable device into the network-restricted environment (or transfer the files to a different device within the network-restricted environment) and mirror the images to the local registry. You can pull the images from the local registry to the target cluster for installation.

Note: In 10.0.5.3 and later, the API Connect operator is uncoupled from the IBM Cloud Pak foundational services operator. To accommodate the change, you will create environment variables and run commands to download and mirror two CASE files instead of one CASE file as in previous releases.

Procedure

1. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in IBM API Connect Version 10 software product compatibility requirements.
      - Configure storage on the cluster and make sure that it is available.
   b. Prepare the portable device:

You must be able to connect your portable device to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry). The portable device must be on a Linux x86_64 or Mac platform with any operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

i. Ensure that the portable device has sufficient storage to hold all of the software that is to be transferred to the local registry.
ii. On the portable device, install either Docker or Podman (not both).
Docker and Podman are used for managing containers; you only need to install one of these applications.

- To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

```
yum check-update
yum install docker
```

- To install Podman, see the Podman installation instructions.
For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

```
yum install podman
```

iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

```
oc ibm-pak --help
```

c. Set up a local image registry and credentials.
The local Docker registry stores the mirrored images in your network-restricted environment.

i. Install a registry, or get access to an existing registry.
You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

The registry product that you use must meet the following requirements:
- Supports multi-architecture images through Docker Manifest V2, Schema 2
For details, see Docker Manifest V2, Schema 2.
- Is accessible from the Red Hat OpenShift Container Platform cluster nodes
- Allows path separators in the image name

Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.
ii. Configure the registry to meet the following requirements:
- Supports auto-repository creation
- Has sufficient storage to hold all of the software that is to be transferred
- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials)
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials)

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries during runtime, use an account that can read from the target local registry.

2. Set environment variables and download CASE files.
Create environment variables to use while mirroring images, connect to the internet, and download the API Connect CASE files.

a. Create the following environment variables with the installer image name and the image inventory on your portable device:
Because you will use values from two different CASE files, you must create environment variables for both; notice that the variables for the foundational services (common services) CASE file are prefixed with "CS_" to differentiate them.

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.0.0
export ARCH=amd64
```

For information on API Connect CASE versions and their corresponding operators and operands, see Operator, operand, and CASE versions.

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

For example, for IBM Cloud Pak foundational services 3.19.X (Long Term Service Release), use version 1.15.10; for foundational services 3.23.X (Continuous Delivery), use version 1.19.2.

For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

b. Connect your portable device to the internet (it does not need to be connected to the network-restricted environment at this time).
c. Download the CASE files to your portable device:
Be sure to download both CASE files as shown in the example:

```
oc ibm-pak get $CASE_NAME --version $CASE_VERSION
```

```
oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
```

If you omit the `--version` parameter, the command downloads the latest version.

3. Mirror the images.
The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before installing API Connect.

a. Generate mirror manifests.

i. Define the environment variable $TARGET_REGISTRY by running the following command:

```
export TARGET_REGISTRY=<target-registry>
```

Replace **<target-registry>** with the IP address (or host name) and port of the local registry; for example: **172.16.0.10:5000**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **172.16.0.10:5000/registry_ns**.

ii. Generate mirror manifests by running the following commands:

```
oc ibm-pak generate mirror-manifests $CASE_NAME file://integration --version $CASE_VERSION --final-registry $TARGET_REGISTRY
```

```
oc ibm-pak generate mirror-manifests $CS_CASE_NAME file://integration --version $CS_CASE_VERSION --final-registry $TARGET_REGISTRY
```

If you need to filter for a specific image group, add the parameter **--filter <image_group>** to the command.

The **generate** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION and ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION:

- catalog-sources.yaml
- catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
- image-content-source-policy.yaml
- images-mapping-to-filesystem.txt
- images-mapping-from-filesystem.txt

The files are used when mirroring the images to the **TARGET_REGISTRY**.

b. Obtain an entitlement key for the entitled registry where the images are hosted:
   i. Log in to the IBM Container Library.
   ii. In the Container software library, select Get entitlement key.
   iii. In the "Access your container software" section, click Copy key.
   iv. Copy the key to a safe location; you will use it to log in to **cp.icr.io** in the next step.

c. Authenticate with the entitled registry where the images are hosted.
The image pull secret allows you to authenticate with the entitled registry and access product images.

   i. Run the following command to export the path to the file that will store the authentication credentials that are generated on a Podman or Docker login:

```
export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
```

The authentication file is typically located at $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

   ii. Log in to the **cp.icr.io** registry with Podman or Docker; for example:

```
podman login cp.icr.io
```

Use **cp** as the username and your entitlement key as the password.

d. Update the API Connect CASE manifest to correctly reference the DataPower Operator image.
Files for the DataPower Operator are now hosted on **icr.io**; however, the CASE manifest still refers to **docker.io** as the image host. To work around this issue, visit Airgap install failure due to 'unable to retrieve source image docker.io' in the DataPower documentation and update the manifest as instructed.
The manifest for API Connect (which uses the DataPower Operator) is stored in ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION.

After the manifest is updated, continue to the next step in this procedure.

e. Mirror the images from the internet to the portable device.
   i. Define the environment variable $IMAGE_PATH by running the following command:

```
export IMAGE_PATH=<image-path>
```

where **<image-path>** indicates where the files will be stored on the portable device's file system.

   ii. Mirror the images to the portable device:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

There might be a slight delay before you see a response to the command.

f. Move the portable device to the restricted-network environment.
The procedure depends on the type of device that you are using:
If you are using a portable computer, disconnect the device from the internet and connect it to the restricted-network environment. The same environment variables can be used.

If you are using portable storage, complete the following steps:
   i. Transfer the following files to a device in the restricted-network environment:
      - The **~/.ibm-pak** directory.
      - The contents of the **<image-path>** that you specified in the previous step.
   ii. Create the same environment variables as on the original device; for example:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.0.0
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64

export REGISTRY_AUTH_FILE=$HOME/.docker/config.json

export IMAGE_PATH=<image-path>
```

g. Authenticate with the local registry.
Log in to the local registry using an account that can write images to that registry; for example:

```
podman login $TARGET_REGISTRY
```

If the registry is insecure, add the following flag to the command: `--tls-verify=false`.

h. Mirror the product images to the target registry.

i. If you are using a portable computer, connect it to the restricted-network environment that contains the local registry.
If you are using portable storage, you already transferred files to a device within the restricted-network environment.

ii. Run the following commands to copy the images to the local registry:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"

oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

Note: If the local registry is not secured by TLS, or the certificate presented by the local registry is not trusted by your device, add the `--insecure` option to the command.
There might be a slight delay before you see a response to the command.

i. Configure the target cluster.
Now that images have been mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

i. Log in to your Red Hat OpenShift Container Platform cluster:

```
oc login <openshift_url> -u <username> -p <password> -n <namespace>
```

ii. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
Note: If you have an insecure registry, add the registry to the cluster's `insecureRegistries` list by running the following command:

```
oc edit image.config.openshift.io/cluster -o yaml
```

and add the TARGET_REGISTRY to `spec.registrySources.insecureRegistries` as shown in the following example:

```
spec:
  registrySources:
    insecureRegistries:
    - insecure0.svc:5001
    - <TARGET_REGISTRY>
```

If the `insecureRegistries` field does not exist, you can add it.

iii. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry (run both commands):

```
oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml

oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
```

iv. Verify that each ImageContentSourcePolicy resource was created:

```
oc get imageContentSourcePolicy
```

v. Verify your cluster node status:

```
oc get MachineConfigPool -w
```

Wait for all nodes to be updated before proceeding to the next step.

4. Apply the catalog sources.
Now that you have mirrored images to the target cluster, apply the catalog sources.

In the following steps, replace `<Architecture>` with either `amd64`, `s390x` or `ppc64le` as appropriate for your environment.

a. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.0.0
export ARCH=amd64
```

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

b. Generate the catalog sources and save them in another directory in case you need to replicate this installation in the future.

i. Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

```
cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Get any architecture-specific catalog sources that you need to back up as well:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

c. Apply the catalog sources to the cluster.

i. Apply the universal catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

```
oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Apply any architecture-specific catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

iii. Confirm that the catalog sources were created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

5. Create the namespace where you will install API Connect.

a. Specify the namespace where you want to install the operator:

```
export NAMESPACE=<APIC-namespace>
```

The namespace where you install API Connect must meet the following requirements:

- Red Hat OpenShift Container Platform (OCP): Only one top-level CR (APIConnectCluster) can be deployed in each namespace.
- Cloud Pak for Integration: Only one API Connect capability can be deployed in each namespace.
- The following namespaces cannot be used to install API Connect because Red Hat OpenShift Container Platform (OCP) restricts the use of default namespaces for installing non-cluster services:
  - `default`
  - `kube-system`
  - `kube-public`
  - `openshift-node`
  - `openshift-infra`
  - `openshift`

b. Create a new namespace for installing the operator:

```
oc new-project $NAMESPACE
```

c. Create an `OperatorGroup`:

i. Create a YAML file called apiconnect-operator-group.yaml similar to the following example, replacing `<APIC-namespace>` with your new namespace:

```
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: ibm-apiconnect-operatorgroup
spec:
  targetNamespaces:
  - <APIC-namespace>
```

ii. Add the new operator group to your namespace:

```
oc apply -f apiconnect-operator-group.yaml -n ${NAMESPACE}
```

6. (10.0.5.3 and later) Create the `ibm-common-services-operator` subscription, if it does not already exist.
This step only applies when you install version 10.0.5.3 or later. If you are installing an older version of API Connect, skip this step.

The `ibm-common-services-operator` is provided by IBM Cloud Pak foundational services.

a. Create a file called common-services-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-common-service-operator
  namespace: <APIC-namespace>
spec:
  channel: <channel>
  installPlanApproval: Automatic
  name: ibm-common-service-operator
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

Where:

- `<APIC-namespace>` the namespace where you will install API Connect.
- `<channel>` is one of the following values:
  - `v3.23` if you are using IBM Cloud Pak foundational services for Continuous Delivery

- `v3` if you are using IBM Cloud Pak foundational services for Long Term Service Release

b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as `ibm-apiconnect` or `ibm-cert-manager-operator` show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the `ibm-common-services` namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the `IBM Cloud Pak foundational services`, `IBM NamespaceScope`, and `Operand Deployment Lifecycle Manager` operators to install.

7. (10.0.5.3 and later) Install cert manager:
This step only applies when you install version 10.0.5.3 or later. If you are installing an older version of API Connect, skip this step.

a. Create a file called cert-manager-operand-request.yaml and paste in the following content:

```
apiVersion: operator.ibm.com/v1alpha1
kind: OperandRequest
metadata:
  name: ibm-apiconnect-cert-manager
  namespace: <namespace>
spec:
  requests:
  - operands:
    - name: ibm-cert-manager-operator
    registry: common-service
    registryNamespace: ibm-common-services
```

where *<namespace>* is the namespace you created for API Connect.

b. Create the `operandRequest` for cert-manager by running the following command:

```
oc apply -f cert-manager-operand-request.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
Wait for the `ibm-cert-manager-operator` to display and if it shows the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Wait for the `IBM Cert Manager` operator to install.

8. Create a `Subscription` for the `IBM APIConnect` operator.

a. Create a YAML file called apic-sub.yaml similar to the following example:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-apiconnect
spec:
  channel: v5.0
  name: ibm-apiconnect
  source: ibm-apiconnect-catalog
  sourceNamespace: openshift-marketplace
```

b. Apply the new subscription to your namespace:

```
oc apply -f apic-sub.yaml -n ${NAMESPACE}
```

9. Install API Connect (the operand).
API Connect provides one top-level CR that includes all of the API Connect subsystems (Management, Developer Portal, Analytics, and Gateway).

a. Create a YAML file to use for deploying the top-level `APIConnectCluster` CR. Use the template that applies to your deployment (non-production or production).
Note: The values shown in the following examples might not be suitable for your deployment. For information on the license, profile, and version settings, as well as additional configuration settings, see API Connect configuration settings.

- Example CR settings for a one replica deployment:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-minimum
  name: <name_of_your_instance>
  namespace: <APIC-namespace>
spec:
  license:
    accept: true
    license: L-KZXM-S7SNCU
    metric: PROCESSOR_VALUE_UNIT
    use: nonproduction
  profile: n1xc17.m48
  version: 10.0.6.0
  storageClassName: <default-storage-class>
```

- Example CR settings for a three replica deployment:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-production
  name: <name_of_your_instance>
  namespace: <APIC-namespace>
spec:
  license:
    accept: true
    license: L-KZXM-S7SNCU
    metric: PROCESSOR_VALUE_UNIT
    use: production
  profile: n3xc16.m48
  version: 10.0.6.0
  storageClassName: <default-storage-class>
```

b. Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, add the following annotation to the `metadata` section of the CR:

```
metadata:
  annotations:
    apiconnect-operator/cp4i: "false"
```

This annotation disables all integration with the Cloud Pak.

c. Apply the YAML file:

```
oc apply -f <your_yaml_file>
```

d. To verify your API Connect cluster is successfully installed, run the following command:

```
oc get apic -n <APIC-namespace>
```

e. Verify that you can log in to the API Connect Cloud Manager UI:
To determine the location for logging in, view all the endpoints:

```
oc get routes -n <APIC-namespace>
```

f. Locate the `mgmt-admin-apic` endpoint, and access the Cloud Manager UI.
g. Login as the API Connect administrator.
When you install with the top-level CR, the password is auto-generated. To get the password:

```
oc get secret -n <APIC-namespace> | grep mgmt-admin-pass
oc get secret -n <APIC-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d &&
echo
```

10. Optional: Increase the timeout settings for the API Connect management endpoints, particularly for large deployments. See Configuring timeouts for management endpoints.

What to do next

When you finish installing API Connect, prepare your deployment for disaster recovery so that your data can be restored in the event of an emergency.

Enable additional features post-install

After installing API Connect, you can enable additional features that are related to inter-subsystem communication.

- **Enable management CA verification on REST API calls**
  Enable the portal and gateway to validate the management subsystem's REST API server certificates.
- **Enable JWT security and disable mTLS between subsystems**
  Postinstallation steps to enable JWT security and disable mTLS between subsystems.

Enable management CA verification on REST API calls

Enable the portal and gateway to validate the management subsystem's REST API server certificates.

About this task

After you install API Connect, you can enable the portal and gateway to verify the REST API server certificate when they make calls to the REST API. The gateway and portal subsystems make calls to the management subsystem REST API during their normal operations. The gateway makes calls to the platform REST API, and the portal makes calls to the platform REST API and the consumer REST API. To verify the CA certificates of the REST API endpoints, enter the secret names of the CA certificates into the portal and gateway subsystem sections of the top-level CR.
Note:
If you are not sure of the secret names, follow these steps to determine their names:

1. Check the management subsystem CR with `oc describe mgmt`, and identify the issuer of the platform and consumer API endpoints:

```
oc describe mgmt -n <namespace>

...
Platform API Endpoint:
    Annotations:
      cert-manager.io/issuer:               <instance name>-ingress-issuer
...
  Consumer API Endpoint:
    Annotations:
      cert-manager.io/issuer:               <instance name>-ingress-issuer
```

2. Describe the issuer with `oc describe issuer`, and identify the secret name:

```
oc describe issuer <instance name>-ingress-issuer -n <namespace>
...
Spec:
  Ca:
    Secret Name:  <instance name>-ingress-ca
...
```

Note: If you are using `in-cluster` communication (see In-cluster service communication between subsystems), then the portal and gateway make REST calls on the service endpoints, instead of the `external` endpoints. In the steps documented in this topic, replace `mgmtPlatformEndpointCASecret` with `mgmtPlatformEndpointSvcCASecret`, and `mgmtConsumerEndpointCASecret` with `mgmtConsumerEndpointSvcCASecret`. For `secretName`, the default for the service endpoints is `mgmt-ca` or `<apic instance name>-mgmt-ca`.

Procedure

1. Edit the top-level CR, `apiconnectcluster`:

```
oc edit apiconnectcluster -n <namesapce>
```

2. In the `spec:` section, insert a portal section with the CA secret names for the platform and consumer REST APIs:

```
spec:
...
  portal:
    mgmtPlatformEndpointCASecret:
      secretName: <instance name>-ingress-ca
    mgmtConsumerEndpointCASecret:
      secretName: <instance name>-ingress-ca
```

Note: If the portal section already exists, insert the `mgmtPlatformEndpointCASecret` and `mgmtConsumerEndpointCASecret` sections inside it.

3. In the `spec:` section, insert a gateway section with the CA secret name for the platform REST API:

```
spec:
...
  gateway:
    mgmtPlatformEndpointCASecret:
      secretName: <instance name>-ingress-ca
```

Note: If the gateway section already exists, insert the `mgmtPlatformEndpointCASecret` section inside it.

4. Check the contents of the `ptl` and `gw` CRs to confirm that the change is applied.

```
oc get ptl -o yaml -n <namesapce>

...
    mgmtPlatformEndpointCASecret:
      secretName: <instance name>-ingress-ca
    mgmtConsumerEndpointCASecret:
      secretName: <instance name>-ingress-ca
...

oc get gw -o yaml -n <namesapce>

...
    mgmtPlatformEndpointCASecret:
      secretName: <instance name>-ingress-ca
...
```

Enable JWT security and disable mTLS between subsystems

Postinstallation steps to enable JWT security and disable mTLS between subsystems.

About this task

JWT security is an alternative to using mTLS to secure inter-subsystem communication. For more information on JWT security and when to use it, see: Enable JWT security instead of mTLS.

If you disable mTLS then you must enable JWT.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow. This flow is secured by mTLS, which cannot be disabled.

Procedure

1. Describe the `apiconnectlcuster` CR to get the JWKS URL:

```
oc describe apiconnectlcuster -n <namespace>

status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

2. For each portal, gateway, and analytics subsystem where you want to use JWT security, edit the section of the top-level CR corresponding to that subsystem, and add the following:

```
spec:
  <subsystem>
    mtlsValidateClient: false
    jwksUrl: <JWKS URL>
```

where
- *<subsystem>* is either **portal**, **analytics**, or **gateway**, depending on which subsystem you want to use JWT security with. If this subsystem section does not already exist in the top-level CR, then add it as shown above.
- *<JWKS URL>* is the URL identified in step 1.

3. Enable JWT on the gateway to analytics communications flow. Enable the Use JWT switch for the registered gateway in the Topology page of the Cloud Manager UI.

Installing with subsystem CRs in a shared namespace on OpenShift

Use the individual subsystem CRs to install API Connect subsystems in a shared namespace on OpenShift.

About this task

API Connect subsystems can be installed by creating individual subsystem CRs in the same shared namespace, instead of using a top-level CR. If you want to install your API Connect subsystems in different namespaces, for example Management server in a namespace that is called **mgmt**, and gateway in a namespace that is called **gway**, then see: Installing with subsystem CRs in different namespaces or environments on OpenShift.

Attention: If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.

1. Installing operators
   Install operators for API Connect, DataPower, and common services so that you can deploy the API Connect subsystems in a shared namespace on OpenShift.
2. Setting up a certificate issuer
   Create the cert-manager issuer for generating the certificates and secrets for use with API Connect.
3. Installing the Management subsystem in a shared namespace
   Install the Management subsystem by creating and applying the mgmt_cr.yaml file.
4. Installing the Gateway subsystem in a shared namespace
   Install the Gateway subsystem by creating and applying the apigateway_cr.yaml file.
5. Installing the Portal subsystem in a shared namespace
   Install the Portal subsystem by creating and applying the portal_cr.yaml file.
6. Installing the Analytics subsystem in a shared namespace
   Install the analytics subsystem by creating and applying the analytics_cr.yaml file.

Installing operators

Install operators for API Connect, DataPower, and common services so that you can deploy the API Connect subsystems in a shared namespace on OpenShift.

Before you begin

The API Connect operator and operand must be from the same release and fix pack level. Table 1 lists the current version of the operator and operand for API Connect.

Table 1. API Connect operator and operand versions

API Connect (operand)	Operator channel version	Highest operator version
10.0.6.0	v5.0	5.0.0

Note: There can be only one instance of the API Connect operator in your OpenShift environment. You cannot have multiple namespaces each with their own API Connect operator.
You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

Procedure

1. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
   The **ibm-pak** plug-in enables you to access hosted product images, and to run **oc ibm-pak** commands against the cluster. To confirm that **ibm-pak** is installed, run the following command and verify that the response lists the command usage:

```
oc ibm-pak --help
```

2. Obtain an entitlement key for the Entitled Registry:
   a. Log in to the IBM Container Library.
   b. In the Container software library, select Get entitlement key.
   c. After the Access your container software heading, click Copy key.
   d. Copy the key to a safe location.

3. Create the namespace where API Connect will be installed, either by selecting Home > Projects > Create Project in the UI, or with the following command:

   ```
   oc create ns <APIC-namespace>
   ```

   The namespace where you install API Connect must meet the following requirements:
   - Red Hat OpenShift: Only one top-level CR (`APIConnectCluster`) can be deployed in each namespace.
   - Cloud Pak for Integration: Only one API Connect capability can be deployed in each namespace.
   - Red Hat OpenShift restricts the use of default namespaces for installing non-cluster services. The following namespaces cannot be used to install API Connect:
     - `default`
     - `kube-system`
     - `kube-public`
     - `openshift-node`
     - `openshift-infra`
     - `openshift`
4. If you are installing the operator into a single namespace, create an OperatorGroup object specifying that namespace.
   Attention: If you are installing the operator into all namespaces, skip this step because the `openshift-operators` namespace already has an appropriate Operator group in place.
   a. Create the apiconnect-operator-group.yaml file with an OperatorGroup object that identifies the namespace in which RBAC permissions for the IBM API Connect Operator will be generated, and where the CSV will be available:

      ```
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: <operator-group-name>
        namespace: <APIC-namespace>
      spec:
        targetNamespaces:
        - <APIC-namespace>
      ```

   b. Apply the OperatorGroup object with the following command:

      ```
      oc apply -f apiconnect-operator-group.yaml
      ```

5. Create a pull secret in the namespaces where you want to install API Connect.
   a. Open the Red Hat OpenShift web console, click Workloads > Secrets.
   b. Ensure that the Project is set to the namespace where you intend to install API Connect.
   c. Click Create and select Image pull secret.
   d. Set the following parameters for the secret:
      - Set Secret name to `ibm-entitlement-key`.
      - Set Authentication type to `Image registry credentials`.
      - Set Registry server address to `cp.icr.io`.
      - Set Username to `cp`.
      - Set Password to the entitlement key generated in Step 1.
      - Click Create to create the secret.

   Note: If your Red Hat OpenShift platform is Red Hat OpenShift on IBM Cloud (ROKS), you might need to reload your worker nodes after the image pull secret is created. You can reload the worker nodes either from the Red Hat OpenShift web console or from the command line with: `ibmcloud oc worker reload`. For information on using the `reload` command, see the Red Hat OpenShift on IBM Cloud documentation.
6. Add the API Connect catalog sources to your cluster.
   Adding catalog sources to your Red Hat OpenShift cluster adds the IBM operators to the list of operators you can install. For most connected and air-gapped clusters, applying individual catalog sources is the most effective way to fully control software versioning on the cluster.

   a. Generate the catalog source files:
      i. Log into your cluster using the `oc login` command and your user credentials:

         ```
         oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
         ```

      ii. Export the variables for the command line to use:

         ```
         export CASE_NAME=ibm-apiconnect
         export CASE_VERSION=5.0.0
         export ARCH=amd64
         ```

         For information on API Connect CASE versions and their corresponding operators and operands, see Operator, operand, and CASE versions.

      iii. Download the files for the operators required by API Connect:

         ```
         oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
         ```

      iv. Generate the catalog sources for API Connect:

         ```
         oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
         ```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
         Get the catalog sources (run both commands):

         ```
         cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

         cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
         ```

   b. Apply the catalog sources:
      i. Apply the catalog sources (run both commands):

         ```
         oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

         oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
         ```

      ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

7. Add the IBM Cloud Pak foundational services (common services) catalog sources to your cluster.
   a. Generate the catalog source files:
      i. Log into your cluster using the `oc login` command and your user credentials:

      ```
      oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
      ```

      ii. Export the variables for the command line to use; substituting the appropriate version for the CASE:

      ```
      export CASE_NAME=ibm-cp-common-services
      export CASE_VERSION=1.15.10
      export ARCH=amd64
      ```

      For example, for IBM Cloud Pak foundational services 3.19.X (Long Term Service Release), use version 1.15.10; for foundational services 3.23.X (Continuous Delivery), use version 1.19.2.

      For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

      iii. Download the files for the operators required by IBM Cloud Pak foundational services (common services):

      ```
      oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
      ```

      iv. Generate the catalog sources:

      ```
      oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
      ```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources:

      ```
      cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      This command might not return anything if there are no architecture-specific catalog sources.

   b. Apply the catalog sources:
      i. Apply the catalog sources:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

      ```
      oc get catalogsource -n openshift-marketplace
      ```

8. Create the `apiconnect` subscription.
   a. Create the `apiconnect` subscription with the appropriate channel by creating a file called `apic-sub.yaml` and pasting in the following contents, updating the namespace as required:

   ```
   apiVersion: operators.coreos.com/v1alpha1
   kind: Subscription
   metadata:
     name: ibm-apiconnect
     namespace: <namespace>
   spec:
     channel: v5.0
     name: ibm-apiconnect
     source: ibm-apiconnect-catalog
     sourceNamespace: openshift-marketplace
   ```

   Where `<namespace>` is one of the following values:
   - `openshift-operators` if you are installing the operator in all namespaces
   - The namespace created in step 3 if you are installing the operator in a single namespace

   b. Apply the subscription with the following command:

   ```
   oc apply -f apic-sub.yaml
   ```

   c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
   If any operators such as `ibm-apiconnect` or `IBM DataPower Gateway` show the status of "Upgrade available", approve the upgrade by completing the following steps:

      i. Click Upgrade available.
      ii. Click Preview InstallPlan.
      iii. Click Approve.
      iv. Wait for the `IBM API Connect` and `IBM DataPower Gateway` operators to install.

   The `IBM DataPower Gateway` operator is a prerequisite to API Connect and must not be removed.

9. Create the `ibm-common-services-operator` subscription, if it does not already exist.
   a. Create a file called common-services-sub.yaml and paste in the following contents:

   ```
   apiVersion: operators.coreos.com/v1alpha1
   kind: Subscription
   metadata:
     name: ibm-common-service-operator
     namespace: <namespace>
   spec:
     channel: <channel>
     name: ibm-common-service-operator
     source: opencloud-operators
     sourceNamespace: openshift-marketplace
   ```

   Where:

- `<namespace>` is one of the following values:
  - `openshift-operators` if you are installing the operator in all namespaces
  - The namespace created in step 3 if you are installing the operator in a single namespace
- `<channel>` is one of the following values:
  - `v3.23` if you are using IBM Cloud Pak foundational services CD (Continuous Delivery)
  - `v3` if you are using IBM Cloud Pak foundational services LTSR (Long Term Service Release)

b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as `ibm-apiconnect`, `IBM Cloud Pak foundational services`, or `Operand Deployment Lifecycle Manager` show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the `ibm-common-services` namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the `IBM Cloud Pak foundational services` and `Operand Deployment Lifecycle Manager` operators to install.

10. Install cert manager:

a. Create a file called cert-manager-operand-request.yaml and paste in the following content:

```
apiVersion: operator.ibm.com/v1alpha1
kind: OperandRequest
metadata:
  name: ibm-apiconnect-cert-manager
  namespace: <namespace>
spec:
  requests:
  - operands:
    - name: ibm-cert-manager-operator
    registry: common-service
    registryNamespace: ibm-common-services
```

where *<namespace>* is the namespace you created for API Connect.

b. Create the `operandRequest` for cert-manager by running the following command:

```
oc apply -f cert-manager-operand-request.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
Wait for the `ibm-cert-manager-operator` to display and if it shows the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Wait for the `IBM Cert Manager` operator to install.

Next topic: Setting up a certificate issuer

Setting up a certificate issuer

Create the cert-manager issuer for generating the certificates and secrets for use with API Connect.

Before you begin

To deploy API Connect, you must first create the cert-manager issuers and certificates that API Connect uses. On OpenShift cert-manager is bundled as a foundational service, so you do not need to install cert-manager itself. For more information on cert-manager: Key Concepts: Cert-manager, Issuers, and Secrets

Procedure

1. Create a file that is called `ingress-issuer-v1.yaml` and paste in the following contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

    - cert-manager
  commonName: gateway-peering
  secretName: gateway-peering
```

```
  issuerRef:
    name: ingress-issuer
  usages:
  - "server auth"
  - "client auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
  secretTemplate:
    labels:
      app.kubernetes.io/instance: "gatewaycluster"
      app.kubernetes.io/managed-by: "ibm-apiconnect"
      app.kubernetes.io/name: "gateway-peering"
```

2. Apply the file to your namespace with `oc apply -f ingress-issuer-v1.yaml -n <apic_namespace>`
3. Verify that the command installation succeeded by running the following command:

   ```
   oc get certificates -n <apic_namespace>
   ```

   All certificates created successfully:

   ```
   NAME                           READY   SECRET                         AGE
   analytics-ingestion-client     True    analytics-ingestion-client     70s
   gateway-peering                True    gateway-peering                69s
   gateway-service                True    gateway-service                69s
   ingress-ca                     True    ingress-ca                     71s
   portal-admin-client            True    portal-admin-client            71s
   ```

Previous topic: Installing operators
Next topic: Installing the Management subsystem in a shared namespace

Installing the Management subsystem in a shared namespace

Install the Management subsystem by creating and applying the mgmt_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Use the OpenShift CLI to edit the custom resource template for the Management subsystem then apply the resource. Verify that the pods are up and running, and validate that you can connect to the API Connect Cloud Manager.

Procedure

1. Create a file that is called `mgmt_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementCluster
metadata:
  name: management
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "management"
  }
spec:
  version: $APP_PRODUCT_VERSION
  profile: $PROFILE
  portal:
    admin:
      secretName: portal-admin-client
```

```
  analytics:
    ingestion:
      secretName: analytics-ingestion-client
  gateway:
    client:
      secretName: gateway-client-client
  cloudManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: admin.$STACK_HOST
      secretName: cm-endpoint
  apiManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: manager.$STACK_HOST
      secretName: apim-endpoint
  platformAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: api.$STACK_HOST
      secretName: api-endpoint
  consumerAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: consumer.$STACK_HOST
      secretName: consumer-endpoint
  databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the YAML file and replace the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.6.0

$PROFILE
Specify your Management subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
cloudManagerEndpoint:
      < ... >
    hosts:
    - name: admin.myhost.subnet.example.com
      secret: cm-endpoint

  apiManagerEndpoint:
      < ... >
    hosts:
    - name: manager.myhost.subnet.example.com
      secret: apim-endpoint

  platformAPIEndpoint:
      < ... >
    hosts:
    - name: api.myhost.subnet.example.com
      secret: api-endpoint

  consumerAPIEndpoint:
      < ... >
    hosts:
    - name: consumer.myhost.subnet.example.com
      secret: consumer-endpoint
```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **cloudManagerEndpoint**, you can replace **admin.$STACK_HOST** with **my.cloudmgr.myhost.subnet.example.com**, where **my.cloudmgr** replaces **admin**, and **myhost.subnet.example.com** replaces **STACK_HOST**. For example:

```
cloudManagerEndpoint:
      < ... >
    hosts:
```

```
    - name: my.cloudmgr.myhost.subnet.example.com
      secret: cm-endpoint
```

You can do this for some or all of the host names, depending on your customization requirements.

`$STORAGE_CLASS`
: The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: `oc get sc`.

```
storageClassName: local-storage
```

`$LICENSE_ACCEPTANCE`
: Set `accept` to `true`. You must accept the license to successfully deploy API Connect.

`$LICENSE_USE`
: Set `use` to either `production` or `nonproduction` to match the license that you purchased.

$LICENSE_ID
: Set `license:` to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, add the following annotation to the **metadata** section of the CR:

```
metadata:
  annotations:
    apiconnect-operator/cp4i: "false"
```

This annotation disables all integration with the Cloud Pak.

4. Configure database backups for the Management subsystem.
To successfully restore API Connect in the event of a disaster where you must redeploy a new cluster, you must configure the database backup settings before the initial installation of the Management subsystem. For instructions on configuring backup settings, see Configuring backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration.

5. Install the Management subsystem by applying the modified CR with the following command:

```
oc apply -f mgmt_cr.yaml -n <management_namespace>
```

6. Verify that the Management subsystem is fully installed by running the following command:

```
oc get ManagementCluster -n <management_namespace>
```

The installation is complete when the `READY` status is `True`, and the `SUMMARY` reports that all services are online:

```
NAME         READY   SUMMARY    VERSION    RECONCILED VERSION   AGE
management   True    16/16       <version>   <version-build>      7m17s
```

7. Verify that you can log in to the API Connect Cloud Manager UI:
   a. Determine the URL for the Cloud Manager UI by running the following command to view the API Connect endpoints:

   ```
   oc get routes -n <management_namespace>
   ```

   b. Locate the `management-admin` endpoint, and note it down.
   c. Determine the Cloud Manager administrator password by running the following commands:

   ```
   oc get secret -n <management-namespace> | grep management-admin-secret

   oc get secret -n <management-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -
   d && echo ""
   ```

   d. Open a browser and go to the `management-admin-apic` endpoint.
   e. Log in to the Cloud Manager as `admin` with the administrator password.
8. Store all secrets and passwords in a safe place.
9. Prepare the Management subsystem for disaster recovery.
Follow the appropriate instructions for your environment:

- Preparing the Management subsystem for disaster recovery on OpenShift
- Preparing the Management subsystem for disaster recovery on Cloud Pak for Integration

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Setting up a certificate issuer
Next topic: Installing the Gateway subsystem in a shared namespace

Installing the Gateway subsystem in a shared namespace

Install the Gateway subsystem by creating and applying the apigateway_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Use the OpenShift CLI to edit the custom resource template for the Gateway, apply the resource, verify that the pods are up and running.

Procedure

1. Create the gateway admin secret with: `oc -n <gateway namespace> create secret generic admin-secret --from-literal=password=admin`
2. If you are installing the API Gateway (v6), create a yaml file that is called `apigateway_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

#

apiVersion: gateway.apiconnect.ibm.com/v1beta1
kind: GatewayCluster
metadata:
  name: gwv5
  labels: {
    app.kubernetes.io/instance: "gateway",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "gwv5"
  }
spec:
  version: $APP_PRODUCT_VERSION
  profile: $PROFILE
  apicGatewayServiceV5CompatibilityMode: true
  gatewayEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: gw.$STACK_HOST
      secretName: gwv5-endpoint
  gatewayManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: gwd.$STACK_HOST
      secretName: gwv5-manager-endpoint
  apicGatewayServiceTLS:
    secretName: gateway-service
  apicGatewayPeeringTLS:
    secretName: gateway-peering
  datapowerLogLevel: 3
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
  adminUser:
    secretName: admin-secret
  # syslogConfig:
  #   enabled: false # if true, provide below details
  #   remoteHost: $DATAPOWER_SYSLOG_TCP_REMOTE_HOST # must be a string
  #   remotePort: $DATAPOWER_SYSLOG_TCP_REMOTE_PORT # must be an int
  #   secretName: $DATAPOWER_SYSLOG_TCP_TLS_SECRET # must be a string
```

3. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.6.0

$PROFILE
Specify your Gateway subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
gatewayEndpoint:
      < ... >
    hosts:
    - name: rgw.myhost.subnet.example.com
      secret: gwv6-endpoint

  gatewayManagerEndpoint:
      < ... >
    hosts:
    - name: rgwd.myhost.subnet.example.com
      secret: gwv6-manager-endpoint
```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, for **gatewayEndpoint**, you can replace **rgw.$STACK_HOST** with **my.gateway.endpoint.myhost.subnet.example.com**, where **my.gateway.endpoint** replaces **rgw**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

```
gatewayEndpoint:
      < ... >
    hosts:
    - name: my.gateway.endpoint.myhost.subnet.example.com
      secret: gwv6-endpoint
```

You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**.

```
storageClassName: local-storage
```

$LICENSE_ACCEPTANCE
Set **accept** to **true**. You must accept the license to successfully deploy API Connect.
$LICENSE_USE
Set **use** to either **production** or **nonproduction** to match the license that you purchased.
$LICENSE_ID
Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

syslogConfig
To enable this feature uncomment this section, set **enabled: true**, and set the properties:
$DATAPOWER_SYSLOG_TCP_REMOTE_HOST
remoteHost: <*remote.host*>
String. The hostname of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_REMOTE_PORT
remotePort: <*remote_port_number*>
Integer. The port number of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_TLS_SECRET
secretName: <*secret*>
String. The TLS secret name of the server for **syslogConfig**.

4. Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, add the following annotation to the **metadata** section of the CR:

```
metadata:
  annotations:
    apiconnect-operator/cp4i: "false"
```

This annotation disables all integration with the Cloud Pak.

5. Optional: If applicable to your deployment, update the gateway CR file to configure **DataPowerService** APIs to customize your DataPower deployment. See Customizing a DataPower deployment.
6. To enable mutual TLS between the Management client and the Gateway service's manager endpoint, add **mtlsValidateClient** to the **spec** section:

```
spec:
  mtlsValidateClient: true
```

This ensures that the gateway service authenticates incoming requests from the API Manager, such as gateway service registration, and publishing APIs to the gateway service. Specifically, the gateway service requires that incoming requests present a certificate that was signed by the same CA that was used to sign the gateway service management endpoint. The gateway service management endpoint secret is specified under **gatewayManagerEndpoint.hosts.secretName**. The API Manager's gateway client's TLS credentials are specified in the ManagementCluster CR under **gateway.client.secretName**.
Note: In releases previous to 10.0.5.3, this property is called **validateApimClient**.
7. Optional: If you want to enable JWT security for communications between the management and gateway, add and set the property **jwksUrl**.

```
spec:
  ...
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.
8. Optional: Update the gateway CR file to enable autoscaling of gateway pods to ensure high availability of DataPower pods. See Enabling autoscaling of gateway pods.
9. Install the Gateway Custom Resource by applying the yaml file:
For a DataPower® API Gateway, run the following command:

```
oc apply -f apigateway_cr.yaml -n <namespace>
```

For a DataPower Gateway (v5 compatible), run the following command:

```
oc apply -f v5cgateway_cr.yaml -n <namespace>
```

10. To verify that the Gateway subsystem is fully installed, run the following command:

```
oc get GatewayCluster -n <namespace>
```

The installation is complete when the **READY** status is **True**, and the **SUMMARY** reports that all services are online (**2/2**) for all the Gateway subsystems that were installed. Example:

```
NAME   READY   SUMMARY   VERSION     RECONCILED VERSION   AGE
gwv6   True    2/2       <version>   <version-build>      7m32s
```

There is no need to wait for the `READY` status to be `True` before moving on to next Subsystem installation.

11. Verify that the gateway is ready to be registered with the Management subsystem by calling the `health` api on the `gatewayManagerEndpoint.hosts.name` defined in your yaml file: `https://gwd.$STACK_HOST/health`.

```
curl -k https://gwd.example.com/health
{"status":"ok"}
```

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the Management subsystem in a shared namespace
Next topic: Installing the Portal subsystem in a shared namespace

Installing the Portal subsystem in a shared namespace

Install the Portal subsystem by creating and applying the portal_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Use the OpenShift CLI to edit the custom resource template for the Portal subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called `portal_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalCluster
metadata:
  name: portal
  labels: {
    app.kubernetes.io/instance: "portal",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "portal"
  }
spec:
  version: $APP_PRODUCT_VERSION
  profile: $PROFILE
  mgmtPlatformEndpointCASecret:
    secretName: ingress-ca
  mgmtConsumerEndpointCASecret:
    secretName: ingress-ca
  mgmtPlatformEndpointSvcCASecret:
    secretName: management-ca
  mgmtConsumerEndpointSvcCASecret:
    secretName: management-ca
  portalAdminEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: api.portal.$STACK_HOST
      secretName: portal-admin
  portalUIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: portal.$STACK_HOST
      secretName: portal-web
```

```
  databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 15Gi
  databaseLogsVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 6Gi
  webVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 8Gi
  backupVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 15Gi
  adminVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 6Gi
  certVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 4Gi
  adminClientSubjectDN: CN=portal-admin-client,O=cert-manager
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the yaml file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.6.0

$PROFILE
Specify your portal subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when you specify endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, for a subdomain of **myhost.subnet.example.com**:

```
portalAdminEndpoint:
    < ... >
    hosts:
    - name: api.portal.myhost.subnet.example.com
      secret: portal-admin

 portalUIEndpoint:
    < ... >
    hosts:
    - name: portal.myhost.subnet.example.com
      secret: portal-web
```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, for **portalAdminEndpoint**, you can replace **api.portal.$STACK_HOST** with **my.api.portal.myhost.subnet.example.com**, where **my.api.portal** replaces **api.portal**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

```
portalAdminEndpoint:
       < ... >
    hosts:
    - name: my.api.portal.myhost.subnet.example.com
      secret: cm-endpoint
```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**. For example, for local storage:

```
databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 120Gi
databaseLogsVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 12Gi
webVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
backupVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 300Gi
adminVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 20Gi
```

```
certVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 4Gi
```

Note:

- The **databaseVolumeClaimTemplate** has a minimum value of 30Gi. The **webVolumeClaimTemplate** has a minimum value of 20Gi. The **backupVolumeClaimTemplate** has a minimum value of 30Gi. However, all three need to be sized according to the installation.
- The **adminVolumeClaimTemplate** and **databaseLogsVolumeClaimTemplate** in this example have their minimum values and you do not need to change them.
- The **certVolumeClaimTemplate** is used by the nginx pod and in 2dcdr (two data center disaster recovery) mode it is also used by the tunnel, db-remote and www-remote pods. It can be sized small, just like the **adminVolumeClaimTemplate**, and does not need to be increased based on the number of sites.

$LICENSE_ACCEPTANCE
: Set **accept** to **true**. You must accept the license to successfully deploy API Connect.

$LICENSE_USE
: Set **use** to either **production** or **nonproduction** to match the license that you purchased.

$LICENSE_ID
: Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, add the following annotation to the **metadata** section of the CR:

```
metadata:
  annotations:
    apiconnect-operator/cp4i: "false"
```

This annotation disables all integration with the Cloud Pak.

4. Optional: If you want to disable mTLS for communications between the management and portal, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.

5. Install the Portal subsystem by applying the modified CR with the following command:

```
oc apply -f portal_cr.yaml -n <namespace>
```

6. Verify that the Portal subsystem is fully installed:

```
oc get PortalCluster -n <namespace>
```

The installation is complete when **STATUS** reports **Running**, **Ready** reports that all services are online (**3/3**), and **MESSAGE** reports "Ready for API Cloud Manager service registration", for example:

```
NAME            READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                  AGE
portal          3/3     Running   <version>  <version>            Ready for API Cloud Manager service registration   2h
```

You do not need to wait for the portal installation to complete before you move on to the next subsystem installation.

7. Verify that you can access the portal web endpoint by browsing to the **portalUIEndpoint.hosts.name** as configured in your yaml file:

```
curl -k https://portal.$STACK_HOST
<!DOCTYPE html>
<html>
<head>
<title>Developer Portal is ready to create sites!</title>
<style>
    body {
        width: 35em;
        margin: 0 auto;
        font-family: Tahoma, Verdana, Arial, sans-serif;
    }
</style>
</head>
<body>Developer Portal is ready to create sites!</h1>
<p>If you see this page, the web server is successfully installed and
working. Further configuration is required.</p>
</body>
</html>
```

8. It is highly recommend that you retain the Portal subsystem encryption secret in a safe location, in case you need to restore the Portal subsystem during a disaster recovery scenario.
The encryption secret is created when the Portal subsystem is initially deployed. You can obtain the name of the encryption secret from the Portal subsystem custom resource after the installation is complete:

    a. Obtain the name of the encryptionSecret:

```
oc get ptl portal -o yaml -n <namespace> | grep encryptionSecret
encryptionSecret: portal-enc-key
```

The name of encryption secret is **portal-enc-key**.

b. Save the secret yaml in a safe location:

```
oc get secret portal-enc-key -o yaml -n <namespace> > portal-enc-key.yaml
```

9. Backup the Portal installation. See Backing up and restoring Developer Portal on OpenShift and Cloud Pak for Integration.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the Gateway subsystem in a shared namespace
Next topic: Installing the Analytics subsystem in a shared namespace

Installing the Analytics subsystem in a shared namespace

Install the analytics subsystem by creating and applying the analytics_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Use the OpenShift CLI to edit the custom resource template for the analytics subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called **analytics_cr.yaml** and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsCluster
metadata:
  name: analytics
  labels: {
    app.kubernetes.io/instance: "analytics",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "analytics"
  }
spec:
  version: $APP_PRODUCT_VERSION
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
  profile: $PROFILE
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  ingestion:
    endpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: ai.$STACK_HOST
        secretName: analytics-ai-endpoint
    clientSubjectDN: CN=analytics-ingestion-client,O=cert-manager
  storage:
```

```
    type: shared # change to 'dedicated' if you want separate master and storage pods. Three-replica deployments only.
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
    # master: # uncomment this section if you set storage.type = dedicated.
    #   volumeClaimTemplate:
    #     storageClassName: $STORAGE_CLASS
```

2. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.6.0

$PROFILE
Specify your analytics subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can customize the subdomain or the complete hostname:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** with the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
  ingestion:
    endpoint:
       < ... >
      hosts:
      - name: ai.myhost.subnet.example.com
        secret: analytics-ai-endpoint
       < .... >
```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, you can replace **$STACK_HOST** with **my.analytics.ingestion.myhost.subnet.example.com**, where **my.analytics.ingestion** replaces **ai**, and **myhost.subnet.example.com** replaces **STACK_HOST**.

```
ingestion:
    endpoint:
      < ... >
      hosts:
      - name: my.analytics.ingestion.myhost.subnet.example.com
        secret: analytics-ai-endpoint
       < ... >
```

$STORAGE_CLASS
The Kubernetes storage class to be used for persistent volume claims. For more information, see Analytics preinstallation planning. Find the available storage classes in the target cluster by running the following command: **oc get sc**. Example:

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
```

$DATA_VOLUME_SIZE
Size of storage allocated for data. To estimate the storage space you require, see Estimating storage requirements. If you are unable to estimate your storage requirement then set it to 500Gi.

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
        volumeSize: 500Gi
```

$LICENSE_ACCEPTANCE
Set **accept** to **true**. You must accept the license to successfully deploy API Connect.
$LICENSE_USE
Set **use** to either **production** or **nonproduction** to match the license that you purchased.
$LICENSE_ID
Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, add the following annotation to the **metadata** section of the CR:

```
metadata:
  annotations:
    apiconnect-operator/cp4i: "false"
```

This annotation disables all integration with the Cloud Pak.

4. Optional: Three replica deployments only: Enable dedicated storage.

If you want to use dedicated storage, update the **spec.storage** section of the yaml file as follows:

```
  storage:
    type: dedicated
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
    master:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
```

For more information about dedicated storage, see dedicated or shared storage.

5. Optional: If you want to disable mTLS for communications between the management and analytics subsystem, and between the gateway and analytics subsystem, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow.

6. Install the analytics subsystem by applying the modified CR with the following command:

```
oc apply -f analytics_cr.yaml -n <namespace>
```

7. Verify that the analytics subsystem is fully installed:

```
oc get AnalyticsCluster -n <namespace>
```

The installation is complete when **READY** shows all pods running (**n/n**), and the **STATUS** reports **Running**. Example:

```
NAME         READY   STATUS    VERSION          RECONCILED VERSION   AGE
analytics    n/n     Running   10.0.5.3   10.0.5.3-1281    86m
```

It is not necessary to wait for analytics installation to complete before you move on to the next subsystem installation.

8. Backup your analytics subsystem and configure scheduled analytics database backups: Preparing the Analytics subsystem for disaster recovery.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the Portal subsystem in a shared namespace

Installing with subsystem CRs in different namespaces or environments on OpenShift

Install API Connect subsystems in different namespaces, for example Management subsystem in a namespace that is called **apicmgmt**, Gateway in a namespace called **apicgway**. These same steps can also be used for installing subsystems in different environments.

About this task

Install API Connect subsystems where you have separate namespaces for each subsystem.

Attention: If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.

1. Installing operators
   Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect subsystems across multiple namespaces on Red Hat OpenShift. If you deploy API Connect subsystems in different environments, then the corresponding operator must be installed in each environment; for example, install the DataPower operator in your Gateway environment, and the API Connect operator in your Portal environment.
2. Installing the Management subsystem
   Install the Management subsystem by creating and applying the ingress-issuer and mgmt_cr yaml files.
3. Extracting the Management ingress-ca certificates
   In order for the Management subsystem to be able to communicate with subsystems in different namespaces, these subsystems need to have the same ingress-ca certificates as the Management subsystem.

4. Installing the Gateway subsystem
   Install the Gateway subsystem by creating and applying the ingress-ca, common-issuer, gateway-certs and gateway_cr yaml files.
5. Installing the Portal subsystem
   Install the Portal subsystem by creating and applying the ingress-ca, common-issuer, and portal_cr yaml files.
6. Installing the Analytics subsystem
   Install the Analytics subsystem by creating and applying the ingress-ca, common-issuer, and analytics_cr yaml files.

Installing operators

Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect subsystems across multiple namespaces on Red Hat OpenShift. If you deploy API Connect subsystems in different environments, then the corresponding operator must be installed in each environment; for example, install the DataPower operator in your Gateway environment, and the API Connect operator in your Portal environment.

Before you begin

The API Connect operator and operand must be from the same release and fix pack level. Table 1 lists the current version of the operator and operand for API Connect.

Table 1. API Connect operator and operand versions

API Connect (operand)	Operator channel version	Highest operator version
10.0.6.0	v5.0	5.0.0

Note: There can be only one instance of the API Connect operator in your OpenShift environment. You cannot have multiple namespaces each with their own API Connect operator.
You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

Procedure

1. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
   The **ibm-pak** plug-in enables you to access hosted product images, and to run **oc ibm-pak** commands against the cluster. To confirm that **ibm-pak** is installed, run the following command and verify that the response lists the command usage:

   ```
   oc ibm-pak --help
   ```

2. Obtain an entitlement key for the Entitled Registry:
   a. Log in to the IBM Container Library.
   b. In the Container software library, select Get entitlement key.
   c. After the Access your container software heading, click Copy key.
   d. Copy the key to a safe location.
3. Create a pull secret in the namespaces where you want to install API Connect.
   a. Open the Red Hat OpenShift web console, click Workloads > Secrets.
   b. Ensure that the Project is set to the namespace where you intend to install API Connect.
   c. Click Create and select Image pull secret.
   d. Set the following parameters for the secret:
      - Set Secret name to **ibm-entitlement-key**.
      - Set Authentication type to **Image registry credentials**.
      - Set Registry server address to **cp.icr.io**.
      - Set Username to **cp**.
      - Set Password to the entitlement key generated in Step 1.
      - Click Create to create the secret.

   Note: If your Red Hat OpenShift platform is Red Hat OpenShift on IBM Cloud (ROKS), you might need to reload your worker nodes after the image pull secret is created. You can reload the worker nodes either from the Red Hat OpenShift web console or from the command line with: **ibmcloud oc worker reload**. For information on using the **reload** command, see the Red Hat OpenShift on IBM Cloud documentation.
4. Add the API Connect catalog sources to your cluster.
   Adding catalog sources to your Red Hat OpenShift cluster adds the IBM operators to the list of operators you can install. For most connected and air-gapped clusters, applying individual catalog sources is the most effective way to fully control software versioning on the cluster.

   a. Generate the catalog source files:
      i. Log into your cluster using the **oc login** command and your user credentials:

      ```
      oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
      ```

      ii. Export the variables for the command line to use:

      ```
      export CASE_NAME=ibm-apiconnect
      export CASE_VERSION=5.0.0
      export ARCH=amd64
      ```

      For information on API Connect CASE versions and their corresponding operators and operands, see Operator, operand, and CASE versions.

      iii. Download the files for the operators required by API Connect:

      ```
      oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
      ```

      iv. Generate the catalog sources for API Connect:

      ```
      oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
      ```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources (run both commands):

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

b. Apply the catalog sources:

i. Apply the catalog sources (run both commands):

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

5. Add the IBM Cloud Pak foundational services (common services) catalog sources to your cluster.

a. Generate the catalog source files:

i. Log into your cluster using the `oc login` command and your user credentials:

```
oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
```

ii. Export the variables for the command line to use; substituting the appropriate version for the CASE:

```
export CASE_NAME=ibm-cp-common-services
export CASE_VERSION=1.15.10
export ARCH=amd64
```

For example, for IBM Cloud Pak foundational services 3.19.X (Long Term Service Release), use version 1.15.10; for foundational services 3.23.X (Continuous Delivery), use version 1.19.2.

For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

iii. Download the files for the operators required by IBM Cloud Pak foundational services (common services):

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

iv. Generate the catalog sources:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

This command might not return anything if there are no architecture-specific catalog sources.

b. Apply the catalog sources:

i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

6. Create the `apiconnect` subscription.

a. Create the `apiconnect` subscription with the appropriate channel by creating a file called `apic-sub.yaml` and pasting in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-apiconnect
  namespace: openshift-operators
spec:
  channel: v5.0
  name: ibm-apiconnect
  source: ibm-apiconnect-catalog
  sourceNamespace: openshift-marketplace
```

b. Apply the subscription with the following command:

```
oc apply -f apic-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as `ibm-apiconnect` or `IBM DataPower Gateway` show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Wait for the `IBM API Connect` and `IBM DataPower Gateway` operators to install.

The `IBM DataPower Gateway` operator is a prerequisite to API Connect and must not be removed.

7. Create the `ibm-common-services-operator` subscription, if it does not already exist.

a. Create a file called common-services-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-common-service-operator
  namespace: openshift-operators
```

```
spec:
  channel: <channel>
  name: ibm-common-service-operator
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

Where **<channel>** is one of the following values:

- **v3.23** if you are using IBM Cloud Pak foundational services CD (Continuous Delivery)
- **v3** if you are using IBM Cloud Pak foundational services LTSR (Long Term Service Release)

b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as **ibm-apiconnect**, **IBM Cloud Pak foundational services**, or **Operand Deployment Lifecycle Manager** show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the **ibm-common-services** namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the **IBM Cloud Pak foundational services** and **Operand Deployment Lifecycle Manager** operators to install.

8. Create the namespaces for your API Connect subsystems either by selecting Project > Create Project in the UI, or with the command:

```
oc create ns <APIC-namespace>
```

Note: Red Hat OpenShift restricts the use of default namespaces for installing non-cluster services. The following namespaces cannot be used to install API Connect:

- **default**
- **kube-system**
- **kube-public**
- **openshift-node**
- **openshift-infra**
- **openshift**

9. Install cert manager:
   a. Create a file called cert-manager-operand-request.yaml and paste in the following content:

```
apiVersion: operator.ibm.com/v1alpha1
kind: OperandRequest
metadata:
  name: ibm-apiconnect-cert-manager
  namespace: <namespace>
spec:
  requests:
  - operands:
    - name: ibm-cert-manager-operator
    registry: common-service
    registryNamespace: ibm-common-services
```

where *<namespace>* is the namespace you created for your API Connect management subsystem.

b. Create the **operandRequest** for cert-manager by running the following command:

```
oc apply -f cert-manager-operand-request.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
Wait for the **ibm-cert-manager-operator** to display and if it shows the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Wait for the **IBM Cert Manager** operator to install.

What to do next

Proceed to install the API Connect subsystems as explained in: Installing the Management subsystem

Next topic: Installing the Management subsystem

Installing the Management subsystem

Install the Management subsystem by creating and applying the ingress-issuer and mgmt_cr yaml files.

Before you begin

When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Create a file called **ingress-issuer-management.yaml** and paste in the following:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "selfsigning-issuer"
  }
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "ingress-issuer"
  }

  privateKey:
    rotationPolicy: Always
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: gateway-client-client
```

```
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "gateway-client-client"
  }
spec:
  subject:
    organizations:
    - cert-manager
  commonName: gateway-client-client
  secretName: gateway-client-client
  issuerRef:
    name: ingress-issuer
  usages:
  - "client auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: analytics-ingestion-client
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "analytics-ingestion-client"
  }
spec:
  subject:
    organizations:
    - cert-manager
  commonName: analytics-ingestion-client
  secretName: analytics-ingestion-client
  issuerRef:
    name: ingress-issuer
  usages:
  - "client auth"
  - "signing"
  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
```

2. Apply the above yaml file with: `oc apply -f ingress-issuer-management.yaml -n <management namespace>`
3. Confirm that the issuers were created and are in ready state:

```
oc get issuers -n <management namespace>
NAME                  READY
ingress-issuer        True
selfsigning-issuer    True
```

Procedure

1. Create a file that is called `mgmt_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementCluster
metadata:
  name: management
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "management"
  }
spec:
  version: $APP_PRODUCT_VERSION
  profile: $PROFILE
  portal:
    admin:
      secretName: portal-admin-client
  analytics:
    ingestion:
```

```
    secretName: analytics-ingestion-client
  gateway:
    client:
      secretName: gateway-client-client
  cloudManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: admin.$STACK_HOST
      secretName: cm-endpoint
  apiManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: manager.$STACK_HOST
      secretName: apim-endpoint
  platformAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: api.$STACK_HOST
      secretName: api-endpoint
  consumerAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: consumer.$STACK_HOST
      secretName: consumer-endpoint
  databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the YAML file and replace the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.6.0

$PROFILE
Specify your Management subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
cloudManagerEndpoint:
     < ... >
    hosts:
    - name: admin.myhost.subnet.example.com
      secret: cm-endpoint

  apiManagerEndpoint:
       < ... >
    hosts:
    - name: manager.myhost.subnet.example.com
      secret: apim-endpoint

  platformAPIEndpoint:
       < ... >
    hosts:
    - name: api.myhost.subnet.example.com
      secret: api-endpoint

  consumerAPIEndpoint:
       < ... >
    hosts:
    - name: consumer.myhost.subnet.example.com
      secret: consumer-endpoint
```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **cloudManagerEndpoint**, you can replace **admin.$STACK_HOST** with **my.cloudmgr.myhost.subnet.example.com**, where **my.cloudmgr** replaces **admin**, and **myhost.subnet.example.com** replaces **STACK_HOST**. For example:

```
cloudManagerEndpoint:
       < ... >
    hosts:
    - name: my.cloudmgr.myhost.subnet.example.com
      secret: cm-endpoint
```

You can do this for some or all of the host names, depending on your customization requirements.

`$STORAGE_CLASS`
: The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: `oc get sc`.

  `storageClassName: local-storage`

`$LICENSE_ACCEPTANCE`
: Set `accept` to `true`. You must accept the license to successfully deploy API Connect.

`$LICENSE_USE`
: Set `use` to either `production` or `nonproduction` to match the license that you purchased.

$LICENSE_ID
: Set `license:` to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, add the following annotation to the **metadata** section of the CR:

   ```
   metadata:
     annotations:
       apiconnect-operator/cp4i: "false"
   ```

   This annotation disables all integration with the Cloud Pak.

4. Configure database backups for the Management subsystem.
   To successfully restore API Connect in the event of a disaster where you must redeploy a new cluster, you must configure the database backup settings before the initial installation of the Management subsystem. For instructions on configuring backup settings, see Configuring backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration.

5. Install the Management subsystem by applying the modified CR with the following command:

   ```
   oc apply -f mgmt_cr.yaml -n <management_namespace>
   ```

6. Verify that the Management subsystem is fully installed by running the following command:

   ```
   oc get ManagementCluster -n <management_namespace>
   ```

   The installation is complete when the `READY` status is `True`, and the `SUMMARY` reports that all services are online:

   ```
   NAME          READY   SUMMARY    VERSION     RECONCILED VERSION    AGE
   management    True    16/16       <version>    <version-build>       7m17s
   ```

7. Verify that you can log in to the API Connect Cloud Manager UI:
   a. Determine the URL for the Cloud Manager UI by running the following command to view the API Connect endpoints:

      ```
      oc get routes -n <management_namespace>
      ```

   b. Locate the `management-admin` endpoint, and note it down.
   c. Determine the Cloud Manager administrator password by running the following commands:

      ```
      oc get secret -n <management-namespace> | grep management-admin-secret

      oc get secret -n <management-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d && echo ""
      ```

   d. Open a browser and go to the `management-admin-apic` endpoint.
   e. Log in to the Cloud Manager as `admin` with the administrator password.
8. Store all secrets and passwords in a safe place.
9. Prepare the Management subsystem for disaster recovery.
   Follow the appropriate instructions for your environment:

   - Preparing the Management subsystem for disaster recovery on OpenShift
   - Preparing the Management subsystem for disaster recovery on Cloud Pak for Integration

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing operators
Next topic: Extracting the Management ingress-ca certificates

Extracting the Management ingress-ca certificates

In order for the Management subsystem to be able to communicate with subsystems in different namespaces, these subsystems need to have the same ingress-ca certificates as the Management subsystem.

About this task

This task describes how to extract the ingress-ca certificates to a yaml file, ready for applying to the subsystems that are in different namespaces.

Procedure

1. Export the ingress-ca secret to a yaml file with: `oc -n <management namespace> get secret ingress-ca -o yaml > ingress-ca.yaml`
2. Edit the ingress-ca.yaml file and remove the following properties: metadata.creationTimestamp, metadata.namespace,metadata.resourceVersion, metadata.uid, metadata.selfLink
3. Keep this file safe. You will need to apply it in the namespaces of your other subsystems so that they can communicate with the Management subsystem.

Previous topic: Installing the Management subsystem
Next topic: Installing the Gateway subsystem

Installing the Gateway subsystem

Install the Gateway subsystem by creating and applying the ingress-ca, common-issuer, gateway-certs and gateway_cr yaml files.

Before you begin

When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Using the file obtained from Extracting the Management ingress-ca certificates, run: `oc apply -f ingress-ca.yaml -n <gateway namespace>`
2. Create a file called `common-issuer-and-gateway-certs.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
```

3. Apply the above yaml file with: oc apply -f common-issuer-and-gateway-certs.yaml -n <gateway namespace>
4. Confirm that the issuers were created and are in ready state:

```
oc get issuers -n <gateway namespace>
NAME                 READY
ingress-issuer       True
selfsigning-issuer   True
```

5. Confirm that the gateway secrets were created with `oc get secrets -n <gateway namespace>`:

```
oc get secrets -n <gateway namespace>
NAME                          TYPE                                  DATA   AGE
...
gateway-peering               kubernetes.io/tls                     3      2m
gateway-service               kubernetes.io/tls                     3      2m3s
...
```

About this task

Use the OpenShift CLI to edit the custom resource template for the Gateway, apply the resource, verify that the pods are up and running.

Procedure

1. Create the gateway admin secret with: `oc -n <gateway namespace> create secret generic admin-secret --from-literal=password=admin`
2. If you are installing the API Gateway (v6), create a yaml file that is called `apigateway_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at

  #   remoteHost: $DATAPOWER_SYSLOG_TCP_REMOTE_HOST # must be a string
  #   remotePort: $DATAPOWER_SYSLOG_TCP_REMOTE_PORT # must be an int
  #   secretName: $DATAPOWER_SYSLOG_TCP_TLS_SECRET # must be a string
```

3. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION

API Connect application version for the subsystems.

`version: <version_number>`

Example version number: 10.0.6.0

$PROFILE

Specify your Gateway subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

  ```
  gatewayEndpoint:
        < ... >
      hosts:
      - name: rgw.myhost.subnet.example.com
        secret: gwv6-endpoint

    gatewayManagerEndpoint:
        < ... >
      hosts:
      - name: rgwd.myhost.subnet.example.com
        secret: gwv6-manager-endpoint
  ```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, for **gatewayEndpoint**, you can replace **rgw.$STACK_HOST** with **my.gateway.endpoint.myhost.subnet.example.com**, where **my.gateway.endpoint** replaces **rgw**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

  ```
  gatewayEndpoint:
        < ... >
      hosts:
      - name: my.gateway.endpoint.myhost.subnet.example.com
        secret: gwv6-endpoint
  ```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**.

```
storageClassName: local-storage
```

$LICENSE_ACCEPTANCE
Set **accept** to **true**. You must accept the license to successfully deploy API Connect.

$LICENSE_USE
Set **use** to either **production** or **nonproduction** to match the license that you purchased.

$LICENSE_ID
Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

syslogConfig
To enable this feature uncomment this section, set **enabled: true**, and set the properties:

$DATAPOWER_SYSLOG_TCP_REMOTE_HOST
remoteHost: <*remote.host*>
String. The hostname of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_REMOTE_PORT
remotePort: <*remote_port_number*>
Integer. The port number of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_TLS_SECRET
secretName: <*secret*>
String. The TLS secret name of the server for **syslogConfig**.

4. Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, add the following annotation to the **metadata** section of the CR:

   ```
   metadata:
     annotations:
       apiconnect-operator/cp4i: "false"
   ```

   This annotation disables all integration with the Cloud Pak.

5. Optional: If applicable to your deployment, update the gateway CR file to configure **DataPowerService** APIs to customize your DataPower deployment. See Customizing a DataPower deployment.
6. To enable mutual TLS between the Management client and the Gateway service's manager endpoint, add **mtlsValidateClient** to the **spec** section:

   ```
   spec:
     mtlsValidateClient: true
   ```

   This ensures that the gateway service authenticates incoming requests from the API Manager, such as gateway service registration, and publishing APIs to the gateway service. Specifically, the gateway service requires that incoming requests present a certificate that was signed by the same CA that was used to sign the gateway service management endpoint. The gateway service management endpoint secret is specified under **gatewayManagerEndpoint.hosts.secretName**. The API Manager's gateway client's TLS credentials are specified in the ManagementCluster CR under **gateway.client.secretName**.
   Note: In releases previous to 10.0.5.3, this property is called **validateApimClient**.
7. Optional: If you want to enable JWT security for communications between the management and gateway, add and set the property **jwksUrl**.

   ```
   spec:
     ...
   ```

```
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the `jwksUrl`, describe the management CR and check the `status:` section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.

8. Optional: Update the gateway CR file to enable autoscaling of gateway pods to ensure high availability of DataPower pods. See Enabling autoscaling of gateway pods.
9. Install the Gateway Custom Resource by applying the yaml file:
   For a DataPower® API Gateway, run the following command:

   ```
   oc apply -f apigateway_cr.yaml -n <namespace>
   ```

   For a DataPower Gateway (v5 compatible), run the following command:

   ```
   oc apply -f v5cgateway_cr.yaml -n <namespace>
   ```

10. To verify that the Gateway subsystem is fully installed, run the following command:

    ```
    oc get GatewayCluster -n <namespace>
    ```

    The installation is complete when the `READY` status is `True`, and the `SUMMARY` reports that all services are online (`2/2`) for all the Gateway subsystems that were installed. Example:

    ```
    NAME   READY   SUMMARY   VERSION     RECONCILED VERSION    AGE
    gwv6   True    2/2       <version>   <version-build>       7m32s
    ```

    There is no need to wait for the `READY` status to be `True` before moving on to next Subsystem installation.
11. Verify that the gateway is ready to be registered with the Management subsystem by calling the `health` api on the `gatewayManagerEndpoint.hosts.name` defined in your yaml file: `https://gwd.$STACK_HOST/health`.

    ```
    curl -k https://gwd.example.com/health
    {"status":"ok"}
    ```

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Extracting the Management ingress-ca certificates
Next topic: Installing the Portal subsystem

Installing the Portal subsystem

Install the Portal subsystem by creating and applying the ingress-ca, common-issuer, and portal_cr yaml files.

Before you begin

When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Using the file obtained from Extracting the Management ingress-ca certificates, run: `oc apply -f ingress-ca.yaml -n <portal namespace>`
2. Create a file called `common-issuer.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
```

```
    app.kubernetes.io/name: "selfsigning-issuer"
  }
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "ingress-issuer"
  }
spec:
  ca:
    secretName: ingress-ca
```

3. Apply the above yaml file with: `oc apply -f common-issuer.yaml -n <portal namespace>`
4. Confirm that the issuers were created and are in ready state:

```
oc get issuers -n <portal namespace>
NAME                 READY
ingress-issuer       True
selfsigning-issuer   True
```

About this task

Use the OpenShift CLI to edit the custom resource template for the Portal subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called `portal_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at

  adminVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 6Gi
  certVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 4Gi
  adminClientSubjectDN: CN=portal-admin-client,O=cert-manager
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the yaml file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.6.0

$PROFILE
Specify your portal subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when you specify endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, for a subdomain of **myhost.subnet.example.com**:

```
portalAdminEndpoint:
    < ... >
    hosts:
    - name: api.portal.myhost.subnet.example.com
      secret: portal-admin

 portalUIEndpoint:
   < ... >
   hosts:
   - name: portal.myhost.subnet.example.com
     secret: portal-web
```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, for **portalAdminEndpoint**, you can replace **api.portal.$STACK_HOST** with **my.api.portal.myhost.subnet.example.com**, where **my.api.portal** replaces **api.portal**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

```
portalAdminEndpoint:
       < ... >
    hosts:
    - name: my.api.portal.myhost.subnet.example.com
      secret: cm-endpoint
```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**. For example, for local storage:

```
databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 120Gi
databaseLogsVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 12Gi
webVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
backupVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 300Gi
adminVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 20Gi
certVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 4Gi
```

Note:

- The **databaseVolumeClaimTemplate** has a minimum value of 30Gi. The **webVolumeClaimTemplate** has a minimum value of 20Gi. The **backupVolumeClaimTemplate** has a minimum value of 30Gi. However, all three need to be sized according to the installation.

- The `adminVolumeClaimTemplate` and `databaseLogsVolumeClaimTemplate` in this example have their minimum values and you do not need to change them.
- The `certVolumeClaimTemplate` is used by the nginx pod and in 2dcdr (two data center disaster recovery) mode it is also used by the tunnel, db-remote and www-remote pods. It can be sized small, just like the `adminVolumeClaimTemplate`, and does not need to be increased based on the number of sites.

`$LICENSE_ACCEPTANCE`
: Set `accept` to `true`. You must accept the license to successfully deploy API Connect.

`$LICENSE_USE`
: Set `use` to either `production` or `nonproduction` to match the license that you purchased.

$LICENSE_ID
: Set `license:` to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, add the following annotation to the **metadata** section of the CR:

```
metadata:
  annotations:
    apiconnect-operator/cp4i: "false"
```

This annotation disables all integration with the Cloud Pak.

4. Optional: If you want to disable mTLS for communications between the management and portal, and enable JWT instead, then add and set the properties `mtlsValidateClient` and `jwksUrl`.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the `jwksUrl`, describe the management CR and check the `status:` section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.

5. Install the Portal subsystem by applying the modified CR with the following command:

```
oc apply -f portal_cr.yaml -n <namespace>
```

6. Verify that the Portal subsystem is fully installed:

```
oc get PortalCluster -n <namespace>
```

The installation is complete when `STATUS` reports `Running`, `Ready` reports that all services are online (`3/3`), and `MESSAGE` reports "Ready for API Cloud Manager service registration", for example:

```
NAME           READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                    AGE
portal         3/3     Running   <version>  <version>            Ready for API Cloud Manager service registration   2h
```

You do not need to wait for the portal installation to complete before you move on to the next subsystem installation.

7. Verify that you can access the portal web endpoint by browsing to the `portalUIEndpoint.hosts.name` as configured in your yaml file:

```
curl -k https://portal.$STACK_HOST
<!DOCTYPE html>
<html>
<head>
<title>Developer Portal is ready to create sites!</title>
<style>
    body {
        width: 35em;
        margin: 0 auto;
        font-family: Tahoma, Verdana, Arial, sans-serif;
    }
</style>
</head>
<body>Developer Portal is ready to create sites!</h1>
<p>If you see this page, the web server is successfully installed and
working. Further configuration is required.</p>
</body>
</html>
```

8. It is highly recommend that you retain the Portal subsystem encryption secret in a safe location, in case you need to restore the Portal subsystem during a disaster recovery scenario.
The encryption secret is created when the Portal subsystem is initially deployed. You can obtain the name of the encryption secret from the Portal subsystem custom resource after the installation is complete:

   a. Obtain the name of the encryptionSecret:

   ```
   oc get ptl portal -o yaml -n <namespace> | grep encryptionSecret
   encryptionSecret: portal-enc-key
   ```

   The name of encryption secret is `portal-enc-key`.

   b. Save the secret yaml in a safe location:

   ```
   oc get secret portal-enc-key -o yaml -n <namespace> > portal-enc-key.yaml
   ```

9. Backup the Portal installation. See Backing up and restoring Developer Portal on OpenShift and Cloud Pak for Integration.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the Gateway subsystem
Next topic: Installing the Analytics subsystem

Installing the Analytics subsystem

Install the Analytics subsystem by creating and applying the ingress-ca, common-issuer, and analytics_cr yaml files.

Before you begin

When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Using the file obtained from Extracting the Management ingress-ca certificates, run: `oc apply -f ingress-ca.yaml -n <analytics namespace>`
2. Create a file called `common-issuer.yaml` and paste in these contents:
   Note: If you have just done Installing the Portal subsystem then you will already have this file.

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "selfsigning-issuer"
  }
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "ingress-issuer"
  }
spec:
  ca:
    secretName: ingress-ca
```

3. Apply the above yaml file with: `oc apply -f common-issuer.yaml -n <analytics namespace>`
4. Confirm that the issuers were created and are in ready state: `oc get issuers -n <analytics namespace>`

```
oc get issuers -n <analytics namespace>
NAME                 READY
ingress-issuer       True
selfsigning-issuer   True
```

About this task

Use the OpenShift CLI to edit the custom resource template for the Analytics subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called `analytics_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsCluster
metadata:
  name: analytics
  labels: {
    app.kubernetes.io/instance: "analytics",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "analytics"
  }
spec:
  version: $APP_PRODUCT_VERSION
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
  profile: $PROFILE
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  ingestion:
    endpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: ai.$STACK_HOST
        secretName: analytics-ai-endpoint
    clientSubjectDN: CN=analytics-ingestion-client,O=cert-manager
  storage:
    type: shared # change to 'dedicated' if you want separate master and storage pods. Three-replica deployments only.
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
    # master: # uncomment this section if you set storage.type = dedicated.
    #   volumeClaimTemplate:
    #     storageClassName: $STORAGE_CLASS
```

2. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.6.0

$PROFILE
Specify your analytics subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Planning your deployment topology.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can customize the subdomain or the complete hostname:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** with the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

  ```
  ingestion:
    endpoint:
      < ... >
    hosts:
    - name: ai.myhost.subnet.example.com
      secret: analytics-ai-endpoint
     < .... >
  ```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, you can replace **$STACK_HOST** with **my.analytics.ingestion.myhost.subnet.example.com**, where **my.analytics.ingestion** replaces **ai**, and **myhost.subnet.example.com** replaces **STACK_HOST**.

  ```
  ingestion:
    endpoint:
      < ... >
    hosts:
    - name: my.analytics.ingestion.myhost.subnet.example.com
      secret: analytics-ai-endpoint
  ```

```
      < ... >
```

`$STORAGE_CLASS`
: The Kubernetes storage class to be used for persistent volume claims. For more information, see Analytics preinstallation planning. Find the available storage classes in the target cluster by running the following command: `oc get sc`. Example:

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
```

$DATA_VOLUME_SIZE
: Size of storage allocated for data. To estimate the storage space you require, see Estimating storage requirements. If you are unable to estimate your storage requirement then set it to 500Gi.

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
        volumeSize: 500Gi
```

`$LICENSE_ACCEPTANCE`
: Set `accept` to `true`. You must accept the license to successfully deploy API Connect.

`$LICENSE_USE`
: Set `use` to either `production` or `nonproduction` to match the license that you purchased.

$LICENSE_ID
: Set `license:` to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you are installing Cloud Pak for Integration 2022.2.1 or 2022.4.1 and you don't want to use the Cloud Pak for Integration endpoints, add the following annotation to the **metadata** section of the CR:

```
metadata:
  annotations:
    apiconnect-operator/cp4i: "false"
```

   This annotation disables all integration with the Cloud Pak.

4. Optional: Three replica deployments only: Enable dedicated storage.
   If you want to use dedicated storage, update the `spec.storage` section of the yaml file as follows:

```
  storage:
    type: dedicated
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
    master:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
```

   For more information about dedicated storage, see dedicated or shared storage.
5. Optional: If you want to disable mTLS for communications between the management and analytics subsystem, and between the gateway and analytics subsystem, and enable JWT instead, then add and set the properties `mtlsValidateClient` and `jwksUrl`.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

   where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the `jwksUrl`, describe the management CR and check the `status:` section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

   For more information about JWT security, see Enable JWT security instead of mTLS.
   Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow.
6. Install the analytics subsystem by applying the modified CR with the following command:

```
oc apply -f analytics_cr.yaml -n <namespace>
```

7. Verify that the analytics subsystem is fully installed:

```
oc get AnalyticsCluster -n <namespace>
```

   The installation is complete when `READY` shows all pods running (`n/n`), and the `STATUS` reports `Running`. Example:

```
NAME         READY   STATUS    VERSION          RECONCILED VERSION   AGE
analytics    n/n     Running   10.0.5.3   10.0.5.3-1281    86m
```

   It is not necessary to wait for analytics installation to complete before you move on to the next subsystem installation.

8. Backup your analytics subsystem and configure scheduled analytics database backups: Preparing the Analytics subsystem for disaster recovery.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the Portal subsystem

Installing a two data center deployment with Cloud Pak for Integration

How to deploy a two data center disaster recovery (2DCDR) deployment on OpenShift with Cloud Pak for Integration.

Introduction

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center deployment strategy on Kubernetes and OpenShift.

Familiarize yourself with the Cloud Pak for Integration installation instructions linked from Deploying on OpenShift and Cloud Pak for Integration.
Note: During a 2DCDR installation, the management subsystem remains in a **`Warning`** state until the management subsystems in both data centers synchronize their databases. The management **`Warning`** status prevents the deployment and registration of the portal, gateway, and analytics subsystems. When the management subsystem databases are synchronized and both in **`Ready`** state, the deployment and registration of the other subsystems starts.

Prerequisites

The prerequisites for a 2DCDR deployment with Cloud Pak for Integration are as follows.

- The management and portal endpoints must be the same on both data centers.
- The network latency between data centers must be no more than 80 ms.
- The management cluster in each data center must use the same encryption secret.
- The portal cluster in each data center must use the same encryption secret.
- The ingress-ca certificate must be the same on both data centers.
- The Cloud Pak for Integration cluster must have a customized hostname and custom certificates.
- The API Connect namespace name must be the same in both clusters.
- The APIConnectCluster CR name must be identical on both clusters.

Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center deployment strategy on Kubernetes and OpenShift).

- **Planning and initial preparation**
  Decide on endpoint, host, and namespace names. Prepare your Cloud Pak for Integration environments for 2DCDR API Connect.
- **Preparing your active data center**
  Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.
- **Preparing your warm-standby data center**
  Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.
- **Installing API Connect on the active data center**
  Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the **`multiSiteHA`** configuration to the API Connect YAML.
- **Installing API Connect on the warm-standby data center**
  Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the **`multiSiteHA`** configuration to the API Connect YAML.

Planning and initial preparation

Decide on endpoint, host, and namespace names. Prepare your Cloud Pak for Integration environments for 2DCDR API Connect.

Procedure

1. Decide on naming. Both data centers must use the same names for:
   - API Connect namespace.
   - API Connect Cluster CR name. Also known as the API Connect instance name, and referred to in this document as **`<apic-instance-name>`**.
   - Portal subsystem endpoints
     - **`portalAdminEndpoint`**
     - **`portalUIEndpoint`**
   - Custom hostname and domain. This will be used in the URL for the Cloud Pak for Integration Platform UI and also for the Management subsystem endpoints. Traffic to this hostname should be directed to whichever data center is the active.

   Important: Each data center must use a different backup path for your Management backups. For portal backups each data center must use the same backup path. For more information, see Backup and restore requirements for a two data center deployment.
2. Create a namespace for your API Connect deployment in both data centers.
   The API Connect namespace must be the same in both data centers, set it with:

   ```
   oc create ns <namespace>
   ```

3. Install the Cloud Pak for Integration operator, Platform Navigator UI, and the API Connect operator in both your data centers. See https://www.ibm.com/docs/en/cloud-paks/cp-integration. Do not create an API Connect instance yet, install only the API Connect operator.
4. Decide which data center will start as the active and which will start as the warm-standby.
5. On the CLI of the active data center, where you run `oc` commands, create a directory called **`2dcdr-active-yamls`**. On the CLI of the warm-standby data center, create a directory called **`2dcdr-ws-yamls`**.

What to do next

Proceed to prepare the replication certificates, secrets, and issuers on your active data center Preparing your active data center.

Preparing your active data center

Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.

About this task

All operations are done on the CLI, in the **`2dcdr-active-yamls`** directory you created in Planning and initial preparation.

In the yaml files and commands that are shown here, replace **`<apic-instance-name>`** with the name you intend to use for your API Connect Cluster CR, and **`<namespace>`** with your API Connect namespace name (which will be the same for both Management and Portal subsystems). As decided in Planning and initial preparation.

Procedure

1. Deploy the cert-manager.
   a. Create a file that is called **`cert-manager.yaml`** and paste in the following contents:

```
apiVersion: operator.ibm.com/v1alpha1
kind: OperandRequest
metadata:
  name: ibm-apiconnect
spec:
  requests:
    - operands:
        - name: ibm-cert-manager-operator
      registry: common-service
      registryNamespace: ibm-common-services
```

   b. Apply this yaml file with:

```
oc apply -f cert-manager.yaml -n <namespace>
```

   c. Confirm that the cert-manager is deployed:

```
oc get deploy -n ibm-common-services | grep ibm-cert-manager-operator
```

   d. Wait for the cert-manager deployment to become available:

```
oc wait --for=condition=available deployment.apps/ibm-cert-manager-operator -n ibm-common-services --timeout=900s
```

   e. Wait for the three cert-manager pods and operator to be in running state:

```
oc get pods -n ibm-common-services | grep cert
```

```
cert-manager-cainjector-566b5d5698-pzccn                1/1     Running   0          18m
cert-manager-controller-766ddff8c4-ftr85                1/1     Running   0          18m
cert-manager-webhook-79bb8f67b7-gvkst                   1/1     Running   0          18m
ibm-cert-manager-operator-fdfd66bd4-6rrz6               1/1     Running   0          19m
```

2. Create the encryption key secrets for the Management and Portal subsystems.
   a. Run the following command to create a file that contains a random string, which is used to create the management encryption key secret:

```
cat /dev/urandom | head -c63 | base64 -w0 > mgmt-enc-key.txt
```

   b. Run the following command to create the management encryption key secret:

```
oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
namespace>
```

   c. Confirm that the secret was created successfully by running:

```
oc get secrets -n <management namespace> | grep mgmt-encryption-key
```

```
mgmt-encryption-key         Opaque                                1      83s
```

   d. Run the following command to create a file that contains a random string, which is used to create the portal encryption key secret:

```
cat /dev/urandom | head -c63 | base64 -w0 > ptl-enc-key.txt
```

   e. Run the following command to create the portal encryption key secret:

```
oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
```

   f. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key

ptl-encryption-key         Opaque                                1      15s
```

3. Create a self-signed issuer.
   a. Create a file that is called `issuer.yaml` and paste in the following contents, replacing `<apic-instance-name>`:

```
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: <apic-instance-name>-self-signed
spec:
  selfSigned: {}
```

   b. Apply this yaml file with:

```
oc apply -f issuer.yaml -n <namespace>
```

   c. Verify that the issuer was created with:

```
oc get issuer -n <namespace>

NAME                READY   AGE
apic-self-signed    True    25s
```

4. Create an ingress-ca certificate:
   a. Create a file that is called `self-signed-issuer-cert.yaml` and paste in the following contents, replacing `<apic-instance-name>`:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-ingress-ca
spec:
  commonName: ingress-ca
  duration: 87600h0m0s
  isCA: true
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-self-signed
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-ingress-ca
```

   b. Apply this yaml file with:

```
oc apply -f self-signed-issuer-cert.yaml -n <namespace>
```

   c. Verify that the certificate was created with:

```
oc get cert -n <namespace>

NAME                            READY   SECRET                          AGE     EXPIRATION
apic-ingress-ca                 True    apic-ingress-ca                 11s     2032-08-15T13:01:47Z
```

5. Create the ingress issuer.
   a. Create a file `ingress-issuer.yaml` and paste in the following contents, replacing `<apic-instance-name>`:

```
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: <apic-instance-name>-ingress-issuer
spec:
  ca:
    secretName: <apic-instance-name>-ingress-ca
```

   b. Apply this yaml file with:

```
oc apply -f ingress-issuer.yaml -n <namespace>
```

   c. Verify that the issuer was created with:

```
oc get issuer -n <namespace>

NAME                    READY   AGE
apic-ingress-issuer     True    20s
```

6. Create a custom hostname and certificate for Cloud Pak for Integration Platform UI and IBM Cloud Pak foundational services.
   a. Create a file `custom-hostname-cert.yaml` and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-custom-hostname-cert
  namespace: <Platform UI namespace>
spec:
  secretName: <apic-instance-name>-custom-hostname-secret
  issuerRef:
    name: <apic-instance-name>-ingress-issuer
    kind: Issuer
  commonName: <custom fqdn>
  duration: 17520h0m0s
  renewBefore: 720h0m0s
  dnsNames:
  - <ocp cluster api address>
```

```
  - <ocp cluster ui address>
  - <cp console ui address>
```

Where:

- **<apic-instance-name>** is the API Connect Cluster CR name.
- **<platform ui namespace>** is the namespace used by your Cloud Pak for Integration Platform UI.
- **<custom fqdn>** it the fully qualified custom hostname.
- **<ocp cluster api address>** is the fully qualified API address of your Cloud Pak for Integration cluster.
- **<ocp cluster ui address>** is the fully qualified UI address of your Cloud Pak for Integration cluster.
- **<cp console ui address>** is the fully qualified address of your Cloud Pak console. Run the following command to see this address: **oc get route -n ibm-common-services cp-console -o jsonpath='{.spec.host}'**.

b. Apply this file with:

```
oc apply -f custom-hostname-cert.yaml -n <namespace>
```

c. Extract the generated certificate files with:

```
oc extract secret/<apic-instance-name>-custom-hostname-secret -n <namespace> --to=. --keys=tls.crt,tls.key,ca.crt --confirm
```

Check that your local directory contains these three extracted files:

```
ca.crt
tls.crt
tls.key
```

d. Follow the steps in the Cloud Pak for Integration documentation to create a custom hostname and certificate https://www.ibm.com/docs/en/cloud-paks/cp-integration. For Cloud Pak for Integration v2022.2 the steps are on this page: Creating a custom hostname and certificate. Use the certificate files you extracted in the previous step.

e. Create a secret in the Platform UI namespace using the same certificates you created in 6.c.

```
oc -n ${PLATFORM UI NAMESPACE} create secret generic route-tls-secret --from-file=ca.crt=ca.crt  --from-file=tls.crt=tls.crt  --from-file=tls.key=tls.key
```

f. Add this new secret to the Platform UI CR, as described in the Cloud Pak for Integration documentation on using custom hostnames and certificates for the Platform UI. For Cloud Pak for Integration v2022.2 the steps are on this page: https://www.ibm.com/docs/en/cloud-paks/cp-integration/2022.2?topic=certificates-using-custom-hostnames-platform-ui.

7. Create the TLS client replication certificates for Management and Portal.

a. Create a yaml file that is called **mgmt-tls-client-cert.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-mgmt-replication-client
spec:
  commonName: <apic-instance-name>-mgmt-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-mgmt-replication-client
```

b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>
```

```
NAME                                              READY   SECRET                                            AGE     EXPIRATION
...
<apic-instance-name>-mgmt-replication-client   True    <apic-instance-name>-mgmt-replication-client   16m     2024-08-17T13:04:27Z
```

d. Create a file **ptl-tls-client-cert.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-ptl-replication-client
spec:
  commonName: <apic-instance-name>-ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-ptl-replication-client
```

e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>

NAME                                                READY   SECRET                                              AGE     EXPIRATION
...
<apic-instance-name>-ptl-replication-client   True    <apic-instance-name>-ptl-replication-client   16m     2024-08-17T13:04:27Z
```

8. Export the ingress-ca issuer secret.
   The ingress-ca issuer secret must be the same on the warm-standby data center. Export it from the active so that it can be imported on the warm-standby data center.
   a. Run the following command to export the secret to a file called **ca-issuer-secret.yaml**:

   ```
   oc get secret <apic-instance-name>-ingress-ca -o yaml -n <namespace>  > ca-issuer-secret.yaml
   ```

   b. Edit the **ca-issuer-secret.yaml** file to remove the creationTimestamp, resourceVersion, uid, and managedFields. Remove the labels and annotations sections completely. The contents should look like this:

   ```
   apiVersion: v1
   data:
     ca.crt: <long cert string>
     tls.crt: <long cert string>
     tls.key: <long cert string>
   kind: Secret
   metadata:
     name: <apic-instance-name>-ingress-ca
     namespace: <namespace>
   type: kubernetes.io/tls
   ```

9. Copy the following files from your **2dcdr-active-yamls** directory to the **2dcdr-ws-yamls** directory in your warm-standby data center.

   ```
   ca-issuer-secret.yaml
   mgmt-enc-key.txt
   ptl-enc-key.txt
   ```

   These files are required to ensure that the ingress-ca and encryption secrets on both sites are the same.
   Tip: To save time during the preparation of your warm-standby data center you can also copy these yaml files:

   ```
   ptl-tls-client-cert.yaml
   mgmt-tls-client-cert.yaml
   ingress-issuer.yaml
   ```

What to do next

Create your secrets, certs, and issuers on your warm-standby data center: Preparing your warm-standby data center.

Preparing your warm-standby data center

Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.

About this task

All operations are done on the CLI, in the **2dcdr-ws-yamls** directory you created in Planning and initial preparation.

In the yaml files and commands that are shown here, replace **<apic-instance-name>** with the name you intend to use for your API Connect Cluster CR, and **<namespace>** with your API Connect namespace name (which will be the same for both Management and Portal subsystems). As decided in Planning and initial preparation.

Procedure

1. Deploy the cert-manager.
   a. Create a file that is called **cert-manager.yaml** and paste in the following contents:

   ```
   apiVersion: operator.ibm.com/v1alpha1
   kind: OperandRequest
   metadata:
     name: ibm-apiconnect
   spec:
     requests:
       - operands:
           - name: ibm-cert-manager-operator
         registry: common-service
         registryNamespace: ibm-common-services
   ```

   b. Apply this yaml file with:

   ```
   oc apply -f cert-manager.yaml -n <namespace>
   ```

   c. Confirm that the cert-manager is deployed:

   ```
   oc get deploy -n ibm-common-services | grep ibm-cert-manager-operator
   ```

   d. Wait for the cert-manager deployment to become available:

   ```
   oc wait --for=condition=available deployment.apps/ibm-cert-manager-operator -n ibm-common-services --timeout=900s
   ```

e. Wait for the three cert-manager pods and operator to be in running state:

```
oc get pods -n ibm-common-services | grep cert

cert-manager-cainjector-566b5d5698-pzccn                1/1     Running   0          18m
cert-manager-controller-766ddff8c4-ftr85                1/1     Running   0          18m
cert-manager-webhook-79bb8f67b7-gvkst                   1/1     Running   0          18m
ibm-cert-manager-operator-fdfd66bd4-6rrz6               1/1     Running   0          19m
```

2. Import the ingress-ca issuer secret.
   This secret was created on your active data center here: Export the ingress-ca issuer secret
   a. Copy the `ca-issuer-secret.yaml` file to your warm-standby data center (if not done already).
   b. Create the secret with:

```
oc apply -f ca-issuer-secret.yaml -n <namespace>
```

   c. Verify that the secret was created with:

```
oc get secret -n <namespace>

NAME                                                    TYPE                                  DATA   AGE
<apic-instance-name>-ingress-ca                         kubernetes.io/tls                     3      19h
```

3. Create the ingress issuer.
   a. Create a file `ingress-issuer.yaml` and paste in the following contents, replacing `<apic-instance-name>`:

```
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: <apic-instance-name>-ingress-issuer
spec:
  ca:
    secretName: <apic-instance-name>-ingress-ca
```

   b. Apply this yaml file with:

```
oc apply -f ingress-issuer.yaml -n <namespace>
```

   c. Verify that the issuer was created with:

```
oc get issuer -n <namespace>

NAME                  READY   AGE
apic-ingress-issuer   True    20s
```

4. Create a custom hostname and certificate for Cloud Pak for Integration Platform UI and IBM Cloud Pak foundational services.
   a. Create a file `custom-hostname-cert.yaml` and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-custom-hostname-cert
  namespace: <Platform UI namespace>
spec:
  secretName: <apic-instance-name>-custom-hostname-secret
  issuerRef:
    name: <apic-instance-name>-ingress-issuer
    kind: Issuer
  commonName: <custom fqdn>
  duration: 17520h0m0s
  renewBefore: 720h0m0s
  dnsNames:
  - <ocp cluster api address>
  - <ocp cluster ui address>
  - <cp console ui address>
```

   Where:
   - `<apic-instance-name>` is the API Connect Cluster CR name.
   - `<platform ui namespace>` is the namespace used by your Cloud Pak for Integration Platform UI.
   - `<custom fqdn>` it the fully qualified custom hostname.
   - `<ocp cluster api address>` is the fully qualified API address of your Cloud Pak for Integration cluster.
   - `<ocp cluster ui address>` is the fully qualified UI address of your Cloud Pak for Integration cluster.
   - `<cp console ui address>` is the fully qualified address of your Cloud Pak console. Run the following command to see this address: `oc get route -n ibm-common-services cp-console -o jsonpath='{.spec.host}'`.

   b. Apply this file with:

```
oc apply -f custom-hostname-cert.yaml -n <namespace>
```

   c. Extract the generated certificate files with:

```
oc extract secret/<apic-instance-name>-custom-hostname-secret -n <namespace> --to=. --keys=tls.crt,tls.key,ca.crt --confirm
```

   Check that your local directory contains these three extracted files:

```
ca.crt
tls.crt
tls.key
```

   d. Follow the steps in the Cloud Pak for Integration documentation to create a custom hostname and certificate https://www.ibm.com/docs/en/cloud-paks/cp-integration. For Cloud Pak for Integration v2022.2 the steps are on this page: Creating a custom hostname and certificate. Use the certificate files you

extracted in the previous step.

e. Create a secret in the Platform UI namespace using the same certificates you created in 4.c.

```
oc -n ${PLATFORM UI NAMESPACE} create secret generic route-tls-secret --from-file=ca.crt=ca.crt  --from-
file=tls.crt=tls.crt  --from-file=tls.key=tls.key
```

f. Add this new secret to the Platform UI CR, as described in the Cloud Pak for Integration documentation on using custom hostnames and certificates for the Platform UI. For Cloud Pak for Integration v2022.2 the steps are on this page: https://www.ibm.com/docs/en/cloud-paks/cp-integration/2022.2?topic=certificates-using-custom-hostnames-platform-ui.

5. Create the encryption key secrets for the Management and Portal subsystems, by using the random string generated on the active data center. Use the **mgmt-enc-key.txt** and **ptl-enc-key.txt** files that were copied to your warm-standby data center here: Copy keys to warm-standby.

a. Run the following command to create the management encryption key secret:

```
oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
namespace>
```

b. Confirm that the secret was created successfully by running:

```
oc get secrets -n <management namespace> | grep mgmt-encryption-key

mgmt-encryption-key         Opaque                                1      83s
```

c. Run the following command to create the portal encryption key secret:

```
oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
```

d. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key

ptl-encryption-key          Opaque                                1      15s
```

6. Create the TLS client replication certificates for Management and Portal.

a. Create a yaml file that is called **mgmt-tls-client-cert.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-mgmt-replication-client
spec:
  commonName: <apic-instance-name>-mgmt-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-mgmt-replication-client
```

b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>

NAME                                            READY   SECRET                                          AGE
EXPIRATION
...
<apic-instance-name>-mgmt-replication-client   True    <apic-instance-name>-mgmt-replication-client   16m     2024-
08-17T13:04:27Z
```

d. Create a file **ptl-tls-client-cert.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-ptl-replication-client
spec:
  commonName: <apic-instance-name>-ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-ptl-replication-client
```

e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>

NAME                                          READY   SECRET                                        AGE
EXPIRATION
...
<apic-instance-name>-ptl-replication-client   True    <apic-instance-name>-ptl-replication-client   16m     2024-08-
17T13:04:27Z
```

What to do next

Install API Connect in your active data center: Installing API Connect on the active data center.

Installing API Connect on the active data center

Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the **multiSiteHA** configuration to the API Connect YAML.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get secrets -n <namespace> | grep <apic-instance-name>
<apic-instance-name>-ingress-ca                kubernetes.io/tls                     3      3d21h
<apic-instance-name>-mgmt-replication-client   kubernetes.io/tls                     3      3d21h
<apic-instance-name>-ptl-replication-client    kubernetes.io/tls                     3      3d21h

oc get certs -n <namespace> | grep <apic-instance-name>
<apic-instance-name>-ingress-ca                True    <apic-instance-name>-ingress-ca                3d21h   2032-08-
15T13:01:47Z
<apic-instance-name>-mgmt-replication-client   True    <apic-instance-name>-mgmt-replication-client   3d21h   2024-08-
17T13:04:27Z
<apic-instance-name>-ptl-replication-client    True    <apic-instance-name>-ptl-replication-client    3d21h   2024-08-
17T13:04:26Z

oc get issuer -n <namespace> | grep <apic-instance-name>
<apic-instance-name>-ingress-issuer   True    3d21h
<apic-instance-name>-self-signed      True    3d21h
```

Where **<apic-instance-name>** is the name you intend to use for your API Connect cluster CR, and **<namespace>** is the namespace you created for API Connect.

Ensure that your network is redirecting the custom hostname to the Platform UI in your active data center.

About this task

In the yaml files that are shown here, replace **<apic-instance-name>** with the name you intend to use for your API Connect Cluster CR. As decided in Planning and initial preparation. Set **<active data center ingress domain>** and **<warm-standby data center ingress domain>** to their appropriate values, which can be determined by running this command in each data center:

```
oc get ingresses.config/cluster -o jsonpath={.spec.domain}
```

Procedure

1. Follow the API Connect installation steps using the Platform UI, as described in the Cloud Pak for Integration documentation https://www.ibm.com/docs/en/cloud-paks/cp-integration. At the point where you specify the configuration properties of your API Connect instance, switch to the YAML tab so you can edit the YAML directly.
   Remember: Use the same **<apic-instance-name>** value when you specify the API Connect instance name in the Cloud Pak for Integration Platform UI.
2. Add the management **multiSiteHA** section to the YAML file under the **spec:** section.

```
  management:
    encryptionSecret:
      secretName: mgmt-encryption-key
    multiSiteHA:
      mode: active
      replicationEndpoint:
        annotations:
          cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
        hosts:
        - name: mgmt-replication.<active data center ingress domain>
          secretName: <apic-instance-name>-mgmt-replication-server
      replicationPeerFQDN: mgmt-replication.<warm-standby data center ingress domain>
      tlsClient:
        secretName: <apic-instance-name>-mgmt-replication-client
```

3. Add the portal **multiSiteHA** section to the YAML file under the **spec:** section:

```
  portal:
    portalAdminEndpoint:
      annotations:
        cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
      hosts:
      - name: <external load balanced portal admin hostname>
        secretName: portal-admin
    portalUIEndpoint:
      annotations:
        cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
      hosts:
      - name: <external load balanced portal web hostname>
        secretName: portal-web
    encryptionSecret:
      secretName: ptl-encryption-key
    multiSiteHA:
      mode: active
      replicationEndpoint:
        annotations:
```

```
      cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
    hosts:
    - name: ptl-replication.<active data center ingress domain>
      secretName: <apic-instance-name>-ptl-replication-server
  replicationPeerFQDN: ptl-replication.<warm-standby data center ingress domain>
  tlsClient:
    secretName: <apic-instance-name>-ptl-replication-client
```

4. Continue the installation steps as described in Deploying on OpenShift and Cloud Pak for Integration.

Results

Confirm that the management subsystem is ready, but in **Warning** state with **oc get mgmt**:

```
oc get mgmt -n <namespace>

NAME          READY    STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n      Warning   10.0.5.3-0   10.0.5.3-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
```

The management CR is expected to report the status of **Warning** until the warm-standby management subsystem is deployed, and both management subsystems complete data replication. When you see the status message "Management is ready. HA Status Warning - see HAStatus in CR for details", you can move on to Installing API Connect on the warm-standby data center.
Note: The portal, analytics, and gateway subsystems are not deployed until the management replication is complete and the management CRs in both data centers report the following:

```
NAME          READY    STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n      Running   10.0.5.3-0   10.0.5.3-0           Management is ready.              8m59s

status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

What to do next

Install API Connect on your warm-standby data center: Installing API Connect on the warm-standby data center.

Installing API Connect on the warm-standby data center

Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the **multiSiteHA** configuration to the API Connect YAML.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get certificate -n <namespace> | grep <apic-instance-name>
NAME                              READY   SECRET                            AGE     EXPIRATION
apic-mgmt-replication-client      True    apic-mgmt-replication-client      57s     2024-08-24T09:45:03Z
apic-ptl-replication-client       True    apic-ptl-replication-client       45s     2024-08-24T09:45:17Z

[root@api.iaincp4ilarge2.cp.fyre.ibm.com ~]# oc get secrets  -n <namespace> | grep <apic-instance-name>
NAME                                TYPE                                DATA   AGE
apic-ingress-ca                     kubernetes.io/tls                   3      4m6s
apic-mgmt-replication-client        kubernetes.io/tls                   3      2m40s
apic-ptl-replication-client         kubernetes.io/tls                   3      2m26s

[root@api.iaincp4ilarge2.cp.fyre.ibm.com ~]# oc get issuer -n <namespace> | grep <apic-instance-name>
NAME                   READY   AGE
apic-ingress-issuer    True    4m8s
```

Where **<apic-instance-name>** is the name you intend to use for your API Connect cluster CR, and **<namespace>** is the namespace you created for API Connect.

Ensure that your network is redirecting the custom hostname to the Platform UI in your warm-standby data center.

About this task

In the yaml files that are shown here, replace **<apic-instance-name>** with the name you intend to use for your API Connect Cluster CR. As decided in Planning and initial preparation. Set **<active data center ingress domain>** and **<warm-standby data center ingress domain>** to their appropriate values, which can be determined by running this command in each data center:

```
oc get ingresses.config/cluster -o jsonpath={.spec.domain}
```

Procedure

1. Follow the API Connect installation steps using the Platform UI, as described in the Cloud Pak for Integration documentation https://www.ibm.com/docs/en/cloud-paks/cp-integration. At the point where you specify the configuration properties of your API Connect instance, switch to the YAML tab so you can edit the YAML directly.
   Remember: Use the same **<apic-instance-name>** value when you specify the API Connect instance name in the Cloud Pak for Integration Platform UI.
2. Add the management **multiSiteHA** section to the YAML file under the **spec:** section.

```
  management:
    encryptionSecret:
      secretName: mgmt-encryption-key
    multiSiteHA:
      mode: passive
      replicationEndpoint:
        annotations:
          cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
        hosts:
        - name: mgmt-replication.<warm-standby data center ingress domain>
          secretName: <apic-instance-name>-mgmt-replication-server
      replicationPeerFQDN: mgmt-replication.<active data center ingress domain>
      tlsClient:
        secretName: <apic-instance-name>-mgmt-replication-client
```

   Note: Warm-standby is referred to as 'passive' in the CR YAML.
3. Add the portal **multiSiteHA** section to the YAML file under the **spec:** section:

```
  portal:
    portalAdminEndpoint:
      annotations:
        cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
      hosts:
      - name: <external load balanced portal admin hostname>
        secretName: portal-admin
    portalUIEndpoint:
      annotations:
        cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
      hosts:
      - name: <external portal load balanced web hostname>
        secretName: portal-web
    encryptionSecret:
      secretName: ptl-encryption-key
    multiSiteHA:
      mode: passive
      replicationEndpoint:
        annotations:
          cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
        hosts:
        - name: ptl-replication.<warm-standby data center ingress domain>
          secretName: <apic-instance-name>-ptl-replication-server
      replicationPeerFQDN: ptl-replication.<active data center ingress domain>
      tlsClient:
        secretName: <apic-instance-name>-ptl-replication-client
```

4. Disable the configurator service, as this will have already run on the active site.
   a. Add the following section to the API Connect cluster CR:

```
  disabledServices:
    - configurator
```

5. Continue the installation steps as described in Deploying on OpenShift and Cloud Pak for Integration.

Results

Installation can take around 1 hour to complete.

While the management subsystems on the warm-standby and active data centers are synchronizing, the management status reports **Warning**, and the **haStatus** reports **pending**:

```
oc get mgmt -n <namespace>
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.5.3-0   10.0.5.3-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s
```

```
status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
```

When the management database replication between sites is complete, the management status reports **Running**, and **status.haStatus** reports **Ready**:

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Running   10.0.5.3-0   10.0.5.3-0           Management is ready.              8m59s

status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

After the management subsystems in the active and warm-standby sites are synchronized, the other subsystems are deployed. Verify on both active and warm-standby sites that all subsystems reach **Running** state:

```
oc get all -n <namespace>
...
NAME                                                              READY   STATUS    VERSION    RECONCILED VERSION   AGE
analyticscluster.analytics.apiconnect.ibm.com/apis-minimum-a7s    n/n     Running   10.0.5.3   10.0.5.3-1281        27m

NAME                                                 READY   STATUS   VERSION    RECONCILED VERSION   AGE
apiconnectcluster.apiconnect.ibm.com/apis-minimum    n/n     Ready    10.0.5.3   10.0.5.3-1281        2d20h

NAME                                                  PHASE     READY   SUMMARY                          VERSION    AGE
datapowerservice.datapower.ibm.com/apis-minimum-gw    Running   True    StatefulSet replicas ready: 1/1  10.5.0.0   25m

NAME                                                  PHASE     LAST EVENT   WORK PENDING   WORK IN-PROGRESS   AGE
datapowermonitor.datapower.ibm.com/apis-minimum-gw    Running                false          false              25m

NAME                                                READY   STATUS    VERSION    RECONCILED VERSION   AGE
gatewaycluster.gateway.apiconnect.ibm.com/apis-minimum-gw   n/n     Running   10.0.5.3   10.0.5.3-1281        27m

NAME                                                          READY   STATUS    VERSION    RECONCILED VERSION   AGE
managementcluster.management.apiconnect.ibm.com/apis-minimum-mgmt   8/8     Running   10.0.5.3   10.0.5.3-1281        2d20h

NAME                                                 READY   STATUS    VERSION    RECONCILED VERSION   AGE
portalcluster.portal.apiconnect.ibm.com/apis-minimum-ptl   n/n     Running   10.0.5.3   10.0.5.3-1281        27m
```

Note: The warm-standby site has fewer **managementcluster** pods than the active site.
If the management database replication between sites fails for any reason other than because an install or upgrade is in progress, the **haStatus** output shows:

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.5.3-0   10.0.5.3-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "Warning"
    }
```

If the warning persists, see Troubleshooting a two data center deployment.

You can validate that your portal deployments are synchronizing by running **oc get pods** on both the active and warm-standby data centers. Confirm that the number and names of the pods all match (the UUIDs in the names might be different on each site), and that all are in the **Ready** state.

For additional replication verification checks, see Verifying replication between data centers. It is recommended to run a test failover, and confirm that all of the expected data is present and correct on the newly active site. See How to perform 2DCDR failover for details.

What to do next

Configure your deployment: Cloud Manager configuration checklist.
Important: It is strongly recommended to complete the disaster recovery preparation on both sites: Disaster recovery on OpenShift and Cloud Pak for Integration. Disaster recovery preparation ensures that you can recover your API Connect installation if both data centers are lost, or if a replication failure occurs. Both sites must use different backup paths for their Management and Portal backups.

Installing a two data center deployment on OpenShift

How to deploy a two data center disaster recovery (2DCDR) deployment on OpenShift.

Introduction

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center deployment strategy on Kubernetes and OpenShift.

Familiarize yourself with the OpenShift installation instructions linked from Deploying on OpenShift and Cloud Pak for Integration.

Note: 2DCDR is not supported on OpenShift where the top-level CR is used. For 2DCDR on OpenShift, you must install API Connect as individual subsystems. See Installing with subsystem CRs in a shared namespace on OpenShift and Installing with subsystem CRs in different namespaces or environments on OpenShift.

Prerequisites

The prerequisites for a 2DCDR deployment on OpenShift are as follows.

- The management and portal endpoints must be the same on both data centers.
- The network latency between data centers must be no more than 80 ms.
- The management cluster in each data center must use the same encryption secret.
- The portal cluster in each data center must use the same encryption secret.
- The ingress-ca certificate must be the same on both data centers.

Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center deployment strategy on Kubernetes and OpenShift).

- **Planning and initial preparation**
  Decide on endpoint names. Prepare your OpenShift environments for 2DCDR API Connect.
- **Preparing your active data center**
  Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.
- **Preparing your warm-standby data center**
  Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.
- **Installing API Connect on the active data center**
  Add the `multiSiteHA` configuration to the API Connect Management and Portal CR YAML files before they are applied.
- **Installing API Connect on the warm-standby data center**
  Add the `multiSiteHA` configuration to the API Connect Management and Portal YAML files before they are applied.

Planning and initial preparation

Decide on endpoint names. Prepare your OpenShift environments for 2DCDR API Connect.

Procedure

1. Decide on naming. Both data centers must use the same names for:
   - Management subsystem endpoints
     - `cloudManagerEndpoint`
     - `apiManagerEndpoint`
     - `platformAPIEndpoint`
     - `consumerAPIEndpoint`
   - Portal subsystem endpoints
     - `portalAdminEndpoint`
     - `portalUIEndpoint`

   Each data center must have a different `siteName`. For example, `dallas` in data center 1, and `raleigh` in data center 2. The site name can contain only `a-z` and `0-9` characters. You set `siteName` in the `ManagementCluster` and `PortalCluster` CRs when the subsystems are first deployed. You cannot change the name after deployment. If you don't specify `siteName` at first deployment, a random `siteName` is created for you.

   Important: Each data center must use a different backup path for your Management backups. For portal backups each data center must use the same backup path. For more information, see Backup and restore requirements for a two data center deployment.
2. Install the API Connect operators in both your data centers. See Installing operators for a single namespace API Connect installation or Installing operators for a multi namespace API Connect installation, depending on whether all your API Connect subsystems are to be in the same namespace or not. Return here when the operators are installed.
3. If not already done, create namespaces for your API Connect subsystems in both data centers.

   ```
   oc create ns <namespace>
   ```

   the data centers do not have to use the same namespace name.
4. Decide which data center will start as the active and which will start as the warm-standby.
5. On the CLI of the active data center, where you run `oc` commands, create a directory called `2dcdr-active-yamls`. On the CLI of the warm-standby data center, create a directory called `2dcdr-ws-yamls`.

What to do next

Proceed to prepare the replication certificates, secrets, and issuers on your active data center Preparing your active data center.

Preparing your active data center

Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.

About this task

All operations are done on the CLI, in the `2dcdr-active-yamls` directory you created in Planning and initial preparation.

In the yaml files and commands that are shown here, replace **<namespace>** with the name of the corresponding subsystem namespace.

Procedure

1. Deploy the cert-manager.
   a. Create a file that is called **cert-manager.yaml** and paste in the following contents:

```
apiVersion: operator.ibm.com/v1alpha1
kind: OperandRequest
metadata:
  name: ibm-apiconnect
spec:
  requests:
    - operands:
        - name: ibm-cert-manager-operator
      registry: common-service
      registryNamespace: ibm-common-services
```

   b. Apply this yaml file with:

```
oc apply -f cert-manager.yaml -n <namespace>
```

   c. Confirm that the cert-manager is deployed:

```
oc get deploy -n ibm-common-services | grep ibm-cert-manager-operator
```

   d. Wait for the cert-manager deployment to become available:

```
oc wait --for=condition=available deployment.apps/ibm-cert-manager-operator -n ibm-common-services --timeout=900s
```

   e. Wait for the three cert-manager pods and operator to be in running state:

```
oc get pods -n ibm-common-services | grep cert

cert-manager-cainjector-566b5d5698-pzccn                1/1     Running   0          18m
cert-manager-controller-766ddff8c4-ftr85                1/1     Running   0          18m
cert-manager-webhook-79bb8f67b7-gvkst                   1/1     Running   0          18m
ibm-cert-manager-operator-fdfd66bd4-6rrz6               1/1     Running   0          19m
```

2. Create the encryption key secrets for the Management and Portal subsystems.
   a. Run the following command to create a file that contains a random string, which is used to create the management encryption key secret:

```
cat /dev/urandom | head -c63 | base64 -w0 > mgmt-enc-key.txt
```

   b. Run the following command to create the management encryption key secret:

```
oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
namespace>
```

   c. Confirm that the secret was created successfully by running:

```
oc get secrets -n <management namespace> | grep mgmt-encryption-key

mgmt-encryption-key         Opaque                                1      83s
```

   d. Run the following command to create a file that contains a random string, which is used to create the portal encryption key secret:

```
cat /dev/urandom | head -c63 | base64 -w0 > ptl-enc-key.txt
```

   e. Run the following command to create the portal encryption key secret:

```
oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
```

   f. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key

ptl-encryption-key          Opaque                                1      15s
```

3. If all your API Connect subsystems are to be installed in the same namespace, then create your certificates, issuers, and secrets as described here: Setting up a certificate issuer. Return here when complete, do not proceed to install the subsystems.
4. If your API Connect subsystems are to be installed in different namespaces, then create your certificates, issuers, and secrets for your Management subsystem as described here Create Management subsystem issuers and secrets. For your Portal subsystem, follow the steps here Create Portal subsystem issuers and secretes. Return here when complete, do not proceed to install either subsystem.
5. Create the TLS client replication certificates for Management and Portal.
   a. Create a yaml file that is called **mgmt-tls-client-cert.yaml** and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: mgmt-replication-client
spec:
  commonName: mgmt-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: mgmt-replication-client
```

b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>
```

```
NAME                        READY   SECRET                      AGE     EXPIRATION
...
mgmt-replication-client     True    mgmt-replication-client     16m     2024-08-17T13:04:27Z
```

d. Create a file `ptl-tls-client-cert.yaml` and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ptl-replication-client
spec:
  commonName: ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: ptl-replication-client
```

e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>
```

```
NAME                        READY   SECRET                      AGE     EXPIRATION
...
ptl-replication-client      True    ptl-replication-client      16m     2024-08-17T13:04:27Z
```

6. Export the ingress-ca issuer secret.
   The ingress-ca issuer secret must be the same on the warm-standby data center. Export it from the active so that it can be imported on the warm-standby data center.
   Note: If you are deploying API Connect subsystems in different namespaces, then you export the Management subsystem ingress-ca secret.
   a. Run the following command to export the secret to a file called `ca-issuer-secret.yaml`:

```
oc get secret ingress-ca -o yaml -n <management namespace>  > ca-issuer-secret.yaml
```

   b. Edit the `ca-issuer-secret.yaml` file to remove the creationTimestamp, resourceVersion, uid, namespace, and managedFields. Remove the labels and annotations sections completely. The resulting contents should look like this:

```
apiVersion: v1
data:
  ca.crt: <long cert string>
  tls.crt: <long cert string>
  tls.key: <long cert string>
kind: Secret
metadata:
  name: ingress-ca
type: kubernetes.io/tls
```

7. Copy the following files from your `2dcdr-active-yamls` directory to the `2dcdr-ws-yamls` directory in your warm-standby data center.

```
ca-issuer-secret.yaml
mgmt-enc-key.txt
ptl-enc-key.txt
```

   These files are required to ensure that the ingress-ca and encryption secrets on both sites are the same.
   Tip: To save time during the preparation of your warm-standby data center you can also copy these yaml files:

```
ptl-tls-client-cert.yaml
mgmt-tls-client-cert.yaml
```

8. If you are installing the Portal subsystem in a different namespace to the Management subsystem on the active data center, use the `ca-issuer-secret.yaml` file to create the issuer in your portal namespace. Follow the 'Before you begin steps here: Create issuer. Do not proceed to install the Portal subsystem after creating the issuer.

What to do next

Prepare your warm-standby data center Preparing your warm-standby data center.

Preparing your warm-standby data center

Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.

About this task

All operations are done on the CLI, in the **2dcdr-ws-yamls** directory you created in Planning and initial preparation.

In the yaml files and commands that are shown here, replace **<namespace>** with the name of the corresponding subsystem namespace.

Procedure

1. Deploy the cert-manager.
   a. Create a file that is called **cert-manager.yaml** and paste in the following contents:

```
apiVersion: operator.ibm.com/v1alpha1
kind: OperandRequest
metadata:
  name: ibm-apiconnect
spec:
  requests:
    - operands:
        - name: ibm-cert-manager-operator
      registry: common-service
      registryNamespace: ibm-common-services
```

   b. Apply this yaml file with:

```
oc apply -f cert-manager.yaml -n <namespace>
```

   c. Confirm that the cert-manager is deployed:

```
oc get deploy -n ibm-common-services | grep ibm-cert-manager-operator
```

   d. Wait for the cert-manager deployment to become available:

```
oc wait --for=condition=available deployment.apps/ibm-cert-manager-operator -n ibm-common-services --timeout=900s
```

   e. Wait for the three cert-manager pods and operator to be in running state:

```
oc get pods -n ibm-common-services | grep cert

cert-manager-cainjector-566b5d5698-pzccn                1/1     Running   0          18m
cert-manager-controller-766ddff8c4-ftr85                1/1     Running   0          18m
cert-manager-webhook-79bb8f67b7-gvkst                   1/1     Running   0          18m
ibm-cert-manager-operator-fdfd66bd4-6rrz6               1/1     Running   0          19m
```

2. Import the ingress-ca issuer secret.
   This secret was created on your active data center here: Preparing your active data center
   a. If you did not do it as part of Preparing your active data center, copy the **ca-issuer-secret.yaml** file to your warm-standby data center.
   b. Create the secret with:

```
oc apply -f ca-issuer-secret.yaml -n <namespace>
```

   c. Verify that the secret was created with:

```
oc get secret -n <namespace>

NAME                            TYPE                                  DATA   AGE
ingress-ca                      kubernetes.io/tls                     3      19h
```

   d. If your Portal subsystem is in a different namespace in your warm-standby data center, then repeat the **oc apply** operation against the portal namespace.
3. Create a file that is called **warm-standby-certs.yaml** and paste in:

```

      app.kubernetes.io/managed-by: "ibm-apiconnect"
      app.kubernetes.io/name: "gateway-peering"
```

4. Apply this file by running against your Management subsystem namespace:

```
oc apply -f warm-standby-certs.yaml -n <namespace>
```

5. Verify that the certificates, secrets, and issuers were created with:

```
oc get secrets -n <namespace>
NAME                          TYPE                                  DATA   AGE
analytics-ingestion-client    kubernetes.io/tls                     3      12s
gateway-client-client         kubernetes.io/tls                     3      21s
gateway-peering               kubernetes.io/tls                     3      11s
gateway-service               kubernetes.io/tls                     3      21s
ingress-ca                    kubernetes.io/tls                     3      18m
portal-admin-client           kubernetes.io/tls                     3      17s

oc get certificates -n <namespace>
NAME                          READY   SECRET                        AGE     EXPIRATION
analytics-ingestion-client    True    analytics-ingestion-client    2m18s   2024-09-04T12:27:38Z
gateway-client-client         True    gateway-client-client         2m19s   2024-09-04T12:27:28Z
gateway-peering               True    gateway-peering               2m17s   2024-09-04T12:27:39Z
gateway-service               True    gateway-service               2m18s   2024-09-04T12:27:28Z
portal-admin-client           True    portal-admin-client           2m19s   2024-09-04T12:27:33Z

oc get issuers -n <namespace>
NAME               READY   AGE
ingress-issuer     True    18m
selfsigning-issuer True    2m42s
```

6. If your Portal subsystem is in a different namespace in your warm-standby data center, then to create your certificates, issuers, and secrets in the Portal subsystem namespace:
   a. Create a file that is called `warm-standby-ptl-certs.yaml` and paste in:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "selfsigning-issuer"
  }
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "ingress-issuer"
  }
spec:
  ca:
    secretName: ingress-ca
```

   b. Apply this file to your Portal subsystem namespace:

```
oc apply -f warm-standby-certs.yaml -n <namespace>
```

   c. Verify that your issuers and secrets were created successfully:

```
oc get issuers -n <portal namespace>
NAME                 READY   AGE
ingress-issuer       True    43s
selfsigning-issuer   True    43s

oc get secrets -n <portal namespace>
NAME                       TYPE                                  DATA   AGE
ingress-ca                 kubernetes.io/tls                     3      4m18s
```

7. Create the encryption key secrets for the Management and Portal subsystems, by using the random string generated on the active data center.
   Use the `mgmt-enc-key.txt` and `ptl-enc-key.txt` files that were copied to your warm-standby data center when you followed Preparing your active data center.
   a. Run the following command to create the management encryption key secret:

```
oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
namespace>
```

   b. Confirm that the secret was created successfully by running:

```
oc get secrets -n <management namespace> | grep mgmt-encryption-key

mgmt-encryption-key        Opaque                                1      83s
```

   c. Run the following command to create the portal encryption key secret:

```
oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
```

   d. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key

ptl-encryption-key         Opaque                                1      15s
```

8. Create the TLS client replication certificates for Management and Portal.
   a. Create a yaml file that is called `mgmt-tls-client-cert.yaml` and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: mgmt-replication-client
spec:
  commonName: mgmt-replication-client
  duration: 17520h0m0s
```

```
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: mgmt-replication-client
```

b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>

NAME                        READY   SECRET                      AGE     EXPIRATION
...
mgmt-replication-client     True    mgmt-replication-client     16m     2024-08-17T13:04:27Z
```

d. Create a file `ptl-tls-client-cert.yaml` and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ptl-replication-client
spec:
  commonName: ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: ptl-replication-client
```

e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>

NAME                        READY   SECRET                      AGE     EXPIRATION
...
ptl-replication-client      True    ptl-replication-client      16m     2024-08-17T13:04:27Z
```

What to do next

Install API Connect on your active data center Installing API Connect on the active data center.

Installing API Connect on the active data center

Add the **multiSiteHA** configuration to the API Connect Management and Portal CR YAML files before they are applied.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get secrets -n <namespace>
ingress-ca              kubernetes.io/tls                     3      3d21h
mgmt-replication-client kubernetes.io/tls                     3      3d21h
ptl-replication-client  kubernetes.io/tls                     3      3d21h

oc get certs -n <namespace>
ingress-ca              True    ingress-ca                3d21h   2032-08-15T13:01:47Z
mgmt-replication-client True    mgmt-replication-client   3d21h   2024-08-17T13:04:27Z
ptl-replication-client  True    ptl-replication-client    3d21h   2024-08-17T13:04:26Z

oc get issuer -n <namespace>
ingress-issuer   True    3d21h
self-signed      True    3d21h
```

Where **<namespace>** are the namespaces you created for API Connect.
Note: If you have separate namespaces for Management and Portal subsystems, then run the check in both namespaces. You should not see the **mgmt-replication-client** in the portal namespace, nor the **ptl-replication-client** in the management namespace.

Procedure

1. Follow these steps for installing the Management subsystem on OpenShift Installing the Management subsystem in a shared namespace, but add the **encryptionSecret**
and **multiSiteHA** section to the **mgmt_cr.yaml** file:

```
  siteName: <dc1 site name>
  encryptionSecret:
    secretName: mgmt-encryption-key
  multiSiteHA:
    mode: active
    replicationEndpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: mgmt-replication.<active data center ingress domain>
        secretName: mgmt-replication-server
    replicationPeerFQDN: mgmt-replication.<warm-standby data center ingress domain>
    tlsClient:
      secretName: mgmt-replication-client
```

where

- **<dc1 site name>** is the site name for this data center, as decided in Planning and initial preparation.
- **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

Note: If you are installing the Management subsystem in a separate namespace, these same steps apply.

2. Apply the update **mgmt_cr.yaml** file as directed in Installing the Management subsystem in a shared namespace. You can monitor the deployment with:

```
oc get ManagementCluster -n <management namespace>
NAME          READY   STATUS    VERSION    RECONCILED VERSION   AGE
management    19/19   Running   10.0.5.0   10.0.5.0-1281        74m
```

3. Follow these steps for installing the Portal subsystem on OpenShift Installing the Portal subsystem in a shared namespace, but add the **encryptionSecret** and **multiSiteHA** section to the **portal_cr.yaml** file.

```
  siteName: <dc1 site name>
  encryptionSecret:
    secretName: ptl-encryption-key
  multiSiteHA:
    mode: active
    replicationEndpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: ptl-replication.<active data center ingress domain>
        secretName: ptl-replication-server
    replicationPeerFQDN: ptl-replication.<warm-standby data center ingress domain>
    tlsClient:
      secretName: ptl-replication-client
```

where

- **<dc1 site name>** is the site name for this data center, as decided in Planning and initial preparation.
- **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

Note: If you are installing the Portal subsystem in a separate namespace, these same steps apply.

4. Apply the updated **portal_cr.yaml** file as directed in Installing the Portal subsystem in a shared namespace.

```
oc get PortalCluster -n <portal namespace>
NAME     READY   STATUS    VERSION    RECONCILED VERSION   AGE
portal   6/6     Running   10.0.5.0   10.0.5.0-1281        49m
```

Results

Confirm that the management subsystem is ready, but in **Warning** state with **oc get mgmt**:

```
oc get mgmt -n <namespace>
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.5.3-0   10.0.5.3-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s
```

```
status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
```

The management CR is expected to report the status of **Warning** until the warm-standby management subsystem is deployed, and both management subsystems complete data replication. When you see the status message "Management is ready. HA Status Warning - see HAStatus in CR for details", you can move on to Installing API Connect on the warm-standby data center.

What to do next

Install API Connect in your warm-standby data center Installing API Connect on the warm-standby data center.

Deploy your Gateway and Analytics subsystems in your active data center. For shared namespace: Installing with subsystem CRs in a shared namespace on OpenShift or multiple namespaces: Installing with subsystem CRs in different namespaces or environments on OpenShift.

Installing API Connect on the warm-standby data center

Add the **multiSiteHA** configuration to the API Connect Management and Portal YAML files before they are applied.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get secrets -n <namespace>
ingress-ca                kubernetes.io/tls                     3      3d21h
mgmt-replication-client   kubernetes.io/tls                     3      3d21h
ptl-replication-client    kubernetes.io/tls                     3      3d21h

oc get certs -n <namespace>
mgmt-replication-client   True    mgmt-replication-client   3d21h   2024-08-17T13:04:27Z
ptl-replication-client    True    ptl-replication-client    3d21h   2024-08-17T13:04:26Z

oc get issuer -n <namespace>
ingress-issuer   True    3d21h
self-signed      True    3d21h
```

Where **<namespace>** are the namespaces you created for API Connect.
Note: If you have separate namespaces for Management and Portal subsystems, then run the check in both namespaces. You should not see the **mgmt-replication-client** in the portal namespace, nor the **ptl-replication-client** in the management namespace.

Procedure

1. Follow these steps for installing the Management subsystem on OpenShift Installing the Management subsystem in a shared namespace, but add the **encryptionSecret** and **multiSiteHA** section to the **mgmt_cr.yaml** file:

   ```
   siteName: <dc2 site name>
   encryptionSecret:
     secretName: mgmt-encryption-key
   multiSiteHA:
     mode: passive
     replicationEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: mgmt-replication.<warm-standby data center ingress domain>
         secretName: mgmt-replication-server
     replicationPeerFQDN: mgmt-replication.<active data center ingress domain>
     tlsClient:
       secretName: mgmt-replication-client
   ```

   where
   - **<dc2 site name>** is the site name for this data center, as decided in Planning and initial preparation.
   - **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

   Note: If you are installing the Management subsystem in a separate namespace, these same steps apply.
   Remember: Make sure that the management endpoints are set the same as for your active data center deployment.
2. Apply the update **mgmt_cr.yaml** file as directed in Installing the Management subsystem in a shared namespace. Monitor the deployment, but note that on the warm-standby there are fewer pods than on the active:

   ```
   oc get ManagementCluster -n <namespace>NAME          READY   STATUS    VERSION    RECONCILED VERSION   AGE
   management   n/n     Running   10.0.5.3   10.0.5.3-1281        62m
   ```

3. Follow these steps for installing the Portal subsystem on OpenShift Installing the Portal subsystem in a shared namespace, but add the **encryptionSecret** and **multiSiteHA** section to the **portal_cr.yaml** file.

   ```
   siteName: <dc2 site name>
   encryptionSecret:
     secretName: ptl-encryption-key
   multiSiteHA:
     mode: passive
     replicationEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: ptl-replication.<warm-standby data center ingress domain>
         secretName: ptl-replication-server
     replicationPeerFQDN: ptl-replication.<warm-standby data center ingress domain>
     tlsClient:
       secretName: ptl-replication-client
   ```

   where
   - **<dc2 site name>** is the site name for this data center, as decided in Planning and initial preparation.
   - **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

   Remember: Make sure that the portal endpoints are set the same as for your active data center deployment.
4. Apply the updated **portal_cr.yaml** file as directed in Installing the Portal subsystem in a shared namespace.

   ```
   oc get PortalCluster -n <namespace>
   NAME     READY   STATUS    VERSION    RECONCILED VERSION   AGE
   ```

```
portal    6/6     Running    10.0.5.3    10.0.5.3-1281         47m
```

Results

While the management subsystems on the warm-standby and active data centers are synchronizing their databases, the management status reports **Warning**, and the **haStatus** reports **pending**:

```
oc get mgmt -n <namespace>
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.5.3-0   10.0.5.3-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
```

When the management database replication between sites is complete, the management status reports **Running**, and **status.haStatus** reports **Ready**:

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Running   10.0.5.3-0   10.0.5.3-0           Management is ready.              8m59s

status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

If the management database replication between sites fails for any reason other than because an install or upgrade is in progress, the **haStatus** output shows:

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.5.3-0   10.0.5.3-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "Warning"
    }
```

If the warning persists, see Troubleshooting a two data center deployment.
You can validate that your portal deployments are synchronizing by running **oc get pods** on both the active and warm-standby data centers. Confirm that the number and names of the pods all match (the UUIDs in the names might be different on each site), and that all are in the **Ready** state.

For additional replication verification checks, see Verifying replication between data centers. It is recommended to run a test failover, and confirm that all of the expected data is present and correct on the newly active site. See How to perform 2DCDR failover for details.

What to do next

Deploy your Gateway and Analytics subsystems for shared namespace: Installing with subsystem CRs in a shared namespace on OpenShift or multiple namespaces: Installing with subsystem CRs in different namespaces or environments on OpenShift

Configure your deployment: Cloud Manager configuration checklist, and complete a test failover to verify that your data replicated to the warm-standby. See How to perform 2DCDR failover for details.

Troubleshooting installation on OpenShift

Review the following known issues and troubleshooting tips if you encounter a problem while installing API Connect on OpenShift, including as a component of IBM Cloud Pak for Integration (CP4I).

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

- One or more pods in CrashLoopBackoff or Error state, and report a certificate error in the logs
- You see the denied: insufficient scope error during an air-gapped deployment
- Apiconnect operator crashes
- Disabling the Portal web endpoint check

One or more pods in `CrashLoopBackoff` or `Error` state, and report a certificate error in the logs

In rare cases, cert-manager might detect a certificate in a bad state right after it has been issued, and then re-issues the certificate. If a CA certificate has been issued twice, the certificate that was signed by the previously issued CA will be left stale and can't be validated by the newly issued CA. In this scenario, one of the following messages displays in the log:

- `javax.net.ssl.SSLHandshakeException: Received fatal alert: certificate_unknown`
- `Error: unable to verify the first certificate`
- `ERROR: openssl verify failed to verify the Portal CA tls.crt, ca.crt chain signed the Portal Server tls.crt cert`

Resolve the problem by completing the following steps:

1. Use `apicops` (v10 version 0.10.57+ required) to validate the certificates in the system:

   ```
   apicops upgrade:stale-certs -n <namespace>
   ```

2. If any certificate that is managed by cert-manager fails the validation, delete the stale certificate secret:

   ```
   oc delete secret <stale-secret> -n <namespace>
   ```

   Cert-manager automatically generates a new certificate to replace the one you deleted.

3. Use `apicops` to make sure all certificates can be verified successfully:

   ```
   apicops upgrade:stale-certs -n <namespace>
   ```

You see the `denied: insufficient scope` error during an air-gapped deployment

Problem: You encounter the `denied: insufficient scope` message while mirroring images during an air-gapped installation or upgrade.

Reason: This error occurs when a problem is encountered with the entitlement key used for obtaining images.

Solution: Obtain a new entitlement key by completing the following steps:

1. Log in to the IBM Container Library.
2. In the Container software library, select Get entitlement key.
3. After the Access your container software heading, click Copy key.
4. Copy the key to a safe location.

Apiconnect operator crashes

Problem: During installation (or upgrade), the Apiconnect operator crashes with the following message:

```
panic: unable to build API support: unable to get Group and Resources: unable to retrieve the complete list of server APIs:
packages.operators.coreos.com/v1: the server is currently unable to handle the request

goroutine 1 [running]:
github.ibm.com/velox/apiconnect-operator/operator-utils/v2/apiversions.GetAPISupport(0x0)
        operator-utils/v2/apiversions/api-versions.go:89 +0x1e5
main.main()
        ibm-apiconnect/cmd/manager/main.go:188 +0x4ee
```

Additional symptoms:

- Apiconnect operator is in crash loopback status
- Kube apiserver pods log the following information:

  ```
  E1122 18:02:07.853093 18 available_controller.go:437] v1.packages.operators.coreos.com failed with:
   failing or missing response from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1:
   bad status from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1: 401
  ```

- The IP logged here belongs to the *package server* pod present in the `openshift-operator-lifecycle-manager` namespace
- Package server pods log the following: `/apis/packages.operators.coreos.com/v1` API call is being rejected with 401 issue

  ```
  E1122 18:10:25.614179 1 authentication.go:53] Unable to authenticate the request due to an error: x509:
  certificate signed by unknown authority I1122 18:10:25.614224 1 httplog.go:90]
  verb="GET" URI="/apis/packages.operators.coreos.com/v1" latency=161.243µs resp=401
  UserAgent="Go-http-client/2.0" srcIP="10.128.0.1:41370":
  ```

- Problem is intermittent

Solution:

- If you find the exact symptoms as described, the solution is to delete package server pods in the `openshift-operator-lifecycle-manager` namespace.
- New package server pods will log the `200 Success` message for the same API call.

Disabling the Portal web endpoint check

When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the `portal-www` pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully.
To disable the endpoint check, complete the following update:

On Kubernetes, OpenShift, and IBM® Cloud Pak for Integration

Add the following section to the Portal custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

Upgrading API Connect

You can upgrade a v10 deployment of API Connect to a newer version.

About this task

Select from the following sections to find detailed information about upgrading your API Connect deployment.
For information about how to maintain a two data center deployment, including upgrade considerations, see Maintaining a two data center deployment.

- **Upgrading on Kubernetes**
  Upgrade API Connect on native Kubernetes distributions.
- **Upgrading on OpenShift and Cloud Pak for Integration**
  You can upgrade API Connect in an OpenShift environment and as part of IBM Cloud Pak for Integration.
- **Upgrading a two data center deployment on Kubernetes and OpenShift**
  How to upgrade a two data center disaster recovery (DR) deployment on Kubernetes and OpenShift.
- **Upgrading a two data center deployment on Cloud Pak for Integration**
  How to upgrade a two data center disaster recovery (DR) deployment on Cloud Pak for Integration.

Upgrading on Kubernetes

Upgrade API Connect on native Kubernetes distributions.

After reviewing the overview, use the procedures in this section to upgrade API Connect on native Kubernetes distributions.

Note: For upgrading from v5, see Migrating a version 5 deployment to version 10.0.6x.

- **Upgrade considerations on native Kubernetes**
  Review the supported versions, requirements, and limitations for upgrading API Connect on Kubernetes.
- **Upgrading subsystems on native Kubernetes**
  Upgrade your API Connect subsystems to the latest version on native Kubernetes.
- **Troubleshooting upgrades on Kubernetes**
  Review the following troubleshooting guidance if you encounter a problem while upgrading API Connect on Kubernetes.

Upgrade considerations on native Kubernetes

Review the supported versions, requirements, and limitations for upgrading API Connect on Kubernetes.

- Supported upgrade paths
- Supported DataPower Gateway versions
- Ensuring compatibility with Drupal 10 for Developer Portal customizations

Tip: After upgrade, clear your browser cache, and open a new browser window. This action avoids stale cache issues in your browser, that can result in unexpected behavior in the Cloud Manager and API Manager UIs.

Supported upgrade paths

Attention: API Connect is not supported in a FIPS-enabled environment.

Table 1. Supported upgrade paths on Kubernetes

Upgrade from:	How to upgrade to 10.0.6.0
• 10.0.5.3 • 10.0.5.2 • 10.0.5.1 • 10.0.5.0	Complete the procedure in Upgrading subsystems on native Kubernetes.

Attention: Different releases of API Connect support different versions of Kubernetes, so you might need to upgrade Kubernetes before upgrading API Connect. For more information, see IBM API Connect Version 10 software product compatibility requirements.

Supported DataPower Gateway versions

You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

However, before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

Ensuring compatibility with Drupal 10 for Developer Portal customizations

If you are upgrading from a release earlier than 10.0.5.3, review the Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10 to ensure that any customizations to the Developer Portal are compatible with Drupal 10.

In API Connect 10.0.5.3, the Developer Portal moved from Drupal 9 to Drupal 10 (this upgrade also requires PHP 8.1). The upgrade tooling will update your Developer Portal sites; however, if you have any custom modules or themes, it is your responsibility to ensure their compatibility with Drupal 10 and PHP 8.1 before starting the upgrade.

Upgrading subsystems on native Kubernetes

Upgrade your API Connect subsystems to the latest version on native Kubernetes.

Before you begin

- To ensure operator compatibility, upgrade API Connect management subsystem first and DataPower gateway subsystem second. This requirement applies to all upgrade scenarios.
  The Gateway subsystem remains available during the upgrade of the Management, Portal, and Analytics subsystems.
- Verify that your installed Kubernetes version is supported by the API Connect version that you are upgrading to. See IBM API Connect Version 10 software product compatibility requirements. If your Kubernetes version is older than the minimum supported version for your target API Connect version, then upgrade Kubernetes first.

Procedure

1. Complete the prerequisites:
   a. Ensure you are upgrading from a supported version and reviewed the upgrade requirements and limitations. See Upgrade considerations on native Kubernetes.
   b. Ensure that the API Connect operator and subsystems are all in **Running** state.
   To verify the health of each subsystem, run the following commands:

   ```
   kubectl get ManagementCluster -n <mgmt_namespace>
   kubectl get GatewayCluster -n <gway_namespace>
   kubectl get PortalCluster -n <portal_namespace>
   kubectl get AnalyticsCluster -n <mgmt_namespace>
   ```

   Check that all pods are **READY**, for example:

   ```
   kubectl get PortalCluster -n apic
   NAME     READY   STATUS    VERSION    RECONCILED VERSION   AGE
   portal   3/3     Running   10.0.6.0   10.0.6.0-95    57m
   ```

   c. Verify that the **pgcluster** is healthy:
      i. Get the name of the **pgcluster**:

      ```
      kubectl get pgcluster -n <APIC_namespace>
      ```

      The response displays the name of the postgres cluster running in the specified namespace.

      ii. Check the status of the **pgcluster**:

      ```
      kubectl get pgcluster <pgcluster_name> -n <APIC_namespace> -o yaml | grep status -A 2 | tail -n3
      ```

      The response for a healthy **pgcluster** looks like the following example, where the state is **Initialized**:

      ```
      status:
          message: Cluster has been initialized
          state: pgcluster Initialized
      ```

   Important: If the **pgcluster** returns any other state, it is not healthy and an upgrade will fail.
   - If there are any on-going backup or restore jobs, wait until they complete and then check the status again. Do not proceed with the upgrade until the status is **Initialized**.
   - If all of the background jobs complete but the **pgcluster** remains unhealthy, contact IBM Support for assistance.

   d. Backup the current deployment.
   Notes:
   - Wait until the backup completes before starting the upgrade.
   - Do not start an upgrade if a backup is scheduled to run within a few hours.
   - Do not perform maintenance tasks such as rotating key-certificates, restoring from a backup, or starting a new backup, at any time while the upgrade process is running.

   For instructions on backing up and disaster recovery preparation, see:
   - v10.0.6: Backups on Kubernetes, Disaster recovery on Kubernetes.

- v10.0.5.x: Backups on Kubernetes, Disaster recovery.

e. If you used any microservice image overrides in the management CR during a fresh install, you must remove the image overrides prior to upgrade.
Important: When upgrading, if you used any microservice image overrides in the management CR during a fresh install then prior to upgrade these image overrides will be automatically removed by the operator during upgrade. You can apply them again after the upgrade is complete.

2. Run the pre-upgrade health check:
Attention: This is a required step. Failure to run this check before upgrading could result in problems during the upgrade.
   a. Verify that the **apicops** utility is installed by running the following command to check the current version of the utility:

      ```
      apicops --version
      ```

      If the response indicates that **apicops** is not available, install it now. See The API Connect operations tool: apicops in the API Connect documentation.

   b. Run the following command to set the KUBECONFIG environment.

      ```
      export KUBECONFIG=</path/to/kubeconfig>
      ```

   c. Run the following command to execute the pre-upgrade script:

      ```
      apicops version:pre-upgrade -n <namespace>
      ```

      If the system is healthy, the results will not include any errors.

      Note: This command asks for the Cloud Manager admin password in order to make a call to the platform API. If you do not have this password, or the platform API URL is not accessible from your **apicops** location, then this part of the pre-upgrade check can be skipped by adding the argument **--no-topology**. The topology check output that is produced by this API call is typically only required for debugging purposes, when the **apicops version:pre-upgrade** returns output that suggests the system is unhealthy.

3. Obtain the API Connect files from IBM Fix Central.
From the IBM Fix Central site, download the Docker image-tool file of the API Connect subsystems. Next, you will upload the image-tool file to your Docker local registry. If necessary, you can populate a remote container registry with repositories. Then you can push the images from the local registry to the remote registry.

   You will also download the Kubernetes operators, API Connect Custom Resource (CR) templates, and Certificate Manager, for use during deployment configuration.

   The following files are used for deployment on native Kubernetes:

   IBM® API Connect *<version>* for Containers
   Docker images for all API Connect subsystems

   IBM® API Connect *<version>* Operator Release Files for Containers
   Kubernetes operators and API Connect Custom Resource (CR) templates

   IBM® API Connect *<version>* Toolkit for *<operating_system_type>*
   Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:
   - IBM® API Connect *<version>* Toolkit for *<operating_system_type>*
   - IBM® API Connect *<version>* Toolkit with Loopback for *<operating_system_type>*
   - IBM® API Connect *<version>* Toolkit Designer with Loopback for *<operating_system_type>*

   Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See Installing the toolkit.

   IBM® API Connect *<version>* Local Test Environment
   Optional test environment. See Testing an API with the Local Test Environment

   IBM® API Connect *<version>* Security Signature Bundle File
   Checksum files that you can use to verify the integrity of your downloads.

4. Next, upload the image files that you obtained from Fix Central in Step 3.
   a. Load the image-tool image for the new version into your Docker local registry:

      ```
      docker load < apiconnect-image-tool-<version>.tar.gz
      ```

      Ensure that the registry has sufficient disk space for the files.

   b. If your Docker registry requires repositories to be created before images can be pushed, create the repositories for each of the images listed by the image tool. If your Docker registry does not require creation of repositories, skip this step and go to Step 4.c.
      i. Run the following command to get a list of the images from image-tool:

         ```
         docker run --rm apiconnect-image-tool-<version> version --images
         ```

      ii. From the output of each entry of the form **<image-name>:<image-tag>**, use your Docker registry repository creation command to create a repository for **<image-name>**.
      For example in the case of AWS ECR the command would be for each **<image-name>**:

         ```
         aws ecr create-repository --repository-name <image-name>
         ```

   c. Upload the image:
      - If you do not need to authenticate with the docker registry, use:

        ```
        docker run --rm apiconnect-image-tool-<version> upload <registry-url>
        ```

      - Otherwise, if your docker registry accepts authentication with username and password arguments, use:

        ```
        docker run --rm apiconnect-image-tool-<version> upload <registry-url> --username <username> --password <password>
        ```

      - Otherwise, such as with IBM Container Registry, if you need the image-tool to use your local Docker credentials, first authenticate with your Docker registry, then upload images with the command:

        ```
        docker run --rm -v ~/.docker:/root/.docker --user 0 apiconnect-image-tool-<version> upload <registry-url>
        ```

        Review the following installation notes as appropriate for your environment:

        - Alternative Docker command for macOS if Docker is configured to use osxkeychain
        - Docker authentication notes

- Providing a certificate for verification, or disabling TLS verification

5. Download and decompress IBM API Connect *<version>* Operator Release Files for Containers.
   Make a directory called **helper_files** and extract the contents of **helper_files.zip** from the release_files.zip into **helper_files**.

6. Apply the new CRDs from the version you just extracted:

   ```
   kubectl apply -f ibm-apiconnect-crds.yaml
   ```

7. Apply the new DataPower Operator YAML into the namespace where the DataPower Operator is running.
   a. Verify that the correct namespace is referenced in the **ibm-datapower.yaml** file:
      If your product was not deployed in the namespace called **default**, open the **ibm-datapower.yaml** file in a text editor and replace all instances of **default** with the appropriate name of the namespace where you deployed the product.

   b. Specify the location of the **datapower-operator** image:
      Open the **ibm-datapower.yaml** file in a text editor and locate the **image:** key in the **containers** section of the deployment file (immediately after **imagePullSecrets:**). Replace the value of the **image:** key with the location of the **datapower-operator** image, either uploaded to your own registry or pulled from a public registry.

   c. Run the following command:

      ```
      kubectl apply -f ibm-datapower.yaml -n <namespace>
      ```

      The Gateway CR goes to **Pending** state when the operator is updated, and then changes to **Running** after installation of the API Connect operator in the next step.

      Troubleshooting: If your DataPower operator pod fails to start, see Troubleshooting upgrade.

8. Upgrade cert-manager to version 1.9.1.
   a. Run the following command to back up the existing certificates and issuers to a file called backup.yaml:

      ```
      kubectl get --all-namespaces -oyaml issuer,clusterissuer,cert,secret > backup.yaml
      ```

   b. Run the following command to verify the version that you are upgrading from:
      - API Connect 10.0.5.0 verify that you are upgrading cert-manager 1.5.1:

        ```
        kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
        v1.5.1
        ```

      - API Connect 10.0.5.1, 10.0.5.2, or 10.0.5.3: verify that you are upgrading cert-manager 1.7.1:

        ```
        kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
        v1.7.1
        ```

   c. Run the following command to upgrade cert-manager to version 1.9.1:

      ```
      kubectl apply -f helper_files/cert-manager-1.9.1.yaml
      ```

9. If you used customized internal certificates, and are upgrading from 10.0.5.1: The **helper_files/custom-certs-internal.yaml** includes a new certificate called **dbClientPrimaryuser**. This new certificate must be created before you update the Management CR.
   Follow the instructions in Generate custom internal certificates to update the **helper_files/custom-certs-internal.yaml** file to match your namespace and site name, and then apply the new **yaml** file with the following command:

   ```
   kubectl apply -f custom-certs-internal.yaml -n <namespace>
   ```

   Alternatively, add the new certificate to your existing **custom-certs-internal.yaml** and apply it, updating the namespace to match your deployment:

   ```
   ---
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: db-client-primaryuser
     labels: {
       app.kubernetes.io/instance: "management",
       app.kubernetes.io/managed-by: "ibm-apiconnect",
       app.kubernetes.io/name: "db-client-primaryuser"
     }
   spec:
     commonName: primaryuser
     secretName: db-client-primaryuser
     dnsNames:
       - "*.<namespace>"
       - "*.<namespace>.svc"
       - "primaryuser.<namespace>.svc"
       - "primaryuser"
     issuerRef:
       name: ingress-issuer
     usages:
     - "client auth"
     - "signing"
     - "key encipherment"
     duration: 17520h # 2 years
     renewBefore: 720h # 30 days
     privateKey:
       rotationPolicy: Always
   ---
   ```

10. Clean up the webhook configuration before deploying the newer API Connect operator:
    a. Run the following command to get the webhook configuration:

       ```
       kubectl get mutatingwebhookconfiguration,validatingwebhookconfiguration | grep ibm-apiconnect
       ```

    b. Use the **kubectl delete** command to delete the webhook configuration; for example:

```
kubectl delete mutatingwebhookconfiguration ibm-apiconnect-mutating-webhook-configuration
kubectl delete validatingwebhookconfiguration ibm-apiconnect-validating-webhook-configuration
```

11. Apply the new API Connect operator YAML into the namespace where the API Connect operator is running.
    - For single namespace deployment:
      - If the operator is not running in the `default` namespace, open the `ibm-apiconnect.yaml` file in a text editor, and then replace all references to `default` with the name of the namespace where you deployed API Connect.
        Note: Skip this step if you are using Operator Lifecycle Manager (OLM).
      - Open `ibm-apiconnect.yaml` in a text editor. Replace the value of each `image:` key with the location of the `apiconnect` operator images (from the `ibm-apiconnect` container and the `ibm-apiconnect-init` container), either uploaded to your own registry or pulled from a public registry.
      - Run the following command:

        ```
        kubectl apply -f ibm-apiconnect.yaml -n <namespace>
        ```

    - For multi-namespace deployment:
      - Locate and open the newly downloaded `ibm-apiconnect-distributed.yaml` in a text editor of choice. Then, find and replace each occurrence of `$OPERATOR_NAMESPACE` with the desired namespace for the deployment.
      - Also in `ibm-apiconnect-distributed.yaml`, locate the `image:` keys in the containers sections of the deployment yaml right below `imagePullSecrets:`. Replace the placeholder values `REPLACE-DOCKER-REGISTRY` of the `image:` keys with the docker registry host location of the API Connect operator image (either uploaded to own registry or pulled from public registry).
      - Install `ibm-apiconnect-distributed.yaml` with the following command

        ```
        kubectl apply -f ibm-apiconnect-distributed.yaml
        ```

12. Verify that the `ibm-datapower-operator` and the `ibm-apiconnect` operators are restarted.
13. Ensure that the `apiconnect` operator recreated the necessary microservices:
    Be sure to complete this step before attempting to upgrade the operands.

    ```
    kubectl get apic -n <namespace>
    ```

14. Upgrade the operands (subsystems):
    a. Upgrading Management subsystem on native Kubernetes
    b. Upgrading Portal subsystem on native Kubernetes
    c. Upgrading Analytics subsystem on native Kubernetes
    d. Upgrading Gateway subsystem on native Kubernetes
15. Verify that the upgraded subsystems report as `Running` and the `RECONCILED VERSION` displays the new version of API Connect.
    Run the following command:

    ```
    kubectl get apic --all-namespaces
    ```

    Example response:

    ```
    NAME                                                READY   STATUS    VERSION              RECONCILED VERSION      AGE
    analyticscluster.analytics.apiconnect.ibm.com/analytics      8/8     Running   10.0.6.0   10.0.6.0-1074   121m

    NAME                                      PHASE     READY   SUMMARY                            VERSION    AGE
    datapowerservice.datapower.ibm.com/gw1    Running   True    StatefulSet replicas ready: 1/1    10.0.6.0   100m

    NAME                                      PHASE     LAST EVENT   WORK PENDING   WORK IN-PROGRESS   AGE
    datapowermonitor.datapower.ibm.com/gw1    Running                false          false              100m

    NAME                                          READY   STATUS    VERSION              RECONCILED VERSION      AGE
    gatewaycluster.gateway.apiconnect.ibm.com/gw1   2/2     Running   10.0.6.0   10.0.6.0-1074  100m

    NAME                                             READY   STATUS    VERSION              RECONCILED VERSION      AGE
    managementcluster.management.apiconnect.ibm.com/m1   16/16   Running   10.0.6.0   110.0.6.0-1074   162m

    NAME                                            READY   STATUS    VERSION              RECONCILED VERSION      AGE
    portalcluster.portal.apiconnect.ibm.com/portal   3/3     Running   10.0.6.0   10.0.6.0-1074   139m
    ```

    Important: If you need to restart the deployment, wait until all Portal sites complete the upgrade. Run the following commands to check the status of the sites:
    a. Log in as an admin user:

    ```
    apic login -s <server_name> --realm admin/default-idp-1 --username admin --password <password>
    ```

    b. Get the portal service ID and endpoint:

    ```
    apic portal-services:get -o admin -s <management_server_endpoint> \
                --availability-zone availability-zone-default <portal-service-name> \
                --output - --format json
    ```

    c. List the sites:

    ```
    apic --mode portaladmin sites:list -s <management_server_endpoint> \
                --portal_service_name <portal-service-name> \
                --format json
    ```

    Any sites currently upgrading display the `UPGRADING` status; any site that completed its upgrade displays the `INSTALLED` status and the new platform version. Verify that all sites display the `INSTALLED` status before proceeding.

    For more information on the `sites` command, see `apic sites:list` and Using the `sites` commands.

    d. After all sites are in `INSTALLED` state and have the new platform listed, run:

    ```
    apic --mode portaladmin platforms:list -s <server_name> --portal_service_name <portal_service_name>
    ```

    Verify that the new version of the platform is the only platform listed.

    For more information on the `platforms` command, see `apic platforms:list` and Using the `platforms` commands.

16. If you are upgrading from v10.0.5.3 or earlier, update the certificates with the ingress-issuer-v1.yaml from your target release.

    ```
    kubectl apply -f helper_files/ingress-issuer-v1.yaml -n <namespace>
    ```

    For a multi-namespace deployment, repeat the command for each namespace.
17. Optional: For the optional components API Connect Toolkit and API Connect Local Test Environment, install the latest version of each after you complete the upgrade of the subsystems.

- **Upgrading Management subsystem on native Kubernetes**
  Upgrade the management subsystem to the latest version of API Connect.
- **Upgrading Portal subsystem on native Kubernetes**
  Upgrade the Portal subsystem to the latest version of API Connect.
- **Upgrading Analytics subsystem on native Kubernetes**
  Upgrade the Analytics subsystem to the latest version of API Connect.
- **Upgrading Gateway subsystem on native Kubernetes**
  Upgrade the Gateway subsystem to the latest version of API Connect.
- **Enabling gateway peering and verifying cluster status**
  To complete the operand upgrade, restart the gateway pods to enable gateway peering.
- **Optional post-upgrade steps if you are upgrading from earlier 10.0.5 releases**
  API Connect version 10.0.5.3 introduced new features related to inter-subsystem communication. If you upgraded from 10.0.5.0, 10.0.5.1, or 10.0.5.2, you can configure inter-subsystem communication features now.

Upgrading Management subsystem on native Kubernetes

Upgrade the management subsystem to the latest version of API Connect.

Before you begin

Complete all steps in Upgrading subsystems on native Kubernetes prior to the step that links to this topic.

About this task

When upgrading to a new mod release the version must be changed to the latest mod release version on each CR. This change will be picked up by the operator, and the operator will then start the upgrade.

Procedure

1. Update the management CR for the new version of API Connect.
   a. Run the following command to edit the CR:

      ```
      kubectl -n $NAMESPACE edit mgmt <CLUSTERNAME>
      ```

      where *CLUSTERNAME* is the name specified in the subsystem CR at installation time.

   b. Update the API Connect `version` in the CR:
      For example:

      ```
      version: 10.0.6.0
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update the license value now.
      For example:

      ```
      license: L-GVEN-GFUPVE
      ```

      For the list of licenses, see API Connect licenses.

   d. Run the following command to save and apply the CR: `wq`
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the known upgrade issues.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl get apic -n <namespace>
   ```

   Example output after upgrading the management subsystem:

   ```
   NAME                                                READY   STATUS    VERSION              RECONCILED VERSION      AGE
   managementcluster.management.apiconnect.ibm.com/m1   16/16   Running   <version>   <version-build>   162m

   NAME                                                                  STATUS    MESSAGE
   AGE
   managementdbupgrade.management.apiconnect.ibm.com/management-up-8c28g   Running   Upgrade is running (DB Schema/data are
   up-to-date)   13m
   ```

3. Restart all nats-server pods by running the following command:

   ```
   kubectl -n <namespace> delete po -l app.kubernetes.io/name=natscluster
   ```

What to do next

Upgrade your Portal subsystem: Upgrading Portal subsystem on native Kubernetes.

Upgrading Portal subsystem on native Kubernetes

Upgrade the Portal subsystem to the latest version of API Connect.

Before you begin

- Complete all steps in Upgrading subsystems on native Kubernetes prior to the step that links to this topic.
- Upgrading from 10.0.5.2 or earlier: If you did not verify that your Portal customizations are compatible with Drupal 10, do that now.
  In API Connect 10.0.5.3, the Developer Portal moved from Drupal 9 to Drupal 10 (this upgrade also requires PHP 8.1). The upgrade tooling will update your Developer Portal sites; however, if you have any custom modules or themes, it is your responsibility to ensure their compatibility with Drupal 10 and PHP 8.1 before starting the upgrade. Review the Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10 to ensure that any customizations to the Developer Portal are compatible with Drupal 10 and PHP 8.1.

About this task

When upgrading to a new mod release, the version must be changed to the latest mod release version on each CR. This change will be picked up by the operator, and the operator will then start the upgrade.

Procedure

1. Update the portal CR for the new version of API Connect.
   a. Run the following command to edit the CR:

      ```
      kubectl -n $NAMESPACE edit ptl <CLUSTERNAME>
      ```

      where ***CLUSTERNAME*** is the name specified in the subsystem CR at installation time.

   b. Update the API Connect **version** in the CR:
      For example:

      ```
      version: 10.0.6.0
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update the license value now.
      For example:

      ```
      license: L-GVEN-GFUPVE
      ```

      For the list of licenses, see API Connect licenses.

   d. Run the following command to save and apply the CR: **wq**
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the known upgrade issues.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl get apic -n <namespace>
   ```

   Example output after upgrading the portal subsystem:

   ```
   NAME                                                READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE
   AGE
   portalcluster.portal.apiconnect.ibm.com/portal      3/3     Running   <version>  <version>            Site Upgrades
   Executing:(1) Queued(5) Failed(0) Success(0)   22h
   ```

   Note: After the portal subsystem code upgrade is complete, each portal site is upgraded. You can monitor the site upgrade progress from the **MESSAGE** column in the **kubectl**
   get apic output. You can still use the portal while sites are upgrading, although a maintenance page is shown for any sites that are being upgraded. When the site upgrades are complete, the **kubectl get apic** output shows how many sites the portal is serving:

   ```
   NAME     READY   STATUS    VERSION          RECONCILED VERSION   MESSAGE              AGE
   portal   3/3     Running   <version>        <version>            Serving 2 sites      22h
   ```

3. Optional: If you are upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2: Review and configure the new inter-subsystem communication features: Optional post-upgrade steps if you are upgrading from earlier 10.0.5 releases.

Upgrading Analytics subsystem on native Kubernetes

Upgrade the Analytics subsystem to the latest version of API Connect.

About this task

When upgrading to a new mod release, the version must be changed to the latest mod release version on each CR. This change will be picked up by the operator, and the operator will then start the upgrade.

Procedure

1. Update the analytics CR for the new version of API Connect.
   a. Run the following command to edit the CR:

      ```
      kubectl -n $NAMESPACE edit a7s <CLUSTERNAME>
      ```

      where ***CLUSTERNAME*** is the name specified in the subsystem CR at installation time.

   b. Update the API Connect **version** in the CR:
      For example:

      ```
      version: 10.0.6.0
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update the license value now.
      For example:

      ```
      license: L-GVEN-GFUPVE
      ```

      For the list of licenses, see API Connect licenses.

   d. Save your changes to the CR.
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the known upgrade issues.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl get apic -n <namespace>
   ```

   Example output after upgrading the analytics subsystem:

   ```
   NAME                                                READY   STATUS    VERSION          RECONCILED VERSION
   AGE
   analyticscluster.analytics.apiconnect.ibm.com/analytics   5/5     Running   <version>   <version-build>   121m
   ```

3. Optional: If you are upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2: Review and configure the new inter-subsystem communication features: Optional post-upgrade steps if you are upgrading from earlier 10.0.5 releases.

Upgrading Gateway subsystem on native Kubernetes

Upgrade the Gateway subsystem to the latest version of API Connect.

Before you begin

1. Complete all steps in Upgrading subsystems on native Kubernetes prior to the step that links to this topic.
2. Ensure your upgrade path is supported.
3. To ensure operator compatibility, upgrade the API Connect management subsystem before you upgrade the DataPower gateway subsystem. This requirement applies to all upgrade scenarios.
4. When you upgrade a cluster of gateway pods in Kubernetes, a small number of API transactions may fail. During the upgrade, Kubernetes removes the pod from the load balancer configuration, deletes the pod and then starts a new pod. The steps are repeated for each pod. Socket hang ups occur on transactions that are in process at the time the pod is killed.
   The number of transactions that fail depends on the rate of incoming transactions and the length of time needed to complete each transaction. Typically the number of failures is a very small percentage. This behavior is expected during an upgrade. If the failure level is not acceptable, schedule the upgrade during an off-hours maintenance window.

   Note also that DataPower Gateway supports long-lived connections such as such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when upgrading. Workloads with long-lived connections are more vulnerable to failed API transactions during upgrading.

   You can limit the number of failed API transactions during the upgrade by using the DataPower Operator's **lifecycle** property to configure the **preStop** container lifecycle hook on the gateway pods. This approach mitigates the risk of API failures during the rolling update of the gateway StatefulSet by sleeping the pod for a span of time, allowing in-flight transactions to complete prior to the SIGTERM being delivered to the container. While this feature does not guarantee that no in-flight APIs would fail, it does provide some mitigation for in-flight transactions that can complete successfully within the configured time window. For more information, see Delaying SIGTERM with preStop in the DataPower documentation.

5. When upgrading a high-availability cluster, ensure that you meet the following requirements:
   - Gateways must be updated one at a time.
   - Before starting the upgrade, a single gateway must be running as primary for all gateway-peering definitions.
   - When upgrading multiple gateways, the primary gateway must be upgraded last.
   - Ensure that the pod with a name like `gwv6-0` or `gwv5-0` is the primary because it is the last node to be upgraded.

   To determine which gateway is running as primary, use either the **show gateway-peering-status** command in the DataPower CLI, or use the Gateway Peering Status display in the WebGUI in the API Connect application domain by running the following command:

   ```
   kubectl attach -it <podname>
   ```

   To move the primary to the DataPower on which you're currently working, you can issue the following command:

   ```
   gateway-peering-switch-primary <peering-object-name>
   ```

   command.

About this task

When upgrading to a new mod release, the version must be changed to the latest mod release version on each CR. This change will be picked up by the operator, and the operator will then start the upgrade.

Procedure

1. Update the gateway CR for the new version of API Connect.
   a. Run the following command to edit the CR:

      ```
      kubectl -n $NAMESPACE edit gw <CLUSTERNAME>
      ```

      where ***CLUSTERNAME*** is the name specified in the subsystem CR at installation time.

   b. Update the API Connect `version` in the CR:
      For example:

      ```
      version: 10.0.6.0
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update the license value now.
      For example:

      ```
      license: L-GVEN-GFUPVE
      ```

      For the list of licenses, see API Connect licenses.

   d. Delete any `template` or `dataPowerOverride` override sections.
      You cannot perform an upgrade if the CR contains an override.

   e. Run the following command to save and apply the CR: `wq`
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the known upgrade issues.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl get apic -n <namespace>
   ```

   Example output after upgrading the gateway subsystem:

   ```
   NAME                                              READY   STATUS    VERSION              RECONCILED VERSION      AGE
   gatewaycluster.gateway.apiconnect.ibm.com/gw1     2/2     Running   <version>  <version-build>  100m
   ```

3. Optional: If you are upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2: Review and configure the new inter-subsystem communication features: Optional post-upgrade steps if you are upgrading from earlier 10.0.5 releases.

Enabling gateway peering and verifying cluster status

To complete the operand upgrade, restart the gateway pods to enable gateway peering.

About this task

Follow these steps to fix gateway peering. Due to the ingress issuer changes, the gateway pods must be scaled down and back up. This process will cause 5 to 10 minutes of API downtime.

Procedure

1. After operand upgrade completes, wait for Management, Portal and Analytics subsystems to report `Running` status.
2. Scale down the gateway firmware containers by editing the Gateway CR and setting `replicaCount` to 0:

   ```
   kubectl edit gw <gw-cr-name>
   ```

   For example:

   ```
   ...
   spec:
     replicaCount: 0
   ...
   ```

3. Wait for the Gateway firmware pods to scale down and terminate. Ensure that the Gateway firmware pods are terminated before moving to next step.
4. Scale up the Gateway firmware containers back to their original value, or remove the `replicaCount` field if none was there before.

   ```
   kubectl edit gw <gw-cr-name>
   ```

5. Your operands should all have an upgraded version. To verify, wait for the cluster status to become `Running`, and Reconciled version to show the new version number.
   For example:

   ```
   kubectl get apic -n <namespace>
   ```

   ```
   NAME                                                    READY   STATUS    VERSION          RECONCILED VERSION
   AGE
   analyticscluster.analytics.apiconnect.example.com/analytics   8/8     Running   10.0.4.0   10.0.4.0-1074   121m
   ```

```
NAME                                        PHASE     READY   SUMMARY                              VERSION    AGE
datapowerservice.datapower.example.com/gw1   Running   True    StatefulSet replicas ready: 1/1   10.0.4.0   100m

NAME                                        PHASE     LAST EVENT   WORK PENDING   WORK IN-PROGRESS   AGE
datapowermonitor.datapower.example.com/gw1   Running                false          false              100m

NAME                                              READY   STATUS    VERSION             RECONCILED VERSION      AGE
gatewaycluster.gateway.apiconnect.example.com/gw1   2/2     Running   10.0.4.0   10.0.4.0-1074   100m

NAME                                                 READY   STATUS    VERSION             RECONCILED VERSION      AGE
managementcluster.management.apiconnect.example.com/m1   16/16   Running   10.0.4.0   10.0.4.0-1074   162m

NAME                                               READY   STATUS    VERSION             RECONCILED VERSION      AGE
portalcluster.portal.apiconnect.example.com/portal   3/3     Running   10.0.4.0   10.0.4.0-1074   139m
```

Troubleshooting: If you find your gateways do not sync with your management service, see known upgrade issues.

Optional post-upgrade steps if you are upgrading from earlier 10.0.5 releases

API Connect version 10.0.5.3 introduced new features related to inter-subsystem communication. If you upgraded from 10.0.5.0, 10.0.5.1, or 10.0.5.2, you can configure inter-subsystem communication features now.

Enabling management CA certification on the REST API

The portal and gateway subsystems make requests to the management subsystem through the REST API that is hosted by the management subsystem. This communication is standard TLS, where each REST API endpoint has a server certificate that is presented to the client during TLS handshaking. For additional security, validation of the management server certificate CA is enabled on all subsystems for new installations of API Connect 10.0.5.3 and later. If you are upgrading from an earlier 10.0.5.x release and want to enable this feature for the portal and gateway, edit the portal and gateway CRs to add the following settings to the `spec:` section depending on if you are using `external` or `in-cluster` inter-subsystem communications (In-cluster service communication between subsystems):

- If you are using `external` inter-subsystem communication, in the portal CR add:

  ```
  spec:
    mgmtPlatformEndpointCASecret:
      secretName: ingress-ca # Or <instance-name>-ingress-ca if using top-level CR. If you have customized certs, change
  ingress-ca to $PLATFORM_CA_SECRET
    mgmtConsumerEndpointCASecret:
      secretName: ingress-ca # Or <instance-name>-ingress-ca if using top-level CR. If you have customized certs, change
  ingress-ca to $CONSUMER_CA_SECRET
  ```

  and in the gateway CR add:

  ```
  spec:
    mgmtPlatformEndpointCASecret:
      secretName: ingress-ca # Or <instance-name>-ingress-ca if using top-level CR. If you have customized certs, change
  ingress-ca to $PLATFORM_CA_SECRET
  ```

  where:
  - *$PLATFORM_CA_SECRET* is the Kubernetes secret object that contains the CA certificate that is used by the platform REST API.
  - *$CONSUMER_CA_SECRET* is the Kubernetes secret object that contains the CA certificate that is used by the consumer REST API.
- If you are using `in-cluster` inter-subsystem communications, in the portal CR add:

  ```
  spec:
    mgmtPlatformEndpointSvcCASecret:
      secretName: management-ca # Or <instance-name>-mgmt-ca if using top-level CR. If you have customized certs, change
  ingress-ca to $PLATFORM_CA_SECRET
    mgmtConsumerEndpointSvcCASecret:
      secretName: management-ca # Or <instance-name>-mgmt-ca if using top-level CR. If you have customized certs, change
  ingress-ca to $CONSUMER_CA_SECRET
  ```

  and in the gateway CR add:

  ```
  spec:
    mgmtPlatformEndpointSvcCASecret:
      secretName: management-ca # Or mgmt-ca or <instance-name>-mgmt-ca if using top-level CR. If you have customized certs,
  change ingress-ca to $PLATFORM_CA_SECRET
  ```

  If changing to use `in-cluster` inter-subsystem communication after an upgrade, you must also reregister all subsystems: Converting existing registered subsystems to use in-cluster communications.

Note: If you are not sure of the secret names, follow these steps:

1. Check the management subsystem CR with `kubectl describe mgmt`, and identify the issuer of the platform and consumer API endpoints:

   ```
   kubectl describe mgmt -n <namespace>

   ...
   Platform API Endpoint:
       Annotations:
         cert-manager.io/issuer:               ingress-issuer
   ...
     Consumer API Endpoint:
       Annotations:
         cert-manager.io/issuer:               ingress-issuer
   ```

2. Describe the issuer with `kubectl describe issuer`, and identify the secret name:

```
kubectl describe issuer ingress-issuer -n <namespace>
...
Spec:
  Ca:
    Secret Name:  ingress-ca
...
```

Enable JWT security and disable mTLS for inter-subsystem communication

If you want to use JWT security instead of mTLS for inter-subsystem communication, then follow these steps. For more information on JWT security, see: Enable JWT security instead of mTLS.

1. Describe the `mgmt` CR to get the JWKS URL:

   ```
   kubectl describe mgmt -n <namespace>

   status:
     - name: jwksUrl
       secretName: api-endpoint
       type: API
       uri: https://api.apic.acme.com/api/cloud/oauth2/certs
   ```

2. For each portal, gateway, and analytics subsystem where you want to use JWT security, edit the CR corresponding that subsystem to disable mTLS and specify the `jwksUrl`:

   ```
   spec:
       ...
       mtlsValidateClient: false
       jwksUrl: <JWKS URL>
   ```

   <JWKS URL> is the URL identified in step 1.
3. Enable JWT on the gateway to analytics communications flow. Enable the Use JWT switch for the registered gateway in the Topology page of the Cloud Manager UI.

Converting existing registered subsystems to use in-cluster communications

If you want to change your existing portal, gateway, and analytics subsystems to use `in-cluster` inter-subsystem communication then they must be reregistered. For more information about `in-cluster` communication, see In-cluster service communication between subsystems.
Important: Understand the following points before you change the communication type of a subsystem:

- Re-registering any of the subsystems requires an outage of that subsystem.
- When you change communication type, any backup of the management subsystem that was taken before this change becomes unusable. Do not change the inter-subsystem communication type if you might want to restore the management subsystem from an earlier backup.
- To reregister the portal, all portal sites must be deleted first. Deleting a portal site means that any customizations that were made to the site must manually be reapplied after the portal is reregistered and the site recreated.
- To reregister the gateway, all published products must be deleted from the gateway.

To re-register a portal subsystem, complete the following steps:

1. Delete all portal sites from the portal service. From the API Manager UI, for each catalog that has a site on the portal, delete the portal site: Edit or delete portal site.
2. Delete the portal service in the Topology section of the Cloud Manager UI.
3. Reregister the portal service, specifying the inter-subsystem communication type that you want, in the Topology section of the Cloud Manager UI. See Register portal service.

To re-register a gateway subsystem, complete the following steps:

1. In the API Manager UI, delete all products from all catalogs that use the gateway service. See Removing a product from a catalog.
2. In the API Manager UI, for each catalog that uses the gateway service, remove the gateway service from the catalog settings. See Configure catalog gateway service.
3. Delete the gateway service in the Topology section of the Cloud Manager UI.
4. Reregister the gateway service, specifying the inter-subsystem communication type that you want, in the Topology section of the Cloud Manager UI. See Registering a gateway service.

To re-register the analytics subsystem, complete the following steps:

1. Unassociate the analytics service from all gateway services that it is associated with. See Unassociate analytics service.
2. Delete the analytics service in the Topology section of the Cloud Manager UI.
3. Reregister the analytics service, specifying the inter-subsystem communication type that you want, in the Topology section of the Cloud Manager UI. See Registering an analytics service.

Troubleshooting upgrades on Kubernetes

Review the following troubleshooting guidance if you encounter a problem while upgrading API Connect on Kubernetes.

In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

- License webhook error
- Postgres error message when you save the updated management CR
- Taskmanager error syncing management and gateway

- Datapower operator fails to start

License webhook error

If you did not update the license ID in the CR, then when you save your changes, the following webhook error might display:

```
admission webhook "vmanagementcluster.kb.io" denied the request:
ManagementCluster.management.apiconnect.ibm.com "management" is invalid:
spec.license.license: Invalid value: "L-RJON-BYGHM4":
License L-RJON-BYGHM4 is invalid for the chosen version 10.0.6.0.
Please refer license document https://ibm.biz/apiclicenses
```

To resolve the error, see API Connect licenses for the list of the available license IDs and select the appropriate License IDs for your deployment. Update the CR with the new license value as in the following example, and then save and apply your changes again.

Postgres error message when you save the updated management CR

If you see an error message when you attempt to save the CR, check if it is one of the following known issues:

- Webhook error: `Original postgres primary is running as replica`
  If you see the error message:

  ```
  Original PostgreSQL primary is running as replica,
  please perform failover to original primary before attempting upgrade. Refer - https://ibm.biz/BdPLWU"
  ```

  you must complete a Postgres failover before the upgrade can proceed, see Postgres failover steps. After you apply the Postgres failover steps, the upgrade resumes automatically.
- Webhook error: `Original PostgreSQL primary not found`
  If you see the error message:

  ```
  Original PostgreSQL primary not found. Upgrade is blocked.
  Set apiconnect-operator/db-primary-not-found-allow-upgrade=true annotation to unblock upgrade.
  Perform db backup and restore after upgrade to restore original primary.
  ```

  take the following actions to complete the upgrade and fix the cause of the error message:
  1. Edit the management CR:

     ```
     kubectl -n $NAMESPACE edit mgmt <CLUSTERNAME>
     ```

  2. Add the following annotation:

     ```
     apiVersion: management.apiconnect.ibm.com/v1beta1
     kind: ManagementCluster
     metadata:
       annotations:
         apiconnect-operator/db-primary-not-found-allow-upgrade=true
         ...
     ```

  3. Continue with the upgrade. When the upgrade is complete, the management CR reports the warning:

     ```
     Original PostgreSQL primary not found, perform db backup and restore to restore original primary.
     ```

  4. Take a new management database backup.
  5. Immediately restore from the new backup taken in the previous step. The action of taking and restoring a management backup results in the establishment of a new Postgres primary, eliminating the CR warning message. Be careful to restore from the backup that is taken after the upgrade, and not from a backup taken before upgrade.

Taskmanager error syncing management and gateway

If the gateways are not in sync with management after upgrade, check if the management subsystem `taskmanager` pods log the following error message. It starts 15 minutes after upgrade and repeats every 15 minutes for any stuck task.

```
TASK: Stale claimed task set to errored state:
```

If these errors are reported, restart all the `management-natscluster` pods, for example: `management-natscluster-1`.

```
kubectl -n <namespace> delete pod management-natscluster-1 management-natscluster-2 management-natscluster-3
```

DataPower operator fails to start

There is a known issue on Kubernetes that can cause the DataPower operator to fail to start. In this case, the DataPower operator pods can fail to schedule, and will display the status message: `no nodes match pod topology spread constraints (missing required label)`. For example:

```
0/15 nodes are available: 12 node(s) didn't match pod topology spread constraints (missing required label),
3 node(s) had taint {node-role.kubernetes.io/master: }, that the pod didn't tolerate.
```

You can workaround the issue by editing the DataPower operator deployment and re-applying it, as follows:

1. Delete the DataPower operator deployment, if deployed already:

   ```
   kubectl delete -f ibm-datapower.yaml -n <namespace>
   ```

2. Open `ibm-datapower.yaml`, and locate the `topologySpreadConstraints:` section. For example:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
   ```

```
  topologyKey: zone
  whenUnsatisfiable: DoNotSchedule
```

3. Replace the values for `topologyKey:` and `whenUnsatisfiable:` with the corrected values shown in the example below:

```
topologySpreadConstraints:
- maxSkew: 1
  topologyKey: topology.kubernetes.io/zone
  whenUnsatisfiable: ScheduleAnyway
```

4. Save `ibm-datapower.yaml` and deploy the file to the cluster:

```
kubectl apply -f ibm-datapower.yaml -n <namespace>
```

Upgrading on OpenShift and Cloud Pak for Integration

You can upgrade API Connect in an OpenShift environment and as part of IBM Cloud Pak for Integration.

- **Upgrading API Connect in Cloud Pak for Integration**
  In Cloud Pak for Integration, the API management capability is provided by API Connect.
- **Upgrade considerations on OpenShift**
  Review the supported upgrade paths and other upgrade considerations on OpenShift or Cloud Pak for Integration.
- **Preparing to upgrade on OpenShift**
  Prepare your OpenShift or Cloud Pak for Integration deployment for upgrading to the newest version of API Connect.
- **Upgrading on OpenShift in an online environment**
  Perform an online (connected to the internet) upgrade of IBM® API Connect on Red Hat OpenShift Container Platform using either the top-level `APIConnectCluster` CR or individual subsystem CRs.
- **Air-gapped upgrade**
  In a disconnected, network-restricted, upgrade API Connect on a Red Hat OpenShift Container Platform (OCP) cluster by mirroring product images to a bastion host or a portable device and then completing the upgrade process.
- **Optional post-upgrade steps for upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2**
  API Connect version 10.0.5.3 introduced new features related to inter-subsystem communication. If you upgraded from 10.0.5.0, 10.0.5.1, or 10.0.5.2, you can configure inter-subsystem communication features now.
- **Troubleshooting upgrade on OpenShift**
  Review the following troubleshooting tips if you encounter a problem while upgrading API Connect on OpenShift, including as a component of IBM Cloud Pak for Integration (CP4I).

Upgrading API Connect in Cloud Pak for Integration

In Cloud Pak for Integration, the API management capability is provided by API Connect.

Before you begin

Cloud Pak for Integration 2023 uses API Connect 10.0.6.x, which requires OpenShift 4.12 and Cloud Pak foundational services 3.19 (or higher). Before you can upgrade to API Connect 10.0.6.x in Cloud Pak for Integration, you must upgrade to a version of API Connect 10.0.5.x to ensure support for the newer versions of OpenShift and foundational services.

Procedure

1. Required: Upgrade to Cloud Pak for Integration 2022 (API Connect 10.0.5.x or later).
   You cannot upgrade to Cloud Pak for Integration from a release earlier than 2022.2.To ensure a successful upgrade to Cloud Pak for Integration 2022.2 with API Connect 10.0.5.x, upgrade your current version of API Connect.

   For instructions, see Upgrading API management in the 2022.4 version of the Cloud Pak for Integration documentation.

2. Then, upgrade to Cloud Pak for Integration 2023 (API Connect 10.0.6.x).
   For instructions, see Upgrading API management in the 2023.2 version of the Cloud Pak for Integration documentation.

Upgrade considerations on OpenShift

Review the supported upgrade paths and other upgrade considerations on OpenShift or Cloud Pak for Integration.

- Supported upgrade paths
- Supported DataPower Gateway versions
- Upgrading multiple instances of API Connect
- API transactions might fail during the upgrade of gateway pods.

Tip: After upgrade, clear your browser cache, and open a new browser window. This action avoids stale cache issues in your browser, that can result in unexpected behavior in the Cloud Manager and API Manager UIs.

Supported upgrade paths

Attention: API Connect is not supported in a FIPS-enabled environment.

Table 1 lists the supported releases of IBM® API Connect v10 that can be upgraded directly to the new version of API Connect.

Table 1. Supported upgrade paths on OpenShift

Upgrade from:	How to upgrade to 10.0.6.0
• 10.0.5.3 • 10.0.5.2 • 10.0.5.1 • 10.0.5.0	Complete the procedure in Upgrading on OpenShift and Cloud Pak for Integration.

Attention: Different releases of API Connect support different versions of OpenShift, so you might need to upgrade OpenShift after upgrading API Connect. For more information, see IBM API Connect Version 10 software product compatibility requirements.
For information on the operator, operand, and CASE version used with each API Connect release, see Operator, operand, and CASE versions.

Supported DataPower Gateway versions

You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

However, before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

Upgrading multiple instances of API Connect

- If a single operator manages multiple instances, all of those instances must be upgraded, one at a time, as soon as possible.
  The operator should not be managing an operand based on an older version any longer than necessary.
- Ensure that each instance is fully upgraded before starting the upgrade on the next instance.

API transactions might fail during the upgrade of gateway pods.

Consider scheduling the upgrade during off-hours to avoid transaction failures.

When you upgrade a cluster of gateway pods in Kubernetes, a small number of API transactions may fail. During the upgrade, Kubernetes removes the pod from the load balancer configuration, deletes the pod, and then starts a new pod. The steps are repeated for each pod. Socket hang ups occur on transactions that are in process at the time the pod is deleted.

The number of transactions that fail depends on the rate of incoming transactions and the length of time needed to complete each transaction. Typically the number of failures is a very small percentage. This behavior is expected during an upgrade. If the failure level is not acceptable, schedule the upgrade during an off-hours maintenance window.

Note also that DataPower Gateway supports long-lived connections such as such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when upgrading. Workloads with long-lived connections are more vulnerable to failed API transactions during upgrading.

You can limit the number of failed API transactions during the upgrade by using the DataPower Operator's **`lifecycle`** property to configure the **`preStop`** container lifecycle hook on the gateway pods. This approach mitigates the risk of API failures during the rolling update of the gateway StatefulSet by sleeping the pod for a span of time, allowing in-flight transactions to complete prior to the SIGTERM being delivered to the container. While this feature does not guarantee that no in-flight APIs would fail, it does provide some mitigation for in-flight transactions that can complete successfully within the configured time window. For more information, see Delaying SIGTERM with preStop in the DataPower documentation.

Preparing to upgrade on OpenShift

Prepare your OpenShift or Cloud Pak for Integration deployment for upgrading to the newest version of API Connect.

Before you begin

Review the Upgrade considerations on OpenShift to ensure that you are following a supported upgrade path and that you understand important changes that might affect your deployment.

About this task

Complete the following steps to prepare your deployment for upgrading to the newest version of API Connect.

Procedure

1. Verify that the **`pgcluster`** is healthy:
   a. Get the name of the **`pgcluster`**:

      ```
      oc get pgcluster -n <APIC_namespace>
      ```

      The response displays the name of the postgres cluster running in the specified namespace.

   b. Check the status of the **`pgcluster`**:

      ```
      oc get pgcluster <pgcluster_name> -n <APIC_namespace> -o yaml | grep status -A 2 | tail -n3
      ```

The response for a healthy **pgcluster** looks like the following example, where the state is **Initialized**:

```
status:
    message: Cluster has been initialized
    state: pgcluster Initialized
```

If the cluster is healthy, proceed to the next step.

Important: If the **pgcluster** is not healthy (returns any other state):
The cluster is not healthy and an upgrade will fail. Complete the following steps:

a. If there are any ongoing backup or restore jobs, wait until they complete and then check the status again. Do not proceed with the upgrade until the status is **Initialized**.
b. If all of the background jobs complete but the **pgcluster** remains unhealthy, contact IBM Support for assistance.

2. Run the pre-upgrade health check:
Attention: This is a required step. Failure to run this check before upgrading could result in problems during the upgrade.
   a. Verify that the **apicops** utility is installed by running the following command to check the current version of the utility:

      ```
      apicops --version
      ```

      If the response indicates that **apicops** is not available, install it now. See The API Connect operations tool: apicops in the API Connect documentation.

   b. Run the following command to set the KUBECONFIG environment.

      ```
      export KUBECONFIG=/path/to/kubeconfig
      ```

   c. Run the following command to execute the pre-upgrade script:

      ```
      apicops version:pre-upgrade -n <namespace>
      ```

      If the system is healthy, the results will not include any errors.

      Note: This command asks for the Cloud Manager admin password in order to make a call to the platform API. If you do not have this password, or the platform API URL is not accessible from your **apicops** location, then this part of the pre-upgrade check can be skipped by adding the argument **--no-topology**. The topology check output that is produced by this API call is typically only required for debugging purposes, when the **apicops version:pre-upgrade** returns output that suggests the system is unhealthy.

3. Back up the current deployment in case the upgrade fails and you need to perform a roll back.
For instructions, see:
   - 10.0.6 and later: Backups on OpenShift
   - 10.0.5.x: Backups on OpenShift

4. If you are upgrading from a release earlier than 10.0.5.3, review the Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10 to ensure that any customizations to the Developer Portal are compatible with Drupal 10.
In API Connect 10.0.5.3, the Developer Portal moved from Drupal 9 to Drupal 10 (this upgrade also requires PHP 8.1). The upgrade tooling will update your Developer Portal sites; however, if you have any custom modules or themes, it is your responsibility to ensure their compatibility with Drupal 10 and PHP 8.1 before starting the upgrade.

Upgrading on OpenShift in an online environment

Perform an online (connected to the internet) upgrade of IBM® API Connect on Red Hat OpenShift Container Platform using either the top-level **APIConnectCluster** CR or individual subsystem CRs.

Before you begin

- If you are upgrading an air-gapped (disconnected from the internet) installation, see Air-gapped upgrade.
- If you are upgrading to a version of API Connect that supports a newer version of Red Hat OpenShift, complete the API Connect upgrade before upgrading Red Hat OpenShift.
- Upgrading from 10.0.5.2 or earlier: If you did not verify that your Portal customizations are compatible with Drupal 10, do that now.
In API Connect 10.0.5.3, the Developer Portal moved from Drupal 9 to Drupal 10 (this upgrade also requires PHP 8.1). The upgrade tooling will update your Developer Portal sites; however, if you have any custom modules or themes, it is your responsibility to ensure their compatibility with Drupal 10 and PHP 8.1 before starting the upgrade. Review the Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10 to ensure that any customizations to the Developer Portal are compatible with Drupal 10 and PHP 8.1.

About this task

The Gateway subsystem remains available during the upgrade of the Management, Portal, and Analytics subsystems.

Procedure

1. Ensure that you have completed all of the steps in Preparing to upgrade on OpenShift, including reviewing the Upgrade considerations on OpenShift.
Do not attempt an upgrade until you have reviewed the considerations and prepared your deployment.

2. Ensure your API Connect deployment is ready to upgrade:
   - Your API Connect release (operand) supports a direct upgrade to this release.
   For information on the operator and operand version that is used with each API Connect release, see Operator, operand, and CASE versions.
   - The DataPower operator version is correct for the currently deployed version of API Connect.
   For information on upgrade paths and supported versions of DataPower Gateway, see Upgrade considerations on OpenShift.
   - Your deployment is running on at least the minimum supported version of Red Hat OpenShift.

3. Update the operator channels for DataPower and API Connect.

- If you previously chose automatic subscriptions, the operator version upgrades automatically when you update the operator channel.
- If you previously chose manual subscriptions and the operator channel is already on the previous version, OpenShift OLM notifies you that an upgrade is available. You must manually approve the upgrade before proceeding.
- Both the API Connect and DataPower channels must be changed before either operator upgrades. The upgrade of both operators begins when the channel is changed for both operators.

a. Upgrade the DataPower operator channel to `v1.7`. From Operators > Installed Operators, select the `IBM DataPower Gateway` operator, then select the `Subscription` tab. Click the channel version underneath `Update channel` to update it.
Troubleshooting: If the DataPower operator upgrade fails, see DataPower operator pod stuck waiting for lock removal.

b. Update the API Connect operator channel to v5.0. From Operators > Installed Operators select the `IBM API Connect` operator, then select the `Subscription` tab. Click the channel version underneath `Update channel` to update it.

Wait for the operators to update, for the pods to restart, and for the instances to display the `Ready` status.

Troubleshooting: If the API Connect operator upgrade fails, see API Connect operator upgrade stuck.

4. Ensure that the operators and operands are healthy before proceeding.
   - Operators: Verify that the OpenShift UI indicates that all operators are in the `Succeeded` state without any warnings.
   - If you are using the top-level CR: To verify that your API Connect cluster is healthy, run the following command:

     ```
     oc get apiconnectcluster -n <APIC_namespace>
     ```

     Confirm that the `apiconnectcluster` CR reports all pods as `READY`.

     ```
     oc get ManagementCluster -n apicupgrade
     NAME          READY   STATUS    VERSION    RECONCILED VERSION   AGE
     management    17/17   Running   10.0.5.1   10.0.5.1-95    70m
     ```

   - If you are using individual subsystem CRs: To verify the health of each subsystem, run the following commands:

     ```
     oc get ManagementCluster -n <mgmt_namespace>
     oc get GatewayCluster -n <gway_namespace>
     oc get PortalCluster -n <portal_namespace>
     oc get AnalyticsCluster -n <mgmt_namespace>
     ```

     Check that all pods are `READY`, for example:

     ```
     oc get PortalCluster -n apic
     NAME     READY   STATUS    VERSION    RECONCILED VERSION   AGE
     portal   3/3     Running   10.0.6.0   10.0.6.0-95    57m
     ```

5. If you are using the top-level CR: Update the top-level `apiconnectcluster` CR:
   The `spec` section of the `apiconnectcluster` looks like the following example:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-production
  name: prod
  namespace: <APIC_namespace>
spec:
  license:
    accept: true
    use: production
    license: L-GVEN-GFUPVE
  profile: n12xc4.m12
  version: 10.0.6.0
  storageClassName: rook-ceph-block
```

   a. Edit the `apiconnectcluster` CR by running the following command:

      ```
      oc -n <APIC_namespace> edit apiconnectcluster
      ```

   b. In the `spec` section, update the API Connect version:
      Change the `version` setting to `10.0.6.0`.
   c. If you are upgrading to a version of API Connect that requires a new license, update the license value now.
      For the list of licenses, see API Connect licenses.

   d. In the `spec.gateway` section, delete any `template` or `dataPowerOverride` override sections.
      You cannot perform an upgrade if the CR contains an override.

   e. Save and close the CR to apply your changes.
      The response looks like the following example:

      ```
      apiconnectcluster.apiconnect.ibm.com/prod configured
      ```

      Troubleshooting: If you see an error message when you attempt to save the CR, see Troubleshooting upgrade on OpenShift.

   f. Run the following command to verify that the upgrade is completed and the status of the top-level CR is `READY`:

      ```
      oc get apiconnectcluster -n <APIC_namespace>
      ```

      Important: If you need to restart the deployment, wait until all Portal sites complete the upgrade. Run the following commands to check the status of the sites:
      i. Get the portal service ID and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
            --availability-zone availability-zone-default <portal-service-name> \
            --output - --format json
```

ii. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
            --portal_service_name <portal-service-name> \
            --format json
```

Any sites currently upgrading display the **UPGRADING** status; any site that completed its upgrade displays the **INSTALLED** status and the new platform version. Verify that all sites display the **INSTALLED** status before proceeding.

For more information on the **sites** command, see **apic sites:list** and Using the **sites** commands.

iii. After all sites are in **INSTALLED** state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <management_server_endpoint> \
             --portal_service_id <portal_service_id_from_above_command> \
             --portal_service_endpoint <portal_service_endpoint_from_above_command> \
             --format json
```

Verify that the new version of the platform is the only platform listed.

For more information on the **platforms** command, see **apic platforms:list** and Using the **platforms** commands.

6. If you are using individual subsystem CRs: Start with the Management subsystem, and update the Management CR as follows:
   a. Edit the **ManagementCluster** CR:

```
oc edit ManagementCluster -n <mgmt_namespace>
```

   b. In the **spec** section, update the API Connect version:
   Change the **version** setting to **10.0.6.0**.
   c. If you are upgrading to a version of API Connect that requires a new license, update the license value now.
   For the list of licenses, see API Connect licenses.
   d. Save and close the CR to apply your changes.
   The response looks like the following example:

```
managementcluster.management.apiconnect.ibm.com/management edited
```

Troubleshooting: If you see an error message when you attempt to save the CR, see Troubleshooting upgrade on OpenShift.

   e. Wait until the Management subsystem upgrade is complete before proceeding to the next subsystem. Check the status of the upgrade with: **oc get ManagementCluster -n** ***<mgmt_namespace>***, and wait until all pods are running at the new version. For example:

```
oc get ManagementCluster -n <mgmt_namespace>
NAME          READY   STATUS    VERSION    RECONCILED VERSION   AGE
management    18/18   Running   10.0.6.0   10.0.6.0-1281        97m
```

   f. Repeat the process for the remaining subsystem CRs in your preferred order: **GatewayCluster**, **PortalCluster**, **AnalyticsCluster**.
   Important: In the **GatewayCluster** CR, delete any **template** or **dataPowerOverride** override sections. You cannot perform an upgrade if the CR contains an override.
   g. If you need to restart the deployment, wait until all Portal sites complete the upgrade. Run the following commands to check the status of the sites:
      i. Log in as an admin user:

```
apic login -s <server_name> --realm admin/default-idp-1 --username admin --password <password>
```

      ii. Get the portal service ID and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
            --availability-zone availability-zone-default <portal-service-name> \
            --output - --format json
```

      iii. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
            --portal_service_name <portal-service-name> \
            --format json
```

Any sites currently upgrading display the **UPGRADING** status; any site that completed its upgrade displays the **INSTALLED** status and the new platform version. Verify that all sites display the **INSTALLED** status before proceeding.

For more information on the **sites** command, see **apic sites:list** and Using the **sites** commands.

      iv. After all sites are in **INSTALLED** state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <server_name> --portal_service_name <portal_service_name>
```

Verify that the new version of the platform is the only platform listed.

For more information on the **platforms** command, see **apic platforms:list** and Using the **platforms** commands.

7. Upgrade to Red Hat OpenShift Container Platform 4.12 if you have not already done so.
   Red Hat OpenShift requires you to upgrade in stages, so that you install every version between your starting point and your ending point. For example, to upgrade from 4.10 to 4.12, you must complete 2 upgrades:
   a. Upgrade to 4.11
   b. Upgrade to 4.12

For upgrade instructions, see the Red Hat OpenShift documentation.

8. If you are upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2: Review and configure the new inter-subsystem communication features: Optional post-upgrade steps for upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2.
9. Restart all nats-server pods by running the following command:

```
oc -n <namespace> delete po -l app.kubernetes.io/name=natscluster
```

What to do next

Update your toolkit CLI by downloading it from FixCentral or from the Cloud Manager UI, see Installing the toolkit.

Air-gapped upgrade

In a disconnected, network-restricted, upgrade API Connect on a Red Hat OpenShift Container Platform (OCP) cluster by mirroring product images to a bastion host or a portable device and then completing the upgrade process.

About this task

If you previously deployed or upgraded API Connect in an air-gapped environment, you can use the same bastion host, portable computer, or portable storage as before and just update the product information for the new release.

- **Upgrading with a bastion host**
  Use a bastion host to perform an air-gapped upgrade of IBM® API Connect on Red Hat OpenShift Container Platform (OCP) using either the top-level `APIConnectCluster` CR or individual subsystem CRs. First the operator is updated, and then the operands (IBM API Connect itself).
- **Upgrading with a portable computer or storage device**
  Use a portable computer or portable storage device to perform an air-gapped upgrade of IBM API Connect on Red Hat OpenShift Container Platform (OCP) using either the top-level `APIConnectCluster` CR or individual subsystem CRs. First the operator is updated, and then the operands (IBM API Connect itself).

Upgrading with a bastion host

Use a bastion host to perform an air-gapped upgrade of IBM® API Connect on Red Hat OpenShift Container Platform (OCP) using either the top-level `APIConnectCluster` CR or individual subsystem CRs. First the operator is updated, and then the operands (IBM API Connect itself).

Before you begin

- If you are upgrading an installation online (connected to the internet), see Upgrading on OpenShift in an online environment.
- The upgrade procedure requires you to use Red Hat Skopeo for moving container images. Skopeo is not available for Microsoft Windows, so you cannot perform this task using a Windows host.
- If you are upgrading to a version of API Connect that supports a newer version of Red Hat OpenShift, complete the API Connect upgrade before upgrading Red Hat OpenShift.
- Upgrading from 10.0.5.2 or earlier: If you did not verify that your Portal customizations are compatible with Drupal 10, do that now.
  In API Connect 10.0.5.3, the Developer Portal moved from Drupal 9 to Drupal 10 (this upgrade also requires PHP 8.1). The upgrade tooling will update your Developer Portal sites; however, if you have any custom modules or themes, it is your responsibility to ensure their compatibility with Drupal 10 and PHP 8.1 before starting the upgrade. Review the Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10 to ensure that any customizations to the Developer Portal are compatible with Drupal 10 and PHP 8.1.

About this task

- The Gateway subsystem remains available during the upgrade of the Management, Portal, and Analytics subsystems.
- Don't use the tilde ~ within double quotation marks in any command because the tilde doesn't expand and your commands might fail.

Procedure

1. Ensure that you have completed all of the steps in Preparing to upgrade on OpenShift, including reviewing the Upgrade considerations on OpenShift.
   Do not attempt an upgrade until you have reviewed the considerations and prepared your deployment.

2. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in IBM API Connect Version 10 software product compatibility requirements.
      - Configure storage on the cluster and make sure that it is available.

   b. Prepare the bastion host:
      You must be able to connect your bastion host to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry) at the same time. Your host must be on a Linux x86_64 or Mac platform with any operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

      i. Ensure that the sites and ports listed in Table 1 can be reached from the bastion host:

      Table 1. Sites that must be reached from the bastion host

Site	Description
`icr.io:443`	IBM entitled registry

Site	Description
`quay.io:443`	Local API Connect image repository
`github.com`	CASE files and tools
`redhat.com`	Red Hat OpenShift Container Platform (OCP) upgrades

ii. On the bastion host, install either Docker or Podman (not both).
Docker and Podman are used for managing containers; you only need to install one of these applications.

- To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

```
yum check-update
yum install docker
```

- To install Podman, see the Podman installation instructions.
For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

```
yum install podman
```

iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

```
oc ibm-pak --help
```

c. Set up a local image registry and credentials.
The local Docker registry stores the mirrored images in your network-restricted environment.

i. Install a registry, or get access to an existing registry.
You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

The registry product that you use must meet the following requirements:
- Supports multi-architecture images through Docker Manifest V2, Schema 2
For details, see Docker Manifest V2, Schema 2.
- Is accessible from the Red Hat OpenShift Container Platform cluster nodes
- Allows path separators in the image name

Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.

ii. Configure the registry to meet the following requirements:
- Supports auto-repository creation
- Has sufficient storage to hold all of the software that is to be transferred
- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials)
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials)

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries during runtime, use an account that can read from the target local registry.

3. Set environment variables and download CASE files.
Create environment variables to use while mirroring images, connect to the internet, and download the API Connect CASE files.
a. Create the following environment variables with the installer image name and the image inventory on your host:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.0.0
export ARCH=amd64
```

For information on API Connect CASE versions and their corresponding operators and operands, see Operator, operand, and CASE versions.

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

For example, for IBM Cloud Pak foundational services 3.19.X (Long Term Service Release), use version 1.15.10; for foundational services 3.23.X (Continuous Delivery), use version 1.19.2.

For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

b. Connect your host to the internet (it does not need to be connected to the network-restricted environment at this time).
c. Download the CASE file to your host:
Be sure to download both CASE files as shown in the example:

```
oc ibm-pak get $CASE_NAME --version $CASE_VERSION
```

```
oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
```

If you omit the `--version` parameter, the command downloads the latest version of the file.

4. Mirror the images.
The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before installing API Connect.

a. Generate mirror manifests.
i. Define the environment variable $TARGET_REGISTRY by running the following command:

```
export TARGET_REGISTRY=<target-registry>
```

Replace **`<target-registry>`** with the IP address (or host name) and port of the local registry; for example: **`172.16.0.10:5000`**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **`172.16.0.10:5000/registry_ns`**.

ii. Generate mirror manifests by running the following commands:

```
oc ibm-pak generate mirror-manifests $CASE_NAME $TARGET_REGISTRY --version $CASE_VERSION

oc ibm-pak generate mirror-manifests $CS_CASE_NAME $TARGET_REGISTRY --version $CS_CASE_VERSION
```

If you need to filter for a specific image group, add the parameter **`--filter`** **`<image_group>`** to this command.

The **`generate`** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION and ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION:

- catalog-sources.yaml
- catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
- image-content-source-policy.yaml
- images-mapping.txt

The files are used when mirroring the images to the **`TARGET_REGISTRY`**.

b. Obtain an entitlement key for the entitled registry where the images are hosted:

i. Log in to the IBM Container Library.
ii. In the Container software library, select Get entitlement key.
iii. In the "Access your container software" section, click Copy key.
iv. Copy the key to a safe location; you will use it to log in to **`cp.icr.io`** in the next step.

c. Authenticate with the entitled registry where the images are hosted.
The image pull secret allows you to authenticate with the entitled registry and access product images.

i. Run the following command to export the path to the file that will store the authentication credentials that are generated on a Podman or Docker login:

```
export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
```

The authentication file is typically located at $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

ii. Log in to the **`cp.icr.io`** registry with Podman or Docker; for example:

```
podman login cp.icr.io
```

Use **`cp`** as the username and your entitlement key as the password.

d. Authenticate with the local registry.
Log in to the local registry using an account that can write images to that registry; for example:

```
podman login $TARGET_REGISTRY
```

If the registry is insecure, add the following flag to the command: **`--tls-verify=false`**.

e. Mirror the product images.

i. Connect the bastion host to both the internet and the restricted-network environment that contains the local registry.
ii. Run the following commands to copy the images to the local registry:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

Note: If the local registry is not secured by TLS, or the certificate presented by the local registry is not trusted by your device, add the **`--insecure`** option to the command.
There might be a slight delay before you see a response to the command.

f. Configure the target cluster.
Now that images have been mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

i. Log in to your Red Hat OpenShift Container Platform cluster:

```
oc login <openshift_url> -u <username> -p <password> -n <namespace>
```

ii. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
Updating the image pull secret provides the cluster with the credentials needed for pulling images from your local registry.

Note: If you have an insecure registry, add the registry to the cluster's **`insecureRegistries`** list by running the following command:

```
oc edit image.config.openshift.io/cluster -o yaml
```

and add the TARGET_REGISTRY to **`spec.registrySources.insecureRegistries`** as shown in the following example:

```
spec:
  registrySources:
    insecureRegistries:
    - insecure0.svc:5001
    - <TARGET_REGISTRY>
```

If the `insecureRegistries` field does not exist, you can add it.

iii. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry (run both commands):

```
oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml

oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
```

iv. Verify that the ImageContentSourcePolicy resource was created:

```
oc get imageContentSourcePolicy
```

v. Verify your cluster node status:

```
oc get MachineConfigPool -w
```

Wait for all nodes to be updated before proceeding to the next step.

5. Apply the catalog sources.
Now that you have mirrored images to the target cluster, apply the catalog sources.

In the following steps, replace ***<Architecture>*** with either **amd64**, **s390x** or **ppc64le** as appropriate for your environment.

a. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.0.0
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

b. Generate the catalog sources and save them in another directory in case you need to replicate this installation in the future.

i. Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Get any architecture-specific catalog sources that you need to back up as well:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

c. Apply the catalog sources to the cluster.

i. Apply the universal catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Apply any architecture-specific catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

iii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

6. Update the API Connect and DataPower operator channels.

a. First, update the API Connect operator channel:

i. Open the Red Hat OpenShift web console and click Operators > Installed Operators > IBM API connect > Subscriptions.

ii. Change the channel to the new version (`v5.0`), which triggers an upgrade of the API Connect operator.

b. Then, immediately update the DataPower operator channel:

i. Open the Red Hat OpenShift web console and click Operators > Installed Operators > IBM Data Power > Subscriptions.

ii. Change the channel to the new version (`v1.7`), which triggers an upgrade of the DataPower operator.

After the operators are updated, the new operator pod starts automatically.

7. Verify that the API Connect operator was updated by completing the following steps:

a. Get the name of the pod that hosts the operator by running the following command:

```
oc get po -n <APIC_namespace> | grep apiconnect
```

The response looks like the following example:

```
ibm-apiconnect-7bdb795465-8f7rm                                   1/1     Running     0          4m23s
```

b. Get the API Connect version deployed on that pod by running the following command:

```
oc describe po <ibm-apiconnect-operator-podname> -n <APIC_namespace> | grep -i productversion
```

The response looks like the following example:

```
productVersion: 10.0.6.0
```

8. If you are using a top-level CR: Update the top-level `APIConnectCluster` CR:
The `spec` section of the `apiconnectcluster` looks like the following example:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
```

```
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-production
  name: prod
  namespace: <APIC_namespace>
spec:
  license:
    accept: true
    use: production
    license: L-GVEN-GFUPVE
  profile: n12xc4.m12
  version: 10.0.6.0
  storageClassName: rook-ceph-block
```

a. Edit the `apiconnectcluster` CR by running the following command:

```
oc -n <APIC_namespace> edit apiconnectcluster
```

b. In the `spec` section, update the API Connect version:
Change the `version` setting to `10.0.6.0`.

c. In the `spec.gateway` section, delete any `template` or `dataPowerOverride` override sections.
You cannot perform an upgrade if the CR contains an override.

d. Save and close the CR.
The response looks like the following example:

```
apiconnectcluster.apiconnect.ibm.com/prod configured
```

Troubleshooting: If you see an error message when you attempt to save the CR, see Troubleshooting upgrade on OpenShift.

9. If you are using individual subsystem CRs: Start with the Management subsystem and update the Management CR as follows:

a. Edit the `ManagementCluster` CR:

```
oc edit ManagementCluster -n <mgmt_namespace>
```

b. In the `spec` section, update the API Connect version:
Change the `version` setting to `10.0.6.0`.

c. If you are upgrading to a version of API Connect that requires a new license, update the license value now.
For the list of licenses, see API Connect licenses.

d. Save and close the CR to apply your changes.
The response looks like the following example:

```
managementcluster.management.apiconnect.ibm.com/management edited
```

Troubleshooting: If you see an error message when you attempt to save the CR, see Troubleshooting upgrade on OpenShift.

e. Confirm that the Management subsystem upgrade is complete before proceeding to the next subsystem.
Check the status of the upgrade with: `oc get ManagementCluster -n <mgmt_namespace>`, and wait until all pods are running at the new version. For example:

```
oc get ManagementCluster -n <mgmt_namespace>
NAME          READY   STATUS    VERSION    RECONCILED VERSION   AGE
management    18/18   Running   10.0.6.0   10.0.6.0-1281        97m
```

f. Repeat the process for the remaining subsystem CRs: `GatewayCluster`, `PortalCluster`, and then `AnalyticsCluster`.
Important: In the `GatewayCluster` CR, delete any `template` or `dataPowerOverride` override sections. You cannot perform an upgrade if the CR contains an override.

10. Validate that the upgrade was successfully deployed by running the following command:

```
oc get apic -n <APIC_namespace>
```

The response looks like the following example:

```
NAME                                                READY   STATUS    VERSION              RECONCILED VERSION
AGE
analyticscluster.analytics.apiconnect.ibm.com/prod-a7s   5/5     Running   10.0.6.0   10.0.6.0   21h

AGE
managementdbupgrade.management.apiconnect.ibm.com/prod-mgmt-up-649mc   Complete   Upgrade is Complete (DB Schema/data are
up-to-date)         142m
managementdbupgrade.management.apiconnect.ibm.com/prod-mgmt-up-9mjhk   Complete   Fresh install is Complete (DB
Schema/data are up-to-date)   22h
```

```
NAME                                              READY   STATUS    VERSION              RECONCILED VERSION       AGE
portalcluster.portal.apiconnect.ibm.com/prod-ptl   3/3     Running   10.0.6.0   10.0.6.0   21h
```

Important: If you need to restart the deployment, wait until all Portal sites complete the upgrade. Run the following commands to check the status of the sites:

a. Log in as an admin user:

```
apic login -s <server_name> --realm admin/default-idp-1 --username admin --password <password>
```

b. Get the portal service ID and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
            --availability-zone availability-zone-default <portal-service-name> \
            --output - --format json
```

c. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
            --portal_service_name <portal-service-name> \
            --format json
```

Any sites currently upgrading display the **UPGRADING** status; any site that completed its upgrade displays the **INSTALLED** status and the new platform version. Verify that all sites display the **INSTALLED** status before proceeding.

For more information on the **sites** command, see **apic sites:list** and Using the **sites** commands.

d. After all sites are in **INSTALLED** state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <server_name> --portal_service_name <portal_service_name>
```

Verify that the new version of the platform is the only platform listed.

For more information on the **platforms** command, see **apic platforms:list** and Using the **platforms** commands.

11. Upgrade to Red Hat OpenShift Container Platform 4.12 if you have not already done so.
    Red Hat OpenShift requires you to upgrade in stages, so that you install every version between your starting point and your ending point. For example, to upgrade from 4.10 to 4.12, you must complete 2 upgrades:
    a. Upgrade to 4.11
    b. Upgrade to 4.12
    For upgrade instructions, see the Red Hat OpenShift documentation.
12. If you are upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2: Review and configure the new inter-subsystem communication features: Optional post-upgrade steps for upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2.
13. Restart all nats-server pods by running the following command:

```
oc -n <namespace> delete po -l app.kubernetes.io/name=natscluster
```

What to do next

Update your toolkit CLI by downloading it from FixCentral or from the Cloud Manager UI, see Installing the toolkit.

Upgrading with a portable computer or storage device

Use a portable computer or portable storage device to perform an air-gapped upgrade of IBM® API Connect on Red Hat OpenShift Container Platform (OCP) using either the top-level **APIConnectCluster** CR or individual subsystem CRs. First the operator is updated, and then the operands (IBM API Connect itself).

Before you begin

- If you are upgrading an installation online (connected to the internet), see Upgrading on OpenShift in an online environment.
- The upgrade procedure requires you to use Red Hat Skopeo for moving container images. Skopeo is not available for Microsoft Windows, so you cannot perform this task using a Windows host.
- If you are upgrading to a version of API Connect that supports a newer version of Red Hat OpenShift, complete the API Connect upgrade before upgrading Red Hat OpenShift.
- Upgrading from 10.0.5.2 or earlier: If you did not verify that your Portal customizations are compatible with Drupal 10, do that now.

In API Connect 10.0.5.3, the Developer Portal moved from Drupal 9 to Drupal 10 (this upgrade also requires PHP 8.1). The upgrade tooling will update your Developer Portal sites; however, if you have any custom modules or themes, it is your responsibility to ensure their compatibility with Drupal 10 and PHP 8.1 before starting the upgrade. Review the Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10 to ensure that any customizations to the Developer Portal are compatible with Drupal 10 and PHP 8.1.

About this task

- The Gateway subsystem remains available during the upgrade of the Management, Portal, and Analytics subsystems.
- Don't use the tilde ~ within double quotation marks in any command because the tilde doesn't expand and your commands might fail.

Procedure

1. Ensure that you have completed all of the steps in Preparing to upgrade on OpenShift, including reviewing the Upgrade considerations on OpenShift.
   Do not attempt an upgrade until you have reviewed the considerations and prepared your deployment.

2. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in IBM API Connect Version 10 software product compatibility requirements.
      - Configure storage on the cluster and make sure that it is available.

   b. Prepare the portable device:
   You must be able to connect your portable device to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry). The portable device must be on a Linux x86_64 or Mac platform with any operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

      i. Ensure that the portable device has sufficient storage to hold all of the software that is to be transferred to the local registry.
      ii. On the portable device, install either Docker or Podman (not both).
      Docker and Podman are used for managing containers; you only need to install one of these applications.

         - To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

           ```
           yum check-update
           yum install docker
           ```

         - To install Podman, see the Podman installation instructions.
           For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

           ```
           yum install podman
           ```

      iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
      The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

      iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
      The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

      ```
      oc ibm-pak --help
      ```

   c. Set up a local image registry and credentials.
   The local Docker registry stores the mirrored images in your network-restricted environment.

      i. Install a registry, or get access to an existing registry.
      You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

      The registry product that you use must meet the following requirements:
         - Supports multi-architecture images through Docker Manifest V2, Schema 2
           For details, see Docker Manifest V2, Schema 2.
         - Is accessible from the Red Hat OpenShift Container Platform cluster nodes
         - Allows path separators in the image name

      Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.
      ii. Configure the registry to meet the following requirements:
         - Supports auto-repository creation
         - Has sufficient storage to hold all of the software that is to be transferred
         - Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials)
         - Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials)

   To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries during runtime, use an account that can read from the target local registry.

3. Set environment variables and download CASE files.
   Create environment variables to use while mirroring images, connect to the internet, and download the API Connect CASE files.

   a. Create the following environment variables with the installer image name and the image inventory on your portable device:
   Because you will use values from two different CASE files, you must create environment variables for both; notice that the variables for the foundational services (common services) CASE file are prefixed with "CS_" to differentiate them.

   ```
   export CASE_NAME=ibm-apiconnect
   export CASE_VERSION=5.0.0
   export ARCH=amd64
   ```

For information on API Connect CASE versions and their corresponding operators and operands, see Operator, operand, and CASE versions.

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

For example, for IBM Cloud Pak foundational services 3.19.X (Long Term Service Release), use version 1.15.10; for foundational services 3.23.X (Continuous Delivery), use version 1.19.2.

For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

b. Connect your portable device to the internet (it does not need to be connected to the network-restricted environment at this time).
c. Download the CASE file to your portable device:
Be sure to download both CASE files as shown in the example:

```
oc ibm-pak get $CASE_NAME --version $CASE_VERSION
```

```
oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
```

If you omit the **--version** parameter, the command downloads the latest version of the file.

4. Mirror the images.
The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before installing API Connect.

a. Generate mirror manifests.
i. Define the environment variable $TARGET_REGISTRY by running the following command:

```
export TARGET_REGISTRY=<target-registry>
```

Replace ***<target-registry>*** with the IP address (or host name) and port of the local registry; for example: **172.16.0.10:5000**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **172.16.0.10:5000/registry_ns**.
ii. Generate mirror manifests by running the following commands:

```
oc ibm-pak generate mirror-manifests $CASE_NAME $TARGET_REGISTRY --version $CASE_VERSION
```

```
oc ibm-pak generate mirror-manifests $CS_CASE_NAME $TARGET_REGISTRY --version $CS_CASE_VERSION
```

If you need to filter for a specific image group, add the parameter **--filter** ***<image_group>*** to this command.

The **generate** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION and ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION:
- catalog-sources.yaml
- catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
- image-content-source-policy.yaml
- images-mapping-to-filesystem.txt
- images-mapping-from-filesystem.txt

The files are used when mirroring the images to the **TARGET_REGISTRY**.

b. Obtain an entitlement key for the entitled registry where the images are hosted:
i. Log in to the IBM Container Library.
ii. In the Container software library, select Get entitlement key.
iii. In the "Access your container software" section, click Copy key.
iv. Copy the key to a safe location; you will use it to log in to **cp.icr.io** in the next step.
c. Authenticate with the entitled registry where the images are hosted.
The image pull secret allows you to authenticate with the entitled registry and access product images.

i. Run the following command to export the path to the file that will store the authentication credentials that are generated on a Podman or Docker login:

```
export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
```

The authentication file is typically located at $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

ii. Log in to the **cp.icr.io** registry with Podman or Docker; for example:

```
podman login cp.icr.io
```

Use **cp** as the username and your entitlement key as the password.

d. Mirror the images from the internet to the portable device.
i. Define the environment variable $IMAGE_PATH by running the following command:

```
export IMAGE_PATH=<image-path>
```

where ***<image-path>*** indicates where the files will be stored on the portable device's file system.
ii. Mirror the images to the portable device:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
```

```
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

There might be a slight delay before you see a response to the command.

e. Move the portable device to the restricted-network environment.
The procedure depends on the type of device that you are using:
If you are using a portable computer, disconnect the device from the internet and connect it to the restricted-network environment. The same environment variables can be used.

If you are using portable storage, complete the following steps:

i. Transfer the following files to a device in the restricted-network environment:
- The `~/.ibm-pak` directory.
- The contents of the ***<image-path>*** that you specified in the previous step.

ii. Create the same environment variables as on the original device; for example:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.0.0
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64

export REGISTRY_AUTH_FILE=$HOME/.docker/config.json

export IMAGE_PATH=<image-path>
```

f. Authenticate with the local registry.
Log in to the local registry using an account that can write images to that registry; for example:

```
podman login $TARGET_REGISTRY
```

If the registry is insecure, add the following flag to the command: `--tls-verify=false`.

g. Mirror the product images to the target registry.

i. If you are using a portable computer, connect it to the restricted-network environment that contains the local registry.
If you are using portable storage, you already transferred files to a device within the restricted-network environment.

ii. Run the following commands to copy the images to the local registry:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"

oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-to-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

Note: If the local registry is not secured by TLS, or the certificate presented by the local registry is not trusted by your device, add the `--insecure` option to the command.
There might be a slight delay before you see a response to the command.

h. Configure the target cluster.
Now that images have been mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

i. Log in to your Red Hat OpenShift Container Platform cluster:

```
oc login <openshift_url> -u <username> -p <password> -n <namespace>
```

ii. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
Updating the image pull secret provides the cluster with the credentials needed for pulling images from your local registry.

Note: If you have an insecure registry, add the registry to the cluster's `insecureRegistries` list by running the following command:

```
oc edit image.config.openshift.io/cluster -o yaml
```

and add the TARGET_REGISTRY to `spec.registrySources.insecureRegistries` as shown in the following example:

```
spec:
  registrySources:
    insecureRegistries:
    - insecure0.svc:5001
    - <TARGET_REGISTRY>
```

If the `insecureRegistries` field does not exist, you can add it.

iii. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry (run both commands):

```
oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml

oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
```

iv. Verify that each ImageContentSourcePolicy resource was created:

```
oc get imageContentSourcePolicy
```

v. Verify your cluster node status:

```
oc get MachineConfigPool -w
```

Wait for all nodes to be updated before proceeding to the next step.

5. Apply the catalog sources.
Now that you have mirrored images to the target cluster, apply the catalog sources.

In the following steps, replace ***<Architecture>*** with either **amd64**, **s390x** or **ppc64le** as appropriate for your environment.

a. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.0.0
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

b. Generate the catalog source and save it in another directory in case you need to replicate this installation in the future.
i. Get the catalog source:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Get any architecture-specific catalog sources that you need to back up as well:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

c. Apply the catalog sources to the cluster.
i. Apply the universal catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Apply any architecture-specific catalog source:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

iii. Confirm that the catalog source was created in the **openshift-marketplace** namespace:

```
oc get catalogsource -n openshift-marketplace
```

6. Update the API Connect and DataPower operator channels.
a. First, update the API Connect operator channel:
i. Open the Red Hat OpenShift web console and click Operators > Installed Operators > IBM API connect > Subscriptions.
ii. Change the channel to the new version (**v5.0**), which triggers an upgrade of the API Connect operator.
b. Then, immediately update the DataPower operator channel:
i. Open the Red Hat OpenShift web console and click Operators > Installed Operators > IBM Data Power > Subscriptions.
ii. Change the channel to the new version (**v1.7**), which triggers an upgrade of the DataPower operator.
After the operators are updated, the new operator pod starts automatically.
7. Verify that the API Connect operator was updated by completing the following steps:
a. Get the name of the pod that hosts the operator by running the following command:

```
oc get po -n <APIC_namespace> | grep apiconnect
```

The response looks like the following example:

```
ibm-apiconnect-7bdb795465-8f7rm                                   1/1     Running     0          4m23s
```

b. Get the API Connect version deployed on that pod by running the following command:

```
oc describe po <ibm-apiconnect-operator-podname> -n <APIC_namespace> | grep -i productversion
```

The response looks like the following example:

```
productVersion: 10.0.6.0
```

8. If you are using a top-level CR: Update the top-level **APIConnectCluster** CR:
The **spec** section of the **apiconnectcluster** looks like the following example:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-production
  name: prod
  namespace: <APIC_namespace>
spec:
  license:
    accept: true
```

```
    use: production
    license: L-GVEN-GFUPVE
  profile: n12xc4.m12
  version: 10.0.6.0
  storageClassName: rook-ceph-block
```

a. Edit the `apiconnectcluster` CR by running the following command:

```
oc -n <APIC_namespace> edit apiconnectcluster
```

b. In the `spec` section, update the API Connect version:
Change the `version` setting to `10.0.6.0`.

c. In the `spec.gateway` section, delete any `template` or `dataPowerOverride` override sections.
You cannot perform an upgrade if the CR contains an override.

d. Save and close the CR.
The response looks like the following example:

```
apiconnectcluster.apiconnect.ibm.com/prod configured
```

Troubleshooting: If you see an error message when you attempt to save the CR, see Troubleshooting upgrade on OpenShift.

9. If you are using individual subsystem CRs: Start with the Management subsystem and update the Management CR as follows:

a. Edit the `ManagementCluster` CR:

```
oc edit ManagementCluster -n <mgmt_namespace>
```

b. In the `spec` section, update the API Connect version:
Change the `version` setting to `10.0.6.0`.

c. If you are upgrading to a version of API Connect that requires a new license, update the license value now.
For the list of licenses, see API Connect licenses.

d. Save and close the CR to apply your changes.
The response looks like the following example:

```
managementcluster.management.apiconnect.ibm.com/management edited
```

Troubleshooting: If you see an error message when you attempt to save the CR, see Troubleshooting upgrade on OpenShift.

e. Confirm that the Management subsystem upgrade is complete before proceeding to the next subsystem.
Check the status of the upgrade with: `oc get ManagementCluster -n <mgmt_namespace>`, and wait until all pods are running at the new version. For example:

```
oc get ManagementCluster -n <mgmt_namespace>
NAME          READY   STATUS    VERSION    RECONCILED VERSION   AGE
management    18/18   Running   10.0.6.0   10.0.6.0-1281        97m
```

f. Repeat the process for the remaining subsystem CRs: `GatewayCluster`, `PortalCluster`, and then `AnalyticsCluster`.
Important: In the `GatewayCluster` CR, delete any `template` or `dataPowerOverride` override sections. You cannot perform an upgrade if the CR contains an override.

10. Validate that the upgrade was successfully deployed by running the following command:

```
oc get apic -n <APIC_namespace>
```

The response looks like the following example:

```
NAME                                                READY   STATUS    VERSION              RECONCILED VERSION
AGE
analyticscluster.analytics.apiconnect.ibm.com/prod-a7s   5/5     Running   10.0.6.0   10.0.6.0   21h

NAME                                          READY   STATUS   VERSION             RECONCILED VERSION       AGE
apiconnectcluster.apiconnect.ibm.com/prod     4/4     Ready    10.0.6.0   10.0.6.0   22h

NAME                                           PHASE     READY   SUMMARY                              VERSION    AGE
datapowerservice.datapower.ibm.com/prod-gw     Running   True    StatefulSet replicas ready: 3/3      10.0.6.0   21h

```
NAME                                                                STATUS     MESSAGE
AGE
managementdbupgrade.management.apiconnect.ibm.com/prod-mgmt-up-649mc   Complete   Upgrade is Complete (DB Schema/data are
up-to-date)          142m
managementdbupgrade.management.apiconnect.ibm.com/prod-mgmt-up-9mjhk   Complete   Fresh install is Complete (DB
Schema/data are up-to-date)   22h
```

```
NAME                                              READY   STATUS    VERSION              RECONCILED VERSION       AGE
portalcluster.portal.apiconnect.ibm.com/prod-ptl   3/3     Running   10.0.6.0   10.0.6.0   21h
```

Important: If you need to restart the deployment, wait until all Portal sites complete the upgrade. Run the following commands to check the status of the sites:

a. Log in as an admin user:

```
apic login -s <server_name> --realm admin/default-idp-1 --username admin --password <password>
```

b. Get the portal service ID and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
            --availability-zone availability-zone-default <portal-service-name> \
            --output - --format json
```

c. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
            --portal_service_name <portal-service-name> \
            --format json
```

Any sites currently upgrading display the **UPGRADING** status; any site that completed its upgrade displays the **INSTALLED** status and the new platform version. Verify that all sites display the **INSTALLED** status before proceeding.

For more information on the **sites** command, see **apic sites:list** and Using the **sites** commands.

d. After all sites are in **INSTALLED** state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <server_name> --portal_service_name <portal_service_name>
```

Verify that the new version of the platform is the only platform listed.

For more information on the **platforms** command, see **apic platforms:list** and Using the **platforms** commands.

11. Upgrade to Red Hat OpenShift Container Platform 4.12 if you have not already done so.
    Red Hat OpenShift requires you to upgrade in stages, so that you install every version between your starting point and your ending point. For example, to upgrade from 4.10 to 4.12, you must complete 2 upgrades:
    a. Upgrade to 4.11
    b. Upgrade to 4.12
    For upgrade instructions, see the Red Hat OpenShift documentation.
12. If you are upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2: Review and configure the new inter-subsystem communication features: Optional post-upgrade steps for upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2.
13. Restart all nats-server pods by running the following command:

```
oc -n <namespace> delete po -l app.kubernetes.io/name=natscluster
```

What to do next

Update your toolkit CLI by downloading it from FixCentral or from the Cloud Manager UI, see Installing the toolkit.

Optional post-upgrade steps for upgrading from 10.0.5.0, 10.0.5.1, or 10.0.5.2

API Connect version 10.0.5.3 introduced new features related to inter-subsystem communication. If you upgraded from 10.0.5.0, 10.0.5.1, or 10.0.5.2, you can configure inter-subsystem communication features now.

Note: If you are using a top-level CR, you must edit the top-level CR instead of the subsystem CR. If the section you want to edit is missing from the top-level CR, copy it from the subsystem CR and paste it into the top-level CR.

Enabling management CA certification on the REST API

The portal and gateway subsystems make requests to the management subsystem through the REST API that is hosted by the management subsystem. This communication is standard TLS, where each REST API endpoint has a server certificate that is presented to the client during TLS handshaking. For additional security, validation of the management server certificate CA is enabled on all subsystems for new installations of API Connect 10.0.5.3 and later. If you are upgrading from an earlier 10.0.5.x release and want to enable this feature for the portal and gateway, edit the portal and gateway CRs to add the following settings to the **spec:** section depending on if you are using **external** or **in-cluster** inter-subsystem communications (In-cluster service communication between subsystems):

- If you are using **external** inter-subsystem communication, in the portal CR add:

```
spec:
  mgmtPlatformEndpointCASecret:
```

```
    secretName: ingress-ca # Or <instance-name>-ingress-ca if using top-level CR. If you have customized certs, change
ingress-ca to $PLATFORM_CA_SECRET
  mgmtConsumerEndpointCASecret:
    secretName: ingress-ca # Or <instance-name>-ingress-ca if using top-level CR. If you have customized certs, change
ingress-ca to $CONSUMER_CA_SECRET
```

and in the gateway CR add:

```
spec:
  mgmtPlatformEndpointCASecret:
    secretName: ingress-ca # Or <instance-name>-ingress-ca if using top-level CR. If you have customized certs, change
ingress-ca to $PLATFORM_CA_SECRET
```

where:

- *$PLATFORM_CA_SECRET* is the Kubernetes secret object that contains the CA certificate that is used by the platform REST API.
- *$CONSUMER_CA_SECRET* is the Kubernetes secret object that contains the CA certificate that is used by the consumer REST API.

- If you are using `in-cluster` inter-subsystem communications, in the portal CR add:

```
spec:
  mgmtPlatformEndpointSvcCASecret:
    secretName: management-ca # Or <instance-name>-mgmt-ca if using top-level CR. If you have customized certs, change
ingress-ca to $PLATFORM_CA_SECRET
  mgmtConsumerEndpointSvcCASecret:
    secretName: management-ca # Or <instance-name>-mgmt-ca if using top-level CR. If you have customized certs, change
ingress-ca to $CONSUMER_CA_SECRET
```

and in the gateway CR add:

```
spec:
  mgmtPlatformEndpointSvcCASecret:
    secretName: management-ca # Or mgmt-ca or <instance-name>-mgmt-ca if using top-level CR. If you have customized certs,
change ingress-ca to $PLATFORM_CA_SECRET
```

If changing to use `in-cluster` inter-subsystem communication after an upgrade, you must also reregister all subsystems: Converting existing registered subsystems to use in-cluster communications.

Note: If you are not sure of the secret name, follow these steps:

1. Check the management subsystem CR with `oc describe mgmt`, and identify the issuer of the platform and consumer API endpoints:

```
oc describe mgmt -n <namespace>

...
Platform API Endpoint:
    Annotations:
      cert-manager.io/issuer:               apic-ingress-issuer
...
  Consumer API Endpoint:
    Annotations:
      cert-manager.io/issuer:               apic-ingress-issuer
```

2. Describe the issuer with `oc describe issuer`, and identify the secret name:

```
oc describe issuer apic-ingress-issuer -n <namespace>
...
Spec:
  Ca:
    Secret Name:  apic-ingress-ca
...
```

Enable JWT security and disable mTLS for inter-subsystem communication

If you want to use JWT security instead of mTLS for inter-subsystem communication, then follow these steps. For more information on JWT security, see: Enable JWT security instead of mTLS

Cloud Pak for Integration and OpenShift top-level CR installations

Configure JWT as described in the post-install steps: Enable JWT security and disable mTLS between subsystems.

Individual subsystem CR installations

1. Describe the `mgmt` CR to get the JWKS URL:

```
kubectl describe mgmt -n <namespace>

status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

2. For each portal, gateway, and analytics subsystem where you want to use JWT security, edit the CR corresponding that subsystem to disable mTLS and specify the `jwksUrl`:

```
spec:
    ...
    mtlsValidateClient: false
    jwksUrl: <JWKS URL>
```

<JWKS URL> is the URL identified in step 1.

3. Enable JWT on the gateway to analytics communications flow. Enable the Use JWT switch for the registered gateway in the Topology page of the Cloud Manager UI.

Converting existing registered subsystems to use in-cluster communications

If you want to change your existing portal, gateway, and analytics subsystems to use **in-cluster** inter-subsystem communication then they must be reregistered. For more information about **in-cluster** communication, see In-cluster service communication between subsystems.
Important: Understand the following points before you change the communication type of a subsystem:

- Re-registering any of the subsystems requires an outage of that subsystem.
- When you change communication type, any backup of the management subsystem that was taken before this change becomes unusable. Do not change the inter-subsystem communication type if you might want to restore the management subsystem from an earlier backup.
- To reregister the portal, all portal sites must be deleted first. Deleting a portal site means that any customizations that were made to the site must manually be reapplied after the portal is reregistered and the site recreated.
- To reregister the gateway, all published products must be deleted from the gateway.

To re-register a portal subsystem, complete the following steps:

1. Delete all portal sites from the portal service. From the API Manager UI, for each catalog that has a site on the portal, delete the portal site: Edit or delete portal site.
2. Delete the portal service in the Topology section of the Cloud Manager UI.
3. Reregister the portal service, specifying the inter-subsystem communication type that you want, in the Topology section of the Cloud Manager UI. See Register portal service.

To re-register a gateway subsystem, complete the following steps:

1. In the API Manager UI, delete all products from all catalogs that use the gateway service. See Removing a product from a catalog.
2. In the API Manager UI, for each catalog that uses the gateway service, remove the gateway service from the catalog settings. See Configure catalog gateway service.
3. Delete the gateway service in the Topology section of the Cloud Manager UI.
4. Reregister the gateway service, specifying the inter-subsystem communication type that you want, in the Topology section of the Cloud Manager UI. See Registering a gateway service.

To re-register the analytics subsystem, complete the following steps:

1. Unassociate the analytics service from all gateway services that it is associated with. See Unassociate analytics service.
2. Delete the analytics service in the Topology section of the Cloud Manager UI.
3. Reregister the analytics service, specifying the inter-subsystem communication type that you want, in the Topology section of the Cloud Manager UI. See Registering an analytics service.

Update duration of certificates

In earlier releases of API Connect, some of the certificates had a duration of 12720 hours. On new API Connect v10.0.6 installations, all certificates have a duration of 17520 hours. After you upgrade to v10.0.6, update API Connect certificates to have a duration of 17520 hours:

1. List all the certificates that have a 12720 hour duration with the following command:

   ```
   oc -n <namespace> get certificate -o custom-columns=NAME:metadata.name,DURATION:spec.duration | grep 12720h0m0s | awk
   '{print $1}'
   ```

   Example output:

   ```
   small-a7s-ai-endpoint
   small-gw-gateway
   small-gw-gateway-manager
   small-mgmt-admin
   small-mgmt-api-manager
   small-mgmt-consumer-api
   small-mgmt-platform-api
   small-ptl-portal-director
   small-ptl-portal-web
   ```

2. Trigger the recreation of each certificate by deleting the certificate:

   ```
   oc -n <namespace> delete certificate <certificate name>
   ```

   For example:

   ```
   oc -n apic delete certificate small-ptl-portal-web

   certificate.cert-manager.io "small-ptl-portal-web" deleted
   ```

3. Verify that the recreated certificate has a 17520 hour duration:

   ```
   oc -n <namespace> get certificate <certificate name> -o custom-columns=DURATION:spec.duration
   ```

   For example:

   ```
   oc -n apic get certificate small-ptl-portal-web -o custom-columns=DURATION:spec.duration
   DURATION
   17520h0m0s
   ```

Note: If you have subsystems in different namespaces, these steps must be repeated in each namespace.

Troubleshooting upgrade on OpenShift

Review the following troubleshooting tips if you encounter a problem while upgrading API Connect on OpenShift, including as a component of IBM Cloud Pak for Integration (CP4I).

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Upgrade stuck in `Pending` state

If your upgrade displays the **`Pending`** status and seems to be stuck, and the postgres-operator pod shows an error like the following example:

```
time="2023-07-17T06:41:09Z" level=error msg="refusing to upgrade due to unsuccessful resource removal"
func="internal/operator/cluster.AddUpgrade()" file="internal/operator/cluster/upgrade.go:134" version=4.7.10
```

You can resolve the problem by deleting the **`clustercreate`** and **`upgrade`** pgtasks, which triggers a new attempt at the upgrade.

First, check the logs to verify the error:

1. Run the following command to get the name of the pod:

   ```
   oc get po -n <APIC_namespace> | grep postgres-operator
   ```

2. Run the following command to get the log itself, using the pod name from the previous step:

   ```
   oc logs <pod-name> -c operator -n <APIC_namespace>
   ```

3. Once you confirm that the problem was caused by the resource-removal issue, delete the **`clustercreate`** and **`upgrade`** pgtasks.
   The following example shows the commands to get the pgtask names and then delete the **`clustercreate`** and **`upgrade`** pgtasks:

   ```
   oc get pgtasks
   NAME                                          AGE
   backrest-backup-large-mgmt-bce926ab-postgres   36h
   large-mgmt-bce926ab-postgres-createcluster     6d5h
   large-mgmt-bce926ab-postgres-upgrade           36h

   oc delete pgtasks large-mgmt-bce926ab-postgres-createcluster
   pgtask.crunchydata.com "large-mgmt-bce926ab-postgres-createcluster" deleted

   oc delete pgtasks large-mgmt-bce926ab-postgres-upgrade
   pgtask.crunchydata.com "large-mgmt-bce926ab-postgres-upgrade" deleted
   ```

Error message when you save the updated management or APIConnectCluster CR

- Webhook error for incorrect license.
  If you did not update the license ID in the CR, then when you save your changes, the following webhook error might display:

  ```
  admission webhook "vapiconnectcluster.kb.io" denied the request:
  APIConnectCluster.apiconnect.ibm.com "<instance-name>" is invalid: spec.license.license:
  Invalid value: "L-RJON-BYGHM4": License L-RJON-BYGHM4 is invalid for the chosen version version.
  Please refer license document https://ibm.biz/apiclicenses
  ```

  To resolve the error, see API Connect licenses for the list of the available license IDs and select the appropriate license IDs for your deployment. Update the CR with the new license value as in the following example, and then save and apply your changes again.
- Webhook error: **`Original PostgreSQL primary not found`**. Take the following actions to complete the upgrade and fix the cause of the error message:
  1. If you are using the top-level CR, edit your **`apiconnectcluster`** CR. If you are using individual subsystem CRs, edit the **`ManagementCluster`** CR. Add the following annotation:

     ```
     ...
     metadata:
       annotations:
         apiconnect-operator/db-primary-not-found-allow-upgrade=true
         ...
     ```

  2. Continue with the upgrade. When the upgrade is complete, the management CR reports the warning:

     ```
     Original PostgreSQL primary not found, perform db backup and restore to restore original primary.
     ```

  3. Take a new management database backup.
  4. Immediately restore from the new backup taken in the previous step. The action of taking and restoring a management backup results in the establishment of a new Postgres primary, eliminating the CR warning message. Be careful to restore from the backup that is taken after the upgrade, and not from a backup taken before upgrade.
- Webhook error: **`Original postgres primary is running as replica`**. Complete a Postgres failover, see Postgres failover steps. After you apply the Postgres failover steps, the upgrade resumes automatically.

DataPower operator pod stuck waiting for lock removal

If you see messages in the **`datapower-operator`** pod log indicating that the pod is waiting for a lock to be removed:

```
{"level":"info","ts":"2021-03-08T19:29:53.432Z","logger":"leader","msg":"Not the leader. Waiting."}
{"level":"info","ts":"2021-03-08T19:29:57.971Z","logger":"leader","msg":"Leader pod has been deleted, waiting for garbage collection to remove the lock."}
```

The DataPower operator cannot be upgraded until this problem is resolved, see: DataPower operator documentation.

API Connect operator upgrade stuck

If you are upgrading from 10.0.4-ifix3 and the API Connect operator does not begin its upgrade within a few minutes, perform the following workaround to delete the **ibm-ai-wmltraining** subscription and the associated csv:

1. Run the following command to get the name of the subscription:

   ```
   oc get subscription --no-headers=true | grep ibm-ai-wmltraining | awk '{print $1}' -n <APIC_namespace>
   ```

2. Run the following command to delete the subscription:

   ```
   oc delete subscription <subscription-name> -n <APIC_namespace>
   ```

3. Run the following command to get the name of the csv:

   ```
   oc get csv --no-headers=true | grep ibm-ai-wmltraining | awk '{print $1}' -n <APIC_namespace>
   ```

4. Run the following command to delete the csv:

   ```
   oc delete csv <csv-name> -n <APIC_namespace>
   ```

Deleting the subscription and csv triggers the API Connect operator upgrade.

You see the `denied: insufficient scope` error during an air-gapped deployment

Problem: You encounter the **denied: insufficient scope** message while mirroring images during an air-gapped installation or upgrade.

Reason: This error occurs when a problem is encountered with the entitlement key used for obtaining images.

Solution: Obtain a new entitlement key by completing the following steps:

1. Log in to the IBM Container Library.
2. In the Container software library, select Get entitlement key.
3. After the Access your container software heading, click Copy key.
4. Copy the key to a safe location.

Apiconnect operator crashes

Problem: During installation (or upgrade), the Apiconnect operator crashes with the following message:

```
panic: unable to build API support: unable to get Group and Resources: unable to retrieve the complete list of server APIs:
packages.operators.coreos.com/v1: the server is currently unable to handle the request

goroutine 1 [running]:
github.ibm.com/velox/apiconnect-operator/operator-utils/v2/apiversions.GetAPISupport(0x0)
        operator-utils/v2/apiversions/api-versions.go:89 +0x1e5
main.main()
        ibm-apiconnect/cmd/manager/main.go:188 +0x4ee
```

Additional symptoms:

- Apiconnect operator is in crash loopback status
- Kube apiserver pods log the following information:

  ```
  E1122 18:02:07.853093 18 available_controller.go:437] v1.packages.operators.coreos.com failed with:
   failing or missing response from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1:
   bad status from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1: 401
  ```

- The IP logged here belongs to the *package server* pod present in the **openshift-operator-lifecycle-manager** namespace
- Package server pods log the following: **/apis/packages.operators.coreos.com/v1** API call is being rejected with 401 issue

  ```
  E1122 18:10:25.614179 1 authentication.go:53] Unable to authenticate the request due to an error: x509:
  certificate signed by unknown authority I1122 18:10:25.614224 1 httplog.go:90]
  verb="GET" URI="/apis/packages.operators.coreos.com/v1" latency=161.243µs resp=401
  UserAgent="Go-http-client/2.0" srcIP="10.128.0.1:41370":
  ```

- Problem is intermittent

Solution:

- If you find the exact symptoms as described, the solution is to delete package server pods in the **openshift-operator-lifecycle-manager** namespace.
- New package server pods will log the **200 Success** message for the same API call.

Upgrading a two data center deployment on Kubernetes and OpenShift

How to upgrade a two data center disaster recovery (DR) deployment on Kubernetes and OpenShift.

To upgrade API Connect in a 2DCDR deployment, use the upgrade instructions for your platform, but with the extra considerations and steps documented in this topic.

- Upgrading on Kubernetes.
- Upgrading on OpenShift and Cloud Pak for Integration.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Before you begin

- Ensure that API Connect is running in both data centers and that replication is working: Verifying replication between data centers.
- Ensure that you have recent backups of Management and Portal subsystems: Backup and restore requirements for a two data center deployment.

Key points applicable to both Management and Portal subsystems

- Your API Connect deployments must be upgraded to the same API Connect release, down to the interim fix level.
- Both data centers must be upgraded in the same maintenance window.
- Upgrade the data center that has the `ingress-ca` Kubernetes cert-manager certificate object first.
- Extra steps must be taken to ensure that the `ingress-ca` secret in both data centers contains the same `ingress-ca` X.509 certificate

The X.509 CA certificate that is used for TLS communication between the API Connect deployments in each data center is referred to as the `ingress-ca` X.509 certificate. This certificate is stored in the `ingress-ca` **secret** in both data centers, and it must be the same in each data center for 2DCDR to function. The cert-manager has a separate object that is referred to as the `ingress-ca` Kubernetes cert-manager certificate object. This object exists on the data center that was the original active data center on installation.

Key points:

- The `ingress-ca` Kubernetes cert-manager certificate object exists on only one of the data centers in a 2DCDR deployment.
- The `ingress-ca` X.509 certificate is contained in the `ingress-ca` **secret** of both data centers in a 2DCDR deployment, as shown:

```
kubectl get secret ingress-ca -n <namespace> -o yaml

apiVersion: v1
data:
  ca.crt: <long cert string>
  tls.crt: <long cert string>
  tls.key: <long cert string>
kind: Secret
...
```

To identify the data center that has the `ingress-ca` Kubernetes cert-manager certificate object, run:

```
kubectl -n <namespace> get cert ingress-ca

   NAME         READY   SECRET       AGE
   ingress-ca   True    ingress-ca   30h
```

Note: If the data center that has the `ingress-ca` Kubernetes cert-manager certificate object is unrecoverable, a new `ingress-ca` Kubernetes cert-manager certificate object can be created on the active data center by using the ingress-ca certificate section of the installation yaml file: `helper_files/ingress-issuer-v1.yaml`:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ingress-ca
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "ingress-ca"
  }
spec:
  secretName: ingress-ca
  commonName: "ingress-ca"
  usages:
  - digital signature
  - key encipherment
  - cert sign
  isCA: true
  duration: 87600h # 10 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
  issuerRef:
    name: selfsigning-issuer
    kind: Issuer
```

Pre-upgrade operations in the upgrade documentation for your platform might result in an update to the `ingress-ca` X.509 certificate. Extra steps must then be taken during the 2DCDR deployment upgrade to ensure that both data centers always use the same `ingress-ca` X.509 certificate.

Note: If you are not using cert-manager and you customized your certificates, the `ingress-ca` certificate might have a different name. Ensure that the CA certificate that is used by both data centers is the same during all stages of the upgrade.

Steps for Management upgrades

1. Remove the `multiSiteHA` section from the management CRs in both data centers, converting them both to stand-alone deployments.
2. Verify that the management subsystem in both data centers is running as a stand-alone, and that all the pods are running:

```
kubectl get mgmt -n <namespace>

NAME                          READY   STATUS    VERSION    RECONCILED VERSION   AGE
<management instance name>   15/15   Running   <version>   <version>-xxxx        14d
```

If one of the data centers returns **6/6** pods then this means it is still running as a warm-standby, wait a few minutes for it to complete the transition to a stand-alone data center. Run **kubectl describe** and confirm that the **multiSiteHA** section is gone from the **spec** section, and that the **Status** section shows **ha mode** of active in both data centers:

```
kubectl describe mgmt -n <namespace>
...
Status
  Ha Mode:                    active
...
```

3. Upgrade both data centers.
4. Verify that both data centers have the same **ingress-ca** X.509 certificate in their **ingress-ca** secret. Run the following command in both data centers and check that the output is the same:

```
openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d)
```

if you do not have the **openssl** command available, you can instead run only the **kubectl** part, which produces a larger output:

```
kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
```

if the outputs are different, follow these steps to synchronize the certificates: Synchronizing **ingress-ca** X.509 certificates.
5. Add the **multiSiteHA** sections to the management CRs, setting one of them to be the active and the other to be the warm-standby.

Steps for Portal upgrades

1. Verify that both data centers have the same **ingress-ca** X.509 certificate in their **ingress-ca** secret. Run the following command in both data centers and check that the output is the same:

```
openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d)
```

if you do not have the **openssl** command available, you can instead run only the **kubectl** part, which produces a larger output:

```
kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
```

if the outputs are different, follow these steps to synchronize the certificates: Synchronizing **ingress-ca** X.509 certificates.
2. Determine which data center has the **ingress-ca** Kubernetes cert-manager certificate object:

```
kubectl get certificates -n <portal namespace> | grep ingress-ca
```

If this data center is the active, failover the portal subsystem to make it the warm-standby data center: How to perform 2DCDR failover.
3. Start the upgrade of your warm-standby data center by following the upgrade documentation for your platform. Stop at the point where the portal CR is updated with the new API Connect version.
4. Verify that both data centers still have the same **ingress-ca** X.509 certificate, repeating step 1. If they are different, then follow these steps: Synchronizing ingress-ca X.509 certificates.
5. Complete the upgrade of your warm-standby data center by updating the portal subsystem CR, following the remaining upgrade steps for your platform.
6. Start the upgrade of your active data center by following the upgrade documentation for your platform. Stop at the point where the portal CR is updated with the new API Connect version.
7. Verify that both data centers still have the same **ingress-ca** X.509 certificate, repeating step 1. If they are different, then follow these steps: Synchronizing ingress-ca X.509 certificates.
8. Upgrade the portal subsystem in your active data center by updating the portal subsystem CR, following the remaining upgrade steps for your platform.

Synchronizing the ingress-ca X.509 certificate across data centers

Follow these steps to extract your **ingress-ca** X.509 certificate from your source data center and prepare it for application on your target data center:

1. Determine which data center has the **ingress-ca** Kubernetes cert-manager certificate object certificate:

```
kubectl get certificates -n <namespace> | grep ingress-ca
```

this is your source data center.
2. Extract the **ingress-ca secret** from your source data center to a file called **new-ca-issuer-secret.yaml**:

```
kubectl get secret ingress-ca -o yaml -n <namespace>  > new-ca-issuer-secret.yaml
```

3. Edit the **new-ca-issuer-secret.yaml** file and remove the **creationTimestamp**, **resourceVersion**, **uid**, **namespace**, and **managedFields**. Remove the labels and annotations sections completely. The resulting contents should include the **ingress-ca** X.509 certificate, and the secret name:

```
apiVersion: v1
data:
  ca.crt: <long cert string>
  tls.crt: <long cert string>
  tls.key: <long cert string>
kind: Secret
metadata:
  name: ingress-ca
type: kubernetes.io/tls
```

4. Copy the **new-ca-issuer-secret.yaml** to the target data center.

Follow these steps to apply the extracted **ingress-ca** X.509 certificate on your target data center:

1. To apply the **new-ca-issuer-secret.yaml** file, run:

```
kubectl apply -f new-ca-issuer-secret.yaml -n <namespace>
```

2. Regenerate all `ingress-ca` end-entity certificates:

   ```
   kubectl get secrets -n <namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n <namespace>
   ```

   All affected pods should automatically restart. For more information on regenerating certificates, see: Renewing certificates with cert-manager.

How to upgrade when one data center is down

If API Connect is still running on the failed data center, follow the steps that are documented previously to upgrade both data centers, before you bring the failed data center back online.

If the failed data center is expected to be down for a long time, you can convert the active data center to a stand-alone data center following these steps: Removing a two data center deployment, but note the following points:

1. Ensure that the network links to the failed data center are removed.
2. Ensure that the failed data center is set to warm-standby in the `multiSiteHA` section. Do not proceed to the next step until the data center completes the transition to warm-standby. View the status of the management and portal CRs to confirm that `HA Mode` reports "passive".
3. Remove the `multiSiteHA` section from failed data center, and ensure that the failed data center resets itself to become an empty stand-alone API Connect deployment (all data is deleted).
4. Before you restore the network links between the data centers, do the following:
   - Upgrade API Connect on the failed data center to the same version as the active.
   - Add the `multiSiteHA` sections to both data centers, setting the failed data center to be warm-standby.
     Important: Do not set the failed data center to be active in the `multiSiteHA` section because it results in an overwrite of the data on your working data center with the empty database of your failed data center.

Upgrading a two data center deployment on Cloud Pak for Integration

How to upgrade a two data center disaster recovery (DR) deployment on Cloud Pak for Integration.

To upgrade a Cloud Pak for Integration deployment of API Connect in a 2DCDR deployment, use the Cloud Pak for Integration upgrade instructions Upgrading API Connect in Cloud Pak for Integration, but with the extra considerations and steps documented in this topic.

Before you begin

- Ensure that API Connect is running in both data centers and that replication is working: Verifying replication between data centers.
- Ensure that you have recent backups of Management and Portal subsystems: Backup and restore requirements for a two data center deployment.

Key points applicable to both Management and Portal subsystems

- Your API Connect deployments must be upgraded to the same API Connect release, down to the interim fix level.
- Both data centers must be upgraded in the same maintenance window.
- Extra steps must be taken to ensure that the `ingress-ca` secret in both data centers contains the same `ingress-ca` X.509 certificate

The X.509 CA certificate that is used for TLS communication between the API Connect deployments in each data center is referred to as the `ingress-ca` X.509 certificate. This certificate is stored in the `ingress-ca` **secret** in both data centers, and it must be the same in each data center for 2DCDR to function. The cert-manager has a separate object that is referred to as the `ingress-ca` Kubernetes cert-manager certificate object.

Pre-upgrade operations might result in an update to the `ingress-ca` X.509 certificate. Extra steps must then be taken during the 2DCDR deployment upgrade to ensure that both data centers always use the same `ingress-ca` X.509 certificate.

2DCDR upgrade steps for Cloud Pak for Integration

In Cloud Pak for Integration, the Management and Portal subsystems are managed by the `apiconnectcluster` CR (also known as the top-level CR). When the `apiconnectcluster` CR is updated with the new API Connect version, all the subsystems are updated automatically. Follow the upgrade process for Cloud Pak for Integration, starting from Upgrading API Connect in Cloud Pak for Integration, along with the following steps.

1. Verify that both data centers have the same `ingress-ca` X.509 certificate in their `<apic instance-name>-ingress-ca` secret. Run the following command in both data centers and check that the output is the same:

   ```
   openssl x509 -noout -fingerprint -sha256 -in <(oc get secret <apic instance-name>-ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d)
   ```

   if you do not have the `openssl` command available, you can instead run only the `oc` part, which produces a larger output:

   ```
   oc get secret <apic instance-name>-ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
   ```

   if the outputs are different, follow these steps to synchronize the certificates: Synchronizing the ingress-ca X.509 certificate across data centers.

2. Remove the **multiSiteHA** section from the Management sections of the **apiconnectcluster** CRs in both data centers, converting them both to stand-alone management deployments. Be careful to do this only in the management sections, and not the portal sections of the **apiconnectcluster** CR.
3. Start the upgrade of your portal warm-standby data center by following the upgrade documentation for the API Management capability in https://www.ibm.com/docs/en/cloud-paks/cp-integration. Stop at the point after the API Connect and DataPower operators are updated but before the operands are updated.
4. Repeat step 1 to verify that the **ingress-ca** X.509 certificates are still the same in both data centers.
5. Complete the upgrade of your portal warm-standby data center, updating the operands as described in the Cloud Pak for Integration documentation.
6. Repeat step 1 to verify that the **ingress-ca** X.509 certificates are still the same in both data centers.
7. Start the upgrade of your portal active data center by following the upgrade documentation for the API Management capability in https://www.ibm.com/docs/en/cloud-paks/cp-integration. Stop at the point after the API Connect and DataPower operators are updated but before the operands are updated.
8. Repeat step 1 to verify that the **ingress-ca** X.509 certificates are still the same in both data centers.
9. Complete the upgrade of the portal active data center, updating the operands as described in the Cloud Pak for Integration documentation.
10. Add the **multiSiteHA** sections to the management section of the **apiconnectcluster** CRs in both data centers. Set the same active data center for management as for portal.

Synchronizing the ingress-ca X.509 certificate across data centers

Follow these steps to extract your **ingress-ca** X.509 certificate from your source data center and prepare it for application on your target data center. Your source data center is the data center that you are upgrading first:

1. Extract the *<apic instance-name>*-**ingress-ca** **secret** from your source data center to a file called **new-ca-issuer-secret.yaml**:

   ```
   oc get secret <apic instance-name>-ingress-ca -o yaml -n <namespace>  > new-ca-issuer-secret.yaml
   ```

2. Edit the **new-ca-issuer-secret.yaml** file and remove the **creationTimestamp**, **resourceVersion**, **uid**, **namespace**, and **managedFields**. Remove the labels and annotations sections completely. The resulting contents should include the **ingress-ca** X.509 certificate, and the secret name:

   ```
   apiVersion: v1
   data:
     ca.crt: <long cert string>
     tls.crt: <long cert string>
     tls.key: <long cert string>
   kind: Secret
   metadata:
     name: ingress-ca
   type: kubernetes.io/tls
   ```

3. Copy the **new-ca-issuer-secret.yaml** to the target data center.

Follow these steps to apply the extracted **ingress-ca** X.509 certificate on your target data center:

1. To apply the **new-ca-issuer-secret.yaml** file, run:

   ```
   oc apply -f new-ca-issuer-secret.yaml -n <namespace>
   ```

2. Regenerate all **ingress-ca** end-entity certificates:

   ```
   oc get secrets -n <namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs oc delete secret -n <namespace>
   ```

   All affected pods should automatically restart. For more information on regenerating certificates, see: Renewing certificates with cert-manager.

How to upgrade when one data center is down

If API Connect is still running on the failed data center, follow the steps that are documented previously to upgrade both data centers, before you bring the failed data center back online.

If the failed data center is expected to be down for a long time, you can convert the active data center to a stand-alone data center following these steps: Removing a two data center deployment, but note the following points:

1. Ensure that the network links to the failed data center are removed.
2. Ensure that the failed data center is set to warm-standby in the **multiSiteHA** section. Do not proceed to the next step until the data center completes the transition to warm-standby. View the status of the management and portal CRs to confirm that **HA Mode** reports "passive".
3. Remove the **multiSiteHA** section from failed data center, and ensure that the failed data center resets itself to become an empty stand-alone API Connect deployment (all data is deleted).
4. Before you restore the network links between the data centers, do the following:
   - Upgrade API Connect on the failed data center to the same version as the active.
   - Add the **multiSiteHA** sections to both data centers, setting the failed data center to be warm-standby.
     Important: Do not set the failed data center to be active in the **multiSiteHA** section because it results in an overwrite of the data on your working data center with the empty database of your failed data center.

Maintaining API Connect

You can use utilities to complete maintenance tasks such as backup, restore, and certificate management on Kubernetes.

Note: When maintaining API Connect, do not use **kubectl exec** or **oc exec** commands to access API Connect pods unless advised by IBM.

- **Advanced configuration**
  You can optionally install and configure advanced features.

- **Backing up and restoring**
  You can backup and restore API Connect subsystems.
- **Disaster recovery**
  Prepare for, or recover from, a disaster affecting an API Connect deployment running on Kubernetes, OpenShift, or Cloud Pak for Integration.
- **Maintaining a two data center deployment**
  How to maintain a two data center disaster recovery (DR) deployment on Kubernetes and OpenShift, including information about normal operation, failure handling, and recovery.
- **Monitoring and health checks**
  Monitor your deployment and complete health checks on subsystems.
- **Logging**
  Configure logging for your deployment on Kubernetes.
- **Troubleshooting**
  Troubleshooting problems with your API Connect subsystems.

Advanced configuration

You can optionally install and configure advanced features.

- **Advanced configuration for the gateway subsystem**
  Specify advanced configuration for the gateway subsystem.

Installing License Service

License Service helps you assess whether your IBM® API Connect deployment in a Kubernetes environment is compliant with licensing requirements.

About this task

License Service provides useful features for managing virtualized environments and measuring license utilization. License Service discovers the software that is installed in your infrastructure, helps you to analyze the consumption data, and allows you to generate audit reports. Each report provides you with different information about your infrastructure, for example the computer groups, software installations, and the content of your software catalog.

By default, every License Service audit report presents data from the previous 90 days. You can customize the type and amount of information that is displayed in a report by using filters, and save your personal settings for future use. You can also export the reports to .csv or pdf format, and schedule report emails so that specified recipients are notified when important events occur.

When you install API Connect, the **`license-use`** setting that is configured in the ibm-apiconnect operator CR (custom resource) for a particular subsystem is reflected in the Pod annotations. For the Analytics, Portal, and Management subsystems the **`license-use`** value can be "production" or "nonproduction". For the Gateway subsystem, the **`license-use`** value can be "production", "nonproduction", or "developer". The subsystem pod annotations are scanned by the ibm-licensing-operator, which reports license and CPU usage for each subsystem.

For more information, see License Service in the IBM Cloud Pak foundational services documentation.

Procedure

Install License Service as explained in the installation instructions in License Service in the IBM Cloud Pak foundational services documentation.
The instructions describe the appropriate License Service installation procedure for API Connect deployments, and apply to the Analytics, Portal, Management, and Gateway subsystems.

Installing the Automated API behavior testing application

Update the custom resource for installing IBM® API Connect to deploy the Automated API behavior testing application on Kubernetes.

About this task

You can install the Automated API behavior testing application as part of a new IBM API Connect deployment, or you can add it to an existing deployment:

- Adding the Automated API behavior testing application to an existing deployment
- Including the Automated API behavior testing application in a new deployment

Note: It is not possible to use the Automated API behavior testing application with a two data center disaster recovery configuration (Two data center deployment strategy on Kubernetes and OpenShift).

Adding the Automated API behavior testing application to an existing deployment

Before you begin

Make sure that the following requirements are met before attempting to deploy the Automated API behavior testing application:

- The IBM API Connect subsystems are installed.
- The cert-manager is installed for use with IBM API Connectand you are using the default certificates that it generates.
  The Automated API behavior testing application requires that the IBM API Connect deployment use the cert-manager and the default certificates. Custom certificates are not supported and if used, the Automated API behavior testing application will not install correctly.

About this task

Edit the deployed CR (custom resource) for the Management subsystem and add the settings for the Automated API behavior testing application.

Procedure

1. Retrieve the name of the deployed Management subsystem's deployed CR by running the following command:

   ```
   kubectl get managementcluster -n <management_namespace>
   ```

2. Edit the deployed CR by running the following command:

   ```
   kubectl edit managementcluster <management-cr-name> -n <management_namespace>
   ```

3. Append the new `testAndMonitor` definition at the end of the `spec` section, making sure to adhere to the spacing used in the file.
   Attention: The hub and turnstile endpoints should be distinct and must not overlap with any of the 4 management endpoints.

   ```
   testAndMonitor:
     enabled: true
     hubEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: hub.$STACK_HOST
         secretName: hub-endpoint
     turnstileEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: turnstile.$STACK_HOST
         secretName: turnstile-endpoint
   ```

   `$STACK_HOST` is the ingress subdomain for the API Connect stack, as documented in Installing the Management subsystem cluster.

4. Save the update.
   The Automated API behavior testing application will be installed into the existing Management subsystem.

5. Check the Hub and Turnstile pods periodically until their "READY" values are both "1/1" and their "STATUS" are both "Running".
   Verify that the Hub and Turnstile pods are running, by executing the following command:

   ```
   kubectl get pods -n <management_namespace>
   ```

   Look for pods with names similar to `management-hub-XXXX-XXXX` and `and management-turnstile-XXXX-XXXX`. The following example shows how the response might look:

   ```
   NAME                                    READY   STATUS    RESTARTS   AGE
   management-hub-68745dc4b7-gmlkk         1/1     Running   0          29m
   management-turnstile-b7d978b56-jghvn    1/1     Running   0          24m
   ```

Including the Automated API behavior testing application in a new deployment

Before you begin

Make sure that the cert-manager is installed for use with IBM API Connect and you are using the default certificates that it generates. The Automated API behavior testing application requires that the IBM API Connect deployment use the cert-manager and the default certificates. Custom certificates are not supported and if used, the Automated API behavior testing application will not install correctly.

About this task

Edit the CR (custom resource) for the Management subsystem and add the settings for the Automated API behavior testing application.

Procedure

1. Edit the **ManagementCluster** custom resource (CR) and add the following definition for the Automated API behavior testing application.
   Append the new definition at the end of the **spec** section, making sure to adhere to the spacing used in the file.

   ```
   testAndMonitor:
     enabled: true
     hubEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: hub.$STACK_HOST
         secretName: hub-endpoint
     turnstileEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: turnstile.$STACK_HOST
         secretName: turnstile-endpoint
   ```

   $STACK_HOST is the ingress subdomain for the API Connect stack, as documented in Installing the Management subsystem cluster.

   Attention: The hub and turnstile endpoints should be distinct and must not overlap with any of the 4 management endpoints.
2. Apply the updated CR by running the following command:

   ```
   kubectl apply -f management_cr.yaml -n <management_namespace>
   ```

   where ***namespace*** is the name of the target installation namespace in the Kubernetes cluster.

   The Automated API behavior testing application will be installed with the Management subsystem.

3. Check the Hub and Turnstile pods periodically until their "READY" values are both "1/1" and their "STATUS" are both "Running".
   Verify that the Hub and Turnstile pods are running, by executing the following command:

   ```
   kubectl get pods -n <management_namespace>
   ```

   Look for pods with names similar to **management-hub-*XXXX-XXXX*** and **and management-turnstile-*XXXX-XXXX***. The following example shows how the response might look:

   ```
   NAME                                    READY   STATUS    RESTARTS   AGE
   management-hub-68745dc4b7-gmlkk         1/1     Running   0          29m
   management-turnstile-b7d978b56-jghvn    1/1     Running   0          24m
   ```

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just to need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
   - To download the toolkit from IBM Fix Central, complete the following steps:
     - Open the IBM Fix Central site in your browser.
     - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
     - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
     - In the Text field, enter `toolkit`, then click Continue.
     - Select the toolkit file that you want to download.
     - Click Continue, then follow the instructions to complete the download operation.
   - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
     - Open the Cloud Manager or API Manager user interface.
     - On the welcome page, click the Download Toolkit tile. The two toolkit options are listed.

- Click your platform alongside either the CLI option or the CLI + LoopBack + Designer option as required, then save the associated compressed file to your local file system.
- To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the designer_credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 6.
- To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 5.
- Close the Install API Connect Toolkit window.

2. Extract the contents of the toolkit compressed file to a folder of your choice.
   The contents of the file depend on the your chosen toolkit option and platform, as follows:

   - The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.
   - The apic or apic.exe file is the CLI for IBM API Connect including LoopBack support.
     Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.
   - The api_designer-*platform* file is the API Designer user interface application for the specified platform.
3. Optional: Delete the **`$HOME/.apiconnect/node_clis`** directory.
   You need to do this only if you replaced a version of **`apic`** or apic.exe and are using the **`apic lb4`** command. You need to delete the directory get **`apic`** to unpack the new loopback.

   On Windows, $HOME is defined by environment USERPROFILE.

4. Run the CLI.
   - For the Mac OSX or Linux® platforms, complete the following steps:
     - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Make the CLI file an executable file by entering the following command:

       ```
       chmod +x download_name
       ```

       Where *download_name* is the name of the toolkit file that you downloaded, either apic or apic-slim.
     - Run CLI commands as follows:

       ```
       ./apic command_name_and_parameters
       ```

       or

       ```
       ./apic-slim command_name_and_parameters
       ```

       For details of the CLI commands, see apic.
   - For the Windows platform, complete the following steps:
     - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Run CLI commands as follows:

       ```
       apic command_name_and_parameters
       ```

       or

       ```
       apic-slim command_name_and_parameters
       ```

       For details of the CLI commands, see apic.

   Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.
5. Install the toolkit credentials.
   If you do not install the toolkit credentials that are provided for download, as detailed previously in the toolkit credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

   ```
   apic client-creds:set toolkit_credentials_file_path/credentials.json
   ```

   where *credentials_file_path* is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.
   Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
   To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

   ```
   apic client-creds:clear
   ```

   For increased security, an administrator can remove the default credentials from the management server by completing the following steps:
   a. Log in to the management server as an administrator; see Logging in to a management server.
   b. Delete the default credentials by running the following commands:

   ```
   apic registrations:delete toolkit --server mgmt_endpoint_url
   apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
   ```

6. Install the API Designer credentials.
   If you do not install the API Designer credentials that are provided for download, as detailed previously in the API Designer credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the **`APIC_DESIGNER_CREDENTIALS`** environment variable to the credentials download location, using the mechanism appropriate for your operating system.

   After you have set the **`APIC_DESIGNER_CREDENTIALS`** environment variable, your API Designer uses the new credentials to authenticate with the management server.

   - Windows:
     If you are using Windows, create an environment variable using one of the following methods:

     - Create a permanent environment variable so that you can start API Designer from any location on your computer:

- Open the Environment Variables page: Click Start > Settings > System and in the "Related Settings" section of the page, click Advanced System Settings.
- On the Advanced tab of the System Properties dialog box, click Environment Variables.
- In the "User variables" section, click New and create an environment variables with the following settings:
  - Variable: `APIC_DESIGNER_CREDENTIALS`
  - Value: *<designer_credentials_file_path>*\designer_credentials.json where `<designer_credentials_file_path>` is the location where you stored the designer_credentials.json file.
- Click OK to save the new environment variable, and then exit the dialog box.

- If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
  - Open the Windows command prompt.
  - Run the following command to set the temporary environment variable:

    ```
    set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
    ```

    where `<designer_credentials_file_path>` is the location where you stored the designer_credentials.json file.

    Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.
  - Now run the following command to start API Designer:

    ```
    C:\"Program Files\API Designer\API Designer.exe"
    ```

    By default, API Designer is installed in the C:\"Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

- Mac:
  If you are using Mac OS X, create an environment variable using one of the following methods:

  - Run the following command to set the global environment variable:

    ```
    launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
    ```

    where `<designer_credentials_file_path>` is the location where you stored the API Designer credentials JSON file.
  - Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

    ```
    APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open
    <designer_application_file_path>/'API Designer.app'
    ```

    where:
    - `<designer_credentials_file_path>` is the location to which you downloaded the API Designer credentials JSON file.
    - `<designer_application_file_path>` is the location to which you downloaded and uncompressed the API Designer application.

7. Start the API Designer application from the location to where you stored the extracted file.
   Note:
   - To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
     - In Windows File Explorer, navigate to the USER_HOME\AppData\Local\Programs\api-designer folder.
     - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
   - To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see Developing your APIs and applications.

For information on using the toolkit CLI, see Using the developer toolkit command-line tool.

Changing deployment profiles on Kubernetes

You can change an API Connect installation to use different deployment profiles.

About this task

After you complete initial installation of the API Connect subsystems, you can change to another of the profiles that are supported for the subsystem. For more information on the available profiles, see: Planning your deployment topology.

Important considerations:

- If you are changing from a one replica profile to a three replica profile, ensure that you have three replica profile hardware (at least 3 worker nodes).
- Based on the resources configured for each microservice in the profile, there might be downtime during the profile change.

Procedure

1. Management subsystem:
   a. Verify that subsystem is in `Running` state.

   ```
   kubectl get ManagementCluster -n <namespace>
   ```

b. Edit the CR:

```
kubectl edit ManagementCluster -n <namespace>
```

Change **spec.profile** value to the new profile you want to use.

c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
d. Verify that subsystem is in **Running** state.

```
kubectl get ManagementCluster -n <namespace>
```

2. Developer Portal subsystem:
   a. Verify that subsystem is in **Running** state.

```
kubectl get PortalCluster -n <namespace>
```

   b. Edit the CR:

```
kubectl edit PortalCluster -n <namespace>
```

Change **spec.profile** value to the new profile you want to use.

   c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
   d. Verify that subsystem is in **Running** state.

```
kubectl get PortalCluster -n <namespace>
```

3. Analytics subsystem:
   a. Verify that subsystem is in **Running** state.

```
kubectl get AnalyticsCluster -n <namespace>
```

   b. Edit the Analytics CR:

```
kubectl edit AnalyticsCluster -n <namespace>
```

Change **spec.profile** value to the new profile you want to use.

   c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
   d. Verify that subsystem is in **Running** state.

```
kubctl get AnalyticsCluster -n <namespace>
```

   e. Restart analytics data collection as explained in the topic, Restarting Analytics pods and data collection.
4. Gateway subsystem
   a. Verify that subsystem is in **Running** state.

```
kubectl get GatewayCluster -n <namespace>
```

   b. Edit the CR:

```
kubectl edit GatewayCluster -n <namespace>
```

Change **spec.profile** value to the new profile you want to use.

   c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
   d. Verify that subsystem is in **Running** state.

```
kubectl get GatewayCluster -n <namespace>
```

Changing deployment profiles on OpenShift

You can change an API Connect installation to use different profiles.

Before you begin

This task assumes that you have already deployed an API Connect cluster as explained in Deploying on OpenShift and Cloud Pak for Integration. If you are changing from a one replica profile to a three replica profile, ensure that you have three replica profile hardware (3 worker nodes) available. For more information on the available profiles, see: Planning your deployment topology.

Procedure

1. Verify that the API Connect cluster is in the **Ready** state by running the following command:

```
oc get apiconnectcluster -n <APIC_namespace>
```

2. Update the API Connect Cluster CR:
   a. Open the API Connect Cluster CR in edit mode by running the following command:

```
oc edit apiconnectcluster <APIC-instance-name> -n <APIC_namespace>
```

b. In the CR, change the `spec.profile` value to the profile that you want to use.
c. Save the change by running the following command: `:wq`

3. Wait for microservice to scale up, or scale down, as needed.
4. Verify that the API Connect cluster is in the `Ready` state by running the following command:

```
oc get apiconnectcluster -n <APIC_namespace>
```

Replica override for microservices

Modify the replica count for microservices by using template overrides for Custom Resources.

When API Connect is deployed, the deployment profile you select drives the number of replicas to be used for most deployment. For one replica profiles, specified by `n1x....`, the replica count is 1. For three replica profiles, specified by `n3x...`, replica count is 3. Note, however, that for Cloud Pak for Integration the API Connect Cluster profile `n3xc4.m16` replica count is 1.

You can override the replica count for individual deployments by using template overrides.

- Template overrides are a piece of yaml that should be added to the Kubernetes custom resource. The examples provided in this topic show only that the `template:` element should be under the main `spec:` element of a CR. The rest of the CR is not shown.
- Specification of microservice overrides in CP4I requires prefixing the microservice name with a designator for the subsystem type, as follows:
  - Management subsystem: `mgmt-`
  - Gateway: `gw-`
  - Analytics: `a7s-`

  For example, for the `apim` Management microservice, use `apim` when defining the override for OpenShift (or Kubernetes), but use `mgmt-apim` for a CP4I override.

Management subsystem

For a Management CR in Kubernetes or OpenShift, the following override specifies 5 replicas for the `apim` deployment:

```
spec:
  template:
  - name: apim
    replicaCount: 5
```

You can also configure replicate count through a similar template override for:

- `juhu`
- `ldap`
- `lur`

The same override for CP4I:

```
spec:
  template:
  - name: mgmt-apim
    replicaCount: 5
```

On CP4I, you can also configure replicate count through a similar template override for:

- `mgmt-juhu`
- `mgmt-ldap`
- `mgmt-lur`

Gateway subsystem

The following override is supported for a Gateway CR in Kuberneter or OpenShift:

```
spec:
 template:
  - name: datapower
    replicaCount: 5
```

The same override for CP4I:

```
spec:
  template:
  - name: gw-datapower
    replicaCount: 5
```

Analytics subsystem

The Analytics microservices that can be scaled using template override are:

- `director`
- `ingestion`
- `mtls-gw`
- `storage`
  Note that this microservice cannot be scaled below 2 replicas when using a three replica deployment profile.

On CP4I, you can also configure replica count through a similar template override for:

- `a7s-directory`

- `a7s-ingestion`
- `a7s-mtls-gw`
- `a7s-storage`
  Note that this microservice cannot be scaled below 2 replicas when using a three replica deployment profile.

Changing the deployment profile on Cloud Pak for Integration

You can change an API Connect installation to use a different profile.

Before you begin

This task assumes that you have already deployed an API Connect cluster as explained in Deploying on OpenShift and Cloud Pak for Integration. If you are switching from a one replica profile to a three replica profile, ensure that you have three replica profile hardware (3 worker nodes) available. For more information on the available profiles, see: Planning your deployment topology.

Procedure

1. Verify that the API Connect cluster is in the **`Ready`** state.
   Open the IBM Cloud Pak Platform UI, locate the API Management capability on the Integration instances tab, and verify that the state displays as **`Ready`**. Leave the page open for the next step.

2. Update the API Management instance:
   a. In the Platform UI, click the overflow menu next to the instance and select Edit.
   b. In the Details section of the deployment pages, navigate to the Deployment profile field.
   c. Click the field and select the new deployment profile.
3. Click Update to save the change.
4. Wait for microservice to scale up, or scale down, as needed.
5. Verify that the status for the API Management instance displays as **`Ready`**.

Enabling Developer Portal feature flags on Kubernetes

Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.

About this task

You can add a template override to the Developer Portal subsystem CR to change the default behavior of the Portal subsystem, or to turn specific features on and off. Table 1 describes the available feature flags.

Table 1. List of available feature flags for the Developer Portal

Feature flag name	Default Value	Pod	Container	Description
`PORTAL_SKIP_WEB_ENDPOINT_VALIDATION`	`true`	`www`	`admin`	Controls whether the Portal subsystem checks whether the Portal web endpoint is accessible. Sometimes, the endpoint cannot be reached, for example due to the complexity of the networks. In which case the following type of error can be seen in the **`portal-www`** pod, and **`admin`** container logs: **`An error occurred contacting the provided portal web endpoint: example.com`** **`The provided Portal web endpoint example.com returned HTTP status code 504`** You can disable the check by setting this flag to **`false`**.

Feature flag name	Default Value	Pod	Container	Description
`ENABLE_TRUSTED_REVERSE_PROXY`	`false`	`www`	`admin`	Controls whether the Drupal `trusted_reverse_proxy` module can manage the reverse proxies list. If you have multiple load balancers and reverse proxies in your upstream network, and the perimeter module is triggered, the incorrect IP address might be banned rather than the intended client IP address. However, you can manage which IP addresses are banned by using the Drupal `trusted_reverse_proxy` module, and setting this feature flag to `true`. The Drupal module inspects the `x-forwarded-for` headers to identify the reverse proxies, and trusts that the first IP address found in the list is the client IP. For example, in `X-Forwarded-For: <client>, <proxy1>, <proxy2>`, the client IP `<client>` will be banned. For more information about this module, see https://www.drupal.org/project/trusted_reverse_proxy. To use this module, you must ensure that all of the proxies in your upstream network, including the ingress controller, are configured correctly so that the `x-forwarded-for` header is passed through to the `portal-www` pod. For example, the default behavior of the `nginx-ingress-controller` is to ignore the inbound `x-forwarded-for` header, and create a new one. To change this behavior, update the `nginx-ingress-controller` `configmap` with the following information: `data:` `  compute-full-forwarded-for: "true"` `  use-forwarded-headers: "true"` Warning: Enable this feature flag only if you trust your upstream reverse proxies, as it is possible to trick the `x-forwarded-for` header.

Procedure

1. If API Connect is already deployed, retrieve the name of the deployed CR for the Developer Portal subsystem by running the following command:

   ```
   kubectl get portalcluster -n <portal_namespace>
   ```

   If API Connect yet is not yet deployed, skip this step.

2. Edit the `portal` CR by running the following command:

   ```
   kubectl edit portalcluster <portal-cr-name> -n <portal_namespace>
   ```

3. In the editor, append the feature flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the `trusted_reverse_proxy` feature.

   ```
   spec:
   ...
     template:
     - containers:
       - env:
           - name: ENABLE_TRUSTED_REVERSE_PROXY
             value: true
         name: container
       name: pod
   ```

   Where:
   - *container* is the name of the portal container.
   - *pod* is the name of the portal pod.

   Note: You can add multiple feature flags to the CR.
4. Save the update.
   The Developer Portal subsystem is updated to enable or disable features as specified.

Enabling Developer Portal feature flags on OpenShift and Cloud Pak for Integration

Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.

About this task

You can add a template override to the Developer Portal subsystem CR to change the default behavior of the Portal subsystem, or to turn specific features on and off. Table 1 describes the available feature flags.

Table 1. List of available feature flags for the Developer Portal

Feature flag name	Default Value	Pod	Container	Description

Feature flag name	Default Value	Pod	Container	Description
`PORTAL_SKIP_WEB_ENDPOINT_VALIDATION`	`true`	`www`	`admin`	Controls whether the Portal subsystem checks whether the Portal web endpoint is accessible. Sometimes, the endpoint cannot be reached, for example due to the complexity of the networks. In which case the following type of error can be seen in the `portal-www` pod, and `admin` container logs: `An error occurred contacting the provided portal web endpoint: example.com` `The provided Portal web endpoint example.com returned HTTP status code 504` You can disable the check by setting this flag to `false`.
`ENABLE_TRUSTED_REVERSE_PROXY`	`false`	`www`	`admin`	Controls whether the Drupal `trusted_reverse_proxy` module can manage the reverse proxies list. If you have multiple load balancers and reverse proxies in your upstream network, and the perimeter module is triggered, the incorrect IP address might be banned rather than the intended client IP address. However, you can manage which IP addresses are banned by using the Drupal `trusted_reverse_proxy` module, and setting this feature flag to `true`. The Drupal module inspects the `x-forwarded-for` headers to identify the reverse proxies, and trusts that the first IP address found in the list is the client IP. For example, in `X-Forwarded-For: <client>, <proxy1>, <proxy2>`, the client IP `<client>` will be banned. For more information about this module, see https://www.drupal.org/project/trusted_reverse_proxy. To use this module, you must ensure that all of the proxies in your upstream network, including the ingress controller, are configured correctly so that the `x-forwarded-for` header is passed through to the `portal-www` pod. For example, the default behavior of the `nginx-ingress-controller` is to ignore the inbound `x-forwarded-for` header, and create a new one. To change this behavior, update the `nginx-ingress-controller` `configmap` with the following information: `data:` `  compute-full-forwarded-for: "true"` `  use-forwarded-headers: "true"` Warning: Enable this feature flag only if you trust your upstream reverse proxies, as it is possible to trick the `x-forwarded-for` header.

Procedure

1. If API Connect is already deployed, retrieve the name of the deployed CR by running the following command:

   ```
   oc get apiconnectcluster -n <APIC_namespace>
   ```

   If API Connect yet is not yet deployed, skip this step.

2. Edit the `apiconnectcluster` CR by running the following command:

   ```
   oc edit apiconnectcluster <APIC_instance_name> -n <APIC_namespace>
   ```

3. In the CR, append the feature flag definition to the end of the `spec.portal` section, making sure to adhere to the spacing used in the file.
   The following example enables the `trusted_reverse_proxy` feature.

   ```
   spec:
   ...
     portal:
       template:
       - containers:
         - env:
           - name: ENABLE_TRUSTED_REVERSE_PROXY
             value: true
           name: container
         name: pod
   ```

   Where:
   - *container* is the name of the portal container.
   - *pod* is the name of the portal pod.

   Note: You can add multiple feature flags to the CR.
4. Close and save the file with the following command:

   ```
   :wq
   ```

   The Developer Portal subsystem is updated to enable or disable features as specified.

Enabling UI feature flags on Kubernetes

Use a template override to update the installation CR with settings that control UI features.

About this task

You can add a template override to the Management subsystem CR and use it to control whether specific features are available in the UI. Some features can be optionally disabled by users (by disabling them in the browser) provided you have enabled the feature for the cluster as a whole. Table 1 describes the available feature flags.

Table 1. Flags and settings for controlling UI features

Feature ID	Default Value	Partial Override For	Description
`ffAdvancedPublish`	`true`		Enable advanced publish option (deprecated)
`allOmniSearch`	`true`		Enables OmniSearch for all lists. This flag is used in conjunction with other flags.
`draftsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for drafts list
`catalogProductsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for catalog
`orgsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for org lists
`appsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apps
`subscriptionsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for subscriptions, if disabled, subscription lists will be removed from catalog list
`requestedApprovalsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for requested approvals
`approvalTasksOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for approvals
`productApisOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apis within products
`membersOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for member lists

Procedure

1. If you already deployed API Connect, retrieve the name of the deployed CR for the Management subsystem by running the following command:

   ```
   kubectl get managementcluster -n <management_namespace>
   ```

   If you did not deploy API Connect yet, skip this step.

2. Edit the `management` CR by running the following command:

   ```
   kubectl edit managementcluster <management-cr-name> -n <management_namespace>
   ```

3. In the editor, append the feature-flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the OmniSearch feature on all possible UI pages.

   ```
   spec:
     template:
       - name: ui
         containers:
         - name: ui
           env:
             - name: APIC_UI_FEATURES
               value: allOmniSearch=always
   ```

   `APIC_UI_FEATURES` is a URL-encoded string. Each parameter is formed as `featureId=$featureValue`, and you can list multiple parameters with the `&` delimiter (`featureId=$featureValue&featureId=$featureValue`).

   Use the `featureId` values from Table 1. For each feature, specify one of the following `featureValue` settings:

   - `true` - On by default, but can be overridden by the user, for their browser alone
   - `false` - Off by default, but can be overridden by the user, for their browser alone
   - `never` - Off regardless of browser setting, disabled in feature flag page
   - `always` - On regardless of browser setting, disabled in feature flag page

4. Save the update.
   The cluster is updated to enable or disable features as specified.

Enabling UI feature flags on OpenShift and Cloud Pak for Integration

Use a template override to update the installation CR with settings that control UI features.

About this task

You can add a template override to the Management subsystem CR and use it to control whether specific features are available in the UI. Some features can be optionally disabled by users (by disabling them in the browser) provided you have enabled the feature for the cluster as a whole. Table 1 describes the available feature flags.

Table 1. Flags and settings for controlling UI features

Feature ID	Default Value	Partial Override For	Description
`ffAdvancedPublish`	`true`		Enable advanced publish option (deprecated)
`allOmniSearch`	`true`		Enables OmniSearch for all lists. This flag is used in conjunction with other flags.
`draftsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for drafts list
`catalogProductsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for catalog
`orgsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for org lists
`appsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apps

Feature ID	Default Value	Partial Override For	Description
`subscriptionsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for subscriptions, if disabled, subscription lists will be removed from catalog list
`requestedApprovalsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for requested approvals
`approvalTasksOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for approvals
`productApisOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apis within products
`membersOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for member lists

Procedure

1. If you already deployed API Connect, retrieve the name of the deployed CR by running the following command:

   ```
   oc get apiconnectcluster -n <APIC_namespace>
   ```

   If you did not deploy API Connect yet, skip this step.

2. Edit the `apiconnectcluster` CR by running the following command:

   ```
   oc edit apiconnectcluster <APIC_instance_name> -n <APIC_namespace>
   ```

3. In the CR, append the feature-flag definition to the end of the `spec.management` section, making sure to adhere to the spacing used in the file.
   The following example enables the OmniSearch feature on all possible UI pages.

   ```
   spec:
     management:
       template:
         - name: ui
           containers:
           - name: ui
             env:
               - name: APIC_UI_FEATURES
                 value: allOmniSearch=always
   ```

   APIC_UI_FEATURES is a URL-encoded string. Each parameter is formed as **featureId=$featureValue**, and you can list multiple parameters with the **&** delimiter (**featureId=$featureValue&featureId=$featureValue**).

   Use the **featureId** values from Table 1. For each feature, specify one of the following **featureValue** settings:

   - **true** - On by default, but can be overridden by the user, for their browser alone
   - **false** - Off by default, but can be overridden by the user, for their browser alone
   - **never** - Off regardless of browser setting, disabled in feature flag page
   - **always** - On regardless of browser setting, disabled in feature flag page

4. Close and save the file with the following command:

   ```
   :wq
   ```

   The cluster is updated to enable or disable features as specified.

Advanced configuration for the management subsystem

Specify advanced configuration for the management subsystem.

See:

- **Configuring maximum size of client requests to the Management subsystem**
  You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.
- **Setting rate limits for public APIs on the management service for a Kubernetes environment**
  Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.
- **Enabling API governance on Kubernetes**
  You can optionally configure API governance in API Connect on a Kubernetes, OpenShift, or IBM® Cloud Pak for Integration deployment by enabling the governance microservice.
- **Configuring monetization on Kubernetes**
  You can optionally configure monetization in API Connect on a Kubernetes deployment by enabling the billing microservice.
- **Overriding resources for Postgres components on Kubernetes**
  You can optionally override the CPU and Memory resources used by postgres database components.
- **Overriding resources for Postgres components on OpenShift**
  You can optionally override the CPU and Memory resources used by postgres database components.

Configuring maximum size of client requests to the Management subsystem

You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.

About this task

The default maximum size is 8 megabytes. You can increase this value.

Increasing the setting can be useful if you get errors when using the CLI to import a large API. Example error:

```
HTTP/1.1 413 Request Entity Too Large
```

Procedure

1. Edit the Management CR. Refer to the Management CR templates:

   ```
   spec:
     ...
     ...
     template:
     - name: juhu
       containers:
       - name: juhu
         env:
         - name: CLIENT_MAX_BODY_SIZE
           value: "12m"
   ```

   Note that the default value is `"8m"`. The `template:` entry must be indented two spaces, and be located within the `spec:` element.

2. Apply the changes:

   ```
   kubectl -n <namespace> apply -f management_cr.yaml
   ```

Setting rate limits for public APIs on the management service for a Kubernetes environment

Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.

Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software may change and this information may become outdated.
These instructions assume you have a working Kubernetes environment with the kubectl command-line tool installed, and that you understand how to manage Kubernetes. For more information, see https://kubernetes.io.

About this task

Rate limits can be set for public APIs on the management service. Rate limits on APIs help provide protection from DDoS (distributed denial of service) attacks. Without a rate limit, API calls from public APIs are unlimited.

The rate limit configuration requires that the header contains the actual client IP address. Any load balancer or proxy (for example, HAProxy) that is installed in front of the management service must be configured to pass the actual client IP address.

This procedure must be performed on a running API Connect deployment.

Rate limits are calculated as requests per seconds per client.

Note: If the rate limit has been reached on the management subsystem, the client will get an HTTP error: `429 Too Many Requests`.

Procedure

- Configure the ingress-nginx-ingress-controller to pass the real client IP address:
  1. Set the `use-proxy-protocol` parameter to `true` by entering the following command:

     ```
     kubectl edit ConfigMap -n kube-system ingress-nginx-ingress-controller
     ```

  2. In the ConfigMap, set the following: `use-proxy-protocol: "true"`
- Set a rate limit:
  1. You can add a `template:` value in your subsystem CR to provide an override.
     For example, the Management CR template value can be:

     ```
     spec:
       ...
       template:
       - name: juhu
         containers:
         - name: juhu
           env:
           - name: RATE_LIMIT_PER_CLIENT
             value: "10"
           - name: LIMIT_REQUEST_OPTION
             value: "burst=10 nodelay"
     ```

     Note that the `template:` entry must be indented two spaces, and must be located in the `spec:` element.

In this example, the first option sets the rate to 10 requests per second (10r/s). The second option allows 10 requests boosted without delay within < 1 second. You can customize as needed.

The **rateLimitPerClient** property sets **rate**, and **limitRequestOption** sets **[burst=number] [nodelay | delay=number]** in the following nginx configuration:

```
limit_req_zone key zone=name:size rate=rate;
limit_req zone=name [burst=number] [nodelay | delay=number];
```

Note that **zone** has been pre-defined and can't be configured. For more details, see the nginx doc http://nginx.org/en/docs/http/ngx_http_limit_req_module.html.

2. Apply the changes:

```
kubectl -n <namespace> apply -f management_cr.yaml
```

3. Validate that the juhu pod has restarted by listing the pods:

```
kubectl get pods -n <namespace> | grep juhu
```

4. Check the AGE column to ensure a new juhu pod has started.
5. If the older juhu pod is still running, delete it with the following command:

```
kubectl delete pods -n <namespace> <old-juhu-pod>
```

- Disable a rate limit:
  1. Validate that the juhu pod has restarted by listing the pods:

```
kubectl get pods -n <namespace> | grep juhu
```

  2. Check the AGE column to ensure a new juhu pod has started.
  3. If the older juhu pod is still running, delete it with the following command:

```
kubectl delete pods -n <namespace> <old-juhu-pod>
```

Enabling API governance on Kubernetes

You can optionally configure API governance in API Connect on a Kubernetes, OpenShift, or IBM® Cloud Pak for Integration deployment by enabling the governance microservice.

About this task

API governance is an optional add-on to IBM API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process.

Note:

- These instructions apply only to Kubernetes, OpenShift, and IBM Cloud Pak for Integration installations. For VMware installations, see Enabling API governance on VMware.
- API governance rulesets cannot be added to your deployment until the governance microservice is enabled.

To enable or disable the governance microservice, you must configure the Management subsystem custom resource (CR) file. See the following instructions:

- **Enabling the governance microservice as part of a new deployment**
- **Enabling the governance microservice as part of an existing deployment**
- **Disabling the governance microservice**

After the governance microservice is enabled, API governance resources can be created. For more information, see Configuring API governance in the Cloud Manager, and Configuring API governance in the API Manager.

Procedure

- **Enabling the governance microservice as part of a new deployment**
  Edit the CR file for the Management subsystem and add the settings for the governance microservice.

  1. Edit the **ManagementCluster** CR and add the following definition for the governance microservice. Append the governance definition to the end of the **spec:** section, making sure to adhere to the spacing used in the file.

```
spec:
  ...
  governance:
    enabled: true
```

  2. Apply the updated CR by running the following command as part of the standard Management subsystem installation (see Installing the Management subsystem cluster for details):

```
kubectl apply -f management_cr.yaml -n <management_namespace>
```

  Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  The governance microservice will be enabled with the Management subsystem.

  3. You can monitor your Kubernetes deployments by running the following command:

```
kubectl get deployments -n <management_namespace>
```

The installation is complete when the `management-compliance` pods are shown in the list of returned values.

- **Enabling the governance microservice as part of an existing deployment**
  Edit the deployed CR for the Management subsystem and add the settings for the governance microservice.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, append the governance definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       governance:
         enabled: true
     ```

  4. Save the update.
     The governance microservice is enabled in the Management subsystem.

  5. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `management-compliance` pods are shown in the list of returned values.

- **Disabling the governance microservice**
  Edit the deployed CR for the Management subsystem and update the settings for the governance microservice.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, change the governance definition to `enabled: false`.

     ```
     spec:
       ...
       governance:
         enabled: false
     ```

  4. Save the update.
     The governance microservice is disabled in the Management subsystem.

Results

Note that when the governance microservice is enabled, there are a number of new deployments, jobs, and pods in the `ManagementCluster` namespace. These Kubernetes governance resources have names containing either `compliance-service` or `compliance-ui`. For example:

```
kubectl get pods -n apic | grep compliance
management-compliance-service-f6cdf95fc-t4qkx                     1/1     Running     0          127m
management-compliance-ui-59897fcc4-zm25v                          1/1     Running     0          126m
management-up-compliance-service-data-populate-0-to-1-t2f4d       0/1     Completed   1          132m
management-up-compliance-service-schema-0-to-1-21kqq              0/1     Completed   0
```

Configuring monetization on Kubernetes

You can optionally configure monetization in API Connect on a Kubernetes deployment by enabling the billing microservice.

About this task

API Connect includes a subscription billing microservice that allows API providers to define pricing plans in their API Products, and monetize their API offerings. If a Product contains a pricing plan, API Consumers must enter their payment information into the Developer Portal before they can subscribe to that plan. API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

Note:

- These instructions apply only to Kubernetes installations. For VMware installations, see Configuring monetization on VMware.

- To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements on Kubernetes and Firewall requirements on VMware for more information about this requirement.
- Provider organizations cannot add any billing integrations until the billing microservice is enabled.
- After provider organizations have added billing integrations, the billing microservice must not be disabled.

To enable or disable the billing microservice, you must configure the Management subsystem custom resource (CR) file. See the following instructions:

- **Enabling the billing microservice as part of a new deployment**
- **Enabling the billing microservice as part of an existing deployment**
- **Disabling the billing microservice**

Procedure

- **Enabling the billing microservice as part of a new deployment**
  Edit the CR file for the Management subsystem and add the settings for the billing microservice.

  1. Edit the `ManagementCluster` CR and add the following definition for the billing microservice. Append the billing definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       billing:
         enabled: true
     ```

  2. Apply the updated CR by running the following command as part of the standard Management subsystem installation (see Installing the Management subsystem cluster for details):

     ```
     kubectl apply -f management_cr.yaml -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
     The billing microservice will be enabled with the Management subsystem.

  3. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `management-billing` pod is shown in the list of returned values.

  After the billing microservice is enabled, provider organization owners can create billing integration resources for API providers in the API Manager UI. For more information, see Monetizing your Products.

- **Enabling the billing microservice as part of an existing deployment**
  Edit the deployed CR for the Management subsystem and add the settings for the billing microservice.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, append the billing definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       billing:
         enabled: true
     ```

  4. Save the update.
     The billing microservice is enabled in the Management subsystem.

  5. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `management-billing` pod is shown in the list of returned values.

  After the billing microservice is enabled, provider organization owners can create billing integration resources for API providers in the API Manager UI. For more information, see Monetizing your Products.

- **Disabling the billing microservice**
  Important: After provider organizations have added billing integrations, the billing microservice must not be disabled.
  Edit the deployed CR for the Management subsystem and update the settings for the billing microservice.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:

- *management-cr-name* is the name of the deployed CR for the Management subsystem.
- *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.

3. In the editor, change the billing definition to `enabled: false`.

```
spec:
  ...
  billing:
    enabled: false
```

4. Save the update.
   The billing microservice is disabled in the Management subsystem.

Overriding resources for Postgres components on Kubernetes

You can optionally override the CPU and Memory resources used by postgres database components.

About this task

There are three postgres components:

- `postgres`
- `pgBouncer`
- `pgBackRest`

The CPU, memory, and PVC resources used by the `postgres`, `pgBouncer`, and `pgBackRest` components depend on the deployment profile that was selected on installation. The resources that are defined for each deployment profile are shown here: Management component deployment profile limits.
Important: The postgres pod is licensed based on CPU use, so adjusting this pod's CPU limit has licensing implications, see: Component profiles, CPU limits, memory limits, and licensing

Procedure

To override resources, complete the following procedure

1. Prepare a patch yaml.
   - Ensure that you specify the name of the container for the resource you want to override. Names:
     - `postgres`
     - `pgBouncer`
     - `pgBackRest`
   - You can override multiple postgres components in parallel. Adding one container section under `pgcluster` template.
   - You can override just a single value, such as CPU limit.

   Examples:
   - Example yaml, to replace all postgres DB resources:

```
spec:
  template:
  - name: pgcluster
    containers:
    - name: postgres
      resources:
        requests:
          cpu: 1500m
          memory: 8Gi
        limits:
          cpu: 600m
          memory: 512Mi
```

   - Example yaml, to replace all pgBouncer resources:

```
spec:
  template:
  - name: pgcluster
    containers:
    - name: pgBouncer
      resources:
        requests:
          cpu: 200m
          memory: 128Mi
        limits:
          cpu: 300m
          memory: 256Mi
```

   - Example yaml,to replace CPU limit of `postgres` database:

```
spec:
  template:
  - name: pgcluster
```

```
    containers:
    - name: postgres
      resources:
        limits:
          cpu: 1000m
```

- Example yaml, to replace CPU limits of `postgres` DB and `pgBouncer`:

```
spec:
  template:
  - name: pgcluster
    containers:
    - name: postgres
      resources:
        limits:
          cpu: 1000m
    - name: pgBouncer
      resources:
        limits:
          cpu: 1000m
```

2. Apply the patch yaml:

```
kubectl patch mgmt <mgmt-cr-name> --type merge --patch "$(cat patch.yaml)"
```

Results

The postgres components will restart with updated values.

Overriding resources for Postgres components on OpenShift

You can optionally override the CPU and Memory resources used by postgres database components.

About this task

There are three postgres components:

- `postgres`
- `pgBouncer`
- `pgBackRest`

The CPU, memory, and PVC resources used by the `postgres`, `pgBouncer`, and `pgBackRest` components depend on the deployment profile that was selected on installation. The resources that are defined for each deployment profile are shown here: Management component deployment profile limits.
Important: The postgres pod is licensed based on CPU use, so adjusting this pod's CPU limit has licensing implications, see: Component profiles, CPU limits, memory limits, and licensing

Procedure

To override resources, complete the following procedure

1. Prepare a patch yaml.
   - Ensure that you specify the name of the container for the resource you want to override. Names:
     - `postgres`
     - `pgBouncer`
     - `pgBackRest`
   - You can override multiple postgres components in parallel. Adding one container section under `mgmt-pgcluster` template.
   - You can override just a single value, such as CPU limit.

   Examples:
   - Example yaml, to replace all postgres DB resources:

```
spec:
  template:
  - name: mgmt-pgcluster
    containers:
    - name: postgres
      resources:
        requests:
          cpu: 1500m
          memory: 8Gi
        limits:
          cpu: 600m
          memory: 512Mi
```

   - Example yaml, to replace all `pgBouncer` resources:

```
spec:
  template:
  - name: mgmt-pgcluster
    containers:
    - name: pgBouncer
      resources:
        requests:
```

```
          cpu: 200m
          memory: 128Mi
        limits:
          cpu: 300m
          memory: 256Mi
```

- Example yaml,to replace CPU limit of `postgres` database:

```
spec:
  template:
  - name: mgmt-pgcluster
    containers:
    - name: postgres
      resources:
        limits:
          cpu: 1000m
```

- Example yaml, to replace CPU limits of `postgres` DB and `pgBouncer`:

```
spec:
  template:
  - name: mgmt-pgcluster
    containers:
    - name: postgres
      resources:
        limits:
          cpu: 1000m
    - name: pgBouncer
      resources:
        limits:
          cpu: 1000m
```

2. Apply the patch yaml:

```
oc patch apiconnectcluster <apiconnectcluster-cr-name> --type merge --patch "$(cat patch.yaml)"
```

Results

The postgres components will restart with updated values.

Advanced configuration for the analytics subsystem

Specify advanced configuration for the analytics subsystem on Kubernetes, OpenShift, or Cloud Pak for Integration.

To manage advanced analytics features, see: Advanced configuration for the analytics subsystem.

Advanced configuration for the gateway subsystem

Specify advanced configuration for the gateway subsystem.

See:

- **Customizing a DataPower deployment**
  Update the `GatewayCluster` CR to configure `DataPowerService` APIs to customize your DataPower deployment.
- **Overriding the default DataPower image, version, and license**
  Update the `GatewayCluster` CR to override the image, version, and license information for the Gateway subsystem.
- **Enabling autoscaling of gateway pods**
  Enable autoscaling of gateway pods to ensure high availability of DataPower pods.
- **Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment**
  In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

Customizing a DataPower deployment

Update the `GatewayCluster` CR to configure `DataPowerService` APIs to customize your DataPower deployment.

You can set the following properties in the CR. Note that each `GatewayCluster` CR property has a corresponding `DataPowerService` API. Refer to the DataPower Operator documentation link for each property:

Table 1. Mapping of `GatewayCluster` properties to `DataPowerService` properties

GatewayCluster property	DataPowerService property	DataPowerService API Docs
`AdditionalDomainConfig`	`domains`	domains For domain configuration, see also: • Guides: Domain Configuration • Features: Configuration Management

GatewayCluster property	DataPowerService property	DataPowerService API Docs
`AdditionalExtraExe`	`extraExe`	extraExe
`AdditionalInitCmds`	`initCmds`	initCmds
`lifecycle`	`lifecycle`	lifecycle
`healthcheck`	`healthcheck`	healthcheck
`readinessTimeoutSeconds`	`readinessTimeoutSeconds`	readinessTimeoutSeconds
`hostAliases`	`hostAliases`	hostAliases

Examples of how to add the DataPower service properties to a `GatewayCluster` CR, in an API Connect deployment on native Kubernetes:

- Adding `additionalDomainConfig`:

```
spec:
  additionalDomainConfig:
  - name: "default"
    certs:
    - certType: "usrcerts"
      secret: "default-cert"
    - certType: "sharedcerts"
      secret: "shared-cert"
    dpApp:
      config:
      - "default-config"
      local:
      - "default-local"
```

- Extending the `apiconnect` domain:

```
spec:
  additionalDomainConfig:
  - name: "apiconnect"
    dpApp:
      config:
      - "custom-apiconnect-config"
      local:
      - "custom-apiconnect-local"
```

Overriding the default DataPower image, version, and license

Update the `GatewayCluster` CR to override the image, version, and license information for the Gateway subsystem.

Procedure

To override these settings in the CR, add a `spec.dataPowerOverride` section as shown in the following example:

```
spec:
   dataPowerOverride:
     image: customregistry.com/custom-image-datapower:10.0.6.0
     version: 10.0.6.0
     license: X-XXXX-XXXXXX
```

Enabling autoscaling of gateway pods

Enable autoscaling of gateway pods to ensure high availability of DataPower pods.

Autoscaling enables the gateway deployment to scale dynamically, either vertically or horizontally.

It is not possible to use both horizontal and vertical pod scaling simultaneously. You must configure either **HPA** (for horizontal scaling) or **VPA** (for vertical scaling) as scaling method.

- To enable HPA, add the following fields to the CR:
  In OpenShift or Cloud Pak for Integration, add the fields to the `spec.gateway` section of the API Connect Cluster CR.

```
  podAutoScaling:
    hpa:
      maxReplicas: 5
      minReplicas: 3
      targetCPUUtilizationPercentage: 90
      targetMemoryUtilizationPercentage: 80
    method: HPA
```

- To enable VPA, add the following fields to the CR:
  In OpenShift or Cloud Pak for Integration, add the fields to the `spec.gateway` section of the API Connect Cluster CR.

```
  podAutoScaling:
    method: VPA
    vpa:
      maxAllowedCPU: 4
      maxAllowedMemory: 16G
```

Note that the values shown in the CR entries are just examples.

Table 1. Autoscaling configuration settings

Setting	Description
`method`	Specifies either Horizontal Pod Autoscaling or Vertical Pod Autoscaling Value must be either **HPA** or **VPA**. To disable autoscaling, leave **method** blank or omit the **podAutoScaling:** section from the CR.
`maxReplicas`	HPA. Maximum pods that can be scaled up to by the horizontal pod autoscaler. Must be a value greater than **minReplicas**.
`minReplicas`	HPA. Minimum pods that can be scaled down to by the horizontal pod autoscaler.
`targetCPUUtilizationPercentage:`	HPA. Percent threshold on average CPU usage by pods for triggering horizontal scaling.
`targetMemoryUtilizationPercentage`	HPA. Percent threshold on average memory usage by pods for triggering horizontal scaling.
`maxAllowedCPU`	VPA. Maximum value for CPU resource that can be assigned to a DataPower container when scaling vertically. Minimum value is set from **DataPowerRequestsSpec.ResourceCPU**
`maxAllowedMemory`	VPA. Maximum amount of memory that can be assigned to a DataPower container when scaling vertically. Minimum value is set from **DataPowerRequestsSpec.ResourceMemory**

Note:
DataPower Gateway supports long-lived connections such as such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when pods are scaled down based on defined CPU or memory thresholds. Workloads with long-lived connections are more vulnerable to failed API transactions when auto-scaling is occurring.

To learn more about HPA and VPA autoscaling, see

- https://ibm.github.io/datapower-operator-doc/features/pod-auto-scaling/
- https://ibm.github.io/datapower-operator-doc/apis/datapowerservice/v1beta3#podautoscaling

Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment

In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

If a Gateway service is not configured properly for resiliency and is restarted, the gateways in the Gateway service will lose the configuration from the Management server. Configuration data from the Management server is maintained on the gateway service according to the gateway peering configuration on the gateways.

Preventing the loss of configuration data

For high availability in production environments, use a minimum of three gateways in the Gateway service.

Forcing re-population of the configuration data

To repopulate the configuration data, complete the steps in the following section to trigger an outage-less DRR.

Triggering an outage-less DRR

To force a Dynamic Reregistration and Reconfiguration across a peer group from within the gateway service without requiring a restart, complete the following steps using the CLI. This process flushes the primary peering object configured for the apic-gw-service. This task can only be performed with CLI, and requires the default admin ID for running the **diag** command.

1. Access the gateway service:
   - For a virtual gateway, run the following command to access the DataPower CLI:

     ```
     kubectl attach -it <pod_name>
     ```

   - For a physical gateway, use **ssh** to connect to the gateway service.
2. Switch to the API Connect application:

   ```
   switch <APIC_APP_DOMAIN>
   ```

3. Show the current gateway-peering-status:

   ```
   show gateway-peering-status
   ```

4. If the server that you connected to is not primary for the apic-gw-service gateway-peering object, force this server to become primary:

   ```
   config; gateway-peering-switch-primary <gateway-peering-name-for-apic-gw-service>;
   ```

5. Flush the apic-gw-service gateway-peering object:

   ```
   diag; gateway-peering-flush <gateway-peering-name-for-apic-gw-service>; exit
   ```

   When prompted, confirm the operation.

6. Disable and then re-enable the apic-gw-service object for every member of the gateway service:

   ```
   config; apic-gw-service; admin-state disabled; exit
   apic-gw-service; admin-state enabled; exit; exit
   ```

7. Confirm that the apic-gw-service was flushed and is now waiting for gateway service registration:

Look in the debug log target for the apic-gw-service, located in logtemp:/// and check for a message similar to the following example:

```
20200618T232339.332Z [0x88e000d7][apic-gw-service][notice]
apic-gw-service(default): tid(2653): Waiting for gateway service registration.
```

The DRR will be triggered by the next arrival of a webhook event. The Management server sends a heartbeat to the gateway at five-minute intervals, prompting the gateway to check whether it has lost its configuration and if so, trigger a DRR. In addition, if the Management server has previously marked a Catalog or cloud as being unavailable for a particular gateway service, a successful heartbeat triggers synchronization for that Catalog or cloud on that gateway service.

8. If you attached to a virtual gateway, you can detach by pressing Ctrl+P and then pressing Ctrl+Q.
9. (Optional) Force a BAU webhook event to be sent from API Manager to trigger the DRR:
   If you do not want to wait for the Management server to send a heartbeat, you can trigger the DRR manually by completing the following steps:

   a. Open the API Manager.
   b. Open the Catalog.
   c. Click Settings > Edit.
   d. Update the Summary field with some text so that it is modified.
   e. Click Save.

When the event is received, the DRR is initiated.

Backing up and restoring

You can backup and restore API Connect subsystems.

API Connect Version 10 uses Kubernetes operators to back up and restore databases.

- Backups are for recovery of the API Connect subsystems in the same environment that the backups were taken. If you want to move your API Connect deployment to a different environment and change the form factor or modify your API Connect endpoints, then see Migrating from v10 to v10 on a different form factor.
- Manual backups
  For the management database, the backup configuration is specified in a Management CR (custom resource). You create the backup CR manually. Once the backup CR is created, the **apiconnect** operator performs backup and updates the status into the backup CR.
- Scheduled backups
  For scheduled backups, you can add a backup schedule to the backup configuration details in the management CR. The apiconnect operator will then trigger and perform backups as specified in the custom **cron** schedule. A backup CR is created for every individual backup invocation as described in the cron schedule. You can view each backup CR to determine the status of each backup.
- Restore
  For restore, you update the backup Management CR. You then create a restore CR with the backup name in it. You can list the backup CRs and determine the backup name by looking at individual backup CR. The **apiconnect** operator performs the restore.
- You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.
- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- When restoring, the Management, Analytics, and Developer Portal subsystems must be at the same version and fix pack level.

Note: For information about how to maintain a two data center deployment, see Maintaining a two data center deployment.

- **Backups on Kubernetes**
  Use the procedures in this section to backup and restore API Connect on generic Kubernetes distributions.
- **Backups on OpenShift**
  You can backup and restore API Connect subsystems on OpenShift and Cloud Pak for Integration.

Backups on Kubernetes

Use the procedures in this section to backup and restore API Connect on generic Kubernetes distributions.

- **Backing up and restoring the management subsystem**
  You can use the following instructions to back up and restore your Management subsystem on API Connect.
- **Backing up and restoring the Developer Portal in a Kubernetes environment**
  You can back up and restore your Developer Portal service in your Kubernetes environment.
- **Backing up and restoring the analytics database**
  The API Connect analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

Backing up and restoring the management subsystem

You can use the following instructions to back up and restore your Management subsystem on API Connect.

- To complete a backup and restore of your Management subsystem, you must have the **custom resource** configured with the **databaseBackup** subsection in the management subsystem custom resource.
- Backups can be scheduled or generated manually (on-demand). You can then list what backups are available and then use one to restore your Management subsystem if required:

  ```
  kubectl get mgmtb -n <namespace>
  ```

- Postgres replica pods depend on a successful completed backup. If backup configuration is not correct, replica pods won't come up.
- Custom resource (CR) templates are provided in the **helper_files** archive to install each API Connect subsystem. You decompressed these files into an installation folder of your choosing in Obtaining product files.
- For points to consider when backing up and restoring a two data center disaster recovery deployment on Kubernetes, see Backup and restore requirements for a two data center deployment.
- Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For information on the registration credentials, see Changing the registration client_id and client_secret for applications.

Note: You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

Types of backups supported

- Cloud-based S3 storage
  - IBM Cloud Object Storage
  - AWS S3
  - **v10.0.2.0 or greater:** Any custom S3, such as minIO.
- SFTP
- Local storage backups

- **Configuring backup settings for fresh install of the Management subsystem**
  You can configure backups for your Management subsystem in your Kubernetes environment.
- **Reconfiguring or adding backup settings after installation of the management subsystem**
  You can reconfigure the backup settings after installation of the management subsystem.
- **Generating a manual backup of the management subsystem**
  You can generate a manual (non-scheduled) backup of the management subsystem
- **Restoring the management subsystem**
  You can restore your Management subsystem in your Kubernetes environment.
- **Troubleshooting management subsystem backups**
  You can troubleshoot failures of the management subsystem backups.

Configuring backup settings for fresh install of the Management subsystem

You can configure backups for your Management subsystem in your Kubernetes environment.

Use the instructions for your backup type:

- **Configuring S3 backup settings for fresh install of the Management subsystem**
  You can configure backups for your management subsystem in your Kubernetes environment.
- **Configuring SFTP backup settings for fresh install of the Management subsystem**
  You can configure backups for your Management subsystem in your Kubernetes environment.
- **Configuring local backup settings for fresh install of the Management subsystem**
  You can configure backups for your Management subsystem in your Kubernetes environment.

Configuring S3 backup settings for fresh install of the Management subsystem

You can configure backups for your management subsystem in your Kubernetes environment.

Before you begin

Review Backing up and restoring the management subsystem.
If you have a two data center disaster recovery deployment, before you configure S3 backup settings you must first disable 2DCDR on both sites. Follow these steps:

1. Remove the **multiSiteHA** section from the **spec** section of the management CRs on both data centers. Take note of which data center is the active and which is the warm-standby. Keep a copy of the **multiSiteHA** sections that you remove.
2. Configure your S3 backup settings. You must specify different backup locations for each data center, see Backup and restore requirements for a two data center deployment.
3. Add the **multiSiteHA** sections back to the management CRs in both data centers, ensuring that your original active is set to be the active again.

About this task

If you haven't already, configure your management subsystem **custom resource** with the **databaseBackup** subsection.

Note: **S3Provider** supports **custom** S3 solutions in 10.0.2.0 and greater. The support includes new backup parameters **backupCerts** and **backups3URIStyle**.

Important: For S3 backups of the management subsystem, do not use retention features provided by Cloud-based S3 storage providers. Use of such features can result in periodic deletion of archived backups, which can cause backup corruptions that can cause database restores to fail.
Warning:
When configuring a new management subsystem for S3 backup, the content of the S3 bucket path must be empty. If you want to configure a management subsystem to use the content of an S3 bucket path already used by another management subsystem, you have two options:

1. Shutdown the postgres database on the existing management subsystem that points to the S3 bucket path before you start the new management subsystem.
2. In a disaster recovery scenario where you want to restore from the backup of an existing installation: Create a new S3 path and use S3 tools to copy the backup content from the existing management subsystem S3 bucket path, to the new bucket path.

Procedure

1. Create a backup secret.
   The backup secret is a Kubernetes secret that contains your username and password for your S3 backup database.

   For examples of how to generate the appropriate access key and secret for two of them, see:

   - IBM (Cloud Object Storage): Service credentials.
   - AWS: Managing access keys.
   - Custom: See documentation for your S3 provider. For example, minIO.

   The secret can be created with the following command:

```
$ kubectl create secret generic mgmt-backup-secret --from-literal=key='<YOUR ACCESS KEY>' \
  --from-literal=keysecret='<YOUR ACCESS KEY SECRET>' -n <namespace_of_management_subsystem>
```

2. Ensure that your Management subsystem `custom resource` is configured with the `databaseBackup` subsection.
   For example:

```
databaseBackup:
  protocol: objstore
  s3provider: ibm
  host: s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard
  path: apic-backup
  credentials: mgmt-backup-secret
  backupCerts: <custom-s3-server-CA-cert>
  backups3URIStyle: host(default)/path
  schedule: "0 3 * * *"
  repoRetentionFull: 2
```

   Note: backupCerts and backups3URIStyle are used for custom s3 only, on **v10.0.2.0 or greater**.

Table 1. Backup configuration settings

Setting	Description
`protocol`	The type of the backup. For s3 storage: `objstore`. When the parameter is not set, the backup type defaults to local storage backup.
`s3provider`	Name of the S3 provider to use. You must specify one of the supported values of `aws`, `ibm`, or `custom`. Support for `custom` is available in **v10.0.2.0 or greater**. Note: The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: `x509: certificate signed by unknown authority`.
`host`	For `objstore` type backup, specify S3 endpoint with the corresponding S3 region in the format `<S3endpoint>/<S3region>`
`path`	The path to the location of the backup: For `objstore` backups, the name of your S3 bucket to store backup data. For example, `bucket-name/folder`. The use of subdirectories in the bucket name is not supported. Note: When your deployment includes a management subsystem in two different clusters (with active databases), the two management subsystems cannot use the same s3 bucket name in the database backup configurations. Each management subsystem must use a unique s3 bucket name. Ensure that `bucket-name/folder` is empty. If the folder was previously used for backups, the folder will not be empty, and stanza create might encounter an error. **Explanation:** Once a folder is used, archive.info and backup.info files are created. During stanza creation, the process compares the database version and database system id between the two info files and the current Postgres database cluster. Stanza creation fails if there is a mismatch. To prevent this possibility, remove all files from the folder before configuring.
`credentials`	For `objstore` type backups, the name of the Kubernetes secret containing your S3 Access Key / Key Secret
`backupCerts`	**v10.0.2.0 or greater** Custom certificate. Used only when `s3Provider` is set to `custom`. Most of the custom S3 providers are created based on custom CA certificate. This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be `ca.crt` and value should be base64 encoded value of CA certificate. The API Connect management subsystem validates the custom S3 certificate against the customer-provided CA certificate. Sample bash script to create the Kubernetes secret: `cat >customs3ca.yaml <<EOF` `apiVersion: v1` `data:` `  ca.crt: $(base64 <path-to-ca-certificate> | tr -d '\n' )` `kind: Secret` `metadata:` `  name: custom-server-ca` `type: generic` `EOF` `kubectl apply -f customs3ca.yaml -n <namespace>`
`backups3URIStyle`	**v10.0.2.0 or greater** Valid values: `host` and `path`. Only allowed if `s3Provider` is set to `custom`. Some custom S3 providers require URI style to be set to `path`. For example, minIO supports both `host` and `path` style setup. You can create a minIO S3 server to only accept `path` style client communications. **Important**: Contact your custom S3 administrator before configuring this field. If not properly configured, upstream custom S3 can reject connections from the client, such as API Connect management subsystem.

Setting	Description
`schedule`	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * • - - - - - • | | | | | • | | | | +----- day of week (0 - 6) (Sunday=0) • | | | +------- month (1 - 12) • | | +--------- day of month (1 - 31) • | +----------- hour (0 - 23) • +------------- min (0 - 59) The timezone for backups is that of the node on which the postgres-operator pod is scheduled. There is no default backup schedule set. Be sure to set your backup schedule. All scheduled Management subsystem backups are of type `full` only.
`repoRetentionFull`	**v10.0.3.0 or later** - The number of full S3 backups to retain. When the next full backup successfully completes, and the specified number of retained backups is reached, the oldest full backup is deleted. All incremental backups and archives associated with the oldest full backup also expire. Incremental backups are not counted for this setting. Applies to both manual backups and scheduled backups. Minimum value: `1` Maximum value: `9999999` Default: none

3. Verify that the configuration deploys successfully.
   When you configure Management subsystem backups, the operator runs a `stanza-create` job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

   Check the status of the `stanza-create` job:

   ```
   kubectl get jobs -n <namespace> | grep stanza
   ```

   - On success:
     - The `stanza-create` job status is `1/1`:

       ```
       kubectl get jobs -n <namespace> | grep stanza
       m1-b722e361-postgres-stanza-create          1/1           5s         127m
       ```

     - The `stanza-create` job shows `status: "True"` and `type: Complete`:

       ```
       kubectl get job -n <namespace> m1-b722e361-postgres-stanza-create -o yaml

       status:
         completionTime: "2021-04-13T18:38:50Z"
         conditions:
           - lastProbeTime: "2021-04-13T18:38:50Z"
             lastTransitionTime: "2021-04-13T18:38:50Z"
             status: "True"
             type: Complete
        startTime: "2021-04-13T18:38:45Z"
        succeeded: 1
       ```

     - The `stanza-create` pod is in `Completed` state:

       ```
       kubectl get pods -n <namespace> | grep stanza
       m1-b722e361-postgres-stanza-create-q4fvp                      0/1     Completed   0          127m
       ```

     - Exec into the pod:

       ```
       kubectl -n <namespace> exec -it <backrest-shared-repo-pod> -- bash
       ```

     - The `pgbackrest` command returns the S3 contents in valid JSON:

       ```
       pgbackrest info --output json --repo1-type s3

       "backup":{"held":false}},"message":"ok"}][pgbackrest@m1-b722e361-postgres-backrest-shared-repo-69cdfdfdd5-rs882
       /
       ```

   - On failure, see Troubleshooting stanza-create job for S3 backup configuration.

Configuring SFTP backup settings for fresh install of the Management subsystem

You can configure backups for your Management subsystem in your Kubernetes environment.

Before you begin

Review Backing up and restoring the management subsystem.

About this task

If you haven't already, configure your Management subsystem `custom resource` with the `databaseBackup` subsection.

Procedure

1. Create a backup secret.
   The backup secret is a Kubernetes secret that contains your credentials for accessing the SFTP backup database. Supported credentials types:

   - Username and password (v10.0.2.0 or later).
   - Username and SSH-key (v10.0.3.0 or later). Only OpenSSH keys are supported.[1]

   Use one of the following commands to create the secret:

   - Username and password credentials

     ```
     $ kubectl create secret generic mgmt-backup-secret --from-literal=username='<YOUR USERNAME>'
     --from-literal=password='<YOUR PASSWORD>' -n <namespace-of-mgmt-subsystem>
     ```

   - **Version 10.0.3.0 or later**: Username and SSH-key credentials:

     ```
     $ kubectl create secret generic mgmt-backup-secret --from-literal=username='<YOUR USERNAME>'
      --from-file=ssh-privatekey='<YOUR PRIVATEKEY FILE>' -n <namespace-of-mgmt-subsystem>
     ```

   Note: If the username contains the backslash character, insert an extra backslash to escape it. For example, if the username is:

   ```
   backup\svc-apic
   ```

   set this as:

   ```
   -from-literal=username='backup\\svc-apic'
   ```

2. Ensure that your Management subsystem `custom resource` is configured with the `databaseBackup` subsection.
   For example:

   ```
   databaseBackup:
     protocol: sftp
     host: <SFTP-host-name>
     port: <SFTP-port>
     path: apic-backup
     retries: 0
     credentials: mgmt-backup-secret
     schedule: "0 3 * * *"
   ```

Table 1. Backup configuration settings

Setting	Description
`protocol`	The type of the backup. For SFTP storage: `sftp`.
`host`	The backups host. For `sftp` type, the SFTP server hostname
`port`	The SFTP server port. Optional. Default: `22`.
`path`	The path to the location of the backup. For `sftp` type, the full absolute path of the folder on the SFTP server, beginning with /.
`retries`	The number of times the `ibm-apiconnect` Operator attempts backups in the event of a failed SFTP backup. Default value: `0`.
`credentials`	Name of the Kubernetes secret containing your SFTP Username/password. For Version 10.0.3.0 or later, the Kubernetes secret can contain your SFTP Username and SSH key.
`schedule`	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * • - - - - - • | | | | | • | | | | +----- day of week (0 - 6) (Sunday=0) • | | | +------- month (1 - 12) • | | +--------- day of month (1 - 31) • | +----------- hour (0 - 23) • +------------- min (0 - 59) The timezone for backups is that of the node on which the postgres-operator pod is scheduled. There is no default backup schedule set. Be sure to set your backup schedule. All scheduled Management subsystem backups are of type `full` only.

[1] PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see https://www.puttygen.com/.

Configuring local backup settings for fresh install of the Management subsystem

You can configure backups for your Management subsystem in your Kubernetes environment.

Before you begin

Review Backing up and restoring the management subsystem.

About this task

If you haven't already, configure your Management subsystem `custom resource`.

Procedure

Configure your Management subsystem `custom resource` with the `databaseBackup` subsection.
Specify `schedule` and `repoRetentionFull`, the default settings are 01:00 UTC and 14 days.

```
databaseBackup:
  schedule: "0 1 * * *"
  repoRetentionFull: 14
```

Table 1. Backup configuration settings

Setting	Description
`schedule`	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * • - - - - - • | | | | | • | | | | +----- day of week (0 - 6) (Sunday=0) • | | | +------- month (1 - 12) • | | +--------- day of month (1 - 31) • | +----------- hour (0 - 23) • +------------- min (0 - 59) The timezone for backups is that of the node on which the postgres-operator pod is scheduled. The default is daily backups at 01:00 UTC. All scheduled Management subsystem backups are of type `full` only.
`repoRetentionFull`	- The number of full local backups to retain. When the next full backup successfully completes, and the specified number of retained backups is reached, the oldest full backup is deleted. All incremental backups and archives associated with the oldest full backup also expire. Incremental backups are not counted for this setting. Applies to both manual backups and scheduled backups. Minimum value: `1` Maximum value: `9999999` Default: 14

Reconfiguring or adding backup settings after installation of the management subsystem

You can reconfigure the backup settings after installation of the management subsystem.

Procedure

1. Make sure that the management cluster status is `Running` and the READY condition displays the same value before and after the "/".
   For example:

   ```
   k get mgmt
   NAME   READY   STATUS    VERSION      RECONCILED VERSION   AGE
   mgmt   16/16   Running   10.0.2.0   10.0.2.0-xxxx       19h
   ```

2. Create backup secret as described in Configuring backup settings for fresh install of the Management subsystem.
3. Complete the following steps, based on your storage type:
   - S3 storage
     You can change or add the `DatabaseBackup` s3 configuration via the Management Cluster CR after fresh install. However, doing so requires a reconfiguration of the database and a brief downtime. The operator restarts the database with the new backup configurations as soon as the new configuration in the management CR is saved.

     If you have a two data center disaster recovery deployment, before you configure S3 backup settings you must first disable 2DCDR on both sites. Follow these steps:
     - Remove the `multiSiteHA` section from the `spec` section of the management CRs on both data centers. Take note of which data center is the active and which is the warm-standby. Keep a copy of the `multiSiteHA` sections that you remove.
     - Configure your S3 backup settings. You must specify different backup locations for each data center, see Backup and restore requirements for a two data center deployment.
     - Add the `multiSiteHA` sections back to the management CRs in both data centers, ensuring that your original active is set to be the active again.

     Note:
     If you have an APIConnectCluster custom resource installed, do not modify the ManagementCluster CR. Instead, modify the APIConnectCluster CR.

     You can verify if you have an `apiconnectcluster` CR with the command

     ```
     $ kubectl get apiconnectcluster -n <your-namespace>
     ```

     Configuration of s3 backups uses a new parameter `restartDB` is required when changing the backup configuration. This parameter is in addition to the parameters described in Configuring backup settings for fresh install of the Management subsystem.

Example CR:

```
databaseBackup:
  protocol: objstore
  s3provider: ibm
  host: s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard
  path: apic-backup
  credentials: mgmt-backup-secret
  schedule: "0 3 * * *"
  restartDB:
    accept: true
```

Table 1. Additional parameter for S3 backup type reconfiguration

Parameter	Description
`restartDB:` `accept: <value>`	Required when changing the backup configuration. The parameter **accept** is a boolen: <**value**> can be **true** or **false**. When **accept** is **true**, and a new configuration for management CR is saved, the operator: • Stops the database and any dependent services • Applies the change • Restarts the stopped components. Note: **restartDB** is not required for initial deployments, only for modifications after the cluster is deployed.

- SFTP
  You can change/add the **DatabaseBackup** SFTP configuration via the Management Cluster CR after fresh install. This process does not involve any downtime. The same backup settings are used for reconfiguring as for initial configuration. For complete description of backup settings, see Configuring backup settings for fresh install of the Management subsystem.

  Example CR:

```
protocol: sftp
host: <SFTP-hostname>
port: <SFTP-port>
path: apic-backup
retries: 0
credentials: mgmt-backup-secret
schedule: "0 3 * * *"
```

Generating a manual backup of the management subsystem

You can generate a manual (non-scheduled) backup of the management subsystem

Procedure

1. Make sure that the management cluster status is Running and the READY condition displays the same value before and after the "/".
   For example:

```
kubectl get mgmt
NAME   READY   STATUS    VERSION      RECONCILED VERSION   AGE
mgmt   16/16   Running   10.0.2.0   10.0.2.0-xxxx       19h
```

   Note: Be sure **READY** status is **16/16**. If you have just configured or reconfigured the backup settings, there is a period of time when the postgres pods are taken offline and brought back up with the new configuration. During this time, the **kubectl get mgmt** command will show **11/11** instead of **16/16**. If you start a backup before the Management cluster is on **16/16**, the backup attempt might stall indefinitely.
2. Decide which of the two types of manual backups you want to do:
   - **full**: backs up the entire Management Subsystem database.
   - **incr**: backs up any data that has not been backed up since the last **full** or **incr** backup.
3. You generate a backup manually by creating a managementBackup custom resource which is detected by the ibm-apiconnect operator that then triggers the backup process.
   You can use **mgmtbackup_cr.yaml** in the **helper_files** directory as an example:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementBackup
metadata:
  generateName: management-
spec:
  type: full
  crType: create
  clusterName: management
```

   Table 1 lists the CR settings for a manual backup.

Table 1. CR settings for manual backup

Setting	Description
type	The type of backup to be done. Valid arguments are: • **full** Backs up the entire Management subsystem database • **incr** Backs up any data that has not been backed up since the last **full** or **incr** backup.
crType	Use **create** to trigger a backup process.
clusterName	The name of the target ManagementCluster you want to backup.

4. Create the ManagementBackup custom resource in the namespace of your Management Subsystem to trigger the backup process:

```
$ kubectl create -f mgmtbackup_cr.yaml -n <namespace-of-mgmt-subsystem>
```

5. (Optional): You can list current backups by using the command:

```
$ kubectl get managementbackup -n <namespace-of-mgmt-subsystem> --sort-by=.metadata.creationTimestamp
```

Here is an example of some possible output:

```
NAME                STATUS   ID                  CLUSTER   TYPE   CR TYPE   AGE
m1-e46bbac4         Ready    20201023-183005F    m1        full   record    66m
mgmt-backup-dnvxw   Ready    20201023-193137F    m1        full   create    9m37s
```

6. (Optional): You can get a detailed view of a specific backup by using the command:

```
$ kubectl get managementbackup <bup-name> -n <namespace-of-mgmt-subsystem> -o yaml
```

Here is an example of some possible output:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementBackup
metadata:
  creationTimestamp: "2020-10-23T18:34:11Z"
  generation: 1
  labels:
    app.kubernetes.io/instance: m1
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: m1-e46bbac4
  name: m1-e46bbac4
  namespace: default

Restoring the management subsystem

You can restore your Management subsystem in your Kubernetes environment.

Before you begin

You must have backups of the management subsystem in order to restore. See Configuring backup settings for fresh install of the Management subsystem and Generating a manual backup of the management subsystem.

About this task

To trigger a restore, you will create a **ManagementRestore** custom resource. When the **ibm-apiconnect** operator detects the new CR, it starts the restore process.

- Ensure that the backup method that you used is complete before you attempt a restore. The backup data that is stored in the remote server is used for restoring the Management subsystem data back to a previous state. Ensure that these backups are on your remote server before you attempt a restore, and that the backup ID in the selected backup exists in remote storage.
- Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For information on the registration credentials, see Changing the registration client_id and client_secret for applications.
- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.

Note: There is a known issue where sometimes a restore from the Management subsystem's SFTP backup succeeds but the data is not restored. If this happens, run the restore again.

Procedure

1. Obtain a list of the available backups, and decide which one to restore your Management subsystem:

   ```
   kubectl get mgmtb -n  <your-namespace>
   ```

   For example:

   ```
   $ kubectl get mgmtb
   NAME                  STATUS   ID                  CLUSTER      TYPE   CR TYPE   AGE
   management-3aa3bebf   Ready    20200929-152150F    management   full   record    10h
   management-3c4ca8df   Ready    20200929-115520F    management   full   record    20h
   management-5tbxj      Ready    20200929-224349F    management   full   create    17h
   management-f10af337   Ready    20200925-133703F    management   full   record    5d2h
   management-jtlcd      Ready    20200929-224349F    management   full   create    25h
   management-zxjtz      Ready    20200929-224349F    management   full   create    28h
   ```

   Attention: You can restore the Management subsystem from any backup where the STATUS is Ready; however, you should avoid restoring to the initial system backup. During installation, the Management database is used for an initial system backup before certain database schema jobs are complete. Restoring to this backup will result in an unstable system.
   You will use one of the values in the **NAME** column.

2. Configure `mgmtrestore_cr.yaml`. Use the copy in the `helper_files` directory as an example:

   ```
   apiVersion: management.apiconnect.ibm.com/v1beta1
   kind: ManagementRestore
   metadata:
     generateName: management-
   spec:
     backupName: management-3aa3bebf
   ```

   `backupName`: is the name of the backup custom resource you want to restore to. Note that the sample uses example output from the previous step, to specify the backup named `management-3aa3bebf`:

   ```
   backupName: management-3aa3bebf
   ```

3. Create the **ManagementRestore** CR in the namespace of the Management Subsystem to trigger the restore process:

   ```
   $ kubectl create -f mgmtrestore_cr.yaml -n <namespace-of-mgmt-susbystem>
   ```

4. You can list current restores using the following command:

   ```
   $ kubectl get managementrestore -n <namespace-of-mgmt-subsystem> --sort-by=.metadata.creationTimestamp
   ```

   Here is an example of some possible output:

   - SFTP:

     ```
     NAME                  STATUS      BACKUP               CLUSTER      MESSAGE
     PITR     AGE
     mgmt-restore-ptx6d    Complete    mgmt-backup-w4h8c    m1           Restore process completed (DB Restore + DRR job)
     6m31s
     ```

   - S3

     ```
     NAME                  STATUS      BACKUP               CLUSTER       MESSAGE
     PITR                     AGE
     mgmt-restore-hr9zx    Complete    mgmt-backup-xnjkl    m1            Restore process completed (DB Restore + DRR job)
     2020-11-23 23:08:32+00   9m8s
     ```

Troubleshooting management subsystem backups

You can troubleshoot failures of the management subsystem backups.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
See:

- **Troubleshooting resiliency issues**
  Resolve resiliency issues with API Connect management system backups.
- **Troubleshooting stanza-create job for S3 backup configuration**
  Troubleshoot configuration of s3 backups when the stanza-create job fails.

- **Restore failure with bootstrap pod error**
  Postgres bootstrap pod reports an error and restore does not progress.
- **Restore failure with compliance pod error on Kubernetes**
  Compliance pod reports an error, and restore does not progress.

Troubleshooting resiliency issues

Resolve resiliency issues with API Connect management system backups.

pgbackrest-shared-repo resiliency problems

If the Kubernetes node hosting pgbackrest-shared-repo pod is down and the PVC attached to the pod has strict zone requirements (for example, in AWS or other clouds) or if the storage class is set to **`local-storage`**, then pgbackrest-shared-repo pod will not get rescheduled to another Kubernetes node.

As a result, there is a single point of failure and the following conditions might occur:

- Backups of the management database fails
- Disk space fills with accumulated Postgres wal (Write-Ahead Logging) files

To avoid this problem, monitor the disk usage: Monitoring Postgres disk usage.

When the Kubernetes node comes back up, the pod is scheduled and all the processes should resume properly.

Troubleshooting stanza-create job for S3 backup configuration

Troubleshoot configuration of s3 backups when the stanza-create job fails.

When you configure Management subsystem backups for s3 providers, the operator runs a **`stanza-create`** job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

Check the status of the **`stanza-create`** job:

```
kubectl get jobs -n <namespace> | grep stanza
```

On failure:

- **`stanza-create`** pods fail, and job status is **`0/1`**:

  ```
  kubectl get jobs | grep stanza
   m1-3bfe12ac-postgres-stanza-create          0/1           32m        32m
  ```

- Listing all pods brought up by **`stanza-create`** job shows multiple pods because a job tries **`backoffLimit`** times to complete the job. By default, there will be **`7`** pods in error state:

  ```
  kubectl get pods | grep stanza
   m1-3bfe12ac-postgres-stanza-create-726z4                      0/1     Error       0          11m
   m1-3bfe12ac-postgres-stanza-create-9vq4n                      0/1     Error       0          22m
   m1-3bfe12ac-postgres-stanza-create-gbtgb                      0/1     Error       0          30m
   m1-3bfe12ac-postgres-stanza-create-gl5g5                      0/1     Error       0          17m
   m1-3bfe12ac-postgres-stanza-create-q8qhw                      0/1     Error       0          26m
   m1-3bfe12ac-postgres-stanza-create-t84zs                      0/1     Error       0          8m54s
   m1-3bfe12ac-postgres-stanza-create-z8tfs                      0/1     Error       0          12m
  ```

  Note: In some cases, the pods are cleaned by Kubernetes and the logs of these pods can be lost.

- Pod log errors show a reason for the failure. For example, when a hostname is not valid:

  ```
  kubectl logs m1-3bfe12ac-postgres-stanza-create-gbtgb

  time="2021-04-13T20:01:19Z" level=info msg="pgo-backrest starts"
  time="2021-04-13T20:01:19Z" level=info msg="debug flag set to false"
  time="2021-04-13T20:01:19Z" level=info msg="backrest stanza-create command
  requested"
  time="2021-04-13T20:01:19Z" level=info msg="s3 flag enabled for backrest command"
  time="2021-04-13T20:01:19Z" level=info msg="command to execute is [pgbackrest
  stanza-create  --db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --
  repo1-type=s3]"
  time="2021-04-13T20:01:19Z" level=info msg="command is pgbackrest stanza-create  --
  db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --repo1-type=s3 "
  time="2021-04-13T20:05:21Z" level=error msg="command terminated with exit code 49"
  time="2021-04-13T20:05:21Z" level=info msg="output=[]"
  ```

- Job status is set to **`type: Failed`** and **`status: "True"`**, with **`reason: BackoffLimitExceeded`**:

  ```
   kubectl get job m1-3bfe12ac-postgres-stanza-create -o yaml

  status:
    conditions:
      - lastProbeTime: "2021-04-13T20:28:03Z"
        lastTransitionTime: "2021-04-13T20:28:03Z"
        message: Job has reached the specified backoff limit
        reason: BackoffLimitExceeded
        status: "True"
  ```

```
      type: Failed
      failed: 7
startTime: "2021-04-13T20:01:18Z"
```

- If pod logs are lost, you can execute a command inside the `backrest-shared-repo` pod:
  1. Obtain the `backrest-shared-repo` pod name:

     ```
     kubectl get pods -n <namespace> | grep backrest-shared-repo
     ```

     For example:

     ```
     kubectl get pods | grep backrest-shared-repo
     m1-eb8edc18-postgres-backrest-shared-repo-98dd46cc6-tw195   1/1     Running
     ```

  2. Exec into the pod:

     ```
     kubectl exec -it <backrest-shared-repo-pod> -- bash
     ```

  3. Run:

     ```
     pgbackrest info --output json --repo1-type s3
     ```

     For example, for invalid hostname:

     ```
     ERROR: [049]: unable to get address for 'test1-v10-backup.s3.exampleaws.com': [-2] Name or service not knownCopy
     ```

     The exact `ERROR:` will vary depending on the misconfiguration. Common errors:

     Invalid access key
     Invalid access key secret
     Invalid bucket region
     Invalid bucket or folder path
- To fix the incorrect settings, see Reconfiguring or adding backup settings after installation of the management subsystem.

Restore failure with bootstrap pod error

Postgres bootstrap pod reports an error and restore does not progress.

Symptoms

The postgres bootstrap pod goes into an error state. Subsequent bootstrap pods come up showing `running`, but the restore does not progress. The logs of the postgres bootstrap pod show:

```
2022-08-01 15:03:58,337 INFO: Lock owner: None; I am management-09384302-postgres-bootstrap-v6xwz

    raise PatroniFatalException('Failed to bootstrap cluster')
patroni.exceptions.PatroniFatalException: 'Failed to bootstrap cluster'
```

Resolution

Delete the Kubernetes API Connect ManagementCluster oplock and restore job, then start the restore again:

```
kubectl delete cm <cr name>-oplock
kubectl delete mgmtr <restoreCR name>
```

Restore failure with compliance pod error on Kubernetes

Compliance pod reports an error, and restore does not progress.

This failure can happen in a situation where a backup is taken on a system where API governance has never been enabled, and the restore of that backup is done onto a system which has API governance enabled. In this situation the API governance database is missing, and consequently the compliance pods report an error.

Symptoms

The compliance service pods are continually restarting, and the restore does not progress. The log of the compliance pod shows the following error:

```
2023-05-19T03:34:31.771Z bhendi:error Database availability check to management-0bfd2507-postgres:5432 failed, try again in
2000 ms,
error: : database "compliance" does not exist, stack: error: database "compliance" does not exist
```

Resolution

Delete all of the compliance jobs, and then start the restore again. For example:

```
kubectl -n <namespace> delete job management-up-compliance-service-data-populate-0-to-1 management-up-compliance-service-
schema-0-to-1
```

Backing up and restoring the Developer Portal in a Kubernetes environment

You can back up and restore your Developer Portal service in your Kubernetes environment.

Before you begin

Important: If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.

About this task

To complete a backup and restore of your Developer Portal, you must have the **custom resource** configured with the **portalBackup** subsection. Backups can be scheduled or generated manually (on-demand). You can then list what backups are available and then use one to restore your Developer Portal if required. Ensure that your backup **path** has the correct permissions to allow your backup user to be able to read and write to it from within the Developer Portal. CR, **custom resource**, templates are provided in the **helper_files** archive to install each API Connect subsystem. You decompressed these files into an installation folder of your choosing in Deploying operators and cert-manager.

Note: For points to consider when you are backing up and restoring a two data center disaster recovery deployment on Kubernetes, see Backup and restore requirements for a two data center deployment.
The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

Tip: If you are using remote backups, and there are a large number of rows in your **portalbackup** list that have a **CR TYPE** of **record**, there might be a slow down in system performance, including during Developer Portal upgrades. Although there is no upper limit to how many portal backups you can have, it is recommended that you prune your remote backups so that the number of rows does not become excessively large. One **portalbackup** row of type **record**, corresponds to one backup file on the configured remote backup server. For more information, see Overview of the Developer Portal backup resources.

Procedure

- If you haven't already, configure your Developer Portal **custom resource** with the **portalBackup** subsection.
  1. Create your Developer Portal backup secret.
     The backup secret is a Kubernetes secret that contains your credentials for accessing the s3 or SFTP backup database.
     - s3
       Only password-based authentication is supported for s3, not authentication based on public certificates and private keys. Password-based authentication for s3 requires that you generate an access key and secret. For example:
       - IBM (Cloud Object Storage): Service credentials.
       - AWS: Managing access keys.

       The secret can be created with the following command:

       ```
       kubectl create secret generic portal-backup-secret --from-literal=username='<YOUR ACCESS KEY OR USER NAME>'
           --from-literal=password='<YOUR ACCESS KEY SECRET OR PASSWORD>' -n <namespace-of-portal-subsystem>
       ```

     - SFTP
       Supported credentials types:
       - Username and password (v10.0.2.0 or later).
       - Username and SSH-key (v10.0.3.0 or later). Only OpenSSH keys are supported.[1]

       Use one of the following commands to create the secret:
       - Username and password credentials

```
$ kubectl create secret generic portal-backup-secret --from-literal=username='<YOUR USERNAME>'
--from-literal=password='<YOUR PASSWORD>' -n <namespace-of-portal-subsystem>
```

- Version 10.0.3.0 or later: Username and SSH-key credentials:

```
$ kubectl create secret generic portal-backup-secret --from-literal=username='<YOUR USERNAME>'
 --from-file=ssh-privatekey='<YOUR PRIVATEKEY FILE>' -n <namespace-of-portal-subsystem>
```

2. Ensure that your Developer Portal **custom resource** is configured with the **portalBackup** subsection.
   - All of your settings must be added in the **spec:** section of the file.
   - To schedule automated backups, specify values for the **schedule** setting.

An example when you use **protocol: objstore**.

```
spec:
  portalBackup:
    credentials: portal-backup-secret
    host: s3.eu-gb.cloud-object-storage.appdomain.cloud/
    path: test-bucket/restore-test
    port: 443
    protocol: objstore
    backupCerts: <custom-s3-server-CA-cert>
    backups3URIStyle: <host-or-path>
    schedule: '0 2 * * *'
```

An example when you use **protocol: sftp**.

```
spec:
  portalBackup:
    credentials:  portal-backup-secret
    host:         sftp-service.example.com
    path:         /home/fvtuser/site-backups
    port:         22
    protocol:     sftp
    schedule:     '0 2 * * *'
```

Notes about **portalBackup:** entry:

- If **portalBackup:** entry is not present or contain nothing, just **local** backups will be taken if a backup CR is created. If the **schedule** exists, backups are taken at the scheduled time.
- For S3 and SFTP, **portalBackup:** entry must contain host, credentials, protocol, and path.
- For s3, the **portalBackup:** section can optionally also contain either, or both, of **backupCerts** and **backupS3URIStyle**.

Table 1. Developer Portal backup settings

Setting	Description
credentials	The name of the secret you created. Supported credential types: • s3 Only password-based authentication is supported for s3, not authentication based on public certificates and private keys. Password-based authentication for s3 requires that you generate an access key and secret. • SFTP • Username and password (v10.0.2.0 or later) • Username and SSH-key (v10.0.3.0 or later) To create a secret, see step 1.
host	• s3 - **host**: is the S3 endpoint with the corresponding S3 region in the format **<S3endpoint>**, or with an optional S3 region in the format **<S3endpoint>/<S3region>**. • sftp - the hostname of the sftp server
path	• S3 - the name of your S3 bucket to store backup data, optionally followed by a **/** and then any subdirectories inside the bucket. Valid examples: **bucket** **bucket/path** **bucket/lots/of/paths** • sftp - the full absolute path of the folder on the SFTP server, beginning with **/**.
port	The port for the protocol to connect to the host. • S3 - Defaults to 443 if not specified. • SFTP - Defaults to 22 if not specified. • local - Ignored for local.
protocol	The protocol that is used to communicate with your remote backup endpoint. Specify one of the following values: • **sftp** - for secure file transfer protocol. • **objstore** - for S3 compatible object storage.

Setting	Description
`backupCerts`	(S3 storage only) `backupCerts` is the name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.2. Note: If you use a public certificate for the S3 storage provider, it must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: `x509:` `certificate signed by unknown authority` This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be `ca.crt` and the value is the base64-encoded value of the CA certificate. If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Portal subsystem already trusts the server certificate. You can test this by configuring the Portal backup to your S3/object-store server without providing the CA certificate. If you do need to provide the CA certificate then you must provide the entire chain in the `ca.crt` member of the secret, as follows: `intermediate-certificate-1` `intermediate-certificate-2` `. . .` `intermediate-certificate-n` `root-certificate` Where the first certificate in the `ca.crt` member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the `ca.crt` member is the issuer of the preceding certificate. The root certificate in the `ca.crt` member must be self-signed. If there are no intermediate certificates involved, then the `ca.crt` member contains only the root certificate. The following sample bash script creates the Kubernetes secret: `cat >customs3ca.yaml <<EOF` `apiVersion: v1` `data:` `ca.crt: $(base64 <path-to-ca-certificate> | tr -d '\n' )` `kind: Secret` `metadata:` `name: custom-server-ca` `type: generic` `EOF` `kubectl apply -f customs3ca.yaml -n <namespace>`
`backups3URIStyle`	(S3 storage only) Optional - `backups3URIStyle` indicates whether URIs to your S3 backup should use specify a host or a path value. When not specified, default to `host`. Supported beginning with 10.0.2. Valid values: `host` and `path`. Some custom S3 providers require URI style to be set to `path`. For example, MinIO supports both `host` and `path` style setup. You can create a MinIO S3 server to only accept `path` style client communications. **Important**: Contact your custom S3 administrator before configuring this field. If not properly configured, an upstream custom S3 can reject connections from the client, such as the API Connect Management subsystem.
`schedule`	The schedule for how often automatic Developer Portal backups are run. The format for the schedule is any valid cron string. The timezone for backups is UTC. Valid for all backup types: s3, sftp, and local. `spec:` `portalBackup:` `...` `schedule: '0 2 * * *'`
`backupRecordDays`	The `backupRecordDays` setting denotes the number of days that backup records (backups that exist on the remote backup server) are shown when you list your remote backups. It is defaulted to 30 days.

- Reconfiguring Developer Portal backups
  You can edit the deployed Developer Portal `custom resource` You might want to do an edit if you did not include a `portalBackup` section before the installation. Or, if you made a mistake in your `portalBackup`, or if you'd like to change the `portalBackup` config. To edit your `portalcluster` CR:
  1. Get the name of your `portalcluster` CR:

     `kubectl get portalcluster -n <namespace-of-portal-subsystem>`

  2. Edit your `portalcluster` CR:

     `kubectl edit portalcluster <name-of-portal-cr> -n <namespace-of-portal-subsystem>`

  3. Inside the `spec`, add the `portalBackup` section as explained in step 2.
  4. Write and quit **wq**.
- How to generate a manual backup.
  You can use these steps to configure a Developer Portal with backups that use IBM's Cloud Object Storage S3, AWS S3, or SFTP.

  Decide which of the three types of manual backups you want to do:
  - `all`: backs up the Developer Portal system and all its sites to the remote server
  - `system`: backs up the Developer Portal system to the remote server
  - `site`: backs up a Developer Portal site to the remote server

  1. You generate a backup manually by creating a `portalBackup` `custom resource` that is detected by the `ibm-apiconnect` operator that then triggers the backup process.
     You can use portalbackup_cr.yaml in the helper_files directory as an example:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalBackup
metadata:
  generateName: portal-bup-
spec:
  type: all
  portalCluster: portal
  crType: create
  comment: "test comment"
```

- `type`: is the type of backup to be done. Valid arguments are:
  - `all`
  - `system`
  - `site`
- `portalCluster`: The name of the portal cluster you want to backup. You can find this with:

  `kubectl get portalcluster -n <namespace>`

- `crType`: Use `create` to trigger a backup process. When the backup is created, the operator generates another backup CR with `crType: record`, which represents the stored backup that you can use for a restore operation.
- `comment`: you can optionally add a comment to the CR before you create a backup.
- `siteName`: used only when you take a site backup. Valid arguments are:
  - site uuid or url - back up that site only to the remote server
  - `installed` - backups all installed sites to the remote server

2. Create the `PortalBackup custom resource` in the `namespace` of your Developer Portal to trigger the backup process:

   `kubectl create -f portalbackup_cr.yaml -n <ns-of-portal-subsystem>`

3. Optional: You can list current backups by using the command:

   `kubectl get portalbackup -n <ns-of-portal-subsystem>`

   Here is an example of some possible output:

```
NAME               ID             STATUS     TYPE     CR TYPE   AGE     COMMENT
p1-bup-gqz8f    20200526.142449  Ready      system   record    55m
p1-bup-jx4vc    20200526.142458  Ready      site     record    54m
p1-bup-st4l2                     Ready      all      create    56m     y
p1-bup-th2dm                     Ready      all      create    4h51m   y
```

   Tip: If you want to order your `portalbackups` by ID, you can use the Kubernetes keyword `--sort-by`. For example:

   `kubectl get pb -n <ns> --sort-by=.status.backupId`

4. Optional: You can get a detailed view of a specific backup by using the command:

   `kubectl get portalbackup <bup-name> -n <ns-of-portal-subsystem> -o yaml`

   Here is an example of some possible output:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalBackup
metadata:
  creationTimestamp: "2020-10-01T10:00:16Z"
  generateName: portal-bup-
  generation: 1
  name: portal-bup-g66gv
  namespace: default
  resourceVersion: "8940"
  selfLink: /apis/portal.apiconnect.ibm.com/v1beta1/namespaces/default/portalbackups/portal-bup-g66gv

```

- How to list available Developer Portal backups on remote server.
  Use command:

  ```
  kubectl get portalbackups -n <ns-of-portal-subsystem>
  ```

  Here is an example of some possible output:

  ```
  kubectl get portalbackup -n <ns-of-portal-subsystem>
    NAME               ID             STATUS     TYPE     CR TYPE   AGE     COMMENT
    p1-bup-gqz8f    20200526.142449  Ready      system   record    55m
    p1-bup-jx4vc    20200526.142458  Ready      site     record    54m
    p1-bup-st4l2                     Ready      all      create    56m     y
    p1-bup-th2dm                     Ready      all      create    4h51m   y
  ```

  Note: You can only restore the Portal subsystem from backups where the `CR TYPE` is `record`.
  Optionally, if you need more information, such as the name of the .tgz file that you can run, use command:

  ```
  kubectl get portalbackups <bup-name> -n <ns-of-portal-subsystem> -o yaml
  ```

  Here is an example of some possible output:

  ```
  apiVersion: portal.apiconnect.ibm.com/v1beta1

- How to restore a Developer Portal subsystem.
  Ensure that the backup method that you used is complete before you attempt a restore. The backup data that is stored in the remote server is used for restoring the Developer Portal subsystem data back to a previous state. Ensure that these backups are on your remote server before you attempt a restore.

  There are three types of restores:
  - `all`: restores the Developer Portal system and all the sites that are found on the remote server by using the latest backup.
  - `system`: restores the Developer Portal system to the remote server
  - `site`: restores the Developer Portal site from the remote server

  1. Decide on the options to use for your `PortalRestore custom resource`. The `PortalRestore custom resource` is detected by the `ibm-apiconnect`operator that then triggers the backup process.
     You can use portalrestore_cr.yaml in the helper_files directory as an example:

     ```
     apiVersion: portal.apiconnect.ibm.com/v1beta1
     kind: PortalRestore
     metadata:
       generateName: portal-restore-
     spec:
     ```

```
  type: all
  portalCluster: portal
  dryRun: true
  timestamp: now
  priorityList:
    - myportal-critical-site.com
    - myportal-important.com
```

- **type**: is the type of restore to be done. Valid arguments are:
  - **all**
  - **system**
  - **site**
- **portalCluster** is the name of the portal cluster you want to restore. You can find this with:

  ```
  kubectl get portalcluster -n <namespace>
  ```

- **siteName**: used only when you took a site backup. Valid arguments are:
  - *ID*, for example `20200526.142458`: the backup ID of a portal backup CR. The ID must be taken from a portal backup that is of **type** **site**, and **crType** **record**.
  - site-1234.tgz: restore the site by using this file name that exists on the local file system or remote server.
  - myportal.com: find the latest backup for this URL (locally or remotely) and restore it.
  - **all**: restore all sites that are found on the remote server by using the latest backup.
  - **site** uuid or url - back up that site only to the remote server
  - **installed** - backups all installed sites to the remote server.
- **systemName** - Valid arguments are:
  - *ID*, for example `20200526.142449`: the backup ID of a portal backup CR. The ID must be taken from a portal backup that is of **type** **system**, and **crType** **record**.
  - system_backup-1234.tgz: restores the system from the given file that exists on the pod's local file system or the remote server.
  - **latest**: restores from latest system backup that is found from either local file system or remote server.
- **timestamp** - Valid arguments are:
  - **now**: use the latest backups available.
  - < TIMESTAMP >: in ***'YYYYMMDD.HHMMSS'*** format, specify a timestamp to retrieve the backup from. The nearest backup, searching backwards from this timestamp, is used.

  Note: From IBM® API Connect Version 10.0.3.0, the timestamp format changed to ***YYYYMMDD.HHMMSS***. For Version 10.0.2.0 and earlier, the timestamp format is ***YYYY-MM-DD HH:MM:SS***.
- **dryRun** - Valid arguments are:
  - **true**: runs a dry run of the command, returning the actions that will be taken. These actions can be found in the custom resource by following step 4.
  - **false**: runs the command, restoring and replacing the system files and all sites. Any existing sites are reinstalled.
- **priorityList** - Prioritizes the restore of any sites. The sites are listed in the order in which they are provided. They are queued for restore first, followed by any remaining sites present in the backup location. Valid arguments are:
  - **myportalsite.com**
  - **mysecondportalsite.com**
- **customPlatformApiHostname** - If the **API** hostname of your management subsystem platform has changed since taking the backup you are restoring, then update it to the new platform API hostname of the management subsystem. (Optional)

Table 2. The options that are needed for each Developer Portal restore

	all	system	site
type	X	X	X
portalCluster	X	X	X
siteName			X
systemName		X	
timestamp	X		
dryRun	X		
priorityList	X		

2. Create the **PortalRestore** **custom resource** in the **namespace** of the Developer Portal subsystem to trigger the restore process:

   ```
   kubectl create -f portalrestore_cr.yaml -n <ns-of-portal-susbystem>
   ```

3. Optional: You can list current restores by using the command:

   ```
   kubectl get portalrestore -n <ns-of-portal-susbystem>
   ```

   Here is an example of some possible output:

   ```
   NAME                   READY     AGE
   portal-restore-twjrp   Ready     28s
   ```

4. Optional: You can get a detailed view of a specific restore by using the command:

   ```
   kubectl get portalrestore <restore-name> -n <ns-of-portal-susbystem> -o yaml
   ```

   Here is an example of some possible output:

   ```
   apiVersion: portal.apiconnect.ibm.com/v1beta1
   kind: PortalRestore
   metadata:
     creationTimestamp: "2020-11-11T10:14:39Z"
     generateName: portal-restore-
     generation: 1
     name: portal-restore-8f4c5
     namespace: portal

- Troubleshooting
  1. Check the Developer Portal backup CR or restore CR.
     Use command:

     ```
     kubectl get <portalbackup/portalrestore> <bup-name/restore-name> -n <namespace> -o yaml
     ```

     Here is an example of some possible output:

     ```
     apiVersion: portal.apiconnect.ibm.com/v1beta1
     kind: PortalRestore
     metadata:
       creationTimestamp: "2020-05-26T13:10:46Z"
       generateName: portal-restore-
       generation: 1
       name: portal-restore-x2bf9
       namespace: portal
       resourceVersion: "1493471"
       selfLink: /apis/portal.apiconnect.ibm.com/v1beta1/namespaces/portal/portalrestores/portal-restore-x2bf9
       uid: 9f6a1e22-55ab-4595-8b98-bdfaec40d58c
     spec:
       portalCluster: portal
       type: site
     status:
       backupId: ""
       commentLeft: ""
       conditions:
       - lastTransitionTime: "2020-05-26T13:10:49Z"
         message: |
           Please provide a site to restore. To restore all sites use value 'all' in the CR
         status: Failed
         type: Ready
       fullBackupName: ""
       id: ""
       message: ""
     ```

     Read the message inside the conditions of the Developer Portal backup CR or the restore CR.

  2. Retrieving logs
     Look for information in the logs of the `ibm-apiconnect` pod:
     - Locate the `ibm-apiconnect` pod with:

       ```
       kubectl get pods -n <namespace-of-portal-subsystem>
       ```

     - View the logs with:

```
kubectl logs <ibm-apiconnect-pod-NAME> -n <namespace-of-portal-subsystem>
```

- **Overview of the Developer Portal backup resources**
  How to manage your Developer Portal remote backup resources.

[1] PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see https://www.puttygen.com/.

Overview of the Developer Portal backup resources

How to manage your Developer Portal remote backup resources.

Note: This information is relevant only if you're taking remote Developer Portal backups.
The Developer Portal uses two types of portal backup resources. When you run the command **`kubectl get portalbackup`**, you see a list of backups, for example:

```
NAME                    ID                TASK ID      STATUS   TYPE     CR TYPE   CLUSTER   AGE     COMMENT
my-backup-f91ms         n/a               20b47fe090f5 Ready    system   create    portal    78m
portal-record-222cg     20220108.010033                Ready    system   record    portal    94m
portal-record-22xdc     20220702.010339                Ready    site     record    portal    9m49s
portal-record-245j7     20221002.010340                Ready    site     record    portal    5m
portal-record-246hm     20221218.010103                Ready    site     record    portal    32m
portal-record-24h44     20220509.010037                Ready    site     record    portal    68m
portal-record-24wb4     20221003.010029                Ready    site     record    portal    60m
portal-record-264mh     20221119.010453                Ready    system   record    portal    78m
```

There are two types of resources listed, and these are denoted by the **`CR TYPE`** column; **`create`** or **`record`** types.

1. **`create`**: This resource is a representation of a **`portalbackup`** task that was created manually. See Backing up and restoring the Developer Portal in a Kubernetes environment, Backing up Developer Portal on OpenShift and Cloud Pak for Integration, or Backing up the Developer Portal subsystem on VMware, for information about how to create a manual portal backup.
2. **`record`**: This resource is generated by the operator, and it's a representation of a backup file that's stored on the remote backup server. A record listing can be modified only to add a comment to it. You can describe each record to understand which file it is referring to by running the following command:

   ```
   kubectl describe portalbackup portal-record-name
   ```

   For example:

   ```
   kubectl describe portalbackup portal-record-zmmfw
   .
   .
   Name:         portal-record-zmmfw
   Namespace:    apic
   Labels:       createdBy
   .
   .
   Full Backup Name:        my-portal-s3-hostname@my-porg@catal-20220604.010302.tar.gz
   ```

Record rows are generated and updated on a schedule, according to the backups that exist on your remote backup server. If you have 10 backup files stored on your remote server, then there will be 10 record rows; one row for each file.

The Developer Portal doesn't have a retention policy for remote backups. Therefore, it's your responsibility to ensure that you're keeping the number of backups that are stored remotely under control. An excessive number of portal backups results in delays administrating and upgrading the Developer Portal. This is due to the operator needing to maintain the excessive number of record rows that correspond to each remote portal backup.

Backing up and restoring the analytics database

The API Connect analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

About this task

Before you can initiate a backup or restore operation, you must update the Analytics CR (custom resource) to configure your settings. Generating a backup for Analytics is performed on demand by deploying a backup CR. You can deploy a restore CR to start the restoration of a previously generated backup.

- **Configuring backup settings for Analytics**
  Configure the API Connect analytics subsystem on Kubernetes to support backing up and restoring the Analytics database.
- **Running a backup of the Analytics database**
  Deploy the analyticsbackup_cr.yaml CR to initiate a backup of the API Connect analytics database on Kubernetes.
- **Restoring the Analytics database**
  Deploy the analyticsrestore_cr.yaml CR to initiate restoration of a backup of the API Connect analytics database on Kubernetes.
- **Troubleshooting Analytics backup and restore**
  If you encounter problems when backing up or restoring the API Connect analytics database on Kubernetes, review the following troubleshooting tips.

Configuring backup settings for Analytics

Configure the API Connect analytics subsystem on Kubernetes to support backing up and restoring the Analytics database.

About this task

The Analytics database can be backed up and restored from an S3 repository. S3-compatible object storage is required; for example, IBM Cloud Object Storage. Generating a backup for Analytics is performed on demand by creating a backup CR (custom resource). You can create a restore CR to start the restoration of a previously generated backup.
Note:

- Only host-style S3 backups are supported. Path-style S3 backups are not supported.
- If you are using a self-managed S3 backup server, check that you have a DNS hostname entry and matching TLS certificate for your S3 backup endpoint.
- When you specify a filepath in a backup setting, be sure to escape any blank spaces in the path.

Note: You can only run one backup or restore process at a time.

Procedure

1. Create the analytics backup secret for your S3-compatible storage:
   a. Obtain an access key and corresponding access key secret from your S3 provider.
   For example, you might obtain the key and secret from one of the following providers, using the instructions found on their sites:

      - IBM Cloud Object Storage
      - AWS

   b. Create the Kubernetes secret by running the following command and filling in your access key, access key secret, and namespace:

      ```
      kubectl create secret generic analytics-backup-secret --from-literal=access_key='Your_Access_Key' --from-literal=secret_key='Your_access_key_secret' -n Namespace_of_Analytics_Subsystem
      ```

2. Add the backup configuration to the Analytics CR:
   a. Open the analytics_cr.yaml file for editing.
   If you already installed Analytics without configuring backup settings, run the following command to open the deployed version of the Analytics CR:

      ```
      kubectl edit analyticscluster analytics_cr -n namespace
      ```

      where:

      - *analytics_cr* is the name of the YAML file containing the Analytics CR
      - *namespace* is the name of the Analytics namespace

   b. In the **spec** section, add a **databaseBackup** section and configure the backup settings as shown in the following example:

      ```
      spec:
        databaseBackup:
          credentials: analytics-backup-secret
          host: s3.eu-gb.cloud-object-storage.appdomain.cloud
          path: my-s3-bucket/apic-analytics-backups
          backupCerts: <custom-s3-server-CA-cert>
          schedule: "0 2 * * *"
          enableCompression: true
          chunkSize: 1GB
          enableServerSideEncryption: false
      ```

      where:

      - **credentials** is the name of the Kubernetes secret you created in step 1
      - **host** is the S3 endpoint with the corresponding S3 region in the format:

        s3.*s3region.s3domain*

        Attention: A path style host value (formatted as ***S3endpoint/S3region***) is not supported.
      - **path** is a combination of the S3 bucket and the base path within the bucket, using the format: ***bucket_name/path***
      - **backupCerts** is the name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.2.
        This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be **ca.crt** and the value is the base64-encoded value of the CA certificate.

        If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Analytics subsystem already trusts the server certificate. You can test this by configuring the Analytics backup to your S3/object-store server without providing the CA certificate.

        If you do need to provide the CA certificate then you must provide the entire chain in the **ca.crt** member of the secret, as follows:

        ```
        intermediate-certificate-1
        intermediate-certificate-2
        . . .
        intermediate-certificate-n
        root-certificate
        ```

        Where the first certificate in the **ca.crt** member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the
        ca.crt member is the issuer of the preceding certificate. The root certificate in the **ca.crt** member must be self-signed.

        If there are no intermediate certificates involved, then the **ca.crt** member contains only the root certificate.

        The following sample bash script creates the Kubernetes secret:

        ```
        cat >customs3ca.yaml <<EOF
        apiVersion: v1
        data:
          ca.crt: $(base64 <path-to-ca-certificate> | tr -d '\n' )
        ```

```
kind: Secret
metadata:
  name: custom-server-ca
type: generic
EOF

kubectl apply -f customs3ca.yaml -n <namespace>
```

- **schedule** is the schedule that determines how often backups will be invoked automatically. The format for the schedule is any valid **cron** string. The timezone for backups is that of the kube-controller-manager. Backing up once a day is probably sufficient; remember that the more frequently you run backups, the more storage space you need.
- Optional: **enableCompression** determines whether metadata files are stored in compressed format. Default value is true.
- Optional: **chunkSize** specifies how large files are stored. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB. Default value is 1GB.
- Optional: **enableServerSideEncryption** determines whether files are encrypted. When set to true, files are encrypted on the server side using AES256. Default value is false.

3. Save and close the file.
4. Install or modify the Analytics subsystem with the updated CR as explained in Installing analytics.

Running a backup of the Analytics database

Deploy the analyticsbackup_cr.yaml CR to initiate a backup of the API Connect analytics database on Kubernetes.

Before you begin

Configure backup settings for Analytics.

About this task

A backup is triggered by creating the analyticsbackup_cr.yaml CR. The new CR is detected by the **ibm-apiconnect** operator, which requests a new backup.

Procedure

1. Create the **AnalyticsBackup** CR for your deployment in a file called analyticsbackup_cr.yaml.
   For example:

```
apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsBackup
metadata:
  generateName: a7s-bup-
  namespace: <analytics namespace>
spec:
  crType: create
  comment: "test comment"
  indices:
  - all
  enableIgnoreUnavailable: true
```

   where:
   - **metadata.generateName** - Use to specify a prefix for your backup name, the remainder of the name will be generated at runtime.
   - **metadata.name** - Use as an alternative to **generateName**, where you want to specify the full name of the backup.
   - Optional: **metadata.namespace** - Specify the analytics namespace.
   - **spec.crType** - Use **create** to trigger a backup process. When the backup is created, the operator generates another backup CR with **crType: record**, which represents the stored backup that you can use for a restore operation.
   - Optional: **spec.comment** - You can use this field to describe the back up for later reference.
   - Optional: **spec.indices** - A list of index names or keywords, indicating which indices you want to back up. Options are: **all|apievents|ui|summary**, or the names of individual indices. **all** includes **apievents**, **ui**, and **summary** indices. If no indices are specified, then all indices are backed up. The default of 'all' is specified explicitly in the above sample.
   - Optional: **spec.enableIgnoreUnavailable** - Default value is **false**. If set to **false**, the backup fails if a specified index is not present. If set to **true**, missing indices are skipped and the backup continues.
2. Deploy your CR by running the following command to create it in the namespace for your Analytics subsystem:

   ```
   kubectl create -f analyticsbackup_cr.yaml -n namespace
   ```

   where ***namespace*** is the name of the Analytics namespace.

   The backup's name and ID are generated when the backup operation runs.

3. To get a list of available backups, run the following command:

   ```
   kubectl get analyticsbackup -n namespace
   ```

   The response looks like the following example:

```
NAME                STATUS   ID                                     CR TYPE   INDICES                AGE   COMMENT
a7s-bup-266p8       Ready                                           create    [all]                  20h   y
a7s-bup-pffdh       Ready                                           create    [all]                  34h   y
```

4. Display the details for a particular backup by running the following command:
   Use the backup name from the results in step 4.

   ```
   kubectl get analyticsbackup backup_NAME -n namespace -o yaml
   ```

   The result looks like the following example:

   ```
   apiVersion: analytics.apiconnect.ibm.com/v1beta1
   kind: AnalyticsBackup
   metadata:
     creationTimestamp: "2020-05-20T16:18:05Z"
     generateName: a7s-bup-
     generation: 1
     name: a7s-bup-gb6s5
     namespace: my-namespace
     resourceVersion: "867329"
     uid: f43b8400-733d-411a-9e9a-de2166bbfb0a
   spec:
     indices:
     - all
   status:
     conditions:
     - lastTransitionTime: "2022-06-30T16:18:24Z"
       message: SUCCESS
       status: Complete
       type: Ready
     details: |
       {Name:my-backup-id
       Version:5.6.16
       Indices:[...]
       StartTime:2022-06-30T16:18:09.698Z
       EndTime:2022-06-30T16:18:16.082Z
       State:SUCCESS
       Failures:[]
       Shards:{Failed:0
       Successful:1}}
     id: my-backup-id
   ```

Restoring the Analytics database

Deploy the analyticsrestore_cr.yaml CR to initiate restoration of a backup of the API Connect analytics database on Kubernetes.

Before you begin

Create a backup.

About this task

A restore operation is triggered by creating the analyticsrestore_cr.yaml CR. The new CR is detected by the **ibm-apiconnect** operator, which requests a restore of the specified backup.

Note: You can only run one backup or restore process at a time.

Procedure

1. Get a list of available backups by running the following command:

   ```
   kubectl get analyticsbackup -n namespace
   ```

   where ***namespace*** is the name of the Analytics namespace.

   The response looks like the following example. Note down the ID of the backup that you want to restore.

   ```
   NAME                  STATUS   ID                                      CR TYPE   INDICES                AGE   COMMENT
   a7s-bup-266p8         Ready                                            create    [all]                  20h   y
   a7s-bup-pffdh         Ready                                            create    [all]                  34h   y
   analytics-bup-kxwq5   Ready    analytics-all-2020-09-07t03:49:15utc    record    [all]                  34h
   analytics-bup-p29z8   Ready    analytics-all-2020-09-07t18:04:03utc    record    [all]                  20h
   ```

   Note: You can only restore the Analytics subsystem from backups where the **CR TYPE** is **record**.
2. Create the **AnalyticsRestore** CR for your deployment in a file called analyticsrestore_cr.yaml.
   The following code shows the sample analyticsrestore_cr.yaml, which is stored in the helper_files directory:

   ```
   apiVersion: analytics.apiconnect.ibm.com/v1beta1
   kind: AnalyticsRestore
   metadata:
     generateName: a7s-restore-
   spec:
     indices:
     - all
     backupID: analytics-all-2022-07-01t03:49:15utc
     enableIgnoreUnavailable: true
     enableOverride: false
   ```

3. In your copy of the CR, update the following settings:

- **indices** - A list of index names or keywords, indicating which indices you want to restore. Options are: **all|apievents|ui|summary**, or the names of individual indices. **all** includes **apievents**, **ui**, and **summary** indices. If no indices are specified, then all indices are restored. The default of 'all' is specified explicitly in the above sample.
- **backupID** - The ID of the backup to be restored, which you obtained in step 2.
- **enableIgnoreUnavailable** - Default value is **false**. If set to **false**, the restore fails if a specified index is not present in the backup identified by the **backupID**. If set to **true**, missing indices are skipped and the restore continues.
- **enableOverride** - Default value is **false**. If set to **true**, then the restore overrides existing indices.
  When **enableOverride** is set to **false** and you specified indices that already exist in the database that you are restoring, then the restore fails. The failure prevents you from accidentally replacing or losing data that exists in the current database.

4. Deploy your CR by running the following command to create it in the namespace for your Analytics subsystem:

   ```
   kubectl create -f analyticsrestore_cr.yaml -n namespace
   ```

   where ***namespace*** is the name of the Analytics namespace.

   The restore's name is generated when the restore operation runs.

5. To get a list of restores, run the following command:

   ```
   kubectl get analyticsrestore -n namespace
   ```

   The response looks like the following example.

   ```
   NAME              STATUS     ID                                          AGE
   a7s-restore-9z4fr Ready      analytics-all-2022-07-01t04:49:15utc                              1h
   ```

6. Display the details for a particular restore by running the following command:
   Use the restore name from the results in step 6.

   ```
   kubectl get analyticsrestore restore_NAME -n namespace -o yaml
   ```

   The result looks like the following example:

   ```
   apiVersion: analytics.apiconnect.ibm.com/v1beta1
   kind: AnalyticsRestore
   metadata:
     creationTimestamp: "2022-07-01T04:06:03Z"
     generateName: a7s-restore-
     generation: 1
     name: a7s-restore-9z4fr
     namespace: my-namespace
     resourceVersion: "975152"
     uid: fdda9105-17ab-44ac-83de-852620a4dcde
   spec:
     backupID: analytics-all-2022-07-01t03:49:15utc
     enableIgnoreUnavailable: false
     enableOverride: true
     indices:
     - all
   status:
     conditions:
     - lastTransitionTime: "2022-07-01T04:08:03Z"
       message: WARNING
       status: Warning
       type: Ready
     details: |
       &{NumberOfDataNodes:1
       Status:yellow
       ActivePrimaryShards:23
       ActiveShards:23
       RelocatingShards:0
       InitializingShards:0
       UnassignedShards:40
       PendingTasks:0}
     id: analytics-all-2022-07-01t04:49:15utc
   ```

   When the restore is successfully started, the **status: condition** section displays **Running**. If the restore does not start correctly, the **status: condition** section displays **Failed**.

   The restore process is successful when the storage cluster status is green, there are no unassigned shards, and there are no initializing shards. At that time the **status: condition** section displays **Complete**. If **status: Complete** is not achieved after 3 hours, the status changes to **Warning** and the details are no longer updated.

   Important: For deployment profiles with fewer than 3 storage nodes, the restore process is never marked as **Complete**. The storage cluster status is expected to be yellow and to have more than 0 unassigned shards. In this situation, the restore process is likely to be complete when there are 0 initializing shards.

Troubleshooting Analytics backup and restore

If you encounter problems when backing up or restoring the API Connect analytics database on Kubernetes, review the following troubleshooting tips.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Check the CR status

Look for messages in the **status** section of the backup or restore CR by running the following command:

```
kubectl get analytics[backup|restore] restore|backup_NAME -n namespace -o yaml
```

where:

- You specify whether to retrieve the **analyticsbackup** CR or the **analyticsrestore** CR
- ***restore|backup_NAME*** is the name that is generated when you initially deploy the backup or restore CR.
- ***namespace*** is the namespace where Analytics is deployed.

For example:

```
kubectl get analyticsbackup a7s-bup-gb6s5 -n analytics -o yaml
```

Check the logs

Look for information in the logs of the **ibm-apiconnect** pod:

1. Locate the **ibm-apiconnect** pod by running the following command:

   ```
   kubectl get pods -n namespace
   ```

2. View the logs with:

   ```
   kubectl logs ibm-apiconnect-pod-NAME -n namespace
   ```

If there is a problem with your **databaseBackup** configuration, there are messages with the label "error" to indicate the problem

Backups on OpenShift

You can backup and restore API Connect subsystems on OpenShift and Cloud Pak for Integration.

- **Backing up and restoring the management subsystem on OpenShift and Cloud Pak for Integration**
  You can use the following instructions to backup and restore your Management subsystem on OpenShift and Cloud Pak for Integration.
- **Backing up and restoring Developer Portal on OpenShift and Cloud Pak for Integration**
  You can back up and restore your Developer Portal service in your OpenShift or Cloud Pak for Integration environment.
- **Backing up and restoring the Analytics database on OpenShift and Cloud Pak for Integration**
  The IBM® API Connect Analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

Backing up and restoring the management subsystem on OpenShift and Cloud Pak for Integration

You can use the following instructions to backup and restore your Management subsystem on OpenShift and Cloud Pak for Integration.

- To complete a backup and restore of your Management subsystem, you must have the **custom resource** configured with the **databaseBackup** subsection in the management subsystem custom resource.
- Backups can be scheduled or generated manually (on-demand). You can then list what backups are available and then use one to restore your Management subsystem if required.
- Postgres replica pods depend on a successful completed backup. If backup configuration is not correct, replica pods won't come up.
- In v10.0.1.1-eus and later, a new parameter called **protocol** is required in **databaseBackup** section
- Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For information on the registration credentials, see Changing the registration client_id and client_secret for applications.

Note: You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

Types of backups supported

- Cloud-based S3 storage
  - IBM Cloud Object Storage
  - AWS S3
- SFTP
  - In v10.0.1.1-eus, SFTP backup/restore procedure is automatically handled by apiconnect operator.
  - In v10.0.1.0 and later, local Backups can be stored remotely on an sftp server, and retrieved later from the sftp server for restore operations. See Using an sftp server for backup files (v10.0.1.0).
- Local storage backups

Support for Cloud Pak for Integration

IBM Cloud Pak for Integration is deployed on OpenShift, and uses the API Connect distribution for OpenShift. The backup and restore instructions in this section apply to both API Connect on OpenShift, and API Connect within a Cloud Pak for Integration environment.

When you perform configuration tasks you can use either a graphical user interface or a command line. The IBM Cloud Pak Platform UI differs from the OpenShift web console. The configuration topics in this section provide instructions for both interfaces. Note that Cloud Pak for Integration uses the OpenShift command line utility `oc`. Command line instructions for configuration are identical for both platforms.

- **Configuring backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration**
  You can configure backups for the API Connect Management subsystem that you will deploy in your OpenShift or Cloud Pak for Integration environment. Use the appropriate instructions for the type of backup that you want to configure:
- **Reconfiguring or adding backup settings after installation of the management subsystem on OpenShift and Cloud Pak for Integration**
  You can reconfigure the backup settings after installation of the management subsystem on OpenShift and Cloud Pak for Integration.
- **Generating a manual backup of the management subsystem on OpenShift and Cloud Pak for Integration**
  You can generate a manual (non-scheduled) backup of the management subsystem in your OpenShift and Cloud Pak for Integration environments.
- **Restoring the management subsystem on OpenShift and Cloud Pak for Integration**
  You can restore your Management subsystem in your OpenShift and Cloud Pak for Integration environments.
- **Troubleshooting management subsystem backups on OpenShift and Cloud Pak for Integration**
  You can troubleshoot failures of the API Connect management subsystem backups in an OpenShift or Cloud Pak for Integration environment.

Configuring backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration

You can configure backups for the API Connect Management subsystem that you will deploy in your OpenShift or Cloud Pak for Integration environment. Use the appropriate instructions for the type of backup that you want to configure:

- **Configuring S3 backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration**
  Configure backups for the API Connect Management subsystem that you will deploy in your OpenShift or Cloud Pak for Integration environment.
- **Configuring SFTP backup settings for fresh install of the Management subsystem on OpenShift and Cloud Pak for Integration**
  Beginning with API Connect V10.0.1.1, you can configure SFTP backups for your Management subsystem in your OpenShift and Cloud Pak for Integration environments.
- **Configuring local backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration**
  Configure local backups for the API Connect Management subsystem that you will deploy in your OpenShift or Cloud Pak for Integration environment.

Configuring S3 backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration

Configure backups for the API Connect Management subsystem that you will deploy in your OpenShift or Cloud Pak for Integration environment.

Before you begin

If the **`APIConnectCluster`** instance is already created, do not use these instructions. Instead, add the Management backup configuration by following the instructions in Reconfiguring or adding backup settings after installation of the management subsystem on OpenShift and Cloud Pak for Integration.

About this task

When creating an instance of API Connect, use the advanced configuration settings to configure database backups for the Management subsystem. Beginning with v10.0.2, the Management subsystem supports custom S3 solutions such as MinIO.

Important: For S3 backups of the management subsystem, do not use retention features provided by Cloud-based S3 storage providers. Use of such features can result in periodic deletion of archived backups, which can cause backup corruptions that can cause database restores to fail.
Warning:
When configuring a new management subsystem for S3 backup, the content of the S3 bucket path must be empty. If you want to configure a management subsystem to use the content of an S3 bucket path already used by another management subsystem, you have two options:

1. Shutdown the postgres database on the existing management subsystem that points to the S3 bucket path before you start the new management subsystem.
2. In a disaster recovery scenario where you want to restore from the backup of an existing installation: Create a new S3 path and use S3 tools to copy the backup content from the existing management subsystem S3 bucket path, to the new bucket path.

Procedure

1. Create a backup secret.
   The backup secret is a Kubernetes secret that contains your username and password for your S3 backup database.

   For examples of how to generate the appropriate access key and secret for two of them, see:

   - IBM (Cloud Object Storage): Service credentials.
   - AWS: Managing access keys.

   The secret can be created with the following command:

   ```
   oc create secret generic mgmt-backup-secret --from-literal=key='<YOUR ACCESS KEY>' --from-literal=keysecret='<YOUR ACCESS KEY SECRET>' -n <namespace_of_management_subsystem>
   ```

2. Configure the Management backup settings.
   Create the **`APIConnectCluster`** installation CR and add the Management backup configuration using one of the following methods:

   - OpenShift web console:

- Navigate to Advanced Configuration > ManagementSubsystem > Advanced Configuration > Database Backups > Advanced Configuration
- See the on-screen instructions for how to fill in each field. See also Management subsystem settings.
  Note that there is downtime involved when changing S3 protocol backup configuration.

- IBM Cloud Pak Platform UI:
  - In the Platform UI for the API Connect cluster instance, select Configuration. On the Form UI tab, set Advanced Options to On.
  - See the on-screen instructions for how to fill in values for:
    - Credentials
    - Hostname
    - Path
    - Protocol
    - Restart DB (toggle on)
    - S3 Provider
    - Backup Credentials
    - Backup URI Style
    - Schedule (The timezone for backups is that of the node on which the postgres-operator pod is scheduled.)
    - Repo Retention

    For more information, see Management subsystem settings.

- YAML file: Use Table 1 for guidance while you define the backup settings as shown in the following example.

```
spec:
  management:
    databaseBackup:
      protocol: objstore
      s3provider: ibm
      host: s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard
      path: apic-backup
      credentials: mgmt-backup-secret
      schedule: "0 3 * * *"
      repoRetentionFull: 2
```

Note: The `protocol` setting was introduced in v10.0.1.1. Do not specify it on v10.0.1.0 or earlier deployments

Table 1. Backup configuration settings

Setting	Description
`protocol`	The type of the backup; required in 10.0.1.1-eus and greater. For s3 storage, use `objstore`. When the parameter is not set, the backup type defaults to local storage backup. Note: The `protocol` setting was introduced in v10.0.1.1. Do not specify it on v10.0.1.0 or earlier deployments
`s3Provider`	Name of the S3 provider to use. You must specify one of the supported values of `aws`, `ibm`, or `custom`. The `custom` option is supported beginning with 10.0.2 or later. If you use a custom S3 provider, you must also specify the `backupCerts`. Note: The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: `x509: certificate signed by unknown authority`.
`backupCerts`	The name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.2. Used only when `s3Provider` is set to `custom`. Most of the custom S3 providers are created based on custom CA certificates. This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be `ca.crt` and the value is the base64-encoded value of the CA certificate. If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Analytics subsystem already trusts the server certificate. You can test this by configuring the Analytics backup to your S3/object-store server without providing the CA certificate. If you do need to provide the CA certificate then you must provide the entire chain in the `ca.crt` member of the secret, as follows: `intermediate-certificate-1` `intermediate-certificate-2` `. . .` `intermediate-certificate-n` `root-certificate` Where the first certificate in the `ca.crt` member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the `ca.crt` member is the issuer of the preceding certificate. The root certificate in the `ca.crt` member must be self-signed. If there are no intermediate certificates involved, then the `ca.crt` member contains only the root certificate. The following sample bash script creates the Kubernetes secret: `cat >customs3ca.yaml <<EOF` `apiVersion: v1` `data:` `  ca.crt: $(base64 <path-to-ca-certificate> | tr -d '\n' )` `kind: Secret` `metadata:` `  name: custom-server-ca` `type: generic` `EOF` `kubectl apply -f customs3ca.yaml -n <namespace>`

Setting	Description
`backups3URIStyle`	Indicates whether URIs to your S3 backup should use specify a host or a path value. Supported beginning with 10.0.2. Valid values: **`host`** and **`path`**. Used only when **`s3Provider`** is set to **`custom`**. Some custom S3 providers require URI style to be set to **`path`**. For example, MinIO supports both **`host`** and **`path`** style setup. You can create a MinIO S3 server to only accept **`path`** style client communications. **Important**: Contact your custom S3 administrator before configuring this field. If not properly configured, an upstream custom S3 can reject connections from the client, such as the API Connect Management subsystem.
`host`	For **`objstore`** type backup, specify S3 endpoint with the corresponding S3 region in the format **`<S3endpoint>/<S3region>`**
`path`	The path to the location of the backup: For **`objstore`** backups, the name of your S3 bucket to store backup data. For example, **`bucket-name/folder`**. The use of subdirectories in the bucket name is not supported. Note: When your deployment includes a management subsystem in two different clusters (with active databases), the two management subsystems cannot use the same s3 bucket name in the database backup configurations. Each management subsystem must use a unique s3 bucket name. Ensure that **`bucket-name/folder`** is empty. If the folder was previously used for backups, the folder will not be empty, and stanza create might encounter an error. **Explanation:** Once a folder is used, archive.info and backup.info files are created. During stanza creation, the process compares the database version and database system id between the two info files and the current Postgres database cluster. Stanza creation fails if there is a mismatch. To prevent this possibility, remove all files from the folder before configuring.
`credentials`	For **`objstore`** type backups, the name of the Kubernetes secret containing your S3 Access Key / Key Secret
`schedule`	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * • - - - - - • | | | | | • | | | | +----- day of week (0 - 6) (Sunday=0) • | | | +------- month (1 - 12) • | | +--------- day of month (1 - 31) • | +----------- hour (0 - 23) • +------------- min (0 - 59) The timezone for backups is that of the node on which the postgres-operator pod is scheduled. There is no default backup schedule set. Be sure to set your backup schedule. All scheduled Management subsystem backups are of type **`full`** only.
`repoRetentionFull`	**v10.0.3.0 or later** - The number of full S3 backups to retain. When the next full backup successfully completes, and the specified number of retained backups is reached, the oldest full backup is deleted. All incremental backups and archives associated with the oldest full backup also expire. Incremental backups are not counted for this setting. Applies to both manual backups and scheduled backups. Minimum value: **`1`** Maximum value: **`9999999`** Default: none

3. Verify that the configuration deploys successfully.
   When you configure Management subsystem backups, the operator runs a **`stanza-create`** job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

   Check the status of the **`stanza-create`** job:

   ```
   oc get jobs -n <namespace> | grep stanza
   ```

   - On success:
     - The **`stanza-create`** job status is **`1/1`**:

       ```
       oc get jobs | grep stanza
       m1-b722e361-postgres-stanza-create          1/1           5s         127m
       ```

     - The **`stanza-create`** job shows **`status: "True"`** and **`type: Complete`**:

       ```
       oc get job m1-b722e361-postgres-stanza-create -o yaml

       status:
         completionTime: "2021-04-13T18:38:50Z"
         conditions:
           - lastProbeTime: "2021-04-13T18:38:50Z"
             lastTransitionTime: "2021-04-13T18:38:50Z"
             status: "True"
             type: Complete
        startTime: "2021-04-13T18:38:45Z"
        succeeded: 1
       ```

     - The **`stanza-create`** pod is in **`Completed`** state:

       ```
       oc get pods | grep stanza
       m1-b722e361-postgres-stanza-create-q4fvp                      0/1     Completed   0          127m
       ```

     - Exec into the pod:

       ```
       oc exec -it <backrest-shared-repo-pod> -- bash
       ```

- The `pgbackrest` command returns the S3 contents in valid JSON:

  ```
  pgbackrest info --output json --repo1-type s3

  "backup":{"held":false}},"message":"ok"}}][pgbackrest@m1-b722e361-postgres-backrest-shared-repo-69cdfdfdd5-rs882
  /
  ```

- On failure, see Troubleshooting the stanza-create job for S3 backup configuration on OpenShift and Cloud Pak for Integration.

Configuring SFTP backup settings for fresh install of the Management subsystem on OpenShift and Cloud Pak for Integration

Beginning with API Connect V10.0.1.1, you can configure SFTP backups for your Management subsystem in your OpenShift and Cloud Pak for Integration environments.

Before you begin

If the `APIConnectCluster` instance is already created, do not use these instructions. Instead, add the Management backup configuration by following the instructions in Reconfiguring or adding backup settings after installation of the management subsystem on OpenShift and Cloud Pak for Integration.

About this task

When creating an instance of API Connect, use the advanced configuration settings to configure database backups for the Management subsystem.

Procedure

1. Create a backup secret.
   The backup secret is a Kubernetes secret that contains your credentials for accessing the SFTP backup database. Supported credentials types:

   - Username and password (v10.0.2.0 or later).
   - Username and SSH-key (v10.0.3.0 or later). Only OpenSSH keys are supported.[1]

   Use one of the following commands to create the secret:

   - Username and password credentials

     ```
     oc create secret generic mgmt-backup-secret --from-literal=username='<YOUR USERNAME>' --from-literal=password='<YOUR
     PASSWORD>' -n <namespace-of-mgmt-subsystem>
     ```

   - **Version 10.0.3.0 or later**: Username and SSH-key credentials:

     ```
     oc create secret generic mgmt-backup-secret --from-literal=username='<YOUR USERNAME>' --from-file=ssh-
     privatekey='<YOUR PRIVATEKEY FILE>' -n <namespace-of-mgmt-subsystem>
     ```

   Note: If the username contains the backslash character, insert an extra backslash to escape it. For example, if the username is:

   ```
   backup\svc-apic
   ```

   set this as:

   ```
   -from-literal=username='backup\\svc-apic'
   ```

2. Configure the Management backup settings.
   Create the `APIConnectCluster` installation CR and add the Management backup configuration using one of the following methods:

   - OpenShift web console:
     - Navigate to Advanced Configuration > ManagementSubsystem > Advanced Configuration > Database Backups > Advanced Configuration
     - See the on-screen instructions for how to fill in each field. See also Management subsystem settings.
       The following fields are unique to SFTP backup configuration:
       - Server port. Default is 22.
       - The fields in the Restart Database section. Changing SFTP (protocol) backup configures does not involve any downtime.
       - Retries.
   - IBM Cloud Pak Platform UI:
     - In the Platform UI for the API Connect cluster instance, select Configuration. On the Common settings tab, set Advanced Options to On.
     - See the on-screen instructions for how to fill in values for:
       - Credentials
       - Server Hostname
       - Path
       - Server Port
       - Protocol
       - Retries
       - Schedule (The timezone for backups is that of the node on which the postgres-operator pod is scheduled.)

       For more information, see Management subsystem settings.

   - YAML file: Use Table 1 for guidance while you define the backup settings as shown in the following example.

     ```
     spec:
       management:
         databaseBackup:
           protocol: sftp
           host: <SFTP-host-name>
           port: <SFTP-port>
     ```

```
    path: apic-backup
    retries: 0
    credentials: mgmt-backup-secret
    schedule: "0 3 * * *"
```

Table 1. Backup configuration settings

Setting	Description
`protocol`	The type of the backup. For SFTP storage: `sftp`.
`host`	The backups host. For `sftp` type, the SFTP server hostname
`port`	The SFTP server port. Optional. Default: `22`.
`path`	The path to the location of the backup. For `sftp` type, the folder name on the SFTP server.
`retries`	The number of times the `ibm-apiconnect` Operator attempts backups in the event of a failed SFTP backup. Default value: `0`.
`credentials`	Name of the Kubernetes secret containing your SFTP Username/password. For Version 10.0.3.0 or later, the Kubernetes secret can contain your SFTP Username and SSH key.
`schedule`	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * • - - - - - • | | | | | • | | | | +----- day of week (0 - 6) (Sunday=0) • | | | +------- month (1 - 12) • | | +--------- day of month (1 - 31) • | +----------- hour (0 - 23) • +------------- min (0 - 59) The timezone for backups is that of the node on which the postgres-operator pod is scheduled. There is no default backup schedule set. Be sure to set your backup schedule. All scheduled Management subsystem backups are of type `full` only.

[1] PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see https://www.puttygen.com/.

Configuring local backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration

Configure local backups for the API Connect Management subsystem that you will deploy in your OpenShift or Cloud Pak for Integration environment.

About this task

When creating an instance of API Connect, use the advanced configuration settings to configure database backups for the Management subsystem.

Procedure

Configure the Management section of the top-level `APIConnectCluster` installation CR with the `databaseBackup` subsection.
Specify `schedule` and `repoRetentionFull`, the default settings are 01:00 UTC and 14 days.

```
databaseBackup:
  schedule: "0 1 * * *"
  repoRetentionFull: 14
```

Table 1. Backup configuration settings

Setting	Description
`schedule`	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * • - - - - - • | | | | | • | | | | +----- day of week (0 - 6) (Sunday=0) • | | | +------- month (1 - 12) • | | +--------- day of month (1 - 31) • | +----------- hour (0 - 23) • +------------- min (0 - 59) The timezone for backups is that of the node on which the postgres-operator pod is scheduled. The default is daily backups at 01:00 UTC. All scheduled Management subsystem backups are of type `full` only.

Setting	Description
`repoRetentionFull`	- The number of full local backups to retain. When the next full backup successfully completes, and the specified number of retained backups is reached, the oldest full backup is deleted. All incremental backups and archives associated with the oldest full backup also expire. Incremental backups are not counted for this setting. Applies to both manual backups and scheduled backups. Minimum value: `1` Maximum value: `9999999` Default: 14

Reconfiguring or adding backup settings after installation of the management subsystem on OpenShift and Cloud Pak for Integration

You can reconfigure the backup settings after installation of the management subsystem on OpenShift and Cloud Pak for Integration.

About this task

Backup configurations under `management.databaseBackup` in `APIConnectCluster` instance can be modified using the OpenShift web console, IBM Cloud Pak Platform UI, or the command-line utility `oc`.

Note:
Using OpenShift web console or Platform UI can prevent updates because `APIConnectCluster` CR refreshes very quickly. If you encounter this problem, use the command line to modify backup configurations; for example:

```
oc edit apiconnectcluster <name-of-instance>
```

Procedure

1. Make sure that the management cluster status is `Running` and the READY condition displays the same value before and after the "/".
   For example:

   ```
   oc get mgmt
   NAME    READY    STATUS    VERSION      RECONCILED VERSION    AGE
   mgmt    16/16    Running   10.0.1-eus   10.0.1.1-eus-0-eus      19h
   ```

2. Create backup secret for your backup type. See the appropriate instructions:
   - Configuring S3 backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration
   - Configuring SFTP backup settings for fresh install of the Management subsystem on OpenShift and Cloud Pak for Integration
     Note that SFTP backups settings are not supported on v10.0.1.0 or earlier.

3. Complete the following steps, based on your storage type:
   - S3 storage
     If you have a two data center disaster recovery deployment, before you configure S3 backup settings you must first disable 2DCDR on both sites. Follow these steps:
     - Remove the `multiSiteHA` section from the `spec` section of the management CRs on both data centers. Take note of which data center is the active and which is the warm-standby. Keep a copy of the `multiSiteHA` sections that you remove.
     - Configure your S3 backup settings. You must specify different backup locations for each data center, see Backup and restore requirements for a two data center deployment.
     - Add the `multiSiteHA` sections back to the management CRs in both data centers, ensuring that your original active is set to be the active again.

     You can change or add the `DatabaseBackup` s3 configuration via the Management section of the API Connect Cluster CR after a fresh install. However, doing so requires a reconfiguration of the database and a brief downtime. The operator restarts the database with the new backup configurations as soon as the new configuration in the management CR is saved.

     ```
     spec:
       management:
         databaseBackup:
           protocol: objstore
           s3provider: ibm
           host: s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard
           path: apic-backup
           credentials: mgmt-backup-secret
           schedule: "0 3 * * *"
           restartDB:
             accept: true
     ```

     Configuration of s3 backups uses a new parameter `restartDB` that is required when changing the backup configuration. `restartDB` is not required for initial deployments, only for modifications after the cluster is deployed.

     Table 1. Additional parameter for S3 backup type reconfiguration

Parameter	Description
`restartDB:` `accept: <value>`	Required when changing the backup configuration. The parameter `accept` is a boolen: <`value`> can be `true` or `false`. When `accept` is `true`, and a new configuration for management CR is saved, the operator: • Stops the database and any dependent services • Applies the change • Restarts the stopped components. Note: `restartDB` is not required for initial deployments, only for modifications after the cluster is deployed.

   - SFTP

You can change/add the **DatabaseBackup** SFTP configuration via the Management section of the API Connect Cluster CR after a fresh install. This process does not involve any downtime. The same backup settings are used for reconfiguring as for initial configuration. For complete description of backup settings, see Configuring SFTP backup settings for fresh install of the Management subsystem on OpenShift and Cloud Pak for Integration.

```
spec:
  management:
    databaseBackup:
      protocol: sftp
      host: <SFTP-hostname>
      port: <SFTP-port> (Optional, default is 22)
      path: apic-backup
      retries: 0
      credentials: mgmt-backup-secret
      schedule: "0 3 * * *"
```

Generating a manual backup of the management subsystem on OpenShift and Cloud Pak for Integration

You can generate a manual (non-scheduled) backup of the management subsystem in your OpenShift and Cloud Pak for Integration environments.

Procedure

1. Make sure that the management cluster status is Running and the READY condition displays matching values before and after the "\".
   You can use either the OpenShift web console or the **oc** command line to verify the health. For example:

   ```
   oc get mgmt
   NAME    READY    STATUS    VERSION      RECONCILED VERSION    AGE
   mgmt    16/16    Running   10.0.1-eus   10.0.1.1-eus-0-eus    19h
   ```

2. Decide which of the two types of manual backups you want to do:
   - **full**: backs up the entire Management Subsystem database.
   - **incr**: backs up any data that has not been backed up since the last **full** or **incr** backup.
3. You generate a backup manually by creating a managementBackup custom resource which is detected by the ibm-apiconnect operator that then triggers the backup process.
   You can create the **ManagementBackup** custom resource by using either the Form UI or the command line. For example:

   ```
   apiVersion: management.apiconnect.ibm.com/v1beta1
   kind: ManagementBackup
   metadata:
     generateName: mgmt
   spec:
     type: full
     crType: create
     clusterName: management
   ```

   Table 1. CR settings for manual backup

Setting	Description
type	The type of backup to be done. Valid arguments are: • **full** Backs up the entire Management subsystem database • **incr** Backs up any data that has not been backed up since the last **full** or **incr** backup.
crType	Use **create** to trigger a backup process.
clusterName	The name of the target ManagementCluster you want to backup.

4. Create the ManagementBackup custom resource in the namespace of your Management Subsystem to trigger the backup process. Use the Form UI or the following command:

   ```
   $ oc create -f mgmtbackup_cr.yaml -n <APIC_namespace>
   ```

5. (Optional): You can list current backups by using Form UI to list **ManagementBackup** resources, or by using **oc**:

   ```
   $ oc get managementbackup -n <APIC_namespace> --sort-by=.metadata.creationTimestamp
   ```

   Here is an example of some possible output:

   ```
   NAME                STATUS   ID                CLUSTER   TYPE   CR TYPE   AGE
   m1-e46bbac4         Ready    20201023-183005F  m1        full   record    66m
   mgmt-backup-dnvxw   Ready    20201023-193137F  m1        full   create    9m37s
   ```

6. (Optional): You can get a detailed view of a specific backup by using the command:

   ```
   $ oc get managementbackup <bup-name> -n <APIC_namespace> -o yaml
   ```

   Here is an example of some possible output:

   ```
   apiVersion: management.apiconnect.ibm.com/v1beta1
   kind: ManagementBackup
   metadata:
     creationTimestamp: "2020-10-23T18:34:11Z"
     generation: 1
     labels:
       app.kubernetes.io/instance: m1
       app.kubernetes.io/managed-by: ibm-apiconnect
   ```

```
    app.kubernetes.io/name: m1-e46bbac4
  name: m1-e46bbac4
  namespace: default
  resourceVersion: "6869"
  selfLink: /apis/management.apiconnect.ibm.com/v1beta1/namespaces/default/managementbackups/m1-e46bbac4
  uid: b7b6be9c-82d4-4737-984f-58584a3fe582
spec:

  phase: Ready
  state: ""
  subsysName: m1
```

7. **Version 10.0.1.0 only**: If a local-backup was performed on v10.0.1.0, and you now wish to upload the local-backup file to an sftp server, see Uploading backup files to an sftp server for the required steps.

Restoring the management subsystem on OpenShift and Cloud Pak for Integration

You can restore your Management subsystem in your OpenShift and Cloud Pak for Integration environments.

Before you begin

You must have backups of the management subsystem in order to restore. See Configuring backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration and Generating a manual backup of the management subsystem on OpenShift and Cloud Pak for Integration.

About this task

To trigger a restore, you will create a **`ManagementRestore`** custom resource. When the **`ibm-apiconnect`** operator detects the new CR, it starts the restore process.

- Ensure that the backup method that you used is complete before you attempt a restore. The backup data that is stored in the remote server is used for restoring the Management subsystem data back to a previous state. Ensure that these backups are on your remote server before you attempt a restore, and that the backup ID in the selected backup exists in remote storage.
- Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For information on the registration credentials, see Changing the registration client_id and client_secret for applications.
- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.

Note: There is a known issue where sometimes a restore from the Management subsystem's SFTP backup succeeds but the data is not restored. If this happens, run the restore again.

Procedure

1. Use the Form UI or the **`oc`** command to obtain a list of the available backups, and decide which one to restore your Management subsystem:

   ```
   oc get mgmtb -n <APIC_namespace>
   ```

   For example:

   ```
   $ oc get mgmtb
   NAME                  STATUS    ID                CLUSTER      TYPE    CR TYPE    AGE
   ```

```
management-3aa3bebf   Ready    20200929-152150F   management   full   record    10h
management-3c4ca8df   Ready    20200929-115520F   management   full   record    20h
management-5tbxj      Ready    20200929-224349F   management   full   create    17h
management-f10af337   Ready    20200925-133703F   management   full   record    5d2h
management-jtlcd      Ready    20200929-224349F   management   full   create    25h
management-zxjtz      Ready    20200929-224349F   management   full   create    28h
```

Attention: You can restore the Management subsystem from any backup where the STATUS is Ready; however, you should avoid restoring to the initial system backup. During installation, the Management database is used for an initial system backup before certain database schema jobs are complete. Restoring to this backup will result in an unstable system.
You will use one of the values in the **NAME** column.

2. Use the instructions that apply to your release of API Connect:
   - Version 10.0.1.1 or later
     - Use the following code as an example:

       ```
       apiVersion: management.apiconnect.ibm.com/v1beta1
       kind: ManagementRestore
       metadata:
         generateName: management-
       spec:
         backupName: management-3aa3bebf
       ```

       Note that `backupName`: is the name of the backup custom resource you want to restore to. For example, using the output from the previous step:

       ```
       backupName: management-3aa3bebf
       ```

     - Use the Form UI or `oc` to create the ManagementRestore custom resource in the namespace of the Management Subsystem, to trigger the restore process:

       ```
       $ oc create -f mgmtrestore_cr.yaml -n <APIC_namespace>
       ```

     - You can list current restores using the following command, or if using OCP UI you can list all `ManagementResource` list:

       ```
       $ oc get managementrestore -n <APIC_namespace> --sort-by=.metadata.creationTimestamp
       ```

       Example output:

       - SFTP:

         ```
         NAME                  STATUS      BACKUP               CLUSTER      MESSAGE
         PITR     AGE
         mgmt-restore-ptx6d   Complete    mgmt-backup-w4h8c   m1           Restore process completed (DB Restore +
         DRR job)             6m31s
         ```

       - S3

         ```
         NAME                  STATUS      BACKUP               CLUSTER       MESSAGE
         PITR                     AGE
         mgmt-restore-hr9zx   Complete    mgmt-backup-xnjkl   m1            Restore process completed (DB Restore +
         DRR job)   2020-11-23 23:08:32+00   9m8s
         ```

   - Version 10.0.1.0
     - Use the following command to obtain the Point-in-Time-Recovery target for the selected backup:

       ```
       oc get mgmtb <backup_name> -o jsonpath="{..status.info.range}"
       ```

       For example:

       ```
       $ oc get mgmtb management-3aa3bebf -o jsonpath="{..status.info.range}"
       2020-09-29 15:21:50 +0000 UTC - 2020-09-29 15:30:56 +0000 UTC
       ```

       The target for recovery is the second half the **range** value in the backup custom resource. In the prior example: `2020-09-29 15:30:56 +0000`.

       The custom resource uses the **pitrTarget** setting to specify the Point-in-Time-Recovery target. You must set **pitrTarget** to be later than the value obtained above (such as by one second newer). Use the format **YYYY-MM-DD HH:MM:SS+Z**.

       Using the example above, where `2020-09-29 15:30:56 +0000` is the **range**, the **pitrTarget** is `2020-09-29 15:30:57+00`:

       ```
         pitrTarget: "2020-09-29 15:30:57+00"
       ```

     - Use the following code as an example:

       ```
       apiVersion: management.apiconnect.ibm.com/v1beta1
       kind: ManagementRestore
       metadata:
         generateName: management-
       spec:
         backupName: management-3aa3bebf
         pitrTarget: "2020-09-30 13:53:21+00" ## Not required in 10.0.1.1-eus and greater
       ```

       - `backupName` - The name of the backup custom resource you want to restore to. For example, using the output from the previous step, `management-3aa3bebf`.
       - `pitrTarget:` - The time you want to restore to, in format `YYYY-MM-DD HH:MM:SS+Z`.

     - Use the Form UI or `oc` to create the ManagementRestore custom resource in the namespace of the Management Subsystem, to trigger the restore process:

       ```
       $ oc create -f mgmtrestore_cr.yaml -n <APIC_namespace>
       ```

     - You can list current restores using the following command, or if using Form UI you can list all `ManagementResource` lists:

```
$ oc get managementrestore -n <APIC_namespace> --sort-by=.metadata.creationTimestamp
```

Example output:

```
NAME                  STATUS      BACKUP               CLUSTER      PITR                        AGE
management-6nzjr      Complete    mgmt-backup-dg4s4    m1           2020-01-05 19:05:00+01      14m
```

- The operator creates an upgrade CR when the postgres database is restarted during the restore:

```
managementdbupgrade.management.apiconnect.ibm.com/m1-up-zqkk5   Complete   Fresh install is Complete (DB
Schema/data are up-to-date)
63s5s
```

Troubleshooting management subsystem backups on OpenShift and Cloud Pak for Integration

You can troubleshoot failures of the API Connect management subsystem backups in an OpenShift or Cloud Pak for Integration environment.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
See:

- **Troubleshooting resiliency issues on OpenShift and Cloud Pak for Integration**
  Resolve resiliency issues with API Connect management system backups.
- **Troubleshooting the stanza-create job for S3 backup configuration on OpenShift and Cloud Pak for Integration**
  Troubleshoot configuration of s3 backups when the stanza-create job fails in an OpenShift or Cloud Pak for Integration environment.
- **Restore failure with compliance pod error on OpenShift and IBM Cloud Pak for Integration**
  Compliance pod reports an error, and restore does not progress.

Troubleshooting resiliency issues on OpenShift and Cloud Pak for Integration

Resolve resiliency issues with API Connect management system backups.

pgbackrest-shared-repo resiliency problems

If the Kubernetes node hosting **pgbackrest-shared-repo** pod is down and the PVC attached to the pod has strict zone requirements (for example, in AWS or other clouds) or if the storage class is set to **local-storage**, then **pgbackrest-shared-repo** pod will not get rescheduled to another Kubernetes node.

As a result, there is a single point of failure and the following conditions might occur:

- Backups of the management database fails
- Disk space fills with accumulated Postgres wal (Write-Ahead Logging) files

To avoid this problem, monitor the disk usage, see: Monitoring Postgres disk usage on OpenShift or Monitoring Postgres disk usage on Cloud Pak for Integration.

When the Kubernetes node comes back up, the pod is scheduled and all the processes should resume properly.

Troubleshooting the stanza-create job for S3 backup configuration on OpenShift and Cloud Pak for Integration

Troubleshoot configuration of s3 backups when the stanza-create job fails in an OpenShift or Cloud Pak for Integration environment.

When you configure Management subsystem backups for s3 providers, the operator runs a **stanza-create** job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

Check the status of the **stanza-create** job:

```
oc get jobs -n <namespace> | grep stanza
```

On failure:

- **stanza-create** pods fail, and job status is **0/1**:

```
oc get jobs | grep stanza
 m1-3bfe12ac-postgres-stanza-create          0/1           32m        32m
```

- Listing all pods brought up by **stanza-create** job shows multiple pods because a job tries **backoffLimit** times to complete the job. By default, there will be **7** pods in error state:

```
oc get pods | grep stanza
 m1-3bfe12ac-postgres-stanza-create-726z4                    0/1     Error       0          11m
 m1-3bfe12ac-postgres-stanza-create-9vq4n                    0/1     Error       0          22m
 m1-3bfe12ac-postgres-stanza-create-gbtgb                    0/1     Error       0          30m
 m1-3bfe12ac-postgres-stanza-create-gl5g5                    0/1     Error       0          17m
```

```
m1-3bfe12ac-postgres-stanza-create-q8qhw                    0/1     Error       0          26m
m1-3bfe12ac-postgres-stanza-create-t84zs                    0/1     Error       0          8m54s
m1-3bfe12ac-postgres-stanza-create-z8tfs                    0/1     Error       0          12m
```

Note: In some cases, the pods are cleaned by Kubernetes and the logs of these pods can be lost.

- Pod log errors show a reason for the failure. For example, when a hostname is not valid:

```
kubectl logs m1-3bfe12ac-postgres-stanza-create-gbtgb

time="2021-04-13T20:01:19Z" level=info msg="pgo-backrest starts"
time="2021-04-13T20:01:19Z" level=info msg="debug flag set to false"
time="2021-04-13T20:01:19Z" level=info msg="backrest stanza-create command
requested"
time="2021-04-13T20:01:19Z" level=info msg="s3 flag enabled for backrest command"
time="2021-04-13T20:01:19Z" level=info msg="command to execute is [pgbackrest
stanza-create  --db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --
repo1-type=s3]"
time="2021-04-13T20:01:19Z" level=info msg="command is pgbackrest stanza-create  --
db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --repo1-type=s3 "
time="2021-04-13T20:05:21Z" level=error msg="command terminated with exit code 49"
time="2021-04-13T20:05:21Z" level=info msg="output=[]"
```

- Job status is set to `type: Failed` and `status: "True"`, with `reason: BackoffLimitExceeded`:

```
oc get job m1-3bfe12ac-postgres-stanza-create -o yaml

status:
  conditions:
    - lastProbeTime: "2021-04-13T20:28:03Z"
      lastTransitionTime: "2021-04-13T20:28:03Z"
      message: Job has reached the specified backoff limit
      reason: BackoffLimitExceeded
      status: "True"
      type: Failed
      failed: 7
startTime: "2021-04-13T20:01:18Z"
```

- If pod logs are lost, you can execute a command inside the `backrest-shared-repo` pod:
  1. Obtain the `backrest-shared-repo` pod name:

     ```
     oc get pods -n <namespace> | grep backrest-shared-repo
     ```

     For example:

     ```
     oc get pods | grep backrest-shared-repo
     m1-eb8edc18-postgres-backrest-shared-repo-98dd46cc6-twl95   1/1     Running
     ```

  2. Exec into the pod:

     ```
     oc exec -it <backrest-shared-repo-pod> -- bash
     ```

  3. Run:

     ```
     pgbackrest info --output json --repo1-type s3
     ```

     For example, for invalid hostname:

     ```
     ERROR: [049]: unable to get address for 'test1-v10-backup.s3.exampleaws.com': [-2] Name or service not knownCopy
     ```

     The exact `ERROR:` will vary depending on the misconfiguration. Common errors:

     Invalid access key
     Invalid access key secret
     Invalid bucket region
     Invalid bucket or folder path
- To fix the incorrect settings, see Reconfiguring or adding backup settings after installation of the management subsystem on OpenShift and Cloud Pak for Integration.

Restore failure with compliance pod error on OpenShift and IBM® Cloud Pak for Integration

Compliance pod reports an error, and restore does not progress.

This failure can happen in a situation where a backup is taken on a system where API governance has never been enabled, and the restore of that backup is done onto a system which has API governance enabled. In this situation the API governance database is missing, and consequently the compliance pods report an error.

Symptoms

The compliance service pods are continually restarting, and the restore does not progress. The log of the compliance pod shows the following error:

```
2023-05-19T03:34:31.771Z bhendi:error Database availability check to management-0bfd2507-postgres:5432 failed, try again in
2000 ms,
error: : database "compliance" does not exist, stack: error: database "compliance" does not exist
```

Resolution

Delete all of the compliance jobs, and then start the restore again. For example:

```
oc -n <namespace> delete job management-up-compliance-service-data-populate-0-to-1 management-up-compliance-service-schema-0-to-1
```

Backing up and restoring Developer Portal on OpenShift and Cloud Pak for Integration

You can back up and restore your Developer Portal service in your OpenShift or Cloud Pak for Integration environment.

About this task

Before you can initiate a backup or restore operation, you must update the Portal CR (custom resource) to configure your settings. Generating a backup for Portal is performed on demand by deploying a backup CR. You can deploy a restore CR to start the restoration of a previously generated backup.

For points to consider when you are backing up and restoring a two data center disaster recovery deployment, see Backup and restore requirements for a two data center deployment.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

Important: Backups of the Management and Portal subsystems must be taken at the same time to ensure that the Portal sites are consistent with Management database. When you perform a restore, you must complete the restoration of the Management subsystem first, and then immediately restore the Developer Portal subsystem.

Configuring backups for Developer Portal on OpenShift and Cloud Pak for Integration

Configure backups for the Developer Portal service in your OpenShift or Cloud Pak for Integration environment.

About this task

Run commands in the namespace where the Developer Portal is installed.

For points to consider when you are backing up and restoring a two data center configuration, see Backup and restore requirements for a two data center deployment.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

Procedure

1. Create your Developer Portal backup secret.
   The backup secret is a Kubernetes secret that contains your credentials for accessing the s3 or sftp backup database.
   - S3
     Only password-based authentication is supported for S3, not authentication based on public certificates and private keys. Password-based authentication for S3 requires that you generate an access key and secret. For example:
     - IBM (Cloud Object Storage): Service credentials.
     - AWS: Managing access keys.

     The secret can be created with the following command:

     ```
     oc create secret generic portal-backup-secret --from-literal=username='Your_access_key-or-user_name'
         --from-literal=password='Your_access_key_secret-or-password' -n <Portal_namespace>
     ```

   - SFTP
     Supported credentials types:

- User name and password (v10.0.2.0 or later).
- User name and SSH-key (v10.0.3.0 or later). Only OpenSSH keys are supported.[1]

Use one of the following commands to create the secret:

- User name and password credentials

```
oc create secret generic portal-backup-secret --from-literal=username='<Your_user_name>'
--from-literal=password='<Your_password>' -n <Portal_namespace>
```

- Version 10.0.3.0 or later: User name and SSH-key credentials:

```
oc create secret generic portal-backup-secret --from-literal=username='<Your_user_name>'
 --from-file=ssh-privatekey='<Your_private_key_file>' -n <Portal_namespace>
```

2. Add a **portalBackup** subsection to the **spec.portal** section of the top-level **apiconnectcluster** CR.
You can edit the YAML in the UI, or you can run the following command and then add the **portalBackup** block:

```
oc edit apiconnectcluster <Portal_namespace>
```

An example when you use **protocol: objstore**:

```
spec:
  portal:
    portalBackup:
      credentials: portal-backup-secret
      host: s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard
      path: test-bucket/restore-test
      port: 443
      backupCerts: <custom-s3-server-CA-cert>
      backups3URIStyle: <host-or-path>
      schedule: '0 2 * * *'
```

An example when you use **protocol: sftp**:

```
spec:
  portal:
    portalBackup:
      credentials:   portal-backup-secret
      host:          sftp-service.example.com
      path:          /home/fvtuser/site-backups
      port:          22
      protocol:      sftp
      schedule:      '0 2 * * *'
```

Notes about the **portalBackup:** entry:

- If **portalBackup:** entry is empty or omitted from the API Connect Cluster CR, then **local** backups will be taken if a backup CR is created. If the **schedule** exists, backups are taken at the scheduled time.
- For S3 and SFTP, the **portalBackup:** entry must contain host, credentials, protocol, and path.
- For S3, the **portalBackup:** section can optionally contain either, or both, of **backupCerts** and **backupS3URIStyle**.

Table 1. Developer Portal backup settings

Setting	Description
credentials	The name of the secret you created. Supported credential types: • S3 Only password-based authentication is supported for S3, not authentication based on public certificates and private keys. Password-based authentication for S3 requires that you generate an access key and secret. • SFTP • User name and password (v10.0.2.0 or later) • User name and SSH-key (v10.0.3.0 or later)
host	• S3 - **host**: is the S3 endpoint with the corresponding S3 region in the format ***<S3endpoint>***, or with an optional S3 region in the format ***<S3endpoint>/<S3region>***. • SFTP - the hostname of the sftp server
path	• S3 - the name of your S3 bucket to store backup data, optionally followed by a **/** and then any subdirectories inside the bucket. Valid examples: **bucket** **bucket/path** **bucket/lots/of/paths** • SFTP - the full absolute path of the folder on the SFTP server, beginning with **/**. Attention: Ensure that your backup **path** has the correct permissions to allow your backup user to be able to read and write to it from within the Developer Portal.
port	The port for the protocol to connect to the host. • S3 - Ignored for S3 (because objstore always connects to port 443) • SFTP - Defaults to 22 if not specified • local - Ignored for local
protocol	The protocol that is used to communicate with your remote backup endpoint. Specify one of the following values: • **sftp** - for secure file transfer protocol. • **objstore** - for S3 compatible object storage.

Setting	Description
`backupCerts`	(S3 storage only) `backupCerts` is the name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.2. Note: If you use a public certificate for the S3 storage provider, it must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: `x509: certificate signed by unknown authority` This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be `ca.crt` and the value is the base64-encoded value of the CA certificate. If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Portal subsystem already trusts the server certificate. You can test this by configuring the Portal backup to your S3/object-store server without providing the CA certificate. If you do need to provide the CA certificate then you must provide the entire chain in the `ca.crt` member of the secret, as follows: `intermediate-certificate-1` `intermediate-certificate-2` `. . .` `intermediate-certificate-n` `root-certificate` Where the first certificate in the `ca.crt` member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the `ca.crt` member is the issuer of the preceding certificate. The root certificate in the `ca.crt` member must be self-signed. If there are no intermediate certificates involved, then the `ca.crt` member contains only the root certificate. The following sample bash script creates the Kubernetes secret: `cat >customs3ca.yaml <<EOF` `apiVersion: v1` `data:` `  ca.crt: $(base64 <path-to-ca-certificate> | tr -d '\n' )` `kind: Secret` `metadata:` `  name: custom-server-ca` `type: generic` `EOF` `kubectl apply -f customs3ca.yaml -n <APIC_namespace>`
`backups3URIStyle`	(S3 storage only) Optional - `backups3URIStyle` indicates whether URIs to your S3 backup should use specify a host or a path value. When not specified, default to `host`. Supported beginning with 10.0.2. Valid values: `host` and `path`. Some custom S3 providers require URI style to be set to `path`. For example, MinIO supports both `host` and `path` style setup. You can create a MinIO S3 server to only accept `path` style client communications. Important: Contact your custom S3 administrator before configuring this field. If not properly configured, an upstream custom S3 can reject connections from the client, such as the API Connect Management subsystem.
`schedule`	The schedule for how often automatic Developer Portal backups are run. The format for the schedule is any valid cron string. The timezone for backups is UTC. Valid for all backup types: S3, SFTP, and local. `spec:` `  portal:` `  portalBackup:` `  ...` `  schedule: '0 2 * * *'`

- **Overview of the Developer Portal backup resources**
  How to manage your Developer Portal remote backup resources.

[1] PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see https://www.puttygen.com/.

Overview of the Developer Portal backup resources

How to manage your Developer Portal remote backup resources.

Note: This information is relevant only if you're taking remote Developer Portal backups.
The Developer Portal uses two types of portal backup resources. When you run the command **`kubectl get portalbackup`**, you see a list of backups, for example:

```
NAME                  ID               TASK ID      STATUS   TYPE     CR TYPE   CLUSTER   AGE     COMMENT
my-backup-f91ms       n/a              20b47fe090f5 Ready    system   create    portal    78m
portal-record-222cg   20220108.010033               Ready    system   record    portal    94m
portal-record-22xdc   20220702.010339               Ready    site     record    portal    9m49s
portal-record-245j7   20221002.010340               Ready    site     record    portal    5m
portal-record-246hm   20221218.010103               Ready    site     record    portal    32m
portal-record-24h44   20220509.010037               Ready    site     record    portal    68m
portal-record-24wb4   20221003.010029               Ready    site     record    portal    60m
portal-record-264mh   20221119.010453               Ready    system   record    portal    78m
```

There are two types of resources listed, and these are denoted by the **CR TYPE** column; **create** or **record** types.

1. **create**: This resource is a representation of a **portalbackup** task that was created manually. See Backing up and restoring the Developer Portal in a Kubernetes environment, Backing up Developer Portal on OpenShift and Cloud Pak for Integration, or Backing up the Developer Portal subsystem on VMware, for information about how to create a manual portal backup.
2. **record**: This resource is generated by the operator, and it's a representation of a backup file that's stored on the remote backup server. A record listing can be modified only to add a comment to it. You can describe each record to understand which file it is referring to by running the following command:

   ```
   kubectl describe portalbackup portal-record-name
   ```

   For example:

   ```
   kubectl describe portalbackup portal-record-zmmfw
   .
   .
   Name:          portal-record-zmmfw
   Namespace:     apic
   Labels:        createdBy
   .
   .
   Full Backup Name:         my-portal-s3-hostname@my-porg@catal-20220604.010302.tar.gz
   ```

Record rows are generated and updated on a schedule, according to the backups that exist on your remote backup server. If you have 10 backup files stored on your remote server, then there will be 10 record rows; one row for each file.

The Developer Portal doesn't have a retention policy for remote backups. Therefore, it's your responsibility to ensure that you're keeping the number of backups that are stored remotely under control. An excessive number of portal backups results in delays administrating and upgrading the Developer Portal. This is due to the operator needing to maintain the excessive number of record rows that correspond to each remote portal backup.

Backing up Developer Portal on OpenShift and Cloud Pak for Integration

Perform a manual backup of the Developer Portal subsystem in your OpenShift or Cloud Pak for Integration environment.

About this task

Run commands in the namespace where the Developer Portal is installed.

Important: Backups of the Management and Portal subsystems must be taken at the same time to ensure that the Portal sites are consistent with Management database. When you perform a restore, you must complete the restoration of the Management subsystem first, and then immediately restore the Developer Portal subsystem.
The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

Tip: If you are using remote backups, and there are a large number of rows in your **portalbackup** list that have a **CR TYPE** of **record**, there might be a slow down in system performance, including during Developer Portal upgrades. Although there is no upper limit to how many portal backups you can have, it is recommended that you prune your remote backups so that the number of rows does not become excessively large. One **portalbackup** row of type **record**, corresponds to one backup file on the configured remote backup server. For more information, see Overview of the Developer Portal backup resources.

Procedure

1. Required: Backup the Management subsystem as explained in Generating a manual backup of the management subsystem on OpenShift and Cloud Pak for Integration.
2. Create the **PortalBackup** CR (custom resource) as a YAML file with the backup options that you want to use for Developer Portal.
   You can use portalbackup_cr.yaml in the helper_files directory as an example:

   ```
   apiVersion: portal.apiconnect.ibm.com/v1beta1
   kind: PortalBackup
   metadata:
     generateName: portal-bup-
   spec:
     crType: create
     portalCluster: portal
     type: all
     comment: "test comment"
   ```

   Set the following backup properties as needed:

   - **crType** - Use **create** to trigger a backup process. When the backup is created, the operator generates another backup CR with **crType: record**, which represents the stored backup that you can use for a restore operation.
   - **portalCluster** - the name of the portal cluster you want to backup. You can find this with:

     ```
     oc get portalcluster -n <namespace>
     ```

   - **record** - Includes a backup ID so you can choose it for restoring. If you plan to preserve the backup for use in recovering from a disaster, use the **record** argument to ensure that all necessary data is captured.
   - **type** - The extent of the backup; select one of the following options:
     - **all** - Backup the Developer Portal subsystem and all of the sites
     - **system** - Backup the Developer Portal subsystem

    - **site** - Backup only a specified Developer Portal site
  - **siteName**: Used only when you perform a **site** backup. Valid arguments are:
    - **site uuid** or **url** - back up only the specified site
    - **installed** - backup all installed sites
  - **comment**: Optional. You can optionally add a comment (such as a description or special notes) to the CR before you create a backup.
3. Run the following command to create the backup CR, which triggers the backup operation:

```
oc create -f portalbackup_cr.yaml -n <APIC_namespace>
```

4. Verify that the backup was successful by completing the following steps:
   a. Run the following command to a get a list of backups:

```
oc get portalbackup -n <APIC_namespace>
```

   The response looks like the following example, where only **crType: record** backups include an ID.

```
NAME               ID              STATUS     TYPE     CR TYPE   AGE     COMMENT
p1-bup-gqz8f    20200526.142449  Ready      system   record    55m
p1-bup-jx4vc    20200526.142458  Ready      site     record    54m
p1-bup-st412                     Ready      all      create    56m     y
p1-bup-th2dm                     Ready      all      create    4h51m   y
```

   b. Run the following command to view the details of a particular backup,, which is specified using the *<bup-name>* from the **NAME** column in the list of backups:

```
oc get portalbackup <bup-name> -n <APIC_namespace> -o yaml
```

   The details of a backup look like the following example:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalBackup
metadata:
  creationTimestamp: "2020-10-01T10:00:16Z"

   c. Check the contents of the backup and make sure that it contains the following statements, which indicate a successful operation:

```
. . .
    reason: BackupComplete
    status: "True"
    type: Ready
```

If the operation did not complete successfully, see Troubleshooting Developer Portal backup and restore on OpenShift and Cloud Pak for Integration for information on reviewing logs to help resolve the problem.

Restoring Developer Portal on OpenShift and Cloud Pak for Integration

You can restore the Developer Portal subsystem and sites in your OpenShift or Cloud Pak for Integration environment.

About this task

Run commands in the namespace where the Developer Portal is installed.

Important: Backups of the Management and Portal subsystems must be taken at the same time to ensure that the Portal sites are consistent with Management database. When you perform a restore, you must complete the restoration of the Management subsystem first, and then immediately restore the Developer Portal subsystem.

Procedure

1. Required: Restore up the Management subsystem as explained in Generating a manual backup of the management subsystem on OpenShift and Cloud Pak for Integration.
2. Choose which backup you want to restore.
   a. Run the following command to a get a list of available backups:

      ```
      oc get portalbackup -n <APIC_namespace>
      ```

      The response looks like the following example:

      ```
      NAME               ID              STATUS     TYPE     CR TYPE   AGE     COMMENT
      p1-bup-gqz8f    20200526.142449  Ready      system   record    55m
      p1-bup-jx4vc    20200526.142458  Ready      site     record    54m
      p1-bup-st4l2                     Ready      all      create    56m     y
      p1-bup-th2dm                     Ready      all      create    4h51m   y
      ```

      Note: You can only restore the Portal subsystem from backups where the `CR TYPE` is `record`.
   b. Run the following command to view the details of a particular backup,, which is specified using the *<bup-name>* from the `NAME` column in the list of backups:

      ```
      oc get portalbackup <bup-name> -n <APIC_namespace> -o yaml
      ```

      The details of a backup look like the following example:

      ```
      apiVersion: portal.apiconnect.ibm.com/v1beta1
      kind: PortalBackup
      metadata:
        creationTimestamp: "2020-10-01T10:00:16Z"
        generateName: portal-bup-
        generation: 1
        name: portal-bup-g66gv
        namespace: default
        resourceVersion: "8940"
        selfLink: /apis/portal.apiconnect.ibm.com/v1beta1/namespaces/default/portalbackups/portal-bup-g66gv
        uid: b1d5b295-b966-48f2-b6ef-dfcd1c499741
      spec:
        comment: test comment
        portalCluster: portal
        crType: record
        siteName: installed
        type: site
      status:
        backupId: ""
        commentLeft: "y"
        conditions:
        - lastTransitionTime: "2020-10-01T10:00:18Z"
          reason: BackupFailed
          status: "False"
          type: Error
        - lastTransitionTime: "2020-10-01T10:01:19Z"
          message: |-
            2020-10-01 10:00:18: CLI task (backup:site) starting.
            2020-10-01 10:00:20: Making a backup for site conor.com
            2020-10-01 10:00:27: A local backup was succesfully created: /var/aegir/backups/conor.com-
      20201001.100021.tar.gz
            2020-10-01 10:00:30: Attempting to upload backup to remote backup server
            2020-10-01 10:00:30: Uploading conor.com-20201001.100021.tar.gz to s3.eu-gb.cloud-object-
      storage.appdomain.cloud/eu-standard:22:cq-test/ptlcq4/ using objstore
            2020-10-01 10:00:33: Site with URL conor.com (conor.com-20201001.100021.tar.gz) successfully uploaded
            2020-10-01 10:00:33: All installed sites have been successfully backed up
            2020-10-01 10:00:33: CLI task (backup:site) completed successfully.
          reason: BackupComplete
          status: "True"
          type: Ready
        - lastTransitionTime: "2020-10-01T10:01:19Z"
          reason: BackupInProgress
          status: "False"
          type: Running
        - lastTransitionTime: "2020-10-01T10:00:18Z"
          reason: BackupStatusUnknown
          status: "False"
          type: Warning
        fullBackupName: ""
        id: f8t0ux7z4zfnnjnu
        message: ""
      ```

```
  phase: Ready
  state: ""
```

3. Create the **PortalRestore** CR (custom resource) as a YAML file with the backup options that you want to use for Developer Portal. You can use portalrestore_cr.yaml in the helper_files directory as an example:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
  generateName: portal-restore-
spec:
  type: all
  portalCluster: portal
  dryRun: true
  timestamp: now
  priorityList:
    - myportal-critical-site.com
    - myportal-important.com
```

Add the following restore options as needed. Table 1 indicates which options are needed for each type of restore operation:

Table 1. The options that are needed for each type of Developer Portal restore operation

Option	Applies to `all`	Applies to `system`	Applies to `site`
`type`	X	X	X
`portalCluster`	X	X	X
`siteName`			X
`systemName`		X	
`timestamp`	X		
`dryRun`	X		
`priorityList`			

- **type**: Indicates the extent of the restore operation; specify one of the following options:
  - **all** - Restore the Developer Portal subsystem and all of the sites (supports only remote restores).
  - **system** - Restore the Developer Portal subsystem.
  - **site** - Restore only a specified Developer Portal site (you will indicate the site with the **siteName** option).
- **portalCluster** is the name of the portal cluster you want to restore. You can find this with:

  ```
  oc get portal -n <namespace>
  ```

- **siteName**: Indicates which site to restore (used only with the **site** option); specify one of the following options:
  - *ID* - Restore the backup specified by the ID. The ID must correspond to a Developer Portal backup of **type: site** and **crType: record**.
  - site-*1234*.tgz - Restore the site by using this file name (which must exist on the local file system or remote server).
  - myportal.com: find the latest backup for this URL (locally or remotely) and restore it.
  - **all** - Restore all sites that are found on the remote server by using the latest backup.
  - **site** - Restore only the site that matches the specified uuid or url.
  - **installed** - Restore all installed sites.
- **systemName** - Restore from a backup that corresponds to the specified system; use one of the following options:
  - *ID* - Restore the backup specified by the ID. The ID must correspond to a Developer Portal backup of **type: site** and **crType: record**.
  - system_backup-*1234*.tgz - Restore the system from the given file that exists on the pod's local file system or the remote server.
  - **latest** - Restore from latest subsystem backup that is found on either the local file system or the remote server.
- **timestamp** - Valid arguments are:
  - **now** - Restore using the latest backups available.
  - *< TIMESTAMP >* - Specified in *'YYYYMMDD.HHMMSS'* format to indicate a timestamp to retrieve the backup from. The nearest backup, searching backwards from this timestamp, is used.

  Note: From IBM® API Connect Version 10.0.3.0, the timestamp format changed to *YYYYMMDD.HHMMSS*. For Version 10.0.2.0 and earlier, the timestamp format is *YYYY-MM-DD HH:MM:SS*.
- **dryRun**: Indicates whether an an actual restore operation is run; use one of the following options:
  - **true** - Execute a test, or dry run, of the command and return the list of actions that will be taken. These actions can be found in the custom resource.
  - **false** - Run a real restore operation, replacing the subsystem files and all sites. Any existing sites are reinstalled.
- **priorityList** - Restore sites in the sequence in which they are listed. The priority sites are queued for restoring first, followed by any remaining sites present in the backup location. Valid arguments are:
  - **myportalsite.com**
  - **mysecondportalsite.com**
- **customPlatformApiHostname** - If the **API** hostname of your management subsystem platform has changed since taking the backup you are restoring, then update it to the new platform API hostname of the management subsystem. (Optional)

4. Run the following command to create the restore CR, which triggers the restore operation:

```
oc create -f portalrestore_cr.yaml -n <APIC_namespace>
```

5. When the restore operation is finished, verify that the restore was successful cy completing the following steps:
   a. Run the following command to get the name of the most recent restore record:

   ```
   oc get portalrestore -n <APIC_namespace>
   ```

   The response looks like the following example:

   ```
   NAME                    READY     AGE
   portal-restore-twjrp    Ready     28s
   ```

   b. Run the following command to view information about a specific restore operation, which is indicated with the *<portal_restore_name>* shown in the **NAME** column:

```
oc get portalrestore <portal_restore_name> -n <APIC_namespace> -o yaml
```

The details of a restore look like the following example:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
  creationTimestamp: "2020-11-11T10:14:39Z"
  generateName: portal-restore-
  generation: 1
  name: portal-restore-8f4c5

If the operation did not complete successfully, see Troubleshooting Developer Portal backup and restore on OpenShift and Cloud Pak for Integration for information on reviewing logs to help resolve the problem.

Troubleshooting Developer Portal backup and restore on OpenShift and Cloud Pak for Integration

Review details on a failed backup or restore operation for Developer Portal backup on OpenShift and Cloud Pak for Integration.

Check the status of a backup operation

1. Run the following command to a get a list of backups:

   ```
   oc get portalbackup -n <Portal_namespace>
   ```

   The response looks like the following example, where only `crType: record` backups include an ID.

   ```
   NAME              ID              STATUS     TYPE     CR TYPE   AGE     COMMENT
   p1-bup-gqz8f    20200526.142449  Ready      system   record    55m
   ```

```
p1-bup-jx4vc    20200526.142458  Ready      site     record    54m
p1-bup-st4l2                     Ready      all      create    56m     y
p1-bup-th2dm                     Ready      all      create    4h51m   y
```

2. Run the following command to view the details of a particular backup,, which is specified using the *<bup-name>* from the **NAME** column in the list of backups:

   ```
   oc get portalbackup <bup-name> -n <Portal_namespace> -o yaml
   ```

   The details of a backup look like the following example:

   ```
   apiVersion: portal.apiconnect.ibm.com/v1beta1
   kind: PortalBackup
   metadata:
     creationTimestamp: "2020-10-01T10:00:16Z"
     generateName: portal-bup-
     generation: 1
     name: portal-bup-g66gv
     namespace: default
     resourceVersion: "8940"
     selfLink: /apis/portal.apiconnect.ibm.com/v1beta1/namespaces/default/portalbackups/portal-bup-g66gv
     uid: b1d5b295-b966-48f2-b6ef-dfcd1c499741
   spec:
     comment: test comment
     portalCluster: portal
     crType: create
     siteName: installed
     type: site
   status:
     backupId: ""
     commentLeft: "y"
     conditions:
     - lastTransitionTime: "2020-10-01T10:00:18Z"

     message: ""
     phase: Ready
     state: ""
   ```

3. If the operation failed, check the associated **message** for more information.

Check the status of a restore operation

1. Run the following command to get the name of the most recent restore record:

   ```
   oc get portalrestore -n <Portal_namespace>
   ```

   The response looks like the following example:

   ```
   NAME                    READY     AGE
   portal-restore-twjrp    Ready     28s
   ```

2. Run the following command to view information about the restore operation; which is indicated with the ***<portal_restore_name>*** shown in the **NAME** column:

   ```
   oc get portalrestore <portal_restore_name> -n <Portal_namespace> -o yaml
   ```

   The details of a failed restore operation look like the following example:

   ```
   apiVersion: portal.apiconnect.ibm.com/v1beta1
   kind: PortalRestore
   metadata:
     creationTimestamp: "2020-05-26T13:10:46Z"
     generateName: portal-restore-
     generation: 1
     name: portal-restore-x2bf9
     namespace: portal
     resourceVersion: "1493471"
     selfLink: /apis/portal.apiconnect.ibm.com/v1beta1/namespaces/portal/portalrestores/portal-restore-x2bf9
     uid: 9f6a1e22-55ab-4595-8b98-bdfaec40d58c
   ```

```
spec:
  type: site
  portalCluster: portal
status:
  backupId: ""
  commentLeft: ""
  conditions:
  - lastTransitionTime: "2020-05-26T13:10:49Z"
    message: |
      Please provide a site to restore. To restore all sites use value 'all' in the CR
    status: Failed
    type: Ready
  fullBackupName: ""
  id: ""
  message: ""
```

3. If the operation failed, check the associated `message` for more information.

Review the logs for additional information

Look for information in the logs of the `ibm-apiconnect` pod:

- Locate the `ibm-apiconnect` pod with:

  ```
  oc get pods -n <Portal_namespace>
  ```

- View the logs with:

  ```
  oc logs <ibm-apiconnect-pod-NAME> -n <Portal_namespace>
  ```

Backing up and restoring the Analytics database on OpenShift and Cloud Pak for Integration

The IBM® API Connect Analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

About this task

Before you can initiate a backup or restore operation, you must update the Analytics CR (custom resource) to configure your settings. Generating a backup for Analytics is performed on demand by deploying a backup CR. You can deploy a restore CR to start the restoration of a previously generated backup.

- **Configuring backup settings for Analytics on OpenShift and Cloud Pak for Integration**
  Configure the API Connect analytics subsystem on OpenShift and Cloud Pak for Integration to support backing up and restoring the Analytics database.
- **Running a backup of the Analytics database on OpenShift and Cloud Pak for Integration**
  Deploy the `AnalyticsBackup` CR to initiate a backup of the IBM API Connect Analytics database on OpenShift or Cloud Pak for Integration.
- **Restoring the Analytics database on OpenShift and Cloud Pak for Integration**
  Deploy the `AnalyticsRestore` CR to initiate restoration of a backup of the IBM API Connect Analytics database on OpenShift or Cloud Pak for Integration.

Configuring backup settings for Analytics on OpenShift and Cloud Pak for Integration

Configure the API Connect analytics subsystem on OpenShift and Cloud Pak for Integration to support backing up and restoring the Analytics database.

About this task

Generating a backup for Analytics is performed on demand by configuring backup settings in the Analytics section of the top-level `APIConnectCluster` CR. You can create a restore CR to start the restoration of a previously generated backup.

- Backups can be scheduled or generated manually (on-demand), but you can only run one backup or restore process at a time.
- The backup and restore solution for Analytics supports only remote, cloud-based S3 storage (such as IBM Cloud Object Storage, or AWS S3).

Note:

- Only host-style S3 backups are supported. Path-style S3 backups are not supported.
- If you are using a self-managed S3 backup server, check that you have a DNS hostname entry and matching TLS certificate for your S3 backup endpoint.
- When you specify a filepath in a backup setting, be sure to escape any blank spaces in the path.

Procedure

1. Create the analytics backup secret for your S3-compatible storage:
   a. Obtain an access key and corresponding access key secret from your S3 provider.
      For example, you might obtain the key and secret from one of the following providers, using the instructions found on their sites:
      - IBM Cloud Object Storage
      - AWS
   b. Create the Kubernetes secret by running the following command and filling in your access key, access key secret, and namespace:

```
oc create secret generic analytics-backup-secret --from-literal=access_key='Your_Access_Key' --from-
literal=secret_key='Your_access_key_secret' -n Analytics_namespace
```

2. Add the backup configuration to the Analytics section of the top-level **APIConnectCluster** CR:
   You can add or modify the Analytics backup configuration using one of the following methods:
   - OpenShift web console:
     - Navigate to Advanced Configuration > Analytics Subsystem > Advanced Configuration > Database Backups > Advanced Configuration.
     - Configure the backup settings using the settings described in Table 1.
   - IBM Cloud Pak Platform UI:
     - Open the API Connect instance for editing.
     - On the Details page, enable Advanced settings, which allows you to add backup configurations in the Analytics subsystem section.
     - Click Analytics subsystem and configure settings in the "Database backups" section using the settings described in Table 1.
   - YAML: Edit the top-level **APIConnectCluster** CR and add a **databaseBackup** section using the settings described in Table 1; for example:

```
spec:
    analytics:
      databaseBackup:
        credentials: analytics-backup-secret
        host: s3.eu-gb.cloud-object-storage.appdomain.cloud
        path: my-s3-bucket/apic-analytics-backups
        backupCerts: <custom-s3-server-CA-cert>
        schedule: "0 2 * * *"
        enableCompression: true
        chunkSize: 1GB
        enableServerSideEncryption: false
```

Table 1. Backup configuration settings for Analytics

Field name in UI	Field name in YAML	Description
Credentials	**credentials**	The name of the Kubernetes secret that you created in step 1.
Server hostname	**host**	The S3 endpoint with the corresponding S3 region in the format **s3.s3region.s3domain**
Backup path	**path**	A combination of the S3 bucket and the base path within the bucket, using the format **bucket_name/base_path**
Schedule	**schedule**	(Optional) The schedule that determines how often backups will be invoked automatically. The format for the schedule is any valid cron string. The timezone for backups is that of the kube-controller-manager. Backing up once a day is probably sufficient; remember that the more frequently you run backups, the more storage space you need.
Compress	**enableCompression**	(Optional) Determines whether metadata files are stored in compressed format. Default value is **true**.
Backup chunk size	**chunkSize**	(Optional) Specifies how large files are stored. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB. Default value is **1GB**.
Enable server side encryption	**enableServerSideEncryption**	(Optional) Determines whether files are encrypted. When set to true, files are encrypted on the server side using AES256. Default value is **false**.
Backup Certs	**backupCerts**	The name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.2. This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be **ca.crt** and the value is the base64-encoded value of the CA certificate. If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Analytics subsystem already trusts the server certificate. You can test this by configuring the Analytics backup to your S3/object-store server without providing the CA certificate. If you do need to provide the CA certificate then you must provide the entire chain in the **ca.crt** member of the secret, as follows: **intermediate-certificate-1** **intermediate-certificate-2** **. . .** **intermediate-certificate-*n*** **root-certificate** Where the first certificate in the **ca.crt** member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the **ca.crt** member is the issuer of the preceding certificate. The root certificate in the **ca.crt** member must be self-signed. If there are no intermediate certificates involved, then the **ca.crt** member contains only the root certificate. The following sample bash script creates the Kubernetes secret: **cat >customs3ca.yaml <<EOF** **apiVersion: v1** **data:** **ca.crt: $(base64 <path-to-ca-certificate> | tr -d '\n')** **kind: Secret** **metadata:** **name: custom-server-ca** **type: generic** **EOF** **kubectl apply -f customs3ca.yaml -n <namespace>**

Running a backup of the Analytics database on OpenShift and Cloud Pak for Integration

Deploy the **AnalyticsBackup** CR to initiate a backup of the IBM® API Connect Analytics database on OpenShift or Cloud Pak for Integration.

Before you begin

Configure backup settings for Analytics.

About this task

A backup is triggered by creating the **AnalyticsBackup** CR. The new CR is detected by the **ibm-apiconnect** operator, which requests a new backup.

Procedure

1. Make sure your analytics cluster status is **Running** and **READY**.
   The cluster is ready when the **READY** condition states **x/y** where x = y. You can check the status in the OpenShift Form UI, or by running the following command:

   ```
   oc get a7s -n <analytics namespace>
   ```

   where ***a7s*** is the name of your Analytics subsystem. The response looks like the following example:

   ```
   NAME         READY   STATUS    VERSION      RECONCILED VERSION   AGE
   analytics    5/5     Running   10.0.5.0     10.0.5.0-426           19h
   ```

2. Create the **AnalyticsBackup** CR using either the IBM Cloud Pak Platform UI, the OpenShift web console, or the CLI.
   For example:

   ```
   apiVersion: analytics.apiconnect.ibm.com/v1beta1
   kind: AnalyticsBackup
   metadata:
     generateName: a7s-bup-
     namespace: <analytics namespace>
   spec:
     crType: create
     comment: "test comment"
     indices:
     - all
     enableIgnoreUnavailable: true
   ```

   where:
   - **metadata.generateName** - Use to specify a prefix for your backup name, the remainder of the name will be generated at runtime.
   - **metadata.name** - Use as an alternative to **generateName**, where you want to specify the full name of the backup.
   - Optional: **metadata.namespace** - Specify the analytics namespace.
   - **spec.crType** - Use **create** to trigger a backup process. When the backup is created, the operator generates another backup CR with **crType: record**, which represents the stored backup that you can use for a restore operation.
   - Optional: **spec.comment** - You can use this field to describe the back up for later reference.
   - Optional: **spec.indices** - A list of index names or keywords, indicating which indices you want to back up. Options are: **all|apievents|ui|summary**, or the names of individual indices. **all** includes **apievents**, **ui**, and **summary** indices. If no indices are specified, then all indices are backed up. The default of 'all' is specified explicitly in the above sample.
   - Optional: **spec.enableIgnoreUnavailable** - Default value is **false**. If set to **false**, the backup fails if a specified index is not present. If set to **true**, missing indices are skipped and the backup continues.
3. Trigger the backup operation by clicking Create in the UI, or by running the following command to deploy the CR in the namespace for your Analytics subsystem:

   ```
   oc create -f analyticsbackup_cr.yaml -n <Analytics-namespace>
   ```

   The backup's name and ID are generated when the backup operation runs.

4. To get a list of available backups, run the following command:

   ```
   oc get analyticsbackup -n <Analytics-namespace>
   ```

   where ***<Analytics-namespace>*** is the namespace where the Analytics subsystem is deployed. The response looks like the following example:

   ```
   NAME                  STATUS   ID                                     CR TYPE   INDICES                AGE   COMMENT
   a7s-bup-266p8         Ready                                           create    [all]                  20h   y
   a7s-bup-pffdh         Ready                                           create    [all]                  34h   y
   ```

5. Display the details for a particular backup by running the following command:
   Use the backup name from the results in the previous step.

   ```
   oc get analyticsbackup backup_NAME -n <Analytics-namespace> -o yaml
   ```

   The result looks like the following example:

   ```
   apiVersion: analytics.apiconnect.ibm.com/v1beta1
   kind: AnalyticsBackup
   metadata:
     creationTimestamp: "2022-06-29T12:48:56Z"
     generateName: analytics-bup-
     generation: 1
   ```

```
  name: analytics-bup-4m7g8
  namespace: apic
  resourceVersion: "11207730"
  uid: e1d1c259-850f-4b90-82b3-6a13c05e5d72
spec:
  comment: ""
  crType: create
  enableIgnoreUnavailable: false
  indices:
  - all
status:

```

Restoring the Analytics database on OpenShift and Cloud Pak for Integration

Deploy the **AnalyticsRestore** CR to initiate restoration of a backup of the IBM® API Connect Analytics database on OpenShift or Cloud Pak for Integration.

Before you begin

Create a backup. If you intend to restore from a recent backup, ensure that the backup is finished before you start the restore operation.

About this task

A restore operation is triggered by creating the **AnalyticsRestore** CR. The new CR is detected by the **ibm-apiconnect** operator, which requests a restore of the specified backup.

Note: You can only run one backup or restore process at a time.

Procedure

1. Find the backup that you want to restore.
   a. Get a list of available backups by running the following command:

      ```
      oc get analyticsbackup -n <APIC_namespace>
      ```

      where ***<APIC_namespace>*** is the namespace where the Analytics subsystem is deployed. The response looks like the following example. Note down the ID of the backup that you want to restore.

      ```
      NAME                   STATUS   ID                                      CR TYPE   INDICES              AGE   COMMENT
      a7s-bup-266p8          Ready                                            create    [all]                20h   y
      a7s-bup-pffdh          Ready                                            create    [all]                34h   y
      analytics-bup-kxwq5    Ready    analytics-all-2020-09-07t03:49:15utc    record    [all]                34h
      analytics-bup-p29z8    Ready    analytics-all-2020-09-07t18:04:03utc    record    [all]                20h
      ```

      Note: You can only restore the Analytics subsystem from backups where the **CR TYPE** is **record**.
2. Create the **AnalyticsRestore** CR using either the IBM Cloud Pak Platform UI, the OpenShift web console, or the CLI.
   In the CR, specify the ID of the backup that you want to restore. For example:

   ```
   apiVersion: analytics.apiconnect.ibm.com/v1beta1
   kind: AnalyticsRestore
   metadata:
     generateName: a7s-restore-
   spec:
     indices:
     - all
     backupID: analytics-all-2022-07-01t03:49:15utc
     enableIgnoreUnavailable: true
     enableOverride: false
   ```

   where:
   - **indices** - A list of index names or keywords, indicating which indices you want to restore. Options are: **all|apievents|ui|summary**, or the names of individual indices. **all** includes **apievents**, **ui**, and **summary** indices. If no indices are specified, then all indices are restored. The default of 'all' is specified explicitly in the above sample.
   - **backupID** - The ID of the backup to be restored. In the example, the backup ID is **analytics-all-2022-07-01t03:49:15utc**.
   - **enableIgnoreUnavailable** - Default value is **false**. If set to **false**, the restore fails if a specified index is not present in the backup identified by the **backupID**. If set to **true**, missing indices are skipped and the restore continues.

- **enableOverride** - Default value is **false**. If set to **true**, then the restore overrides existing indices. This might result in a loss of data from the current database.
  When **enableOverride** is set to **false** and you specified indices that already exist in the database that you are restoring, then the restore fails. The failure prevents you from accidentally replacing or losing data that exists in the current database.

3. Trigger the restore operation by clicking Create in the UI, or by running the following command to deploy the CR in the namespace for your Analytics subsystem:

   ```
   oc create -f analyticsrestore_cr.yaml -n <APIC_namespace>
   ```

   The restore's name is generated when the restore operation runs.

4. To get a list of restores, run the following command:

   ```
   oc get analyticsrestore -n <APIC_namespace>
   ```

   The response looks like the following example.

   ```
   NAME              STATUS    ID                                        AGE
   a7s-restore-01    Running   analytics-all-2026-07-01t12:48:49utc   11s
   ```

5. Display the details for a particular restore by running the following command:
   Use the restore name from the results in the previous step.

   ```
   oc get analyticsrestore <restore_NAME> -n <APIC_namespace> -o yaml
   ```

   The result looks like the following example,:

   ```
   apiVersion: analytics.apiconnect.ibm.com/v1beta1
     kind: AnalyticsRestore
     metadata:
       generateName: a7s-restore-
       selfLink: >-
         /apis/analytics.apiconnect.ibm.com/v1beta1/namespaces/apic/analyticsrestores/a7s-restore-01
       resourceVersion: '11267266'
       name: a7s-restore-01
       uid: e772c6c9-754a-45da-a7c7-507a56cbb94a
       creationTimestamp: '2022-07-01T12:48:50Z'
       generation: 1
       namespace: apic
     spec:
       backupID: 'analytics-all-2026-07-01t12:48:49utc'
       enableIgnoreUnavailable: false
       enableOverride: true
       indices:
         - all
     status:
       backupID: ''
       commentLeft: ''
       conditions:
     conditions:
     - lastTransitionTime: "2022-07-01T14:08:03Z"
       message: WARNING
       status: Warning
       type: Ready
     details: |
       &{NumberOfDataNodes:1
       Status:yellow
       ActivePrimaryShards:23
       ActiveShards:23
       RelocatingShards:0
       InitializingShards:0
       UnassignedShards:40
       PendingTasks:0}
     id: analytics-all-2022-07-01t14:49:15utc
   ```

   When the restore is successfully started, the **status: condition** section displays **Running**. If the restore does not start correctly, the **status: condition** section displays **Failed**.

   The restore process is successful when the storage cluster status is green, there are no unassigned shards, and there are no initializing shards. At that time the **status: condition** section displays **Complete**. If **status: Complete** is not achieved after 3 hours, the status changes to **Warning** and the details are no longer updated.

   Attention: For deployment profiles with fewer than 3 storage nodes, the restore process is never marked as **Complete**. The storage cluster status is expected to be yellow and to have more than 0 unassigned shards. In this situation, the restore process is likely to be complete when there are 0 initializing shards.

Disaster recovery

Prepare for, or recover from, a disaster affecting an API Connect deployment running on Kubernetes, OpenShift, or Cloud Pak for Integration.

The backups that you create for disaster recovery are for recovery of the API Connect subsystems in the same environment that the backups were taken, or in a different environment that has the same network configuration and API Connect form factor. If you want to move your API Connect deployment to a different environment and change the form factor or modify your API Connect endpoints, then see Migrating from v10 to v10 on a different form factor.

- **Disaster recovery on Kubernetes**
  Prepare for disaster events and recover API Connect on Kubernetes if a disaster event occurs.

- **Disaster recovery on OpenShift and Cloud Pak for Integration**
  Prepare for, or recover from, a disaster affecting an API Connect deployment running on OpenShift or Cloud Pak for Integration

Disaster recovery on Kubernetes

Prepare for disaster events and recover API Connect on Kubernetes if a disaster event occurs.

You must complete preparation steps prior to a disaster in order to recover API Connect on Kubernetes.

Note: For information about how to maintain a two data center deployment, including failover and recovery procedures, see Maintaining a two data center deployment.

- **Preparing for a disaster**
  Prepare your API Connect deployment for disaster recovery in a Kubernetes environment.
- **Recovering from a disaster**
  Recover the API Connect subsystems on Kubernetes.

Preparing for a disaster

Prepare your API Connect deployment for disaster recovery in a Kubernetes environment.

Begin preparing for disaster recovery by creating a back-up copy of the installation CR for each subsystem with the following commands:

1. `kubectl -n <namespace> get mgmt <mgmt-subsystem-name> -o yaml > mgmt-susbsystem-cr.yaml`
2. `kubectl -n <namespace> get a7s <a7s-subsystem-name> -o yaml > a7s-susbsystem-cr.yaml`
3. `kubectl -n <namespace> get ptl <ptl-subsystem-name> -o yaml > ptl-susbsystem-cr.yaml`

- **Preparing the management subsystem for disaster recovery**
  You can prepare a Management subsystem for disaster recovery from S3 or SFTP backups by taking specific steps before and after the installation of the subsystem.
- **Preparing the Developer Portal for disaster recovery**
  You can prepare a Developer Portal subsystem for disaster recovery by taking specific steps before and after the installation of the subsystem.
- **Preparing the Analytics subsystem for disaster recovery**
  Prepare the API Connect Analytics subsystem for disaster recovery in a Kubernetes environment.

Preparing the management subsystem for disaster recovery

You can prepare a Management subsystem for disaster recovery from S3 or SFTP backups by taking specific steps before and after the installation of the subsystem.

About this task

- This task must be performed before any disaster event occurs, and also prior to the installation of a replacement Management subsystem during the recovery process. Best practice is to complete these steps immediately after initial configuration of a management subsystem during your original v10 deployment.
- Any **`local`** backups are presumed to have been lost in the disaster scenario and are non-recoverable in this procedure.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

Procedure

1. Prior to initial installation, configure the Management subsystem for database backups:
   See Configuring backup settings for fresh install of the Management subsystem.
2. After installation, back up essential Kubernetes secrets that are used by the Management subsystem.
   The Kubernetes secrets are created during installation. You must save these in case a restore is needed after a disaster has occurred. At that time, you will use them in the setup of the restored Management subsystem:

   a. Obtain and save the Management database encryption secret.
      Use the following command to find the name of the secret in the status of the Management Subsystem. Replace **`<namespace>`** with the namespace used for the subsystem installation:

      ```
      kubectl get mgmt -n <namespace> -o yaml | grep encryption
      ```

      The output of this command shows the name of the Kubernetes secret storing the database encryption key, for example:

      ```
      encryptionSecret: management-enc-key
      ```

      In this case, the name of the Management database encryption secret is **`management-enc-key`**. Use the following command to back up this secret locally:

      ```
      kubectl get secret management-enc-key -n <namespace> -o yaml > management_enc_key.yaml
      ```

      The secret is stored in a file called **`management_enc_key.yaml`**, located in the present working directory.

b. Obtain and save the Management client application credential secrets.

i. Use the following command to find the names of the secrets in the status of the Management subsystem:

```
kubectl get mgmt -n <namespace> -o yaml | grep CredentialSecret
```

The output of this command shows the names of the Kubernetes Secrets used to store the various client application credentials. For example:

```
atmCredentialSecret: management-atm-cred
consumerToolkitCredentialSecret: management-ccli-cred
consumerUICredentialSecret: management-cui-cred
designerCredentialSecret: management-dsgr-cred
juhuCredentialSecret: management-juhu-cred
toolkitCredentialSecret: management-cli-cred
uiCredentialSecret: management-ui-cred
```

Here, for example, the name of the ATM Client Application Credential Secret is **management-atm-cred**.

ii. Next, back up all of the secrets locally. Use the following command for each listed Credential Secret, replacing **<secret_name>** with the secret name listed each time:

```
kubectl get secret <secret_name> -n <namespace> -o yaml > <secret_name>.yaml
```

For example, use the following command to backup the ATM Client Credential Secret:

```
kubectl get secret management-atm-cred -n <namespace> -o yaml > management-atm-cred.yaml
```

iii. After you save each of the client application Credential Secrets locally, open each of the YAML files saved for each secret in turn. Remove both the **ownerReferences** subsection and the **selfLink** property. Re-save the file.
For example, the **ownerReferences** and **selfLink** properties to be removed appear in the YAML files similar to the following:

```
ownerReferences:
  - apiVersion: management.apiconnect.ibm.com/v1beta1
    blockOwnerDeletion: true
    controller: true
    kind: ManagementCluster
    name: management
    uid: 623e6b20-7eb8-46ce-94ac-6b64cd71afc4
  selfLink: /api/v1/namespaces/default/secrets/management-atm-cred
```

c. Ensure that all of the YAML files that contain the various backed-up Secrets are stored persistently and safely.
Important: If the files are lost, you cannot restore after a disaster event.

d. Take note of the following values in the Management subsystem CR. You will need them to restore the Management subsystem.

Table 1. Management subsystem CR settings

Setting	Used with Protocol	Example value
name	S3 and SFTP	**management**
siteName	S3 and SFTP	**82b290a2**
originalUID	S3 and SFTP	**fa0f6f49-b931-4472-b84d-0922a9a92dfd** : During restore, if you do not specify **originalUID**, the operator automatically sets its value in the new CR to the value of **metadata.uid**. If the **originalUID** in the new CR does not match **originalUID** in the saved CR, the restore will fail.
.databaseBackup.protocol	S3 and SFTP only	• S3: **objstore** • SFTP: **sftp**
databaseBackup.s3provider	S3 only	**aws**
databaseBackup.host	S3 and SFTP	• SFTP **<SFTP-host-name>** • S3: **s3.amazonaws.com/eu-west-1**
databaseBackup.path	S3 and SFTP	• SFTP **<SFTP-path>** • S3: **my-bucket/mgmt**
databaseBackup.schedule	S3 and SFTP	**0 3 * * ***
databaseBackup.credentials	SFTP only	***secret-containing-SFTP-credentials***
databaseBackup.backupCerts	S3 (custom only, v10.0.2.0 or later)	**my-custom-s3-ca-cert**
databaseBackup.backups3URIStyle	S3 (custom only, v10.0.2.0 or later)	**my-s3-uri-style**

- The values **name** and **siteName** form the name of the database cluster name, such as **management-82b290a2-postgres** and is needed to synchronize the backups from your old Management subsystem to your new one.
  The **siteName** is either be a randomly generated alphanumeric ID, or a custom name that was specified by the administrator in the Management Subsystem CR helper YAML file at deploy time. Use the following command to get the **siteName**:

  ```
  kubectl get mgmt -o yaml -n <namespace> | grep siteName
  ```

- The **databaseBackup.host** and **databaseBackup.path** settings must be identical to what was configured on your old Management subsystem. This is the location of your old Management subsystem backups from where we will recover from.
- Take note of **databaseBackupschedule**. The schedule will be included during the restoration.

3. Make sure that you have a backup that can be used in case of a disaster event:
   - If scheduled backups were configured as part of Configuring backup settings for fresh install of the Management subsystem, backups to the specified cloud storage will take place as scheduled.
   - You can also perform a manual backup at any time by creating a manual backup CR. See Generating a manual backup of the management subsystem.

What to do next

You should now complete the preparation steps for the Developer Portal subsystem; see Preparing the Developer Portal for disaster recovery.

Preparing the Developer Portal for disaster recovery

You can prepare a Developer Portal subsystem for disaster recovery by taking specific steps before and after the installation of the subsystem.

About this task

- This task must be performed before any disaster event occurs, and also prior to the installation of a replacement Developer Portal subsystem for the recovery process. Best practice is to complete these steps immediately after initial configuration of a Developer Portal subsystem during your original v10 deployment.
- Any **`local`** backups are presumed to have been lost in the disaster scenario and are non-recoverable in this procedure.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. For information about preparing the Management subsystem, see Preparing the management subsystem for disaster recovery on Kubernetes. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

Procedure

1. Before the initial installation, configure the Developer Portal subsystem for database backups:
   a. Ensure that the Developer Portal backup subsystem secret is created in the cluster.
   This secret contains the credentials (username and password) for the remote storage, such as S3 or IBM Cloud Object Storage, that is used for storing the database backups.

   b. Ensure that the Developer Portal subsystem is configured for database backups.
   Add a **`databaseBackups`** subsection to the **`spec`** subsection of the Developer Portal subsystem Custom Resource (CR) YAML file. For example:

   ```
   portalBackup:
      credentials: portal-backup-secret
      host: s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard
      path: test-bucket/restore-test
      port: 443
      protocol: objstore
      schedule: ''
   ```

   See also: Backing up and restoring the Developer Portal in a Kubernetes environment
2. After installation, you must back up essential Kubernetes secrets that are used by the Developer Portal subsystem.
   The Kubernetes secrets are created during installation. You must save these secrets in case a restore is needed after a disaster. Then, you use them in the setup of the restored Developer Portal subsystem:

   a. Obtain and save the Developer Portal database encryption secret.
   Use the following command to find the name of the secret in the status of the Developer Portal Subsystem. Replace **`<namespace>`** with the namespace used for the subsystem installation:

   ```
   kubectl get portal -n <namespace> -o yaml | grep encryption
   ```

   The output of this command shows the name of the Kubernetes secret that is storing the database encryption key, for example:

   ```
   encryptionSecret: portal-enc-key
   ```

   In this case, the name of the Developer Portal database encryption secret is **`portal-enc-key`**. Use the following command to back up this secret locally:

   ```
   kubectl get secret portal-enc-key -n <namespace> -o yaml --export > portal_enc_key.yaml
   ```

   The secret is stored in a file that is called **`portal_enc_key.yaml`**, located in the present working directory.

   b. Obtain the endpoint definitions as they need to stay the same during the restore.
   Get the **`portalAdminEndpoint`** name:

   ```
   kubectl get portalcluster.portal.apiconnect.ibm.com portal -o jsonpath="{..portalAdminEndpoint.hosts[0].name}"
   ```

   Get the **`portalUIEndpoint`** name:

   ```
   kubectl get portalcluster.portal.apiconnect.ibm.com portal -o jsonpath="{..portalUIEndpoint.hosts[0].name}"
   ```

   Note: If you have more than one host specified in the **`portalUIEndpoint`** definition, you must get the name for each one.
   c. Ensure that all of these YAML files that contain the various backed-up Secrets are stored persistently and safely.
   Important: If the files are lost, you cannot restore after a disaster event.
3. Take note of the value of **`originalUID`** in the Portal subsystem CR. You will need it to restore the Portal subsystem. For example:

   ```
   spec:
     originalUID: "447ea4b3-9514-4a84-a34b-ce0b349838da"
   ```

   Note:
   - **Version 10.0.3.0 or later**: During restore, if you do not specify **`originalUID`**, the operator automatically sets its value in the new CR to the value of **`metadata.uid`**. If the **`originalUID`** in the new CR does not match **`originalUID`** in the saved CR, the restore will fail.
   - **Version 10.0.2 backups:** If planning to restore a Version 10.0.2 backup on Version 10.0.3.0 or later, make a note of the subsystem CR **`metadata.uid`**. You must use it when performing a restore on v10.0.3.0 or later, to populate the **`spec.originalUID`** value of the CR.

- **Limitation for Version 10.0.2**: If planning to restore on Version 10.0.2, performing a restore may not work if the subsystem CR name exceeds 15 characters.

4. If Scheduled backups are set as part of the `databaseBackup` subsection in the Developer Portal Subsystem CR helper YAML file (`portal_cr.yaml`), backups to the specified cloud storage take place.
   You can also complete a manual backup at any time by creating a manual backup CR.

   a. To complete a manual backup, use the Developer Portal backup CR helper YAML file (`portalbackup_cr.yaml`). For example:

   ```
   apiVersion: portal.apiconnect.ibm.com/v1beta1
   kind: PortalBackup
   metadata:
     generateName: portal-bup-
   spec:
     type: all
     crType: create
     comment: "test comment"
   ```

   Run the following command to start a manual backup to the configured cloud storage:

   ```
   kubectl create -f portalbackup_cr.yaml -n <namespace>
   ```

   b. Use the following command to list the backups:

   ```
   kubectl get portalbackup -n <namespace>
   ```

   For example:

   ```
   loginabc@localhost ibm-apiconnect]$ kubectl get pb
   NAME              ID                STATUS   TYPE   CR TYPE   AGE     COMMENT
   portal-bup-g66gv                    Ready    site   create    5m27s   y
   portal-bup-z7wgk  20201001.100021   Ready    site   record    4m24s
   ```

   With stored backups, secrets and `siteName` saved, the stack is now ready for a restore after a disaster event.

What to do next

To restore the Developer Portal on Kubernetes after a disaster, see Recovering the Developer Portal after a disaster.

Preparing the Analytics subsystem for disaster recovery

Prepare the API Connect Analytics subsystem for disaster recovery in a Kubernetes environment.

About this task

Preparing for disaster recovery involves backing up data and making a local copy of the Custom Resource (CR) that was used for installing the Analytics subsystem.

Procedure

1. Perform a backup of the Analytics database.
   Scheduling automatic backups ensures that a recovery includes recent updates. For more information on configuring backups, see Configuring backup settings for Analytics.

2. Make a copy of the AnalyticsCluster CR (custom resource).
   a. Find the Analytics cluster's name by running the following command and looking for the value in the `NAME` column:

   ```
   kubectl get AnalyticsCluster
   ```

   The response looks like the following example:

   ```
   NAME             READY   STATUS    VERSION      RECONCILED VERSION   AGE
   gj01-analytics   6/6     Running   10.0.1-eus   10.0.1.1-1402-eus    22h
   ```

   In this example the cluster's name is `gj01-analytics`.

   b. Get the YAML that describes the Analytics cluster, and save it in a file using the following command:
   Use the name of the AnalyticsCluster that you obtained in the previous step.

   ```
   kubectl get AnalyticsCluster gj01-analytics -o yaml > gj01-analytics.yaml
   ```

   c. Save the file locally.

Recovering from a disaster

Recover the API Connect subsystems on Kubernetes.

- **Recovering the management subsystem on Kubernetes**
  Recover the management subsystem on Kubernetes.
- **Recovering the Developer Portal after a disaster**
  You can restore the Developer Portal subsystem after a disaster event.
- **Recovering the Analytics subsystem after a disaster**
  Recover the API Connect analytics subsystem in a Kubernetes environment.

Recovering the management subsystem on Kubernetes

Recover the management subsystem on Kubernetes.

The recovery procedures for the management subystem are specific to the type of backup. Use the instructions for your backup type:

- **Recovering the management subsystem from S3 backups**
  You can recover the management subsystem from S3 backups after a disaster event.
- **Recovering the management subsystem from SFTP backups**
  You can recover the management subsystem from SFTP backups after a disaster event.

Recovering the management subsystem from S3 backups

You can recover the management subsystem from S3 backups after a disaster event.

Before you begin

To successfully recover the management subsystem, you must have previously completed the steps in Preparing the management subsystem for disaster recovery.
Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

About this task

To recover from a disaster event, you must create a new IBM API Connect® installation with a running IBM API Connect Operator.

Note: Limitation for backups created on Version 10.0.2

- If restoring a Version 10.0.2 backup onto a new Version 10.0.2 deployment, performing a restore may not work if the subsystem CR name exceeds 15 characters. This limitation applies only to restoring onto Version 10.0.2.
- Restoration is supported for Version 10.0.2 backups onto a Version 10.0.3.0 or later deployment when subsystem name exceeds 15 characters, as long as the correct `spec.originalUID` is specified upon restore. See Step 3.f.

Procedure

1. Determine which backup to restore from.
   - For IBM®'s Cloud Object Storage, you can check currently stored backups in the COS console. Select Buckets > Objects. See the Object Names displayed on the <*cos_name*>/backup/db panel. For example:

     ```
     20200605-105429F
     20200605-100008F
     20200605-11040F
     ```

   - For Amazon's AWS, you can check currently stored backups in the S3 console For example, under Amazon S3 > *cluster_name* > old cluster > backup > db:

     ```
     20200606-144315F
     20200606-145011F
     ```

   The format of the backup ID is `YYYYMMDD-HHMMSS<F|I>`

   Take note of the ID of the backup you wish to restore to. Each ID contains the date, time, and type of the backup stored. This will be used later in the procedure.

   a. Incremental backups are denoted with a suffix `I` on the ID, ensure each incremental backup has it's prior backup also present in storage. You can check this by examining the ID `<prior-backup-id>_<backup-id>`.
   b. Full backups are denoted with a suffix `F` on the ID.

   Note:
   During the disaster recovery process, the S3 configuration detail of the older management system is used, but the older management system must be in offline mode. The old subsystem must be offline because you cannot have two management systems simultaneously using the same s3 bucket name in the database backup configurations.

2. Make sure you know the management database cluster name.
   You can get this name from the original management subsystem CR. You made note of this name in Step 2.d in Preparing the management subsystem for disaster recovery.

   If you are not able to recover the original management subsystem CR, use the following steps to recover the Management database cluster name:

   a. Open your IBM Cloud® Object Storage or AWS S3 console and proceed to the bucket location where the old Management subsystem backups are located.
   b. Download `backup/db/<backup-id>/pg_data/postgresql.conf.gz`. Open `postgresql.conf` to view the database cluster name:
      - IBM Cloud Object Storage

        ```
        .
        .
        cluster_name = 'm1-a6287572-postgres'
        .
        .
        ```

        - `m1` - Management subsystem name

- **a6287572** - site name
- AWS S3

```
.
.
cluster_name = 'm1-c91dc0b9-postgres'
.
.
```

- **m1** - Management subsystem name
- **c91dc0b9** - site name

3. Before installing the replacement management subsystem CR:
   a. Apply the YAML file that contains the Management Database Encryption Secret into the cluster. For example, where **encryption-bin-secret.yaml** is the local YAML file containing the backup-up encryption secret:

   ```
   kubectl apply -f encryption-bin-secret.yaml -n <namespace>.
   ```

   Replace **<namespace>** with the namespace being used for the management subsystem installation.

   This command re-creates the original Management Database encryption secret on the cluster. It will be named as the original name of the secret.

   b. Add the following **encryptionSecret** subsection to the **spec** of the Management CR. For example, if **management-enc-key** is the name of the newly created secret on the cluster containing the original Management Database encryption secret from the previous step:

   ```
   encryptionSecret:
     secretName: management-enc-key
   ```

   c. For each of the saved YAML Files that contain the Management Client Application Credential Secrets, apply each file into the cluster using the following command:

   ```
   kubectl create -f <secret_name>.yaml -n <namespace>
   ```

   where **<secret_name>** is the local YAML file containing one of the backed-up Credential Secrets.

   Repeat this for each of the backed-up Credential Secrets. These are the secrets you saved n Step 2.b in Preparing the management subsystem for disaster recovery.

   These commands will re-create the original Management Client Application Credential Secrets on the cluster. Each will be named as the original name of the Secret.

   d. Add the following **customApplicationCredentials** subsection to the **spec** subsection of the Management CR:

   ```
   customApplicationCredentials:
   - name: atm-cred
     secretName: management-atm-cred
   - name: ccli-cred
     secretName: management-ccli-cred
   - name: cli-cred
     secretName: management-cli-cred
   - name: cui-cred
     secretName: management-cui-cred
   - name: dsgr-cred
     secretName: management-dsgr-cred
   - name: juhu-cred
     secretName: management-juhu-cred
   - name: ui-cred
     secretName: management-ui-cred
   ```

   For each named credential above, the **secretName** is given as the corresponding name of the newly created secret from Step 3.c.

   e. Add the **siteName** property to the **spec** of the Management CR.
   For example, if **a2a5e6e2** is the original **siteName** that was noted after the installation of the original Management Subsystem:

   ```
   siteName: a2a5e6e2
   ```

   f. **Version 10.0.3.0 or later**: Add the **originalUID:** property to the **spec** of the Management CR.
   When recreating a system, to restore a backup into it, you must specify the same **spec.originalUID** in the CR as was present in the system that was backed up. If the **spec.originalUID** in the new CR for recreating the system does not match the **spec.originalUID** that was present in the system that was backed up, the restore will fail.

   ```
   spec:
     originalUID: "fa0f6f49-b931-4472-b84d-0922a9a92dfd"
   ```

   Note:
   - For Version 10.0.3.0 or later, if you do not specify **spec.originalUID** in the new CR, the operator automatically sets the Management CR value of **spec.originalUID** to match the new CR value **metadata.uid**. In this case, the restore will fail because the **spec.originalUID** in the saved (backed-up) CR does not match **spec.originalUID** in the new CR.
   - The originalUID is only essential when the subsystem CR name exceeds 15 characters in length, or 10 characters limit for the API Connect Cluster CR. Recommended practice is that all backups should include the originalUID for Management.
   - See also Step 2.d in Preparing the management subsystem for disaster recovery.

   g. Verify that the name of the management subsystem in the CR matches with the old management subsystem name, as described in Step 2.d in Preparing the management subsystem for disaster recovery.
4. Install the Management subsystem CR with the values obtained in Step 2.d in Preparing the management subsystem for disaster recovery.
   Important: The hostnames of the endpoints cannot be changed, and must remain the same in the Management CR YAML file used for installation now as they were for the original installation.
   To review installation of the management subsystem, see Installing the Management subsystem cluster.

   Once the Management subsystem is installed you may notice **backup** job pods and **stanza-create** job pods in **Error** state.

```
m1-82b290a2-postgres-stanza-create-4zcgz                  0/1     Error       0          35m
m1-82b290a2-postgres-full-sch-backup-2g9hm                0/1     Error       0          20m
```

This is expected behavior.

- The `stanza-create` job normally expects buckets or subdirectories within buckets to be empty. However, since we have configured the Management subsystem with a pre-populated bucket (ie. where our backups exist), the job will go into `Error` state.
- Any scheduled or manual backups will go into `Error` state. While we have configured the Management subsystem with our already populated S3 bucket, the new database isn't yet configured to write backups into remote storage.

Important:
For S3, the recovery remains in an intermediate state until the restore is complete, and Postgres wal files might cause serious disk issues. To avoid this possibility, continue immediately with the next step.

Note that if you delay completion of the restore:

- Health check might fail. In this case, you can still proceed to the next step and perform a restore.
- Postgres wal files might cause problems by consuming all disk space. In this case, you must either:
  - Re-install the system, prepare again for disaster recovery, and perform the restore.
  - Or increase disk space so that the system returns to a stable state, and then proceed with the restore.

5. Get a list of available backups and confirm that the backup ID noted in Step 1 is in the backup list.
   The API Connect Operator automatically reads backups from configured remote storage and populates the list of available backups we can restore to.

```
$ kubectl get mgmtb
NAME                 STATUS     ID                CLUSTER                  SUBSYSTEM   TYPE   CR TYPE   AGE
mgmt-backup-4z87f    Complete   20200606-145011F  m1-82b290a2-postgres     m1          full   record    11m
mgmt-backup-6bms2    Complete   20200606-144315F  m1-82b290a2-postgres     m1          full   record    11m
```

6. Update the Management subsystem CR `databaseBackup.schedule` to what was noted in Step 2.d in Preparing the management subsystem for disaster recovery.
7. Perform a Management Restore using the name of the backup that has the ID you want to restore. For example, as shown in Step 5, for ID `20200606-145011F` the backup name is `mgmt-backup-4z87f`.
   For more info on restoring the management subsystem, see Restoring the management subsystem.
8. Use the following command to check the status of the restore:

   `kubectl get mgmtr -n <namespace>`

   Once the Management Restore has completed and the database is running again, the data of the old Management subsystem will be successfully restored onto the new Management subsystem. Note:

   - Manual and scheduled backups should perform as normal once again
   - `stanza-create` jobs will continue to report `Error` state as stated in Step 4.
9. Verify that the Cloud Manager UI can now be logged-in to as before, and that Provider Orgs exist as before.
   The restore from the disaster event is now complete.

What to do next

You should now complete the recovery steps for the Developer Portal subsystem on Kubernetes, see Recovering the Developer Portal after a disaster.

Recovering the management subsystem from SFTP backups

You can recover the management subsystem from SFTP backups after a disaster event.

Before you begin

To successfully recover the management subsystem, you must have previously completed the steps in Preparing the management subsystem for disaster recovery.
Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

About this task

To recover from a disaster event, you must create a new IBM API Connect installation with a running IBM API Connect Operator.

Note: Limitation for backups created on Version 10.0.2

- If restoring a Version 10.0.2 backup onto a new Version 10.0.2 deployment, performing a restore may not work if the subsystem CR name exceeds 15 characters. This limitation applies only to restoring onto Version 10.0.2.
- Restoration is supported for Version 10.0.2 backups onto a Version 10.0.3.0 or later deployment when subsystem name exceeds 15 characters, as long as the correct `spec.originalUID` is specified upon restore. See Step 3.f.

Procedure

1. Determine which backup to restore from.
   View the SFTP backups available on your remote storage site:

```
-rw-r--r--    1 root     root     13092333 Aug 26 08:56 20200826-154646F.tgz
-rw-r--r--    1 root     root     18703758 Aug 26 09:10 20200826-160010F.tgz
```

```
-rw-r--r--    1 root     root     24318561 Aug 26 09:21 20200826-161301F.tgz
```

Take note of the backup ID of the backup you wish to restore to. Each filename contains the date, time, and type of the backup stored. This will be used later in the procedure.

The format of the backup ID is **YYYYMMDD-HHMMSS<F|I>**. For example, if we want to use the Aug 26, 09:21 backup, it's backup ID will be **20200826-161301F**

a. Incremental backups are denoted with a suffix **I** on the ID, ensure each incremental backup has it's prior backup also present in storage. You can check this by examining the ID **<prior-backup-id>_<backup-id>**.
b. Full backups are denoted with a suffix **F** on the ID.

2. Make sure you know the management database cluster name.
You can get this name from the original management subsystem CR. You made note of this name in Step 2.d in Preparing the management subsystem for disaster recovery.

If you are not able to recover the original management subsystem CR, you can also recover the Management database cluster name and siteName by examining the SFTP backup tar:

a. Download or move the SFTP backup tar file and decompress (untar) it.
b. Open **<management-subsystem-name>-<siteName>-postgres-backrest-shared-repo/backup/db/<backup-id>/pg_data/postgresql.conf.gz** which contains the management subsystem name and siteName. For example:

```
# Do not edit this file manually!
# It will be overwritten by Patroni!
include 'postgresql.base.conf'

archive_command = 'source /opt/cpm/bin/pgbackrest/pgbackrest-set-env.sh && pgbackrest archive-push "%p"'
archive_mode = 'True'
archive_timeout = '60'
autovacuum_vacuum_cost_limit = '1000'
autovacuum_vacuum_scale_factor = '0.01'
cluster_name = 'm1-f785a3e3-postgres'
```

In this example:

- **cluster_name** has both the management subsystem name and siteName
- **m1** - Management subsystem name
- **f785a3e3** - site name

3. Before installing the replacement management subsystem CR:
a. Apply the YAML file that contains the Management Database Encryption Secret into the cluster. For example, where **encryption-bin-secret.yaml** is the local YAML file containing the backup-up encryption secret:

```
kubectl create -f encryption-bin-secret.yaml -n <namespace>.
```

Replace **<*namespace*>** with the namespace being used for the management subsystem installation.

This command re-creates the original Management Database encryption secret on the cluster. It will be named as the original name of the secret.

b. Add the following **encryptionSecret** subsection to the **spec** of the Management CR. For example, if **management-enc-key** is the name of the newly created secret on the cluster containing the original Management Database encryption secret from the previous step:

```
encryptionSecret:
  secretName: management-enc-key
```

c. For each of the saved YAML Files that contain the Management Client Application Credential Secrets, apply each file into the cluster using the following command:

```
kubectl create -f <secret_name>.yaml -n <namespace>
```

where **<secret_name>** is the local YAML file containing one of the backed-up Credential Secrets.

Repeat this for each of the backed-up Credential Secrets. These are the secrets you saved in Step 2.b in Preparing the management subsystem for disaster recovery.

These commands will re-create the original Management Client Application Credential Secrets on the cluster. Each will be named as the original name of the Secret.

d. Add the following **customApplicationCredentials** subsection to the **spec** subsection of the Management CR:

```
customApplicationCredentials:
- name: atm-cred
  secretName: management-atm-cred
- name: ccli-cred
  secretName: management-ccli-cred
- name: cli-cred
  secretName: management-cli-cred
- name: cui-cred
  secretName: management-cui-cred
- name: dsgr-cred
  secretName: management-dsgr-cred
- name: juhu-cred
  secretName: management-juhu-cred
- name: ui-cred
  secretName: management-ui-cred
```

For each named credential above, the **secretName** is given as the corresponding name of the newly created secret from Step 3.c.

e. Add the **siteName** property to the **spec** of the Management CR.
For example, if **a2a5e6e2** is the original **siteName** that was noted after the installation of the original Management Subsystem:

```
siteName: a2a5e6e2
```

f. **Version 10.0.3.0 or later**: Add the **originalUID:** property to the **spec** of the Management CR.

When recreating a system, to restore a backup into it, you must specify the same **spec.originalUID** in the CR as was present in the system that was backed up. If the **spec.originalUID** in the new CR for recreating the system does not match the **spec.originalUID** that was present in the system that was backed up, the restore will fail.

```
spec:
  originalUID: "fa0f6f49-b931-4472-b84d-0922a9a92dfd"
```

Note:

- For Version 10.0.3.0 or later, if you do not specify **spec.originalUID** in the new CR, the operator automatically sets the Management CR value of **spec.originalUID** to match the new CR value **metadata.uid**. In this case, the restore will fail because the **spec.originalUID** in the saved (backed-up) CR does not match **spec.originalUID** in the new CR.
- The originalUID is only essential when the subsystem CR name exceeds 15 characters in length, or 10 characters limit for the API Connect Cluster CR. Recommended practice is that all backups should include the originalUID for Management.
- See also Step 2.d in Preparing the management subsystem for disaster recovery.

g. Verify that the name of the management subsystem in the CR matches with the old management subsystem name, as described in Step 2.d in Preparing the management subsystem for disaster recovery.

4. Install the Management subsystem CR with the values obtained in Step 2.d in Preparing the management subsystem for disaster recovery..
   Important: The hostnames of the endpoints cannot be changed, and must remain the same in the Management CR YAML file used for installation now as they were for the original installation.
   To review installation of the management subsystem, see Installing the Management subsystem cluster.

5. Get a list of available backups and confirm that the backup ID noted in Step 1 is in the backup list.
   The API Connect Operator automatically reads backups from configured remote storage and populates the list of available backups we can restore to.

```
$ kubectl get mgmtb
NAME                STATUS     ID                 CLUSTER                 SUBSYSTEM   TYPE   CR TYPE   AGE
mgmt-backup-4z87f   Complete   20200606-145011F   m1-82b290a2-postgres    m1          full   record    11m
mgmt-backup-6bms2   Complete   20200606-144315F   m1-82b290a2-postgres    m1          full   record    11m
```

6. Perform a Management Restore using the name of the backup that has the ID you want to restore. For example, as shown in Step 5, for ID **20200606-145011F** the backup name is **mgmt-backup-4z87f**.
   For more info on restoring the management subsystem, see Restoring the management subsystem.

7. Use the following command to check the status of the restore:

   ```
   kubectl get mgmtr -n <namespace>
   ```

   Once the Management Restore has completed and the database is running again, the data of the old Management subsystem will be successfully restored onto the new Management subsystem. Manual and scheduled backups should perform as normal once again.

What to do next

You should now complete the recovery steps for the Developer Portal subsystem on Kubernetes, see Recovering the Developer Portal after a disaster.

Recovering the Developer Portal after a disaster

You can restore the Developer Portal subsystem after a disaster event.

Before you begin

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

About this task

To recover from a disaster event, you must create a new IBM API Connect installation with a running IBM API Connect Operator.

Note: Limitation for backups created on Version 10.0.2:

- If restoring a Version 10.0.2 backup onto a new Version 10.0.2 deployment, performing a restore may not work if the subsystem CR name exceeds 15 characters. This limitation applies only to restoring onto Version 10.0.2.
- Restoration is supported for Version 10.0.2 backups onto a Version 10.0.3.0 or later deployment when subsystem name exceeds 15 characters, as long as the correct **spec.originalUID** is specified upon restore. See Step 1.f.

Procedure

1. To prepare for the restoration, you must complete some steps before you reinstall the Developer Portal subsystem.
   Warning:
   - Ensure that the hostnames of the endpoints remain the same in the Developer Portal subsystem that is used for installation now as they were for the original installation. The hostnames for the endpoints cannot be changed.

   a. Ensure that the Developer Portal backup subsystem secret is created in the cluster.
   This secret contains the credentials (username and password) for the remote storage, such as S3 or IBM Cloud Object Storage, that is used for storing the database backups. This secret must be the same secret as used for the original installation.

   b. Ensure that the Developer Portal subsystem is configured for database backups.

Configuration is done by adding a **databaseBackups** subsection to the **spec** subsection of the Developer Portal subsystem Custom Resource (CR) YAML file, **portal_cr.yaml**. The file is located in the **helper_files** archive that was extracted as part of the preparation for installation. See Backing up and restoring the Developer Portal in a Kubernetes environment.

For example:

```
portalBackup:
      credentials: portal-backup-secret
      host: <backup-host>
      path: <backup-path>
      port: 22
      protocol: sftp
      schedule: ''
```

The **host** and **path** must be the same as was specified for the original installation so that the IBM API Connect Operator can access the saved Developer Portal database backups.

c. Apply the saved YAML file that contains the Developer Portal database encryption secret into the cluster.
Use the following command, where **portal_enc_key.yaml** is the local YAML file that contains the backup encryption secret. Replace ***<namespace>*** with the namespace that is being used for subsystem installation:

```
kubectl apply -f portal_enc_key.yaml -n <namespace>
```

This command re-creates the original Developer Portal database encryption secret on the cluster, which is named as the original name of the secret.

d. Add the **encryptionSecret** to the Developer Portal subsystem Custom Resource (CR) YAML file, **portal_cr.yaml**.
For example, add the following **encryptionSecret** subsection to the **spec** section. In this example, **portal-enc-key** is the name of the new created secret on the cluster that contains the original Developer Portal Database Encryption Secret. The name of the secret that is created in Step 1.a is used here:

```
encryptionSecret:
  secretName: portal-enc-key
```

e. Ensure the name **spec.metadata.name** of the new Developer Portal cluster CR is the same as the previous Developer Portal CR.
f. **Version 10.0.3.0 or later**: Add the **originalUID:** property to the **spec** of the Portal CR.
When recreating a system, to restore a backup into it, you must specify the same **spec.originalUID** in the CR as was present in the system that was backed up. If the **spec.originalUID** in the new CR for recreating the system does not match the **spec.originalUID** that was present in the system that was backed up, the restore will fail.

```
spec:
  originalUID: "447ea4b3-9514-4a84-a34b-ce0b349838da"
```

Note:
- For Version 10.0.3.0 or later, if you do not specify **spec.originalUID** in the new CR, the operator automatically sets the Portal CR value of **spec.originalUID** to match the new CR value **metadata.uid**. In this case, the restore will fail because the **spec.originalUID** in the saved (backed-up) CR does not match **spec.originalUID** in the new CR.
- The originalUID is only essential when the subsystem CR name exceeds 15 characters in length, or 10 characters limit for the API Connect Cluster CR. Recommended practice is that all backups should include the originalUID for Portal.
- See also Preparing the Developer Portal for disaster recovery.

g. Ensure that the endpoint definitions are the same as the previous Developer Portal CR.

2. Apply the Developer Portal subsystem custom resource (CR) YAML file (**portal_cr.yaml**) to the cluster as documented as part of the original installation instructions.
You can do this step now because the secrets are re-created, and additions made to **portal_cr.yaml**.

Note: Wait for the Developer Portal subsystem to become fully up and running before proceeding.

3. Use the following command to check that the Developer Portal database backups that are stored in the configured cloud storage are now present as Developer Portal backup CRs:
Note: You might wait for the cron job at the 10th minute ***/10 * * * *** to re-create your Developer Portal backup CRs.

```
kubectl get portalbackups -n <namespace>
```

For example:

```
loginabc@localhost ibm-apiconnect]$ kubectl get pb
NAME              ID                STATUS   TYPE   CR TYPE   AGE     COMMENT
portal-bup-g66gv                    Ready    site   create    5m27s   y
portal-bup-z7wgk  20201001.100021   Ready    site   record    4m24s
```

The **AGE** of each is new.

4. Perform a Developer Portal restore. See Backing up and restoring the Developer Portal in a Kubernetes environment
For a disaster recovery scenario, it is advised that you restore all sites and systems. An example restore CR:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
  generateName: portal-restore-
spec:
  type: all
  dryRun: false
  timestamp: now
  priorityList:
    - myportal-critical-site.com
    - myportal-important.com
```

5. When the Developer Portal restore CR is marked as **Ready**, the Disaster recovery is complete for the Developer Portal.

```
kubectl get portalrestore
```

6. Verify that you can access the restored Developer Portal sites and that you are able to log in to each one.
   The restore from the disaster event is now complete.

Recovering the Analytics subsystem after a disaster

Recover the API Connect analytics subsystem in a Kubernetes environment.

About this task

Recovering the Analytics subsystem involves deploying a new installation of the Analytics subsystem, updating it with a saved copy of the Custom Resource (CR) that was originally used for installing Analytics, and then restoring the Analytics database from a back-up copy.

Procedure

1. Deploy the Analytics subsystem by applying the analytics_cr.yaml CR to the cluster as explained in Installing analytics.
2. Restore your local copy of the original AnalyticsCluster CR by running the following command:

   ```
   kubectl  apply -f gj01-analytics.yaml
   ```

   Replace ***gj01-analytics.yaml*** with the file name that you used for your saved CR.

3. Restore the Analytics data from a back up, as explained in Restoring the Analytics database.

Disaster recovery on OpenShift and Cloud Pak for Integration

Prepare for, or recover from, a disaster affecting an API Connect deployment running on OpenShift or Cloud Pak for Integration

You must complete preparation steps prior to a disaster in order to recover API Connect.

- **Preparing for disaster recovery on OpenShift**
  Back up data and essential deployment information from each API Connect subsystem so that you can use it to recover your deployment after a disaster.
- **Recovering from a disaster on OpenShift**
  Install and configure API Connect, then restore backed up data to recover the deployment after a disaster.
- **Preparing for disaster recovery on Cloud Pak for Integration**
  Back up data and essential deployment information from each API Connect subsystem so that you can use it to recover your deployment after a disaster.
- **Recovering from a disaster on Cloud Pak for Integration**
  Install and configure API Connect, then restore the backed up data to recover the deployment after a disaster.

Preparing for disaster recovery on OpenShift

Back up data and essential deployment information from each API Connect subsystem so that you can use it to recover your deployment after a disaster.

About this task

To prepare your deployment for disaster, complete this task to copy the API Connect deployment settings, and then proceed to the following tasks to backup additional information for each subsystem.

Procedure

Complete the following steps to copy the API Connect deployment settings for use when you recover the deployment.

1. Find the API Connect cluster's name by running the following command and looking for the value in the NAME column:

   ```
   oc get APIConnectCluster
   ```

   The response looks like the following example:

   ```
   NAME           READY   STATUS    VERSION    RECONCILED VERSION   AGE
   apic-cluster   7/7     Running   10.0.3   10.0.3-149         6d4h
   ```

2. Create a back-up copy of the installation CR for each subsystem, as well as the top-level APIConnectCluster CR, with the following commands:

   a. `oc -n <APIC_namespace> get apiconnectcluster apic-cluster-name -o yaml > apic-cluster-cr.yaml`

   b. `oc -n <APIC_namespace>> get mgmt apic-cluster-name-mgmt -o yaml > mgmt-susbsystem-cr.yaml`

   c. `oc -n <APIC_namespace> get a7s apic-cluster-name-a7s -o yaml > a7s-susbsystem-cr.yaml`

   d. `oc -n <APIC_namespace> get ptl apic-cluster-name-ptl -o yaml > ptl-susbsystem-cr.yaml`

What to do next

Proceed to Preparing the Management subsystem for disaster recovery on OpenShift.

1. Preparing the Management subsystem for disaster recovery on OpenShift
   Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.
2. Preparing the Portal subsystem for disaster recovery on OpenShift
   Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.
3. Preparing the Analytics subsystem for disaster recovery on OpenShift
   Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.

Preparing the Management subsystem for disaster recovery on OpenShift

Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.

About this task

Make sure to store all backups and deployment information to a secure location where you can access it after a disaster. You cannot recover a deployment without the information that you collect during this task.

Procedure

1. Save a copy of the Management database encryption secret.
   a. Run the following command to get the name of the encryption secret:

      ```
      oc get mgmt -n <APIC-namespace> -o yaml | grep encryption
      ```

      The output of this command shows the name of the secret that is storing the database encryption key, for example:

      ```
      encryptionSecret: management-enc-key
      ```

   b. Run the following command to save a local copy of the secret as a YAML file:

      ```
      oc get secret management-enc-key -n <APIC-namespace> -o yaml > management-enc-key.yaml
      ```

2. Save a copy of the Management client application credential secrets.
   Save the credential secrets (the **client_id** and **client_secret**) for client applications provided by the Management subsystem.

   a. Run the following command to get the names of the secrets:

      ```
      oc get mgmt -n <APIC-namespace> -o yaml | grep CredentialSecret
      ```

      The output of this command shows the names of the secrets used to store each of the client application credentials. For example:

      ```
      atmCredentialSecret: production-mgmt-atm-cred
      consumerToolkitCredentialSecret: production-mgmt-ccli-cred
      consumerUICredentialSecret: production-mgmt-cui-cred
      designerCredentialSecret: production-mgmt-dsgr-cred
      governanceCredentialSecret: production-mgmt-governance-cred
      juhuCredentialSecret: production-mgmt-juhu-cred
      toolkitCredentialSecret: production-mgmt-cli-cred
      uiCredentialSecret: production-mgmt-ui-cred
      ```

   b. Run the following command to save a local copy of each secret as a YAML file, replacing **<secret_name>** with the name of the application credential secret:

      ```
      oc get secret <secret_name> -n <APIC-namespace> -o yaml > <secret_name>.yaml
      ```

   c. Edit each of the saved YAML files and remove both the **ownerReferences** subsection and the **selfLink** property, and then save the updated file.
      The information to remove looks like the following example:

      ```
      ownerReferences:
        - apiVersion: management.apiconnect.ibm.com/v1beta1
          blockOwnerDeletion: true
          controller: true
          kind: ManagementCluster
          name: management
          uid: 623e6b20-7eb8-46ce-94ac-6b64cd71afc4
      selfLink: /api/v1/namespaces/default/secrets/management-atm-cred
      ```

3. Run a backup of the Management subsystem database.
   a. Configure the Management subsystem for backups.
   b. Perform a backup of the Management subsystem.
   c. Get the name and ID of the newest Management backup and save them for reference during a recovery.
      Run the following command to list the Management backups:

      ```
      oc get mgmtb -n <APIC-namespace>
      ```

      The response looks like the following example; the newest backup is the one with the smallest **AGE**:

      ```
      NAME                  STATUS   ID                 CLUSTER      TYPE   CR TYPE   AGE
      management-3aa3bebf   Ready    20200929-152150F   management   full   record    10h
      management-3c4ca8df   Ready    20200929-115520F   management   full   record    20h
      management-5tbxj      Ready    20200929-224349F   management   full   create    17h
      management-f10af337   Ready    20200925-133703F   management   full   record    5d2h
      management-jtlcd      Ready    20200929-224349F   management   full   create    25h
      management-zxjtz      Ready    20200929-224349F   management   full   create    28h
      ```

4. Save a copy of the username and password for a Cloud Manager administrator.

When you recover the deployment, you will need to log in to the Cloud Manager as an administrator using the Cloud Manager User Registry. Any user with Administrator permission defined in the Cloud Manager User Registry can be used. Before backing up the information, verify that you an log in to Cloud Manager using that account.

If you want to backup the secret that contains the administrator password that was created by the API Connect operator during the original deployment, run the following command to get the secret:

```
oc --kubeconfig kubeconfig -n <APIC_namespace> get secret <instance-name>-mgmt-admin-pass -o jsonpath="{.data.password}" |
base64 -d
```

It is possible that the password was changed at some point and the secret is now out-of-date. Be sure to verify that you can log in to Cloud Manager with the password contained in the secret. If the password is not valid, then make sure you have another Cloud Manager administrator account in the Cloud Manager User Registry, and back up that username and password instead.

5. Copy all of the information that you saved to a secure location.

What to do next

Immediately proceed to Preparing the Portal subsystem for disaster recovery on OpenShift.

Important: Backups of the Management and Portal subsystems must be performed in sequence, and close together in time, to ensure that the Portal sites are consistent with Management database.
Next topic: Preparing the Portal subsystem for disaster recovery on OpenShift

Preparing the Portal subsystem for disaster recovery on OpenShift

Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.

Before you begin

Perform a backup of the Management subsystem.

Important: Backups of the Management and Portal subsystems must be performed in sequence, and close together in time, to ensure that the Portal sites are consistent with Management database.

About this task

Make sure to store all backups and deployment information to a secure location where you can access it after a disaster. You cannot recover a deployment without the information that you collect during this task.

Procedure

1. Save the ID of the Portal subsystem.
   If your original CR `name` was 10 characters or longer, you must add the `originalUID` (Version 10.0.3 or later) or `metadata.uid` (Version 10.0.2 or earlier) value from the original Portal subsystem into the appropriate section of the installation CR during the recovery process.

   When you deployed API Connect using the top-level APIConnectCluster CR, the deployment settings were added to subsystem-specific CRs that are managed by the top-level CR. When you recover the Portal subsystem after a disaster, you can locate the subsystem's ID in the saved copy of the Portal subsystem CR.

   a. Find the API Connect cluster's name by running the following command and looking for the value in the NAME column:

   ```
   oc get APIConnectCluster
   ```

   The response looks like the following example:

   ```
   NAME            READY   STATUS    VERSION    RECONCILED VERSION   AGE
   apic-cluster-name   7/7     Running   10.0.3   10.0.3-149         6d4h
   ```

   b. Get the YAML that describes the Portal subsystem CR and save it in a file using the following command:

   ```
   oc get ptl apic-cluster-name-ptl -o yaml >  apic-cluster-name-ptl.yaml
   ```

2. Back up the Developer Portal database encryption secret.
   a. Run the following command to get the name of the encryption secret:

   ```
   oc get ptl -n <APIC-namespace> -o yaml | grep encryption
   ```

   The output of this command shows the name of the secret that is storing the database encryption key, for example:

   ```
   encryptionSecret: portal-enc-key
   ```

   b. Run the following command to save a local copy of the secret as a YAML file:

   ```
   oc get secret portal-enc-key -n <APIC-namespace> -o yaml > portal-enc-key.yaml
   ```

3. Back up the Portal endpoint definitions.
   Save the information to a file because you must use the same names in the recovered deployment.

   a. Get the `portalAdminEndpoint` definition by running the following command:

   ```
   oc get route | grep portal-director | awk '{print $2}'
   ```

The response looks like the following example:

```
dr-ptl-portal-director-apic.apps.vlxocp-1556.cp.fyre.ibm.com
```

b. Get the `portalUIEndpoint` definition by running the following command:

```
oc get route | grep portal-web | awk '{print $2}'
```

The response looks like the following example:

```
dr-ptl-portal-web-apic.apps.vlxocp-1556.cp.fyre.ibm.com
```

4. Back up the Portal subsystem database.
   a. Configure the Portal subsystem for backups.
   b. Perform a backup of the Portal subsystem.
   Note: Make sure that you set the property `type: all` when you backup the Portal database, to ensure that you capture data for the Portal subsystem and all Portal sites.
   c. Get the name of the newest Portal backup and save it for reference during a recovery.
   Run the following command to list the Portal backups:

```
oc get portalbackup -n <APIC-namespace>
```

The response looks like the following example; the newest backup is the one with the smallest `AGE`:

```
NAME                      ID    TASK ID            STATUS   TYPE   CR TYPE   CLUSTER          AGE   COMMENT
portal-manual-bup-9lghk   n/a   p5rkbbpyejrbqjab   Ready    all    create    production-ptl   15h   test comment
portal-manual-bup-jqbdm   n/a   cn8frkey1vgbls2u   Ready    all    create    production-ptl   15h   test comment
```

5. Copy all of the information that you saved to a secure location.

What to do next

Proceed to Preparing the Analytics subsystem for disaster recovery on OpenShift.

Previous topic: Preparing the Management subsystem for disaster recovery on OpenShift
Next topic: Preparing the Analytics subsystem for disaster recovery on OpenShift

Preparing the Analytics subsystem for disaster recovery on OpenShift

Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.

About this task

Make sure to store all backups and deployment information to a secure location where you can access it after a disaster. You cannot recover a deployment without the information that you collect during this task.

Procedure

1. Backup the Analytics subsystem database.
   a. Configure the Analytics subsystem for backups.
   b. Perform a backup of the Analytics subsystem.
   Note: Be sure to specify `indices: all` when you backup the Analytics database. Backing up a full set of indices ensures that your complete Analytics configuration, event data, and custom UI configuration (such as custom dashboards) can be restored.
   c. Get the name of the newest Analytics backup and save it for reference during a recovery.
   Run the following command to list the Analytics backups:

```
oc get analyticsbackup -n <APIC-namespace>
```

The response looks like the following example; the newest backup is the one with the smallest `AGE`:

```
NAME                  STATUS ID                                      CR TYPE   INDICES                AGE   COMMENT
a7s-bup-266p8         Ready                                          create    [all]                  20h   y
a7s-bup-pffdh         Ready                                          create    [all]                  34h   y
analytics-bup-kxwq5   Ready  analytics-all-2020-09-07t03:49:15utc    record    [ui apievents config]  34h
analytics-bup-p29z8   Ready  analytics-all-2020-09-07t18:04:03utc    record    [ui apievents config]  20h
```

2. Copy all of the information that you saved to a secure location.

Previous topic: Preparing the Portal subsystem for disaster recovery on OpenShift

Recovering from a disaster on OpenShift

Install and configure API Connect, then restore backed up data to recover the deployment after a disaster.

Before you begin

To successfully recover API Connect from a disaster, you must have previously completed the steps to prepare the Management, Portal, and Analytics subsystems for disaster recovery. Make sure that you can access the backups and deployment information because you cannot recover your deployment without it.

Attention: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal.

About this task

To recover from a disaster event, recreate your API Connect Cluster CR and add recovery details as explained in the following procedure. Use the file containing the original CR (which you saved during the preparation task) as a reference.

Important: Do not install API Connect until you have configured the CR as explained in this task.

Procedure

1. Make a local copy of the apiconnectcluster_cr.yaml template custom resource so that you can customize it for your deployment.
   Template files are stored in helper_files.zip. For both OpenShift and CP4I, you can configure settings directly in the YAML file as explained in this task. In CP4I, you will then copy the YAML code and paste it in using the YAML tab in IBM Cloud Pak Platform UI.

2. Configure backup and restore settings for each subsystem.
   Remember to create the backup secret for each subsystem as well, using the same name that you used in the original deployment (you can see the name in the **credentials** setting of each subsystem's backup section). The backup and restore settings, including the secrets, must exactly match the settings that you created in the original deployment. See the following topics for instructions on configuring backup and restore settings:

   - Configuring backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration
   - Configuring backups for Developer Portal on OpenShift and Cloud Pak for Integration
   - Configuring backup settings for Analytics on OpenShift and Cloud Pak for Integration

   Note:
   During the disaster recovery process, the S3 configuration detail of the older management system is used, but the older management system must be in offline mode. The old subsystem must be offline because you cannot have two management systems simultaneously using the same s3 bucket name in the database backup configurations.

3. Apply the Management and Portal encryption secrets to the cluster.
   a. Apply the YAML file that contains the Management database encryption secret into the cluster.
      Run the following command, using the filename of the encryption secret that you saved when you prepared the Management subsystem for disaster recovery:

      ```
      oc -n <APIC_namespace> apply -f mgmt-enc-key.yaml
      ```

   b. Apply the YAML file that contains the Portal encryption secret into the cluster.
      Run the following command, using the filename of the encryption secret that you saved when you prepared the Portal subsystem for disaster recovery:

      ```
      oc -n <APIC_namespace> apply -f portal-enc-key.yaml
      ```

4. Important: Make sure that your new version of the API Connect Cluster installation CR uses the same value for the **name** setting as the original CR.
   Edit the YAML file that you copied from the template in the helper_files.zip. In the following steps, you will configure additional deployment and recovery settings in the new API Connect Cluster installation CR before you install API Connect.

5. Add the Management and Portal encryption secrets to the API Connect Cluster CR.
   Add each secret to the appropriate **spec.*subsystem*** section of the CR, as shown in the following example:

   ```
   spec:
     management:
       encryptionSecret:
         secretName: mgmt-enc-key
     portal:
       encryptionSecret:
         secretName: portal-enc-key
   ```

6. Apply each of the Management client application credential secrets to the cluster.
   Run the following command to apply each secret, using the filename of each client application credential secret that you saved when you prepared the Management subsystem for disaster recovery:

   ```
   oc -n <APIC_namespace> apply -f <secretName>.yaml
   ```

   For example, a deployment might use the following names for the secrets:

   ```
   atmCredentialSecret: management-atm-cred
   consumerToolkitCredentialSecret: management-ccli-cred
   consumerUICredentialSecret: management-cui-cred
   designerCredentialSecret: management-dsgr-cred
   governanceCredentialSecret: management-governance-cred
   juhuCredentialSecret: management-juhu-cred
   toolkitCredentialSecret: management-cli-cred
   uiCredentialSecret: management-ui-cred
   ```

7. Add the credential secrets to the **spec.management** section of API Connect Cluster CR.
   For example:

   ```
   spec:
     management:
       customApplicationCredentials:
       - name: atm-cred
         secretName: management-atm-cred
       - name: governance-cred
         secretName: management-governance-cred
   ```

```
    - name: ccli-cred
      secretName: management-ccli-cred
    - name: cui-cred
      secretName: management-cui-cred
    - name: dsgr-cred
      secretName: management-dsgr-cred
    - name: juhu-cred
      secretName: management-juhu-cred
    - name: cli-cred
      secretName: management-cli-cred
    - name: ui-cred
      secretName: management-ui-cred
```

8. Add the **siteName** property to the **spec.management** and **spec.portal** sections of the API Connect Cluster CR.
   For example, if the **a2a5e6e2** is the original **siteName** of the Management subsystem, and **890772e3** is the original **siteName** of the Developer Portal subsystem, the CR looks like the following example:

```
spec:
  management:
    siteName: "a2a5e6e2"
  portal:
    siteName: "890772e3"
```

9. If your original CR **name** was 10 characters or longer, you must add the **originalUID** or **metadata.uid** value from the original Management and Portal subsystems into the appropriate sections of the installation CR.
   Important: If your original CR name was 10 characters or longer and you do not add this value, the deployments and routes that are generated during installation will include a different UID, which will cause the recovery process to fail.
   The IDs were created with the original deployment of the Management and Portal subsystems, and the recovered subsystems must continue to use the same IDs. You can locate the ID in the Management (*apic-cluster-name*-mgt.yaml) or Portal (*apic-cluster-name*-ptl.yaml) CR that you saved while preparing for disaster recovery. (Do not use the **metadata.uid** setting from the API Connect Cluster CR).

   The CR setting that contains the ID depends on the version of API Connect that you are recovering:

   - Version 10.0.3 or later: **spec.originalUID**
   - Version 10.0.2 or earlier: **metadata.uid**

   Locate each of the original settings in the appropriate subsystem CR, and copy them to corresponding sections of the new API Connect Cluster CR using the same key and value.

   For example, if you originally deployed version 10.0.2, the setting name was **uid**. If you are deploying Version 10.0.3 as part of disaster recover, copy the original value and use it for the **originalUID** setting in the new CR. For example, in 10.0.3:

```
spec:
  management:
    originalUID: "fa0f6f49-b931-4472-b84d-0922a9a92dfd"
  portal:
    originalUID: "447ea4b3-9514-4a84-a34b-ce0b349838da"
```

10. If you installed the API Connect using an S3 provider for the Management subsystem backups, add the following annotation to the **apiconnectcluster** CR.
    If you specified SFTP or local as the backup, skip this step.

    - Using the Platform UI:
      - Edit the API Management instance and click the YAML tab to edit the CR.
      - Add the following statement to the **spec.metadata.annotations** section:

        ```
        apiconnect-operator/deployment-mode: disasterRecovery
        ```

        For example:

        ```
        metadata:
          annotations:
            apiconnect-operator/deployment-mode: disasterRecovery
        ```

    - Using the CLI:
      - Get the name of the CR by running the following command:

        ```
        oc get apiconnectcluster -o name -n <APIC_namespace>
        ```

        The response looks like the following example:

        ```
        apiconnectcluster.apiconnect.domain/instance_name
        ```

      - Add the following annotation to the **spec.metadata.annotations** section of the CR by running the following command:

        ```
        oc annotate apiconnectcluster/instance_name apiconnect-operator/deployment-mode="disasterRecovery" -n
        <APIC_namespace>
        ```

        The response looks like the following example:

        ```
        apiconnectcluster.apiconnect.domain/instance_name annotated
        ```

11. Verify that you correctly added all of the settings to the API Connect Cluster CR.
    For example, the completed CR might look like the following example:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  namespace: apiconnect
  name: apis-minimum
  labels:
    app.kubernetes.io/instance: apiconnect
```

```
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-minimum
  annotations:
    apiconnect-operator/deployment-mode: disasterRecovery
spec:
  license:
    accept: true
    license: L-RJON-C2YLGB
    metric: VIRTUAL_PROCESSOR_CORE
    use: nonproduction
  management:
    originalUID: "fa0f6f49-b931-4472-b84d-0922a9a92dfd"
    encryptionSecret:
      secretName: apis-minim-faaa44bf-enc-key
    siteName: "faaa44bf"
    customApplicationCredentials:
      - name: atm-cred
      - secretName: apis-minim-faaa44bf-atm-cred
      - name: governance-cred
      - secretName: management-governance-cred
      - name: ccli-cred
      - secretName: apis-minim-faaa44bf-ccli-cred
      - name: cli-cred
      - secretName: apis-minim-faaa44bf-cli-cred
      - name: cui-cred
      - secretName: apis-minim-faaa44bf-cui-cred
      - name: dsgr-cred
      - secretName: apis-minim-faaa44bf-dsgr-cred
      - name: juhu-cred
      - secretName: apis-minim-faaa44bf-juhu-cred
      - name: ui-cred
      - secretName: apis-minim-faaa44bf-ui-cred
    analytics:

    portalBackup:
      credentials: portal-backup-secret
      host: s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard
      path: ocp-dr-portal
      protocol: objstore
      schedule: 0 1 * * *
  version: 10.0.3
```

12. Prepare your environment for installing API Connect by completing the prerequisites and all components of step 1 in Installing API Connect.
    After you prepare your environment, continue with this procedure to install API Connect and then restore data.

13. Install API Connect by creating the CR with the following command:
    Replace ***<cr_name>*** with the value of the **name** setting in the API Connect Cluster CR.

    ```
    oc -n <APIC_namespace> create -f <cr_name>.yaml
    ```

14. Wait for **all** subsystems to be created.
    When the Management subsystem is installed, you might see **backup** job pods and **stanza-create** job pods in **Error** state; for example:

    ```
    m1-82b290a2-postgres-stanza-create-4zcgz                  0/1     Error       0          35m
    m1-82b290a2-postgres-full-sch-backup-2g9hm                0/1     Error       0          20m
    ```

    This is expected behavior, for the following reasons:

    - The **stanza-create** job normally expects buckets or subdirectories within buckets to be empty. However, since you configured the Management subsystem with your already-populated S3 bucket (where your backups exist), the job will enter the **Error** state.

- Any scheduled or manual backups will enter the **`Error`** state. Although you configured the Management subsystem with your already-populated S3 bucket, the new database isn't yet configured to write backups into remote storage.

The errors will not prevent a successful restore, so continue to the next step.

Important:
For S3, the recovery remains in an intermediate state until the restore is complete, and Postgres wal files might cause serious disk issues. To avoid this possibility, continue immediately with the next step.

Note that if you delay completion of the restore:

- Health check might fail. In this case, you can still proceed to the next step and perform a restore.
- Postgres wal files might cause problems by consuming all disk space. In this case, you must either:
  - Re-install the system, prepare again for disaster recovery, and perform the restore.
  - Or increase disk space so that the system returns to a stable state, and then proceed with the restore.

15. Restore the subsystems in the following sequence:
    a. Restore the Management subsystem.
    When you perform a restore, you must complete the restoration of the Management subsystem first, and then immediately restore the Portal subsystem.

    Important: Be sure to restore the Management subsystem from the backup whose name and ID of the you noted while preparing for disaster recovery.
    b. Restore the Developer Portal subsystem.
    Use the restore type **`all`** to ensure that you restore the complete subsystem and all Portal sites.

    c. Restore the Analytics subsystem.
16. Version 10.0.2 or earlier: Update the Management OIDC credentials as explained in Configuring the OIDC credentials on OpenShift.
17. Verify that the recovery was successful:
    a. Ensure that you can log in to the Cloud Manager UI.
    b. Verify that your provider organizations exist.
    c. Ensure that you can log in to each Developer portal.
    d. Ensure that the Analytics dashboard contains all of the analytics data that you preserved.
18. After the successful recovery, remove the annotation that you added to the **`apiconnectcluster`** CR in step 10.
    If you skipped step 10, then skip this step as well.

    - Using the Platform UI:
      - Edit the API Management instance and click the YAML tab to edit the CR.
      - Delete the following statement from the **`spec.metadata.annotations`** section:

        `apiconnect-operator/deployment-mode: disasterRecovery`

    - Using the CLI:
      - Get the name of the CR by running the following command:

        `oc get apiconnectcluster -o name -n <APIC_namespace>`

        The response looks like the following example:

        `apiconnectcluster.apiconnect.domain/instance_name`

      - Remove the annotation by running the following command, making sure to include the trailing "-" on **`deployment-mode-`** to indicate the removal:

        `oc -n <APIC_namespace> annotate apiconnectcluster/instance_name apiconnect-operator/deployment-mode-`

        The response looks like the following example:

        `apiconnectcluster.apiconnect.domain/instance_name annotated`

- **Configuring the OIDC credentials on OpenShift**
  When you recover API Connect V10.0.x, you must manually update the values for the Management OIDC credentials (**`client_ID`** and **`client_secret`**) in the Common Services User Registry.

Configuring the OIDC credentials on OpenShift

When you recover API Connect V10.0.x, you must manually update the values for the Management OIDC credentials (**`client_ID`** and **`client_secret`**) in the Common Services User Registry.

Before you begin

This task is required for all of the 10.0.x releases up to, and including, version 10.0.2 (skip this task for version 10.0.3 and later). The procedure requires you to log in to the Cloud Manager on the new API Connect deployment. Use the Cloud Manager administrator username and password that you saved while preparing for disaster recovery.

About this task

When you deploy API Connect, the OIDC **`client_ID`** and **`client_secret`** resources are automatically generated and added to the Common Services User Registry. These resources enable single sign-on with the IBM Cloud Pak platform. When you reinstall API Connect as part of disaster recovery, the original versions of those resources are retained but cannot be used. You must update the Common Services User Registry and replace the original values with the values from the new deployment.

Procedure

1. Retrieve the **`client_ID`** and **`client_secret`** from the stored secret in API Connect.
   a. Run the following command to retrieve the **`client_ID`**:

```
oc -n <APIC_namespace> get secret <instance_name>-oidc-client -o jsonpath="{.data.CLIENT_ID}" | base64 -D
```

b. Run the following command to retrieve the `client_secret`:

```
oc -n <APIC_namespace> get secret <instance_name>-oidc-client -o jsonpath="{.data.CLIENT_SECRET}" | base64 -D
```

2. Update the Common Services User Registry with the new values.
Using the Cloud Manager UI:

a. In API Connect, open the Cloud Manager interface.
b. Select the Cloud Manager User Registry.
You will use the Cloud Manager User Registry to modify settings for the Common Service User Registry.

c. Log in to the Cloud Manager User Registry using the administrator username and password that you saved while preparing for disaster recovery.
d. In Cloud Manager, click Resources > User Registries and edit Common Services User Registry.
e. In the Client information section, paste the `client_ID` value from step 1 into the Client ID field.
f. Paste the `client_secret` value from step 1 into the Client secret field.
g. Save your changes.

Using the toolkit CLI:

a. Run the following command to determine the `<mgmt_endpoint_URL>` that you will use for accessing the management server:

```
oc -n <APIC_namespace> get mgmt <instance_name> -o jsonpath="{.status.zenRoute}" && echo ""
```

b. Log in to the management server:
i. Run the following command to start the login process:

```
apic login --server <mgmt_endpoint_URL>
```

ii. Provide your login credentials:
- `Realm?` Type your realm (for example: `admin/default-idp-1`) and press Enter.
The realm refers to your identity provider. For information on determining your realm value, see How to determine the identity provider.
- `Username?` Type your Cloud Manager administrator username and press Enter.
- `Password?` Type the password for your Cloud Manager administrator account and press Enter.

c. Run the following command to download the Common Service User Registry as a YAML file:

```
apic user-registries:get common-services --server <mgmt_endpoint_URL> -o admin --fields name,configuration
```

d. Edit the file and update the `client_ID` and `client_secret` settings with the values you obtained in step 1.
e. Save and close the file.
f. Run the following command to upload the modified file to Cloud Manager:

```
apic user-registries:update common-services --server <mgmt_endpoint_URL> -o admin common-services.yaml
```

Preparing for disaster recovery on Cloud Pak for Integration

Back up data and essential deployment information from each API Connect subsystem so that you can use it to recover your deployment after a disaster.

About this task

To prepare your deployment for disaster, complete this task to copy the API Connect deployment settings, and then proceed to the following tasks to backup additional information for each subsystem.

Procedure

Complete the following steps to copy the API Connect deployment settings for use when you recover the deployment.

1. Find the API Connect cluster's name by running the following command and looking for the value in the NAME column:

```
oc get APIConnectCluster
```

The response looks like the following example:

```
NAME           READY   STATUS    VERSION    RECONCILED VERSION   AGE
apic-cluster   7/7     Running   10.0.3   10.0.3-149         6d4h
```

2. Create a back-up copy of the installation CR for each subsystem, as well as the top-level APIConnectCluster CR, with the following commands:

a. `oc -n <APIC_namespace> get apiconnectcluster apic-cluster-name -o yaml > apic-cluster-cr.yaml`

b. `oc -n <APIC_namespace>> get mgmt apic-cluster-name-mgmt -o yaml > mgmt-susbsystem-cr.yaml`

c. `oc -n <APIC_namespace> get a7s apic-cluster-name-a7s -o yaml > a7s-susbsystem-cr.yaml`

d. `oc -n <APIC_namespace> get ptl apic-cluster-name-ptl -o yaml > ptl-susbsystem-cr.yaml`

What to do next

Proceed to Preparing the Management subsystem for disaster recovery on Cloud Pak for Integration.

1. Preparing the Management subsystem for disaster recovery on Cloud Pak for Integration
Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.

2. Preparing the Portal subsystem for disaster recovery on Cloud Pak for Integration
   Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.
3. Preparing the Analytics subsystem for disaster recovery on Cloud Pak for Integration
   Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.

Preparing the Management subsystem for disaster recovery on Cloud Pak for Integration

Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.

About this task

Make sure to store all backups and deployment information to a secure location where you can access it after a disaster. You cannot recover a deployment without the information that you collect during this task.

Procedure

1. Save a copy of the Management database encryption secret.
   a. Run the following command to get the name of the encryption secret:

      ```
      oc get mgmt -n <APIC-namespace> -o yaml | grep encryption
      ```

      The output of this command shows the name of the secret that is storing the database encryption key; for example:

      ```
      encryptionSecret: management-enc-key
      ```

   b. Run the following command to save a local copy of the secret as a YAML file:

      ```
      oc get secret management-enc-key -n <APIC-namespace> -o yaml > management-enc-key.yaml
      ```

2. Save a copy of the Management client application credential secrets.
   Save the credential secrets (the **client_id** and **client_secret**) for client applications provided by the Management subsystem.

   a. Run the following command to get the names of the secrets:

      ```
      oc get mgmt -n <APIC-namespace> -o yaml | grep CredentialSecret
      ```

      The output of this command shows the names of the secrets used to store each of the client application credentials; for example:

      ```
      atmCredentialSecret: management-atm-cred
      consumerToolkitCredentialSecret: management-ccli-cred
      consumerUICredentialSecret: management-cui-cred
      designerCredentialSecret: management-dsgr-cred
      governanceCredentialSecret: management-governance-cred
      juhuCredentialSecret: management-juhu-cred
      toolkitCredentialSecret: management-cli-cred
      uiCredentialSecret: management-ui-cred
      ```

   b. Run the following command to save a local copy of each secret as a YAML file, replacing **<secret_name>** with the name of the application credential secret:

      ```
      oc get secret <secret_name> -n <APIC-namespace> -o yaml > <secret_name>.yaml
      ```

   c. Edit each of the saved YAML files and remove both the **ownerReferences** subsection and the **selfLink** property, and then save the updated file.
      The information to remove looks like the following example:

      ```
      ownerReferences:
        - apiVersion: management.apiconnect.ibm.com/v1beta1
          blockOwnerDeletion: true
          controller: true
          kind: ManagementCluster
          name: management
          uid: 623e6b20-7eb8-46ce-94ac-6b64cd71afc4
        selfLink: /api/v1/namespaces/default/secrets/management-atm-cred
      ```

3. Save a copy of the CP4I credentials secret.
   a. Run the following command to get the name of the encryption secret and save a local copy of the secret as a YAML file:

      ```
      oc get secrets <instance_name>-cp4i-creds -o yaml > <cp4i_creds_secret>.yaml
      ```

   b. Edit the saved YAML file and remove both the **ownerReferences** subsection and the **selfLink** property, and then save the updated file.
4. Run a backup of the Management subsystem database.
   a. Configure the Management subsystem for backups.
   b. Perform a backup of the Management subsystem.
   c. Get the name and ID of the newest Management backup and save them for reference during a recovery.
      Run the following command to list the Management backups:

      ```
      oc get mgmtb -n <APIC-namespace>
      ```

      The response looks like the following example; the newest backup is the one with the smallest **AGE**:

      ```
      NAME                   STATUS   ID                 CLUSTER      TYPE   CR TYPE   AGE
      management-3aa3bebf    Ready    20200929-152150F   management   full   record    10h
      management-3c4ca8df    Ready    20200929-115520F   management   full   record    20h
      management-5tbxj       Ready    20200929-224349F   management   full   create    17h
      ```

```
management-f10af337   Ready    20200925-133703F   management   full   record    5d2h
management-jtlcd      Ready    20200929-224349F   management   full   create    25h
management-zxjtz      Ready    20200929-224349F   management   full   create    28h
```

5. Save a copy of the username and password for a Cloud Manager administrator.
   When you recover the deployment, you will need to log in to the Cloud Manager as an administrator using the Cloud Manager User Registry. Any user with Administrator permission defined in the Cloud Manager User Registry can be used. Before backing up the information, verify that you an log in to Cloud Manager using that account.

   If you want to backup the secret that contains the administrator password that was created by the API Connect operator during the original deployment, run the following command to get the secret:

   ```
   oc -n <APIC_namespace> get secret <instanceName>-mgmt-admin-pass -o jsonpath="{.data.password}" | base64 -d
   ```

   It is possible that the password was changed at some point and the secret is now out-of-date. Be sure to verify that you can log in to Cloud Manager with the password contained in the secret. If the password is not valid, then make sure you have another Cloud Manager administrator account in the Cloud Manager User Registry, and back up that username and password instead.

6. Copy all of the information that you saved to a secure location.

What to do next

Immediately proceed to Preparing the Portal subsystem for disaster recovery on Cloud Pak for Integration.

Important: Backups of the Management and Portal subsystems must be performed in sequence, and close together in time, to ensure that the Portal sites are consistent with Management database.
Next topic: Preparing the Portal subsystem for disaster recovery on Cloud Pak for Integration

Preparing the Portal subsystem for disaster recovery on Cloud Pak for Integration

Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.

Before you begin

Perform a backup of the Management subsystem.

Important: Backups of the Management and Portal subsystems must be performed in sequence, and close together in time, to ensure that the Portal sites are consistent with Management database.

About this task

Make sure to store all backups and deployment information to a secure location where you can access it after a disaster. You cannot recover a deployment without the information that you collect during this task.

Procedure

1. Save the ID of the Portal subsystem.
   If your original CR **name** was 10 characters or longer, you must add the **originalUID** (Version 10.0.3 or later) or **metadata.uid** (Version 10.0.2 or earlier) value from the original Portal subsystem into the appropriate section of the installation CR during the recovery process.

   When you deployed API Connect using the top-level APIConnectCluster CR, the deployment settings were added to subsystem-specific CRs that are managed by the top-level CR. When you recover the Portal subsystem after a disaster, you can locate the subsystem's ID in the saved copy of the Portal subsystem CR.

   a. Find the API Connect cluster's name by running the following command and looking for the value in the NAME column:

      ```
      oc get APIConnectCluster
      ```

      The response looks like the following example:

      ```
      NAME           READY   STATUS    VERSION    RECONCILED VERSION   AGE
      apic-cluster-name   7/7     Running   10.0.3   10.0.3-149         6d4h
      ```

   b. Get the YAML that describes the Portal subsystem CR and save it in a file using the following command:

      ```
      oc get ptl apic-cluster-name-ptl -o yaml >  apic-cluster-name-ptl.yaml
      ```

2. Back up the Developer Portal database encryption secret.
   a. Run the following command to get the name of the encryption secret:

      ```
      oc get ptl -n <APIC-namespace> -o yaml | grep encryption
      ```

      The output of this command shows the name of the secret that is storing the database encryption key, for example:

      ```
      encryptionSecret: portal-enc-key
      ```

   b. Run the following command to save a local copy of the secret as a YAML file:

      ```
      oc get secret portal-enc-key -n <APIC-namespace> -o yaml > portal-enc-key.yaml
      ```

3. Back up the Portal endpoint definitions.
   Save the information to a file because you must use the same names in the recovered deployment.

a. Get the `portalAdminEndpoint` definition by running the following command:

```
oc get route | grep portal-director | awk '{print $2}'
```

The response looks like the following example:

```
dr-ptl-portal-director-apic.apps.vlxocp-1556.cp.fyre.ibm.com
```

b. Get the `portalUIEndpoint` definition by running the following command:

```
oc get route | grep portal-web | awk '{print $2}'
```

The response looks like the following example:

```
dr-ptl-portal-web-apic.apps.vlxocp-1556.cp.fyre.ibm.com
```

4. Back up the Portal subsystem database.
   a. Configure the Portal subsystem for backups.
   b. Perform a backup of the Portal subsystem.
   Note: Be sure to `type: all` when you backup the Portal database, to ensure that you capture data for the Portal subsystem and all Portal sites.
   c. Get the ID of the latest `all` Portal backup and save it for reference during a recovery.
   Run the following command to list the Portal backups:

```
oc get portalbackup -n <APIC-namespace>
```

The response looks like the following example; the latest backup is the one with a `TYPE` of `all` and the smallest `AGE`:

```
NAME               ID              STATUS      TYPE     CR TYPE   AGE     COMMENT
p1-bup-gqz8f    20200526.142449  Ready       system   record    55m
p1-bup-jx4vc    20200526.142458  Ready       site     record    54m
p1-bup-st412                     Ready       all      create    56m     y
p1-bup-th2dm                     Ready       all      create    4h51m   y
```

5. Copy all of the information that you saved to a secure location.

What to do next

Proceed to Preparing the Analytics subsystem for disaster recovery on Cloud Pak for Integration.

Previous topic: Preparing the Management subsystem for disaster recovery on Cloud Pak for Integration
Next topic: Preparing the Analytics subsystem for disaster recovery on Cloud Pak for Integration

Preparing the Analytics subsystem for disaster recovery on Cloud Pak for Integration

Back up data and essential deployment information so that you can use it to recover your deployment after a disaster.

About this task

Make sure to store all backups and deployment information to a secure location where you can access it after a disaster. You cannot recover a deployment without the information that you collect during this task.

Procedure

1. Backup the Analytics subsystem database.
   a. Configure the Analytics subsystem for backups.
   b. Perform a backup of the Analytics subsystem.
   Note: Be sure to specify `indices: all` when you backup the Analytics database. Backing up a full set of indices ensures that your complete Analytics configuration, event data, and custom UI configuration (such as custom dashboards) can be restored.
   c. Get the name of the newest Analytics backup and save it for reference during a recovery.
   Run the following command to list the Analytics backups:

```
oc get analyticsbackup -n <APIC-namespace>
```

The response looks like the following example; the newest backup is the one with the smallest `AGE`:

```
NAME                STATUS  ID                                      CR TYPE   INDICES                AGE  COMMENT
a7s-bup-266p8       Ready                                           create    [all]                  20h  y
a7s-bup-pffdh       Ready                                           create    [all]                  34h  y
analytics-bup-kxwq5 Ready   analytics-all-2020-09-07t03:49:15utc    record    [ui apievents config]  34h
analytics-bup-p29z8 Ready   analytics-all-2020-09-07t18:04:03utc    record    [ui apievents config]  20h
```

2. Copy all of the information that you saved to a secure location.

Previous topic: Preparing the Portal subsystem for disaster recovery on Cloud Pak for Integration

Recovering from a disaster on Cloud Pak for Integration

Install and configure API Connect, then restore the backed up data to recover the deployment after a disaster.

Before you begin

To successfully recover API Connect from a disaster, you must have previously completed the steps to prepare the Management, Portal, and Analytics subsystems for disaster recovery. Make sure that you can access the backups and deployment information because you cannot recover your deployment without it.

Attention: Successful disaster recovery depends on recovery of both the Management subsystem and the Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management subsystem first, and then immediately restore the Portal subsystem.

About this task

To recover from a disaster event, recreate your API Connect Cluster CR and add recovery details as explained in the following procedure. Use the file containing the original CR (which you saved during the preparation task) as a reference.

Note: Your recovery installation of Cloud Pak for Integration must include the Platform UI if your original deployment used it. In addition, the CR must use the same settings as in the original deployment.

Procedure

1. Prepare your Cloud Pak for Integration environment for deploying API Connect as explained in the appropriate version of the Cloud Pak for Integration documentation.
   After you prepare your environment, return to this procedure to configure the installation CR, deploy API Connect, and then restore data to the API Connect subsystems.

   Important: Do not install API Connect until you have configured the CR as explained in following steps.
2. Apply the Management and Portal encryption secrets to the cluster where you will install API Connect.
   a. Apply the YAML file that contains the Management database encryption secret into the cluster.
      Run the following command, using the filename of the encryption secret that you saved when you prepared the Management subsystem for disaster recovery:

      ```
      oc apply -f mgmt-enc-key.yaml
      ```

   b. Apply the YAML file that contains the Portal encryption secret into the cluster.
      Run the following command, using the filename of the encryption secret that you saved when you prepared the Portal subsystem for disaster recovery:

      ```
      oc apply -f portal-enc-key.yaml
      ```

3. Apply the YAML file that contains the CP4I credentials secret into the cluster.
   Run the following command, using the filename of the secret that you saved when you prepared the Management subsystem for disaster recovery:

   ```
   oc apply -f <cp4i_creds_secret>.yaml -n <APIC_namespace>
   ```

4. Set up the installation CR for deploying API Connect.
   In this step, you perform the initial steps for deploying API Connect in Cloud Pak for Integration, but you do not begin the actual installation until step 15. Instead, you will complete a series of steps to configure the CR with deployment settings and additional recovery settings.

   a. Log in to the IBM Cloud Pak Platform UI.
   b. On the home page, click Create capability.
   c. Select the API Connect tile and click Next.
   d. On the Create an instance of API Connect cluster page, select the deployment type and click Next.
      Choose the same deployment type that you used when you originally deployed API Connect.

   e. On the deployment settings page, click the YAML tab to edit the installation CR in YAML format.
   f. Copy the content of the saved CR into the YAML tab, replacing the default CR.
      Keep the YAML tab open. In the following steps, you will configure additional deployment and recovery settings in the new API Connect Cluster installation CR before you install API Connect.

5. Important: Make sure that your new version of the API Connect Cluster installation CR uses the same value for the **name** setting as the original CR.
6. Verify the backup and restore settings for each subsystem.
   For more information on the backup settings, see the following topics for instructions on configuring backup and restore settings:

   - Configuring backup settings for a fresh install of the Management subsystem on OpenShift or Cloud Pak for Integration
   - Configuring backups for Developer Portal on OpenShift and Cloud Pak for Integration
   - Configuring backup settings for Analytics on OpenShift and Cloud Pak for Integration

7. Generate the Kubernetes secret for each subsystem's backups by running the appropriate command:
   For each secret, use the same name that you used in the original deployment (you can see the name in the **credentials** setting of each subsystem's backup section).

   - Management subsystem:
     - S3:

       ```
       oc create secret generic mgmt-backup-secret --from-literal=username='<Your_access_key-or-user_name>'
       --from-literal=password='<Your_access_key_secret-or-password>' -n <APIC_namespace>
       ```

     - SFTP with username and password:

       ```
       oc create secret generic mgmt-backup-secret --from-literal=username='<Your_user_name>'
       --from-literal=password='<Your_password>' -n <APIC_namespace>
       ```

     - SFTP with username and SSH-key

       ```
       oc create secret generic mgmt-backup-secret --from-literal=username='<Your_user_name>'
       --from-file=ssh-privatekey='<Your_private_key_file>' -n <APIC_namespace>
       ```

- Portal subsystem:
  - S3:

    ```
    oc create secret generic portal-backup-secret --from-literal=username='<Your_access_key-or-user_name>'
    --from-literal=password='<Your_access_key_secret-or-password>' -n <APIC_namespace>
    ```

  - SFTP with username and password:

    ```
    oc create secret generic portal-backup-secret --from-literal=username='<Your_user_name>'
    --from-literal=password='<Your_password>' -n <APIC_namespace>
    ```

  - SFTP with username and SSH-key

    ```
    oc create secret generic portal-backup-secret --from-literal=username='<Your_user_name>'
    --from-file=ssh-privatekey='<Your_private_key_file>' -n <APIC_namespace>
    ```

- Analytics:

  ```
  oc create secret generic analytics-backup-secret --from-literal=access_key='<Your_Access_Key>' --from-
  literal=secret_key='<Your_access_key_secret>' -n <APIC_namespace>
  ```

8. Add the saved Management and Portal encryption secrets to the installation CR.
   Add each secret to the appropriate **spec.*subsystem*** section of the CR, as shown in the following example:

   ```
   spec:
     management:
       encryptionSecret:
         secretName: mgmt-enc-key
     portal:
       encryptionSecret:
         secretName: portal-enc-key
   ```

9. Apply each of the Management client application credential secrets to the cluster.
   Run the following command to apply each secret, using the filename of each client application credential secret that you saved when you prepared the Management subsystem for disaster recovery:

   ```
   oc apply -f <secretName>.yaml
   ```

   For example, a deployment might use the following names for the secrets:

   ```
   atmCredentialSecret: management-atm-cred
   consumerToolkitCredentialSecret: management-ccli-cred
   consumerUICredentialSecret: management-cui-cred
   designerCredentialSecret: management-dsgr-cred
   governanceCredentialSecret: management-governance-cred
   juhuCredentialSecret: management-juhu-cred
   toolkitCredentialSecret: management-cli-cred
   uiCredentialSecret: management-ui-cred
   ```

10. Add each of the credential secrets to the **spec.management** section of installation CR.
    For example:

    ```
    spec:
      management:
        customApplicationCredentials:
        - name: atm-cred
          secretName: management-atm-cred
        - name: ccli-cred
          secretName: management-ccli-cred
        - name: cui-cred
          secretName: management-cui-cred
        - name: dsgr-cred
          secretName: management-dsgr-cred
        - name: governance-cred
          secretName: management-governance-cred
        - name: juhu-cred
          secretName: management-juhu-cred
        - name: cli-cred
          secretName: management-cli-cred
        - name: ui-cred
          secretName: management-ui-cred
    ```

11. Add the **siteName** property to the **spec.management** and **spec.portal** sections of the installation CR.
    For example, if the **a2a5e6e2** is the original **siteName** of the Management subsystem, and **890772e3** is the original **siteName** of the Portal subsystem, the CR looks like the following example:

    ```
    spec:
      management:
        siteName: "a2a5e6e2"
      portal:
        siteName: "890772e3"
    ```

12. If your original CR **name** was 10 characters or longer, you must add the **originalUID** or **metadata.uid** value from the original Management and Portal subsystems into the appropriate sections of the installation CR.
    Important: If your original CR name was 10 characters or longer and you do not add this value, the deployments and routes that are generated during installation will include a different UID, which will cause the recovery process to fail.
    The IDs were created with the original deployment of the Management and Portal subsystems, and the recovered subsystems must continue to use the same IDs. You can locate the ID in the Management (*apic-cluster-name*-mgt.yaml) or Portal (*apic-cluster-name*-ptl.yaml) CR that you saved while preparing for disaster recovery. (Do not use the **metadata.uid** setting from the API Connect Cluster CR).

    The CR setting that contains the ID depends on the version of API Connect that you are recovering:

- Version 10.0.3 or later: `spec.originalUID`
- Version 10.0.2 or earlier: `metadata.uid`

Locate each of the original settings in the appropriate subsystem CR, and copy them to corresponding sections of the new API Connect Cluster CR using the same key and value.

For example, if you originally deployed version 10.0.2, the setting name was `uid`. If you are deploying Version 10.0.3 as part of disaster recover, copy the original value and use it for the `originalUID` setting in the new CR. For example, in 10.0.3:

```
spec:
  management:
    originalUID: "fa0f6f49-b931-4472-b84d-0922a9a92dfd"
  portal:
    originalUID: "447ea4b3-9514-4a84-a34b-ce0b349838da"
```

13. If you installed the API Connect using an S3 provider for the Management subsystem backups, add the following annotation to the `apiconnectcluster` CR. If you specified SFTP or local as the backup, skip this step.

    - Using the Platform UI:
      - Edit the API Management instance and click the YAML tab to edit the CR.
      - Add the following statement to the `spec.metadata.annotations` section:

        ```
        apiconnect-operator/deployment-mode: disasterRecovery
        ```

        For example:

        ```
        metadata:
          annotations:
            apiconnect-operator/deployment-mode: disasterRecovery
        ```

    - Using the CLI:
      - Get the name of the CR by running the following command:

        ```
        oc get apiconnectcluster -o name -n <APIC_namespace>
        ```

        The response looks like the following example:

        ```
        apiconnectcluster.apiconnect.domain/instance_name
        ```

      - Add the following annotation to the `spec.metadata.annotations` section of the CR by running the following command:

        ```
        oc annotate apiconnectcluster/instance_name apiconnect-operator/deployment-mode="disasterRecovery" -n
        <APIC_namespace>
        ```

        The response looks like the following example:

        ```
        apiconnectcluster.apiconnect.domain/instance_name annotated
        ```

14. Verify that you correctly added all of the settings to the installation CR.
    For example, the completed CR might look like the following example:

```
apiVersion: apiconnect.ibm.com/v1beta1

      schedule: 0 1 * * *
  version: 10.0.3
```

Important: If you are restoring your deployment in a different data center, the endpoints that are used in your original deployment must be the same in your new data center. The Platform UI in Cloud Pak for Integration autogenerates the endpoints if they are left empty in the CR, therefore ensure that you explicitly set the endpoints in the CR to match what was set in your original data center. For example:

```
apiManagerEndpoint:
      annotations:
        cert-manager.io/issuer: prod-ingress-issuer
        haproxy.router.openshift.io/timeout: 240s
      hosts:
        - name: prod-api-manager.example.com
        secretName: prod-be787dd3-api-manager
```

15. On the deployment page, install API Connect by clicking Create.
16. Wait for **all** subsystems to be created.
    When the Management subsystem is installed, you might see **backup** job pods and **stanza-create** job pods in **Error** state; for example:

```
m1-82b290a2-postgres-stanza-create-4zcgz                          0/1     Error       0          35m
m1-82b290a2-postgres-full-sch-backup-2g9hm                        0/1     Error       0          20m
```

    This is expected behavior, for the following reasons:

    - The **stanza-create** job normally expects buckets or subdirectories within buckets to be empty. However, since you configured the Management subsystem with your already-populated S3 bucket (where your backups exist), the job will enter the **Error** state.
    - Any scheduled or manual backups will enter the **Error** state. Although you configured the Management subsystem with your already-populated S3 bucket, the new database isn't yet configured to write backups into remote storage.
    - The configurator job will fail because the CP4I credentials secret that you manually restored does not match the value in the Management database. As a result, the state of new cluster is not "Ready" and will show "6/7". This error will be resolved when you restore the Management subsystem from the backup that you prepared earlier.

    The errors will not prevent a successful restore, so continue to the next step.

17. Restore the subsystems in the following sequence:
    Important: Make sure that you restore using the backup (locate the one with the correct backup name and ID) that you created when you prepared each subsystem for disaster recovery.
    a. Restore the Management subsystem.
       When you perform a restore, you must complete the restoration of the Management subsystem first. Verify that the restoration completed successfully and that the Management subsystem is Ready. When the Management subsystem is healthy, proceed to the next step and restore the Portal subsystem.

    b. Restore the Developer Portal subsystem.
       Use the restore type **all** to ensure that you restore the complete subsystem and all Portal sites.

    c. Restore the Analytics subsystem.
18. Force the configurator to run again.
    The cluster will still not be ready after restore at this stage because the configurator has yet to successfully complete (refer to point 12). In order for the configurator to run again, delete the associated job so that a new pod will start running:

    a. Run the following command to get the list of jobs:

       ```
       oc get jobs -n <APIC_namespace>
       ```

    b. Run the following command to determine the name of your API Connect instance:

       ```
       oc get apiconnectcluster -n <APIC_namespace>
       ```

c. Run the following command to delete the configurator job:

```
oc -n <APIC_namespace> delete job <instance_name>-configurator
```

19. Version 10.0.2 or earlier: Update the Management OIDC credentials as explained in Configuring the OIDC credentials on Cloud Pak for Integration.
20. Verify that the recovery was successful:
    a. Ensure that you can log in to the Cloud Manager UI.
    b. Verify that your provider organizations exist.
    c. Ensure that you can log in to each Developer portal.
    d. Ensure that the Analytics dashboard contains all of the analytics data that you preserved.
21. After the successful recovery, remove the annotation that you added to the `apiconnectcluster` CR in step 13.
    If you skipped step 13, then skip this step as well.

    - Using the Platform UI:
      - Edit the API Management instance and click the YAML tab to edit the CR.
      - Delete the following statement from the `spec.metadata.annotations` section:

        ```
        apiconnect-operator/deployment-mode: disasterRecovery
        ```

    - Using the CLI:
      - Get the name of the CR by running the following command:

        ```
        oc get apiconnectcluster -o name -n <APIC_namespace>
        ```

        The response looks like the following example:

        ```
        apiconnectcluster.apiconnect.domain/instance_name
        ```

      - Remove the annotation by running the following command, making sure to include the trailing "-" on `deployment-mode-` to indicate the removal:

        ```
        oc -n <APIC_namespace> annotate apiconnectcluster/instance_name apiconnect-operator/deployment-mode-
        ```

        The response looks like the following example:

        ```
        apiconnectcluster.apiconnect.domain/instance_name annotated
        ```

- **Configuring the OIDC credentials on Cloud Pak for Integration**
  When you recover API Connect V10.0.x, you must manually update the values for the Management OIDC credentials (`client_ID` and `client_secret`) in the Common Services User Registry.

Configuring the OIDC credentials on Cloud Pak for Integration

When you recover API Connect V10.0.x, you must manually update the values for the Management OIDC credentials (`client_ID` and `client_secret`) in the Common Services User Registry.

Before you begin

This task is required for all of the 10.0.x releases up to, and including, version 10.0.2 (skip this task for version 10.0.3 and later). The procedure requires you to log in to the Cloud Manager on the new API Connect deployment. Use the Cloud Manager administrator username and password that you saved while preparing for disaster recovery.

About this task

When you deploy API Connect, the OIDC `client_ID` and `client_secret` resources are automatically generated and added to the Common Services User Registry. These resources enable single sign-on with the IBM Cloud Pak platform. When you reinstall API Connect as part of disaster recovery, the original versions of those resources are retained but cannot be used. You must update the Common Services User Registry and replace the original values with the values from the new deployment.

Procedure

1. Retrieve the `client_ID` and `client_secret` from the stored secret in API Connect.
   a. Run the following command to retrieve the `client_ID`:

   ```
   oc -n <APIC_namespace> get secret <instance_name>-oidc-client -o jsonpath="{.data.CLIENT_ID}" | base64 -D
   ```

   b. Run the following command to retrieve the `client_secret`:

   ```
   oc -n <APIC_namespace> get secret <instance_name>-oidc-client -o jsonpath="{.data.CLIENT_SECRET}" | base64 -D
   ```

2. Update the Common Services User Registry with the new values.
   Using the Cloud Manager UI:

   a. In API Connect, open the Cloud Manager interface.
   b. Select the Cloud Manager User Registry.
   You will use the Cloud Manager User Registry to modify settings for the Common Service User Registry.

   c. Log in to the Cloud Manager User Registry using the administrator username and password that you saved while preparing for disaster recovery.
   d. In Cloud Manager, click Resources > User Registries and edit Common Services User Registry.
   e. In the Client information section, paste the `client_ID` value from step 1 into the Client ID field.
   f. Paste the `client_secret` value from step 1 into the Client secret field.
   g. Save your changes.
   Using the toolkit CLI:

a. Run the following command to determine the **<mgmt_endpoint_URL>** that you will use for accessing the management server:

```
oc -n <APIC_namespace> get mgmt <instance_name> -o jsonpath="{.status.zenRoute}" && echo ""
```

b. Log in to the management server:
   i. Run the following command to start the login process:

```
apic login --server <mgmt_endpoint_URL>
```

   ii. Provide your login credentials:
   - **Realm?** Type your realm (for example: **admin/default-idp-1**) and press Enter.
     The realm refers to your identity provider. For information on determining your realm value, see How to determine the identity provider.
   - **Username?** Type your Cloud Manager administrator username and press Enter.
   - **Password?** Type the password for your Cloud Manager administrator account and press Enter.

c. Run the following command to download the Common Service User Registry as a YAML file:

```
apic user-registries:get common-services --server <mgmt_endpoint_URL> -o admin --fields name,configuration
```

d. Edit the file and update the **client_ID** and **client_secret** settings with the values you obtained in step 1.
e. Save and close the file.
f. Run the following command to upload the modified file to Cloud Manager:

```
apic user-registries:update common-services --server <mgmt_endpoint_URL> -o admin common-services.yaml
```

Maintaining a two data center deployment

How to maintain a two data center disaster recovery (DR) deployment on Kubernetes and OpenShift, including information about normal operation, failure handling, and recovery.

See the following topics for information about failure handling, backup, upgrade, and removing a 2DCDR deployment.

For general information about two data center disaster recovery in API Connect, see Two data center deployment strategy on Kubernetes and OpenShift.

- **Key concepts of 2DCDR and failure scenarios**
  Understand how API Connect 2DCDR works and what to do when a data center fails.
- **How to perform 2DCDR failover**
  How to complete service failover in a 2DCDR deployment on Kubernetes, OpenShift, and Cloud Pak for Integration.
- **Recovering from a failover of a two data center deployment**
  What to do after completing a 2DCDR failover.
- **Backup and restore requirements for a two data center deployment**
  Points to consider when you configure backup and restore settings on a two data center disaster recovery (2DCDR) deployment.
- **Removing a two data center deployment**
  Convert your 2DCDR deployment to a stand-alone deployment on Kubernetes, OpenShift, and Cloud Pak for Integration.
- **Verifying replication between data centers**
  How to verify that your API Connect data is replicating to your warm-standby data center.
- **Troubleshooting a two data center deployment**
  What to check when a 2DCDR deployment is not starting or not replicating data.

Key concepts of 2DCDR and failure scenarios

Understand how API Connect 2DCDR works and what to do when a data center fails.

This topic discusses the concepts around the operation and maintenance of an existing API Connect 2DCDR deployment. For information on the planning and installation of a 2DCDR deployment, see: Two data center deployment strategy on Kubernetes and OpenShift.

Failover of services and reverting to a stand-alone deployment

Failover means the API Connect management and portal subsystems on the warm-standby data center, become the active management and portal subsystems. Whether it is possible to convert the original active data center to be the warm-standby at the same time depends on the problems the active data center has that required the failover. However, the failed active data center must be set to warm-standby before you re-establish its connectivity to the new active data center.
Important: When the active data center is set to warm-standby, all data is deleted from its management database. The management data from the new active (what was the warm-standby) is replicated to the new warm-standby data center. Do not set the active data center to warm-standby until you confirm that data replication is working, see: Verifying replication between data centers, or you have backups of your management data.
If you want to revert to a stand-alone API Connect deployment, before you start the process, ensure that the data center where you choose to keep API Connect is set to active.

- When API Connect is reverted to be a stand-alone deployment on the warm-standby data center, all management and portal data is deleted from that data center. It becomes an empty stand-alone deployment.
- When API Connect on the active data center is reverted to be a stand-alone deployment, all management and portal data remains.

Failure scenarios

The action that you should take when a failure occurs depends on the type of failure and which data center the failure occurs in:

API Connect failure in the active data center.
When the active data center is still working correctly, and still has connectivity to the warm-standby data center, but API Connect is not working correctly:

1. It might be possible to recover API Connect on the active data center. Review the troubleshooting documentation:
   - Troubleshooting two data center replication problems.
   - Installation troubleshooting.
   - Troubleshooting operational problems.
2. Follow the failover steps to make the warm-standby the active data center. If your failed active data center cannot be changed to warm-standby, then disable the network link used by API Connect between the data centers.
3. Gather API Connect post-mortem logs from the failed data center and open a support request: Gathering post-mortem logs.
4. Do not restore the network connection between data centers until API Connect on the failed data center is recovered and set to warm-standby.

Complete active data center failure
When the active data center has a failure, and API Connect is not accessible, follow these steps:

1. Disable the network connection between the active and the warm-standby data center.
2. Follow the failover steps to make the warm-standby the active data center: How to perform 2DCDR failover.
3. Do not restore the network connection between data centers until API Connect on the failed data center is recovered and set to warm-standby.

Network failure that prevents API calls or user access to Management and Portal subsystems on active data center.
In this scenario, the API Connect 2DCDR deployment is working correctly, but unusable because the active data center is not accessible for API calls or for Management and Portal UI/CLI/REST API users.

1. Complete a failover, setting warm-standby to active, and the active to warm-standby: How to perform 2DCDR failover.

API Connect failure on the Warm-standby data center
Where the API Connect pods on the warm-standby data center are not running as expected.

1. Review the troubleshooting documentation Troubleshooting two data center replication problems.
2. Gather API Connect post-mortem logs from the failed data center and open a support case: Gathering post-mortem logs.

Warm-standby data center failure
The data center where API Connect was running as warm-standby fails. In this case when the data center is recovered:

1. Verify that API Connect is running correctly as warm-standby and that the data from the active is replicated to it:Verifying replication between data centers.

Network failure between data centers
When the network connection between data centers is recovered, verify that 2DCDR database replication resumes: Verifying replication between data centers.

Operational states

API Connect has various transitory states that it passes through during startup and failover. The current 2DCDR operational state can be observed from the CR status section, for example:

```
kubectl describe mgmt -n <namespace>

...
Status:
...
  Ha Mode: active
```

Table 1. 2DCDR Management subsystem operational states

Operational state	Description
`progressing to active`	Pods are progressing to the active state, but the subsystem is not capable of serving traffic.
`active`	All of the pods are ready and in the correct disaster recovery state for the active data center.
`progressing to passive`	Pods are progressing to the warm-standby state. The subsystem is not capable of serving traffic.
`passive`	All of the pods are ready and in the correct disaster recovery state for the warm-standby data center.

Table 2. 2DCDR Portal subsystem operational states

Operational state	Description
`progressing to active`	Pods are progressing to the active state, but the subsystem is not capable of serving traffic.
`progressing to active (ready for traffic)`	At least one pod of each type is ready for traffic. The dynamic router can be linked to this service.
`active`	All of the pods are ready and in the correct disaster recovery state for the active data center.
`progressing to passive`	Pods are progressing to the warm-standby state. The subsystem is not capable of serving traffic.
`progressing to passive (ready for traffic)`	At least one pod of each type is ready for traffic.
`passive`	All of the pods are ready and in the correct disaster recovery state for the warm-standby data center.
`progressing to down`	Portal is preparing to do a factory reset. This is what happens to a warm-standby portal data center when the `multiSiteHA` section is removed.

How to perform 2DCDR failover

How to complete service failover in a 2DCDR deployment on Kubernetes, OpenShift, and Cloud Pak for Integration.

Before you begin

Ensure that you have read and understand the 2DCDR concepts and reviewed the failure scenarios that are described in Key concepts of 2DCDR and failure scenarios. Do not proceed with the failover until you confirm that it is the correct course of action for your situation.

About this task

Carefully follow the steps in this topic. Be aware of the following important points:

- The first step in the process is to set the active data center to warm-standby. When the active data center is set to warm-standby, all data is deleted from the active data center's management database, to be replaced by data copied from the warm-standby when it becomes active. Do not proceed with failover if you suspect there is also a problem on the warm-standby data center and you are unsure it has the most recent management data. See Verifying replication between data centers, and consider restoring your active site from backup instead of attempting a failover: Backup and restore requirements for a two data center deployment.
- If the warm-standby data center is offline for more than 24 hours, there can be issues with the disk space on the active data center. In this case, you should revert your deployment to a single data center topology. For more information, see Removing a two data center deployment.
- Avoid both data centers being set to active at the same time while the network links between data centers are enabled. This causes split-brain.
- If the active data center failure prevents you from updating the active data center API Connect custom resources (CRs), then you should disable the network links used by API Connect between the data centers.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR you must edit the multiSiteHA section for the subsystem in the top-level CR, instead of directly in the subsystem CRs. If the subsystem section is not included in the top-level CR, copy and paste the section from the subsystem CR to the top-level CR.

Procedure

- **Management subsystem failover. In this example, DC1 is the active and DC2 is the warm-standby.**
  To initiate a failover from DC1 to DC2, you first must set DC1 to warm-standby before you set the DC2 data center to active. This action is needed to prevent split-brain, as there can't be two active data centers at the same time. The following instructions show how to failover DC1 to DC2 for the Management subsystem.

  1. Set the DC1 Management subsystem to be warm-standby.
     Edit the DC1 `ManagementCluster` custom resource (CR) by running the following command:

     ```
     kubectl edit mgmt -n <namespace>
     ```

     and change the `mode` to `passive`:

     ```
     multiSiteHA:
       mode: passive
     ```

     Note: If API Connect on DC1 is down, such that you can't set it to be warm-standby, you must ensure that the network links between DC1 and DC2 are disabled before you set DC2 to be active. You must then not restore the network links until you can set DC1 to be warm-standby.
  2.
  3. Run the following command on DC1 to check that the Management subsystem HA mode is no longer `active`:

     ```
     kubectl describe mgmt -n <namespace>
     ```

     During transition to warm-standby, the `Ha mode` part of the `Status` output shows `progressing to passive`. When the transition is complete, it shows `passive`.

     ```
     Status:
       ...
       Ha mode:                              passive
       ...
     ```

     You can proceed to set DC2 to active while DC1 is still `progressing to passive`.

  4. Change the DC2 Management subsystem from warm-standby to active.
     Edit the DC2 `ManagementCluster` custom resource (CR) by running the following command:

     ```
     kubectl edit mgmt -n <namespace>
     ```

     and change the `mode` to `active`:

     ```
     multiSiteHA:
       mode: active
     ```

  5. Run the following command on DC2 to check that the Management subsystem is ready for traffic:

     ```
     kubectl describe mgmt -n <namespace>
     ```

     The services are ready for traffic when the `Ha mode` part of the `Status` object is set on DC2 to `active`. For example:

     ```
     Status:
       ...
       Ha mode:                              active
       ...
     ```

     Note: Failover can take 10 minutes or more to complete. If there are any problems, you can check the API Connect operator pod log for errors (search for the word "Multi").
  6. Update your dynamic router to redirect all traffic to DC2 instead of DC1. Until the DC2 site becomes `active`, the UIs might not be operational.
- **Developer Portal subsystem failover**
  If you have multiple portal services, you can failover a specific portal service, or all of the portal services that are running in a particular data center.

  The following instructions show how to failover DC1 to DC2 for the Developer Portal subsystem. If you have multiple Developer Portal services, you must repeat these steps for each Developer Portal subsystem that you want to failover.

  Note:

- Developer Portal failover does result in a temporary Developer Portal website outage until the warm-standby data center is ready to accept traffic.
- If you want to monitor the failover process, you can run the following command to check the status:

  ```
  kubectl describe ptl
  ```

- Do not edit the portal CR file during the failover process.

1. Set the DC1 Developer Portal subsystem to be warm-standby.
   Edit the DC1 `PortalCluster` custom resource (CR) by running the following command:

   ```
   kubectl edit ptl <ptl-cluster-name> -n <namespace>
   ```

   and change the `mode` to `passive`:

   ```
   multiSiteHA:
     mode: passive
   ```

   Where *<ptl-cluster-name>* is the name of your portal cluster if you have more than one. To see a list of your portal clusters, run:

   ```
   kubectl get PortalCluster -n <namespace>
   ```

   Note: If API Connect on DC1 is down, such that you can't set it to be warm-standby, you must ensure that the network links between DC1 and DC2 are disabled before you set DC2 to be active. You must then not restore the network links until you can set DC1 to be warm-standby.
2. Run the following command on DC1 to check the Developer Portal subsystem status:

   ```
   kubectl describe ptl <ptl-cluster-name> -n <namespace>
   ```

   You can continue to the next step when the `Ha mode` part of the `Status` object is set to `progressing to passive`, or any of the `passive` states. For example:

   ```
   Status:
     ...
     Ha mode:                              progressing to passive
     ...
   ```

   Important: You must not set DC2 to active until DC1 is either in `passive` or `progressing to passive` state. In other words, DC1 and DC2 must never both be in active state at the same time.
3. Change the DC2 Developer Portal subsystem from warm-standby to active.
   Edit the DC2 `PortalCluster` custom resource (CR) by running the following command:

   ```
   kubectl edit ptl <ptl-cluster-name> -n <namespace>
   ```

   and change the `mode` to `active`:

   ```
   multiSiteHA:
     mode: active
   ```

   Where *<ptl-cluster-name>* is the name of your portal cluster if you have more than one. To see a list of your portal clusters, run:

   ```
   kubectl get PortalCluster -n <namespace>
   ```

4. Update your dynamic router to redirect all traffic to DC2 instead of DC1.
5. Run the following command to check that the Developer Portal services on DC1 and DC2 are ready for traffic:

   ```
   kubectl describe ptl <ptl-cluster-name> -n <namespace>
   ```

   The services are ready for traffic when the `Ha mode` part of the `Status` object is set on DC1 to `passive`, and is set on DC2 to `active`. For example, on DC2:

   ```
   Status:
     ...
     Ha mode:                              active
     ...
   ```

- **Failover of both Management and Portal subsystems**
  Failover the Management subsystem first, followed by the Portal subsystem.

  How long it takes to complete the failover varies, and depends on hardware speed, network latency, and the size of the databases. Approximate timings are:

  For the Management subsystem:
  - `warm-standby` to `active`: 5 minutes
  - `active` to `warm-standby`: 15 minutes

  For the Developer Portal:
  - `warm-standby` to `active`: 15 - 40 minutes
  - `active` to `warm-standby`: 10 minutes

What to do next

As soon as the failure on the data center is resolved, the failed data center should be brought back online and relinked to the currently active data center to maintain the highest availability; see Recovering from a failover of a two data center deployment for more information.

Recovering from a failover of a two data center deployment

What to do after completing a 2DCDR failover.

Ensure that you have read and understand the concepts of 2DCDR. See Two data center deployment strategy on Kubernetes and OpenShift and Key concepts of 2DCDR and failure scenarios.

This topic describes what to do after you have completed a failover of your 2DCDR deployment, as described in How to perform 2DCDR failover.

If after the failover operation, the failed data center was successfully updated to warm-standby, then verify that replication is working: Verifying replication between data centers. If replication is working, you can either:

- Revert your 2DCDR deployment to the original active and warm-standby data center designations. To revert your deployment, follow the same failover steps: How to perform 2DCDR failover.
- Do nothing, and continue with your current active and warm-standby data center designations.

If your failed data center could not be updated to warm-standby, then ensure that the network links between the data centers are disabled. If the network links remain enabled then a split-brain could occur if your failed data center recovers before you are able to set it to warm-standby.

When you are able to recover the failed data center, ensure that API Connect is set to warm-standby before restoring the network connectivity to the active data center.

If you expect your failed data center to be down for a long time, then convert your active data center to a stand-alone deployment:

- Remove the `multiSiteHA` section from the `spec` sections of your management and portal CRs.

The steps to restore 2DCDR when the failed data center is recovered depend on the state of API Connect on the recovered data center.

- If API Connect is still working on the recovered data center, re-enable 2DCDR as follows:
  1. Add the `multiSiteHA` section back to your working stand-alone deployment. Ensure that it is set to `active`.
  2. Ensure that the `multiSiteHA` section is set to warm-standby (`passive`) on the recovered data center.
  3. Restore the network links between data centers.
- If the API Connect installation on the failed data center is not recoverable, then reinstall API Connect on this data center, and re-enable 2DCDR as follows:
  1. Add the `multiSiteHA` section back to your working stand-alone deployment. Ensure that it is set to `active`.
  2. Ensure that the `multiSiteHA` section is set to warm-standby (`passive`) on the recovered data center.
  3. Copy the `ingress-ca` X.509 certificate from the active data center and apply it on your reinstalled warm-standby data center. For more information, see Check the ingress-ca X.509 certificates match.
  4. Restore the network links between data centers.

Note: If your original active data center was in a failed state for some time, when it is recovered to warm-standby state it will take time for the data from your active data center to replicate across. The time that is taken depends on the size of your management and portal databases and how many changes were made to them while your original active data center was in a failed state.

Backup and restore requirements for a two data center deployment

Points to consider when you configure backup and restore settings on a two data center disaster recovery (2DCDR) deployment.

The 2DCDR backup requirements are different for the Portal and Management subsystems.

Ensure that you have read and understand the concepts of 2DCDR. See Two data center deployment strategy on Kubernetes and OpenShift and Key concepts of 2DCDR and failure scenarios

Management subsystem 2DCDR backup and restore requirements

- Different remote backup locations must be specified for each data center.
- Disable 2DCDR before changing the configuration of S3 backups:
  1. Remove the `multiSiteHA` section from the `spec` section of the management CRs on both data centers. Take note of which data center is the active and which is the warm-standby. Keep a copy of the `multiSiteHA` sections that you remove.
  2. Configure your S3 backup settings. You must specify different backup locations for each data center, see Backup and restore requirements for a two data center deployment.
  3. Add the `multiSiteHA` sections back to the management CRs in both data centers, ensuring that your original active is set to be the active again.

  You do not need to do this for SFTP or local backups.
- Both active and warm-standby Management subsystems run the scheduled backup job.
- To restore from a management backup, follow these steps:

1. Make each management data center a stand-alone API Connect deployment: Remove the `multiSiteHA` section from the `spec` section of the management CRs on both data centers. Keep a copy of the `multiSiteHA` sections that you remove, they are added back at the end of the restore process.
2. You now have two stand-alone API Connect deployments. Decide which data center is to be the active, and restore the backup from that data center. Do not attempt to restore the backup from one data center, to the other data center.
3. Add the `multiSiteHA` section back to the management CR in the restored data center. Ensure that the `multiSiteHA` section defines the data center as the active.
4. Add the `multiSiteHA` section back to the management CR in the other data center. Ensure that the `multiSiteHA` section defines the data center as the warm-standby (passive).
5. The management database takes some time to resync across the data centers. To confirm that replication is working, see: Verifying replication between data centers.

Portal subsystem 2DCDR backup requirements

- The backup settings for both the active and warm-standby portal must be identical.
- Only the active data center portal takes backups. On failover, the backup job of the new warm-standby is disabled, and the backup job of the new active is enabled.
- Portal restores are only done on the active data center.

Configuring backups for 2DCDR deployments

The steps for configuring backups for both subsystems are the same as for a single API Connect deployment, but keep the additional 2DCDR requirements in mind when following them:

- Backups on Kubernetes
- Backups on OpenShift

Related concepts

- Two data center deployment strategy on Kubernetes and OpenShift

Removing a two data center deployment

Convert your 2DCDR deployment to a stand-alone deployment on Kubernetes, OpenShift, and Cloud Pak for Integration.

Ensure that you have read and understand the concepts of 2DCDR. See Two data center deployment strategy on Kubernetes and OpenShift and Key concepts of 2DCDR and failure scenarios.
Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR you must edit the multiSiteHA section for the subsystem in the top-level CR, instead of directly in the subsystem CRs. If the subsystem section is not included in the top-level CR, copy and paste the section from the subsystem CR to the top-level CR.
If you want to revert to a single data center topology:

1. Decide which data center you want to keep. If this data center is not the current active data center, then complete the failover operation to make it the active: How to perform 2DCDR failover.
2. Remove the `spec.multiSiteHA` section from the management subsystem CR on the active data center.
   a. Run:

      ```
      kubectl edit mgmt -n <namespace>
      ```

   b. Delete the `spec.multiSiteHA` section.
3. Remove the `spec.multiSiteHA` section from the portal subsystem CR on the active data center.
   a. Run:

      ```
      kubectl edit ptl <ptl-cluster-name> -n <namespace>
      ```

      Where *<ptl-cluster-name>* is the name of your portal cluster if you have more than one. To see a list of your portal clusters, run:

      ```
      kubectl get PortalCluster -n <namespace>
      ```

   b. Delete the `spec.multiSiteHA` section.
   c. Repeat for each portal cluster if you have more than one.
4. If you want to permanently revert to a single data center topology, then uninstall API Connect on the warm-standby data center. See: Uninstalling API Connect.
   If you plan to restore your 2DCDR deployment in the future with the same warm-standby data center, then you do not need to uninstall API Connect on the warm-standby. Instead, remove the `spec.multiSiteHA` sections from the management and portal CRs, as you did on the active data center. When the `spec.multiSiteHA` section is removed from the CR of the warm-standby data center, all API Connect data is deleted from it, and it remains in an unconfigured state.

Verifying replication between data centers

How to verify that your API Connect data is replicating to your warm-standby data center.

The Management and Portal UIs are not accessible on the warm-standby data center, so it is not possible to check that data replication is working by logging in to the UIs. Instead, you can verify that the warm-standby Management and Portal databases are in sync with command-line operations.
Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Verifying Management replication

The management CR reports a warning if it detects a problem with management data replication:

```
NAME          READY    STATUS     VERSION      RECONCILED VERSION    MESSAGE
AGE
management    n/n      Warning    10.0.5.3-0   10.0.5.3-0            Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "Warning"
    }
```

If the warning persists, then see Troubleshooting a two data center deployment.
To verify replication by creating new data on the active and checking that it is copied to the warm-standby, follow these steps:

1. Login to the Cloud Manager UI.
2. Create a local user registry called **2dcdrtest**: Configuring a Local User Registry.
3. Run the following command in your warm-standby data center to query the management database for the new user registry:

   ```
   kubectl exec -n <namespace> `kubectl -n <namespace> get po -l role=master -o name` -- bash -c "psql apim -c \"select
   name,created_at from user_registry where name = '2dcdrtest'\""
   ```

   Expected output is:

   ```
   Defaulted container "database" out of: database, set-libpq-certs (init)
      name    |       created_at
   -----------+------------------------
    2dcdrtest | <date and time when step 2 was done>
   (1 row)
   ```

   If `2dcdrtest` is returned and has a creation time consistent with when you did step 2, then replication is working. If it is not returned, then either replication is not working, or the data is not yet replicated. If an older creation date is returned, then it's possible the registry was not deleted after a previous check, in which case delete the registry and repeat this test. If replication is not working, follow the 2DCDR troubleshooting steps: Troubleshooting a two data center deployment.
4. Return to the Cloud Manager UI, and delete the **2dcdrtest** user registry.

Verifying Portal replication

Follow these steps to verify that the portal database is replicating from the active data center to the warm-standby data center.

1. In the active data center, identify the active db pod:

   ```
   kubectl get pods -n <namespace> | grep "<active site name>-db"
   ```

   Example output:

   ```
   <portal instance name>-<active site name>-db-0                                    2/2     Running     0
   22h
   ```

   where *<active site name>* is the `siteName` property from the portal CR on your active data center. The active data center db pods have 2 containers, so show a status of 2/2. A three replica deployment has three db pods and you can pick any one of them for the next step.
2. In the active data center, run the following command:

   ```
   kubectl exec -ti -n <namespace> <active portal db pod> -c db -- bash -ic "dbstatus 2>&1 | grep Last | sed 's/.*committed:
   \([0-9]*\).*/\1/'"
   ```

   Example output:

   ```
   355175
   ```

   where *<active portal db pod>* is the pod name that is returned from step 1. The command returns a number.
3. In the warm-standby data center, identify the warm-standby db pod:

   ```
   kubectl get pods -n <namespace> | grep "<warm-standby site name>-db"
   ```

   Example output:

   ```
   <portal instance name>-<warm-standby site name>-db-0                              2/2     Running     0
   22h
   ```

   where *<warm-standby site name>* is the `siteName` property from the portal CR on your warm-standby data center. The warm-standby data center db pods have 1 container, so show a status of 1/1. A three replica deployment has three db pods and you can pick any one of them for the next step.

4. In the warm-standby data center, run the following command:

   ```
   kubectl exec -ti -n <namespace> <passive portal db pod> -c db -- bash -ic "dbstatus 2>&1 | grep Last | sed 's/.*committed: \([0-9]*\).*/\1/'"
   ```

   Example output:

   ```
   355495
   ```

   where *<passive portal db pod>* is the pod name that is returned from step 3. The command returns a number.
5. The numbers that are returned from steps 2 and 4 represent the portal database's last committed transaction number. When the active data center commits a new transaction the number is incremented, this update is replicated to the warm-standby data center. If replication is working the number that is returned from the warm-standby data center should always be close to the number that is returned from the active data center. It is unlikely to be the same number that is returned, unless you are able run step 4 and step 2 at precisely the same time.
6. Repeat steps 2 and 4 several times to confirm that the warm-standby number is keeping up with the active number. If the number returned from the warm-standby data center is far behind, or ahead of the number that is returned from the active, then there is likely to be a replication problem, see Troubleshooting a two data center deployment.

Troubleshooting a two data center deployment

What to check when a 2DCDR deployment is not starting or not replicating data.

Typical causes of 2DCDR failures are network problems between data centers, TLS certificate mismatches, or environmental problems on one of the data centers.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Check that API Connect pods are running

Confirm that all the pods are ready and running:

- To check portal, run:

  ```
  kubectl get ptl -n <namespace>
  ```

  ```
  NAME                          READY                                 STATUS    VERSION    RECONCILED VERSION   MESSAGE
  AGE
  <portal instance name>        <ready pods>/<total number of pods>   Running   10.0.5.x   10.0.5.x-xxxx        Serving 1
  site   14d
  ```

- To check management, run:

  ```
  kubectl get mgmt -n <namespace>
  ```

  ```
  NAME                          READY                                 STATUS    VERSION    RECONCILED VERSION   AGE
  <management instance name>    <ready pods>/<total number of pods>   Running   10.0.5.x   10.0.5.x-xxxx        14d
  ```

The number of *<ready pods>* must match the *<total number of pods>*. If not all the pods are in ready state, run

```
kubectl get <mgmt or ptl> -n <namespace> -o yaml
```

and check the `status.conditions` output, for example:

```
  conditions:
  - lastTransitionTime: "2022-09-27T21:37:21Z",
    message: "Management installation in progress. Not all services are ready, pending services: analytics-proxy, apim, client-downloads-server, juhu, ldap, ...",
    reason: na
    status: "True"
    type: Pending
```

Also, check which pods are not running with:

```
kubectl get pods -n <namespace>
```

and review their logs:

```
kubectl logs <pod name> -n <namespace>
```

Note: The warm-standby management subsystem has fewer pods than the active management subsystem. The active and warm-standby portal subsystems have the same number of pods.

Check the multiSiteHA sections of the management and portal CRs

Run `kubectl describe` on your management and portal CRs to confirm that the `multiSiteHA` specification and status sections of the CR are as expected. For example, on the warm-standby management CR you should see:

```
kubectl describe mgmt -n <namespace>
```

```
...
spec:
  Multi Site HA:
    Mode:  passive
    Replication Endpoint:
      Annotations:
        cert-manager.io/issuer:  ingress-issuer
```

```
      Hosts:
        Name:                mgmt-replication.apps.example.com
        Secret Name:         mgmt-replication-server
    Replication Peer FQDN:   mgmt-replication.apps.example.com
    Tls Client:
      Secret Name:  mgmt-replication-client
...
Status
...
  Ha Mode:                                passive
...
  Multi Site HA:
    Remote Site Deployment Name:  management
    Remote Site Name:             passive
    Remote UUID:                  c736b702-b1ab-4fe2-b132-9c9d3b3a3bd3.9f986be1-14fc-4b3a-8eee-094217ce361e
    Replication Peer:             https://mgmt-replication.apps.example.com/
```

Check that the **Hosts** and **Replication Peer** properties are set correctly in the **multiSiteHA** section, and that the hostnames resolve correctly in each data center.

Check the `ingress-ca` X.509 certificates match

Replication fails if both data centers do not have the same X.509 certificate in their **ingress-ca** secrets. Run the following command in both data centers to see the X.509 certificate, and check that the output is the same:

```
openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d)
```

If you do not have the **openssl** command available, you can instead run only the **kubectl** part, which produces a larger output:

```
kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
```

if the outputs are different, follow these steps to synchronize the certificates:

1. If you installed API Connect on Kubernetes or OpenShift using individual subsystem CRs, determine which data center has the **ingress-ca** Kubernetes cert-manager certificate object:

   ```
   kubectl get certificates -n <namespace> | grep ingress-ca
   ```

   this is your source data center.
2. If you installed API Connect on Cloud Pak for Integration, use the current active data center as the source data center, and the warm-standby as the target data center.
3. Extract the **ingress-ca secret** from your source data center to a file called **new-ca-issuer-secret.yaml**:

   ```
   kubectl get secret ingress-ca -o yaml -n <namespace>  > new-ca-issuer-secret.yaml
   ```

4. Edit the **new-ca-issuer-secret.yaml** file and remove the **creationTimestamp**, **resourceVersion**, **uid**, **namespace**, and **managedFields**. Remove the labels and annotations sections completely. The resulting contents should include the **ingress-ca** X.509 certificate, and the secret name:

   ```
   apiVersion: v1
   data:
     ca.crt: <long cert string>
     tls.crt: <long cert string>
     tls.key: <long cert string>
   kind: Secret
   metadata:
     name: ingress-ca
   type: kubernetes.io/tls
   ```

5. Copy the **new-ca-issuer-secret.yaml** to the target data center.

Follow these steps to apply the extracted **ingress-ca** X.509 certificate on your target data center:

1. To apply the **new-ca-issuer-secret.yaml** file, run:

   ```
   kubectl apply -f new-ca-issuer-secret.yaml -n <namespace>
   ```

2. Regenerate all **ingress-ca** end-entity certificates:

   ```
   kubectl get secrets -n <namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n <namespace>
   ```

   All affected pods should automatically restart. For more information on regenerating certificates, see: Renewing certificates with cert-manager.

Check the operator and tunnel pod logs

The API Connect operator pod manages the 2DCDR deployment. The tunnel pods manage the communication between data centers.

Check the logs of the API Connect operator pod and search for the text "multi" to see any errors that are related to 2DCDR. For example:

```
kubectl logs <ibm-apiconnect operator pod> -n <operator namespace> | grep -i multi
```

The *<ibm-apiconnect operator pod>* has **ibm-apiconnect** in its name, and might be in a different namespace to your API Connect operand pods.

Check the logs of your API Connect **tunnel** pods. These pods always have **tunnel** in their name. For example:

```
kubectl logs portal-tunnel-0 -n <namespace> --since=10m

...
```

```
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 2022-12-02T12:27:33.786Z    INFO    tls     incoming
request {"remote-addr": "10.254.20.144:55042", "uri": "/portal-active-db-0/3060"}
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 2022-12-02T12:27:33.786Z    INFO    tls     connect to
upstream        {"remote-addr": "10.254.20.144:55042", "uri": "/portal-active-db-0/3060"}
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 2022-12-02T12:27:33.817Z    INFO    tls     closing
connection      {"remote-addr": "10.254.20.144:55042", "uri": "/portal-active-db-0/3060"}
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 10.254.20.144 - - [02/Dec/2022:12:27:33 +0000] "GET
/portal-active-db-0/3060 HTTP/1.1" 101 0
```

Note: It is normal for the management tunnel pod to repeatedly log:

```
2022/12/02 12:29:17 http: TLS handshake error from 10.254.16.1:44812: EOF
```

This message can be filtered out with `grep -v`:

```
kubectl logs management-tunnel-574bdcd865-48zh6 -n <namespace> | grep -v "http: TLS handshake error from"
```

Monitoring and health checks

Monitor your deployment and complete health checks on subsystems.

See:

- **Monitoring on Kubernetes**
  Monitor the API Connect subsystems on Kubernetes.
- **Monitoring on OpenShift**
  Monitor your API Connect deployment on OpenShift.
- **Monitoring on Cloud Pak for Integration**
  Monitor your API Connect deployment on Cloud Pak for Integration.
- **Obtaining simple health check data of Developer Portal sites by using a REST API call**
  Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

Monitoring on Kubernetes

Monitor the API Connect subsystems on Kubernetes.

See:

- **Monitoring subsystems on Kubernetes**
  Use `kubectl get` to check the health of the API Connect clusters in your Kubernetes deployment.
- **Monitoring Postgres disk usage**
  Monitor disk usage by the Postgres database in the management subsystem.
- **Monitoring platform health using Kubernetes events**
  Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

Monitoring subsystems on Kubernetes

Use `kubectl get` to check the health of the API Connect clusters in your Kubernetes deployment.

The APIConnect operator controls the life-cycle of management subsystem microservices. When you install, you create the following custom resources (CRs) in order to install API Connect and all subsystems:

- `ManagementCluster` or `mgmt`
- `AnalyticsCluster` or `a7s`
- `PortalCluster` or `ptl`
- `GatewayCluster` or `gw`
  Every CR has a `status` section. The APIConnect operator regularly updates this section with the current status of the subsystem.

For example, use the following command to obtain the status of `ManagementCluster`:

```
kubectl get mgmt -n <namespace>
```

Example:

```
kubectl get mgmt
NAME    READY   STATUS    VERSION      RECONCILED VERSION      AGE
m1      16/16   Running   10.0.6.0      10.0.6.0-44   24m
```

Output:

- `NAME`: Name of the Management Subsystem
- `READY`: Current number of management subsystem which are up, followed by the expected number of management subsystem components which should be up. For example: `16/16`.
- `STATUS`: Current status of Management Subsystem
  During fresh install, upgrade or any maintenance operation, such as changing configuration for S3 backups, Management CR status can go to different states depending on the action, but ultimately it should **always** reach `Running` status.

If the status says **Warning**, then run **kubectl describe mgmt -n <*namespace*>** and check for more details in the **Status** section. For example, a known issue on v10.0.6 and previous with WAL archiving:

```
Status:
  ...
  Conditions:
    ...
    Message:                              WAL Archiving is not working. Last successful archive time: 2022-07-26
20:37:14.456465 +0000 UTC. Last archive failed time: 2022-07-26 21:10:34.172539 +0000 UTC
    Reason:                               WALArchiveNotWorking
    ...
```

Note: If you see the **WAL Archiving is not working** warning message, then verify your S3 backup settings (bucket name, folder name, credentials, certificates), gather logs and open a support request.

- **VERSION**: Version chosen in **spec.version** in the management CR.
- **RECONCILED VERSION**: Current management subsystem version. Includes a build number.
- **AGE**: Age of the management subsystem CR.

Monitoring Postgres disk usage

Monitor disk usage by the Postgres database in the management subsystem.

Postgres Database is the core database used in Management Subsystem. It is important to monitor the Postgres disk usage.

In 10.0.3.0 and greater, the APIConnect operator tracks the current disk usage of the Postgres components, and regularly updates the **ManagementCluster** status. When one or more of the Postgres components occupy 50% of the PVC (persistent volume claim) capacity, the APIConnect operator changes the status from **Running** to **Warning**.

APIConnect operator **brings down** Postgres if the disk allocation reaches **80%**. In this case, you must contact IBM support.

Note that there are various types of storage classes which can be used to deploy Management Subsystem. For example, **local-storage** or **ceph block**.

Management Cluster disk stats

The **ManagementCluster** instance has **.status.postgresDataStats** where the operator prints the current disk usage of Postgres components. For example:

```
kubectl get mgmt m1  -o json | jq .status.postgresDataStats
[
  {
    "instanceName": "m1-ed60c42d-postgres",
    "podName": "m1-ed60c42d-postgres-86766f69cb-xs7t5",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres",
    "pvcType": "PostgreSQL",
    "pvcUsed": 60895232,
    "pvcUsedPercentage": 0
  },
  {
    "instanceName": "m1-ed60c42d-postgres-backrest-shared-repo",
    "podName": "m1-ed60c42d-postgres-backrest-shared-repo-859484b5f6-r7cv6",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-pgbr-repo",
    "pvcType": "pgBackRest",
    "pvcUsed": 16203776,
    "pvcUsedPercentage": 0
  },
  {
    "instanceName": "m1-ed60c42d-postgres",
    "podName": "m1-ed60c42d-postgres-86766f69cb-xs7t5",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-wal",
    "pvcType": "WAL",
    "pvcUsed": 201338880,
    "pvcUsedPercentage": 0
  },
  {
    "instanceName": "m1-ed60c42d-postgres-fqbg",
    "podName": "m1-ed60c42d-postgres-fqbg-84869d976c-49qgc",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-fqbg",
    "pvcType": "PostgreSQL",
    "pvcUsed": 59994112,
    "pvcUsedPercentage": 0
  },
  {
    "instanceName": "m1-ed60c42d-postgres-fqbg",
    "podName": "m1-ed60c42d-postgres-fqbg-84869d976c-49qgc",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-fqbg-wal",
    "pvcType": "WAL",
    "pvcUsed": 201334784,
    "pvcUsedPercentage": 0
  },
  {
```

```
    "instanceName": "m1-ed60c42d-postgres-cimo",
    "podName": "m1-ed60c42d-postgres-cimo-5769868b75-5z7ln",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-cimo",
    "pvcType": "PostgreSQL",
    "pvcUsed": 59994112,
    "pvcUsedPercentage": 0
  },
  {
    "instanceName": "m1-ed60c42d-postgres-cimo",
    "podName": "m1-ed60c42d-postgres-cimo-5769868b75-5z7ln",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-cimo-wal",
    "pvcType": "WAL",
    "pvcUsed": 201334784,
    "pvcUsedPercentage": 0
  }
]
```

Warning condition is populated at 50% usage

When one of the Postgres components occupy 50% usage, the operator marks the overall status of the **ManagementCluster** to **Warning** with an appropriate warning message. The operator also updates the **postgresDataStats** section with the current data usage of the Postgres components.

Example of warning state:

```
kubectl get mgmt m1

NAME    READY   STATUS    VERSION      RECONCILED VERSION      AGE
m1      17/17   Warning   10.0.1-eus   10.0.1.4-ifix1-44-eus   26h

kubectl get mgmt m1 -o json | jq .status.phase

"Warning"
```

Example of list of warning conditions:

```
kubectl get mgmt m1 -o json | jq .status.conditions

[
  {
    "lastTransitionTime": "2021-09-08T19:49:51Z",
    "message": "Current WAL disk usage of m1-ed60c42d-postgres is 51 percent. DATABASE SHUTDOWN starts at 80 percent
utilization. Please contact IBM Support immediately",
    "reason": "disk_usage_more_than_50_percent",
    "status": "True",
    "type": "Warning"
  },
  {
    "lastTransitionTime": "2021-09-08T19:42:30Z",
    "message": "",
    "reason": "na",
    "status": "False",
    "type": "Ready"
  },
  {
    "lastTransitionTime": "2021-09-08T19:41:35Z",
    "message": "",
    "reason": "na",
    "status": "False",
    "type": "Pending"
  },
  {
    "lastTransitionTime": "2021-09-07T17:18:02Z",
    "message": "",
    "reason": "na",
    "status": "False",
    "type": "Error"
  },
  {
    "lastTransitionTime": "2021-09-07T17:18:02Z",
    "message": "",
    "reason": "na",
    "status": "False",
    "type": "Failed"
  }
]
```

The warning condition explains why the warning condition was set. For example:

```
Current WAL disk usage of m1-ed60c42d-postgres is 51 percent. DATABASE SHUTDOWN starts at 80 percent utilization. Please
contact IBM Support immediately
```

If you encounter the warning, contact IBM support to fix the root cause.

Error condition is populated at 80% usage

An error condition is populated when the operator brings down Postgres because is using 80% of available disk space. Postgres is brought down to avoid problems, such as disk corruption, that can occur if the disk becomes completely filled.

```
- lastTransitionTime: "2021-08-28T01:42:56Z"
  message: Current WAL disk usage of nihar-stac-3955b42d-site1-postgres is more
    than 70 percent, initiating DATABASE SHUTDOWN
  reason: disk_usage_more_than_70_percent
  status: "True"
  type: Error
```

If you encounter the error, contact IBM support to fix the root cause.

Important:
When **local-storage** is used, it uses the entire disk that is allocated to the worker node. In some cases, Kubernetes itself can face disk pressure before the operator reacts to 80% usage, and will start evicting pods. In these cases, you might need to increase the disk allocated to the worker node, in order to stabilize the worker node, by following Recovering when disks are filled by the management database.

Monitoring platform health using Kubernetes events

Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

What are the Kubernetes events?

The CR for every subsystem of API Connect has a status condition section, which is regularly updated by the API Connect operator with the current status. The API Connect operator additionally generates a Kubernetes event whenever there is a change in the CR status.

Events are enabled in API Connect operator for the following resources.

- **APIConnectCluster** CR
- **ManagementCluster** CR
- **GatewayCluster** CR
- **AnalyticsCluster** CR
- **PortalCluster** CR

Two types of events are generated when the CR status changes:

- **Normal** - Indicates that the status change is not causing any issues.
- **Warning** - Indicates that there a problem that requires your attention.

You can automatically monitor the status condition in your existing alerting system, or by integrating the Kubernetes events into a third-party alerting solution. For more information, see the following blog post: How to use Kubernetes events for effective alerting and monitoring.

Viewing the events

The default retention period of events in Kubernetes is 1 hour (controlled by **kube-apiserver**). To view the events, complete the following steps:

1. Run the **kubectl describe** against the resource you want to monitor; for example:

   ```
   kubectl describe APIConnectCluster
   ```

2. In the response, scroll to the end to see the events information, which looks like the following example:

   ```
          Name:           10.0.5.3-1
      Reconciled:         10.0.5.3-1
   Events:
     Type    Reason     Age    From                       Message
     ----    ------     ----   ----                       -------
     Normal  Running    10h    ibm-apiconnect-operator    All services ready.
     Normal  Deploying  10h    ibm-apiconnect-operator    Not all services are ready, pending services: management
   ```

Monitoring on OpenShift

Monitor your API Connect deployment on OpenShift.

See:

- **Monitoring the API Connect cluster on OpenShift**
  Monitor the status of the API Connect cluster on OpenShift using either the command line or the OpenShift web console.
- **Monitoring Postgres disk usage on OpenShift**
  In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.
- **Monitoring platform health on Red Hat OpenShift using Kubernetes events**
  Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

Monitoring the API Connect cluster on OpenShift

Monitor the status of the API Connect cluster on OpenShift using either the command line or the OpenShift web console.

You deploy the API Connect subsystems on OpenShift with the **APIConnect** operator and the **apiconnectcluster** CR. The CR contains a status section that is regularly updated by the operator to display the current status of the all the API Connect subsystems.

When you finish deploying API Connect, you can monitor the status of **apiconnectcluster** using the command line or the OpenShift web console.

- Monitoring the API Connect cluster using the command line
- Monitoring the API Connect cluster using the OpenShift web console

Note: You can also monitor the disk usage of Postgres microservices. The **APIConnect** operator continuously tracks the disk usage of postgres microservices and provides useful information in the **ManagementCluster** custom resource. For information on viewing the postgres disk status, see Monitoring Postgres disk usage on OpenShift.

Monitoring the API Connect cluster using the command line

Run the following command to display the status of the API Connect cluster:

```
oc get apiconnectcluster -n <APIC_namespace>
```

The response looks like the following example:

```
NAME          READY   STATUS   VERSION         RECONCILED VERSION   AGE
production    7/7     Ready    10.0.6.0    10.0.6.0-3323    24h
```

The following list explains the values in the response:

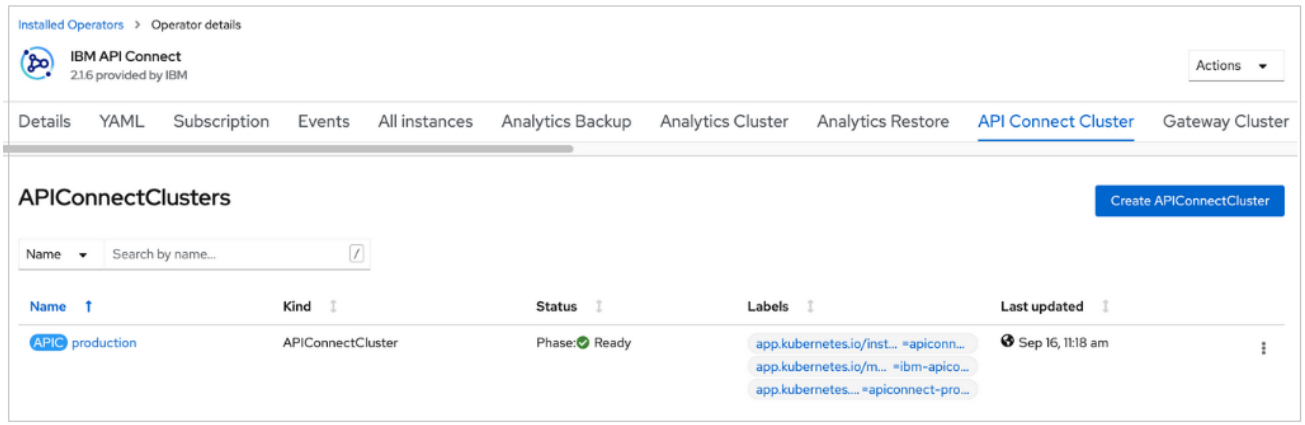
- **NAME**: Name of the API Connect instance (in the example, the instance name is "production").
- **READY**: Current number of subsystems and components that are running **/** Expected number of subsystems and components that should be running.
- **STATUS**: Current status of API Connect.
  If the status says **Warning**, then run **oc describe apiconnectcluster -n <namespace>** and check for more details in the **Status** sections. For example, a known issue on v10.0.6 and previous with WAL archiving:

  ```
  Status:
    ...
    Conditions:
      ...
      Message:                              WAL Archiving is not working. Last successful archive time: 2022-07-26
  20:37:14.456465 +0000 UTC. Last archive failed time: 2022-07-26 21:10:34.172539 +0000 UTC
      Reason:                               WALArchiveNotWorking
      ...
  ```

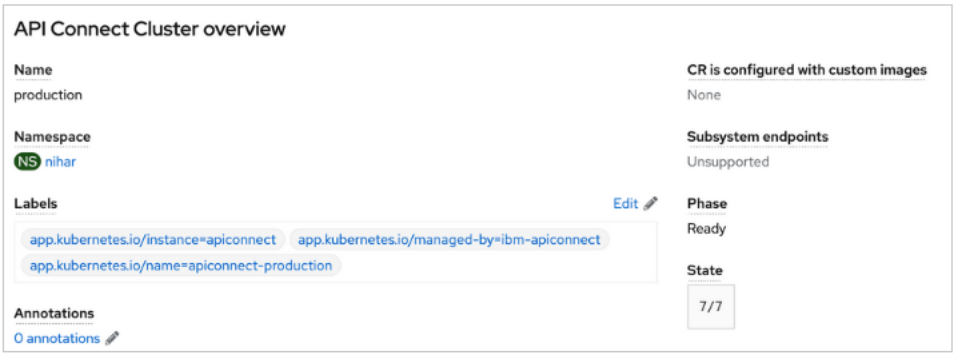
  Note: If you see the **WAL Archiving is not working** warning message, then verify your S3 backup settings (bucket name, folder name, credentials, certificates), gather logs and open a support request.
- **VERSION**: API Connect version specified in the CR's **spec.version** setting.
- **RECONCILED VERSION**: Current API Connect version.
- **AGE**: Age of the **apiconnectcluster** CR.

Monitoring the API Connect cluster using the OpenShift web console

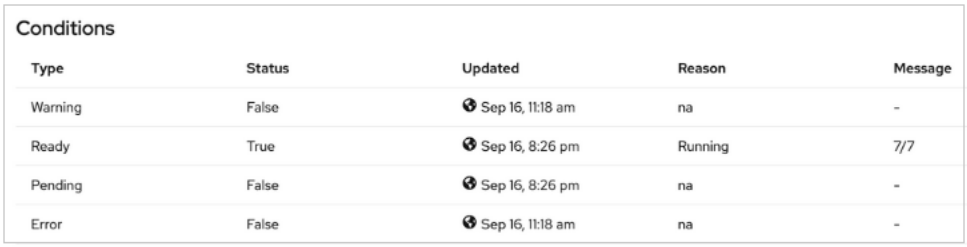
1. Start the OpenShift web console.
2. Click Installed operators.
3. Locate the namespace (project) where you installed API Connect:
   - If you installed the API Connect operator in all namespaces, select openshift-operators
   - if you installed the API Connect operator in a single namespace, select specific project
4. Hover next to the name of the API Connect namespace and click API Connect Cluster.
5. On the API Connect Clusters page, check the Status column.
   The status should display "Ready" as in the following image:



6. Click the instance name (in the example, the instance name is production to display the status overview page.
   The overview page displays high-level information about your deployment, as in the following image:



Also on the overview page, the "Conditions" section displays the list of possible service conditions, as in the following image:



A healthy deployment displays "True" for the "Ready" status.

During a fresh install, an upgrade or a day-2 operation (such as a Management backup S3 configuration change), the **`apiconnectcluster`** CR status might change to a different state depending on the action, but ultimately it should always reach the **`Ready`** status.

Monitoring Postgres disk usage on OpenShift

In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.

The Postgres database is the core database used in the Management subsystem. It is important to monitor the Postgres disk usage to avoid running out of space and causing an outage in your deployment.

In Version 10.0.3 and later, the **`APIConnect`** operator tracks the current disk usage of the Postgres components, and regularly updates the **`ManagementCluster`** CR's status. When one or more of the Postgres components occupy 50% of the PVC (persistent volume claim) capacity, the **`APIConnect`** operator changes the CR's status from **`Running`** to **`Warning`**.

Important: If the Postgres disk usage reaches 80%, then the **`APIConnect`** operator brings down Postgres. If this situation occurs, contact IBM Support.
Note that there are various types of storage classes which can be used to deploy Management subsystem; for example, **`local-storage`** or **`ceph block`**. When **`local-storage`** is used, the entire disk is allocated to the worker node. In some cases, before the **`APIConnect`** operator reacts to an 80% usage condition, Kubernetes itself might face disk pressure and start evicting pods. In this situation, you might want to increase the size of the disk allocated to the worker node as explained in Recovering on OpenShift and Cloud Pak for Integration when disks are filled by the management database.

Viewing the current disk usage

The **`ManagementCluster`** instance includes the **`.status.postgresDataStats`** field, where the operator displays the current disk usage of Postgres components. Run the following command to get the disk usage:

```
ocp get mgmt m1 -n APIC_namespace -o json | jq .status.postgresDataStats
```

The response looks like the following example:

```
[
  {
    "instanceName": "m1-ed60c42d-postgres",
    "podName": "m1-ed60c42d-postgres-86766f69cb-xs7t5",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres",
    "pvcType": "PostgreSQL",
    "pvcUsed": 60895232,
    "pvcUsedPercentage": 0
  },
  {

    "podName": "m1-ed60c42d-postgres-backrest-shared-repo-859484b5f6-r7cv6",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-pgbr-repo",
    "pvcType": "pgBackRest",
    "pvcUsed": 16203776,
    "pvcUsedPercentage": 0
  },
  {
    "instanceName": "m1-ed60c42d-postgres",
    "podName": "m1-ed60c42d-postgres-86766f69cb-xs7t5",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-wal",
```

```
    "pvcType": "WAL",
    "pvcUsed": 201338880,
    "pvcUsedPercentage": 0
  },
  {
    "instanceName": "m1-ed60c42d-postgres-fqbg",
    "podName": "m1-ed60c42d-postgres-fqbg-84869d976c-49qgc",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-fqbg",
    "pvcType": "PostgreSQL",
    "pvcUsed": 59994112,
    "pvcUsedPercentage": 0
  },
  {
    "instanceName": "m1-ed60c42d-postgres-fqbg",
    "podName": "m1-ed60c42d-postgres-fqbg-84869d976c-49qgc",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-fqbg-wal",
    "pvcType": "WAL",
    "pvcUsed": 201334784,
    "pvcUsedPercentage": 0
  },
  {
    "instanceName": "m1-ed60c42d-postgres-cimo",
    "podName": "m1-ed60c42d-postgres-cimo-5769868b75-5z7ln",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-cimo",
    "pvcType": "PostgreSQL",
    "pvcUsed": 59994112,
    "pvcUsedPercentage": 0
  },
  {
    "instanceName": "m1-ed60c42d-postgres-cimo",
    "podName": "m1-ed60c42d-postgres-cimo-5769868b75-5z7ln",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres-cimo-wal",
    "pvcType": "WAL",
    "pvcUsed": 201334784,
    "pvcUsedPercentage": 0
  }
]
```

Warning condition is populated at 50% usage

When one of the Postgres components uses 50% of its allocated space, the operator changes the overall status of the **ManagementCluster** to **Warning** with an appropriate warning message. The operator also updates the **postgresDataStats** section with the current data usage of the Postgres components.

Attention: If you encounter the **Warning** condition, contact IBM Support for help correcting the root cause.
To view the status, run the following command:

```
oc get mgmt m1
```

The following example response shows the warning state:

```
NAME   READY   STATUS    VERSION      RECONCILED VERSION      AGE
m1     17/17   Warning   10.0.1-eus   10.0.1.4-ifix1-44-eus   26h
```

To view just the status, run the following command:

```
oc get mgmt m1 -o json | jq .status.phase
```

In this example, the status displayed in the response is "Warning":

```
"Warning"
```

To see the list of current status conditions, run the following command:

```
oc get mgmt m1 -o json | jq .status.conditions
```

The following example response displays the list of status conditions. Notice that the **Warning**"condition is set to "True" and the other conditions are set to "False":

```
[
  {
    "lastTransitionTime": "2021-09-08T19:49:51Z",
    "message": "Current WAL disk usage of m1-ed60c42d-postgres is 51 percent. DATABASE SHUTDOWN starts at 80 percent
utilization. Please contact IBM Support immediately",
    "reason": "disk_usage_more_than_50_percent",
    "status": "True",
    "type": "Warning"
  },
  {
    "lastTransitionTime": "2021-09-08T19:42:30Z",
    "message": "",
    "reason": "na",
    "status": "False",
    "type": "Ready"
  },
  {
    "lastTransitionTime": "2021-09-08T19:41:35Z",
    "message": "",
    "reason": "na",
    "status": "False",
```

```
    "type": "Pending"
  },
  {
    "lastTransitionTime": "2021-09-07T17:18:02Z",
    "message": "",
    "reason": "na",
    "status": "False",
    "type": "Error"
  },
  {
    "lastTransitionTime": "2021-09-07T17:18:02Z",
    "message": "",
    "reason": "na",
    "status": "False",
    "type": "Failed"
  }
]
```

The warning condition includes an explanation of why the condition was set to "True"; for example:

```
Current WAL disk usage of m1-ed60c42d-postgres is 51 percent. DATABASE SHUTDOWN starts at 80 percent utilization. Please
contact IBM Support immediately
```

Error condition is populated at 80% usage

When one of the Postgres components uses 80% of its allocated space, the operator changes the overall status of the **ManagementCluster** to **Error** and brings down Postgres avoid problems that can occur if the disk becomes completely filled.

Attention: If you encounter the **Error** condition, contact IBM Support for help correcting the root cause.
In this case, when you run the following command to view the status conditions, you will see that the "Error" condition is set to "True:

```
oc get mgmt m1 -o json | jq .status.conditions
```

For example, the following condition shows the **Error** status set to "True" due to disk usage:

```
- lastTransitionTime: "2021-08-28T01:42:56Z"
  message: Current WAL disk usage of nihar-stac-3955b42d-site1-postgres is more
    than 70 percent, initiating DATABASE SHUTDOWN
  reason: disk_usage_more_than_70_percent
  status: "True"
  type: Error
```

Monitoring platform health on Red Hat OpenShift using Kubernetes events

Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

What are the Kubernetes events?

The CR for every subsystem of API Connect has a status condition section, which is regularly updated by the API Connect operator with the current status. The API Connect operator additionally generates a Kubernetes event whenever there is a change in the CR status.

Events are enabled in API Connect operator for the following resources.

- **APIConnectCluster** CR
- **ManagementCluster** CR
- **GatewayCluster** CR
- **AnalyticsCluster** CR
- **PortalCluster** CR

Two types of events are generated when the CR status changes:

- **Normal** - Indicates that the status change is not causing any issues.
- **Warning** - Indicates that there a problem that requires your attention.

You can automatically monitor the status condition in your existing alerting system, or by integrating the Kubernetes events into a third-party alerting solution. For more information, see the following blog post: How to use Kubernetes events for effective alerting and monitoring.

Viewing the events

The default retention period of events in Red Hat OpenShift is 3 hours (controlled by **kube-apiserver**). To view the events, complete the following steps:

1. In the Web UI, click Operators > Installed Operators > IBM API Connect > API Connect Clusters.
2. Select an instance by clicking its name: Management cluster, Gateway cluster, Portal cluster, or Analytics cluster. If you installed using the top-level **APIConnectCluster** CR, you can additionally select API Connect cluster.
3. Select the Events tab to see all of the events that were generated for that instance.

Monitoring on Cloud Pak for Integration

Monitor your API Connect deployment on Cloud Pak for Integration.

See:

- **Monitoring the API Connect cluster on Cloud Pak for Integration**
  Monitor the status of the API Connect cluster on Cloud Pak for Integration using either the command line or the IBM Cloud Pak Platform UI.
- **Monitoring Postgres disk usage on Cloud Pak for Integration**
  In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.

Monitoring the API Connect cluster on Cloud Pak for Integration

Monitor the status of the API Connect cluster on Cloud Pak for Integration using either the command line or the IBM Cloud Pak Platform UI.

In Cloud Pak for Integration, the API Management capability is provide by API Connect. You deploy the API Connect subsystems on Cloud Pak for Integration with the **APIConnect** operator and the **apiconnectcluster** CR. The CR contains a status section that is regularly updated by the operator to display the current status of the all the API Connect subsystems.

When you finish deploying API Connect, you can monitor the status of **apiconnectcluster** using the command line or the OpenShift web console.

- Monitoring the API Connect cluster using the command line
- Monitoring the API Connect cluster using the Platform UI

Note: You can also monitor the disk usage of Postgres microservices. The **APIConnect** operator continuously tracks the disk usage of postgres microservices and provides useful information in the **ManagementCluster** custom resource. For information on viewing the postgres disk status, see Monitoring Postgres disk usage on Cloud Pak for Integration.

Monitoring the API Connect cluster using the command line

Run the following command to display the status of the API Connect cluster:

```
oc get apiconnectcluster -n <APIC_namespace>
```

The response looks like the following example:

```
NAME          READY   STATUS   VERSION         RECONCILED VERSION   AGE
production    7/7     Ready    10.0.6.0        10.0.6.0-3323        24h
```

The following list explains the values in the response:

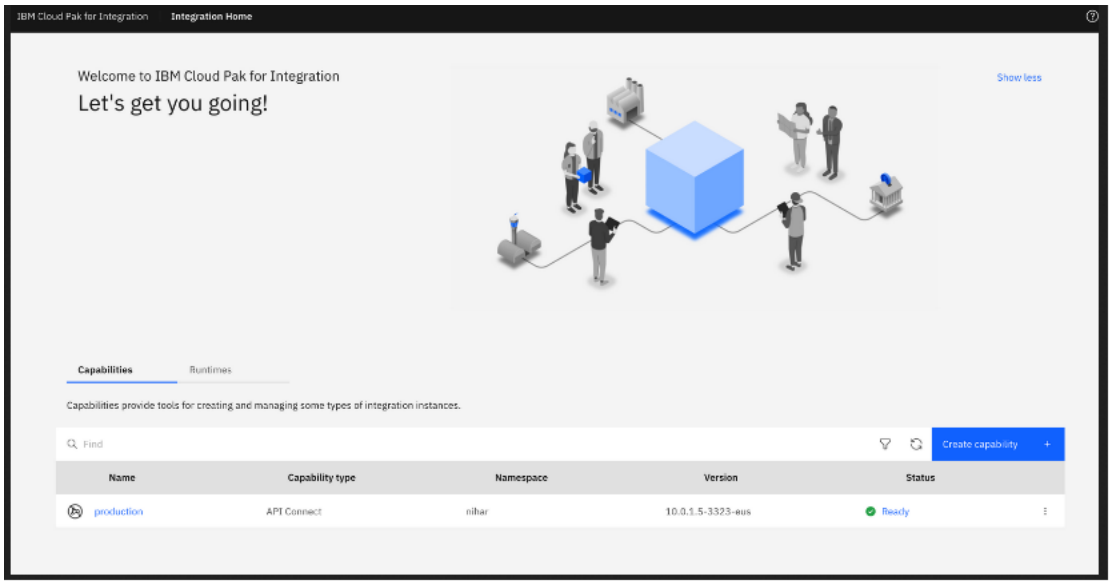
- **NAME**: Name of the API Connect instance (in the example, the instance name is "production").
- **READY**: Current number of subsystems and components that are running **/** Expected number of subsystems and components that should be running.
- **STATUS**: Current status of API Connect.
  If the status says **Warning**, then run **oc describe apiconnectcluster -n <namespace>** and check for more details in the **Status** sections. For example, a known issue on v10.0.6 and previous with WAL archiving:

  ```
  Status:
    ...
    Conditions:
      ...
      Message:                            WAL Archiving is not working. Last successful archive time: 2022-07-26
  20:37:14.456465 +0000 UTC. Last archive failed time: 2022-07-26 21:10:34.172539 +0000 UTC
      Reason:                             WALArchiveNotWorking
      ...
  ```

  Note: If you see the **WAL Archiving is not working** warning message, then verify your S3 backup settings (bucket name, folder name, credentials, certificates), gather logs and open a support request.
- **VERSION**: API Connect version specified in the CR's **spec.version** setting.
- **RECONCILED VERSION**: Current API Connect version.
- **AGE**: Age of the **apiconnectcluster** CR.

Monitoring the API Connect cluster using the Platform UI

1. Start the Platform UI.
2. Click the Integration instances tab.
3. Locate the "API Connect" capability that uses the instance name that you specified as the Name during installation.
   A healthy API Connect deployment displays "Ready" in the Status column



4. Click the status value to display information about the current conditions, as in the following image:

A healthy deployment displays "True" for the "Ready" status.

During a fresh install, an upgrade or a day-2 operation (such as a Management backup S3 configuration change), the **apiconnectcluster** CR status might change to a different state depending on the action, but ultimately it should always reach the **Ready** status.

Monitoring Postgres disk usage on Cloud Pak for Integration

In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.

The Postgres database is the core database used in the Management subsystem. It is important to monitor the Postgres disk usage to avoid running out of space and causing an outage in your deployment.

In API Connect 10.0.3 and later, the **APIConnect** operator tracks the current disk usage of the Postgres components, and regularly updates the **ManagementCluster** CR's status. When one or more of the Postgres components occupy 50% of the PVC (persistent volume claim) capacity, the **APIConnect** operator changes the CR's status from **Running** to **Warning**.

Important: If the Postgres disk usage reaches 80%, then the **APIConnect** operator brings down Postgres. If this situation occurs, contact IBM Support.
Note that there are various types of storage classes which can be used to deploy Management subsystem; for example, **local-storage** or **ceph block**. When **local-storage** is used, the entire disk is allocated to the worker node. In some cases, before the **APIConnect** operator reacts to an 80% usage condition, Kubernetes itself might face disk pressure and start evicting pods. In this situation, you might want to increase the size of the disk allocated to the worker node as explained in Recovering on OpenShift and Cloud Pak for Integration when disks are filled by the management database.

Viewing the current disk usage

The **ManagementCluster** instance includes the **.status.postgresDataStats** field, where the operator displays the current disk usage of Postgres components. Run the following command to get the disk usage:

```
ocp get mgmt m1 -n APIC_namespace -o json | jq .status.postgresDataStats
```

The response looks like the following example:

```
[
  {
    "instanceName": "m1-ed60c42d-postgres",
    "podName": "m1-ed60c42d-postgres-86766f69cb-xs7t5",
    "pvcCapacity": 250181844992,
    "pvcName": "m1-ed60c42d-postgres",
    "pvcType": "PostgreSQL",
    "pvcUsed": 60895232,
    "pvcUsedPercentage": 0
  },
```

```
  {
    "instanceName": "m1-ed60c42d-postgres-backrest-shared-repo",
    "podName": "m1-ed60c42d-postgres-backrest-shared-repo-859484b5f6-r7cv6",

    "pvcName": "m1-ed60c42d-postgres-cimo-wal",
    "pvcType": "WAL",
    "pvcUsed": 201334784,
    "pvcUsedPercentage": 0
  }
]
```

Warning condition is populated at 50% usage

When one of the Postgres components uses 50% of its allocated space, the operator changes the overall status of the **ManagementCluster** CR and the **APIConnectCluster** CR to **Warning** with an appropriate warning message. The operator also updates the **postgresDataStats** section with the current data usage of the Postgres components.

Attention: If you encounter the **Warning** condition, contact IBM Support for help correcting the root cause.
To view the status from the command line, run the following command:

- **APIConnectCluster** CR:

  ```
  oc get apiconnect
  ```

  The following example response shows the warning status:

  ```
  NAME         READY
  STATUS   VERSION        RECONCILED VERSION   AGE
  production   Current WAL disk usage of production-mgmt-31be1757-postgres is 60 percent. DATABASE SHUTDOWN starts at 80
  percent utilization. Please contact IBM Support immediately.   Warning    10.0.1.5-eus   10.0.1.5-3394-eus    11d
  ```

- **ManagementCluster** CR:

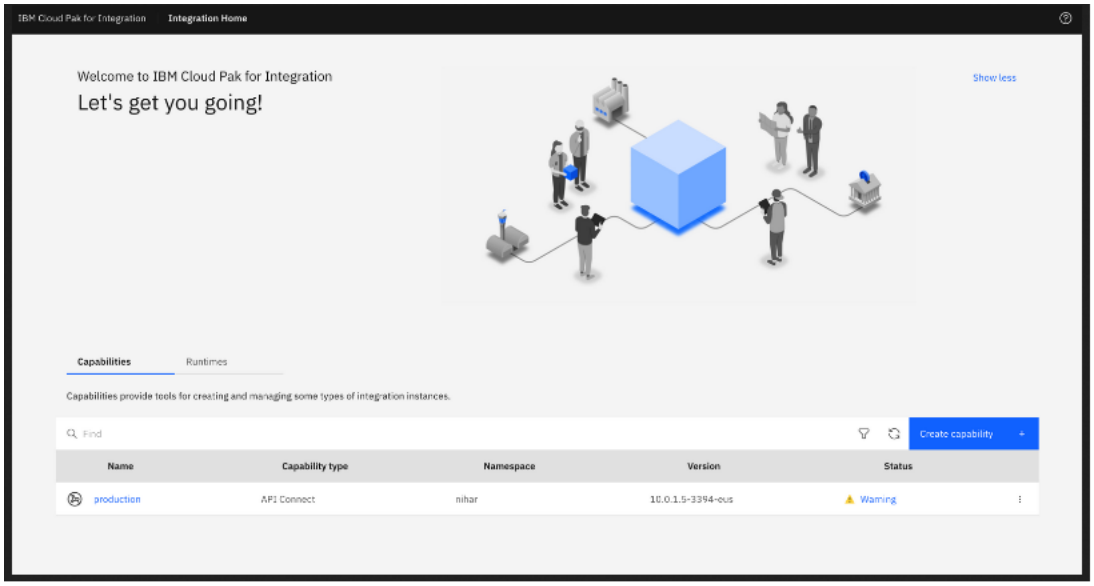
  ```
  oc get mgmt
  ```

  The following example response shows the warning status:

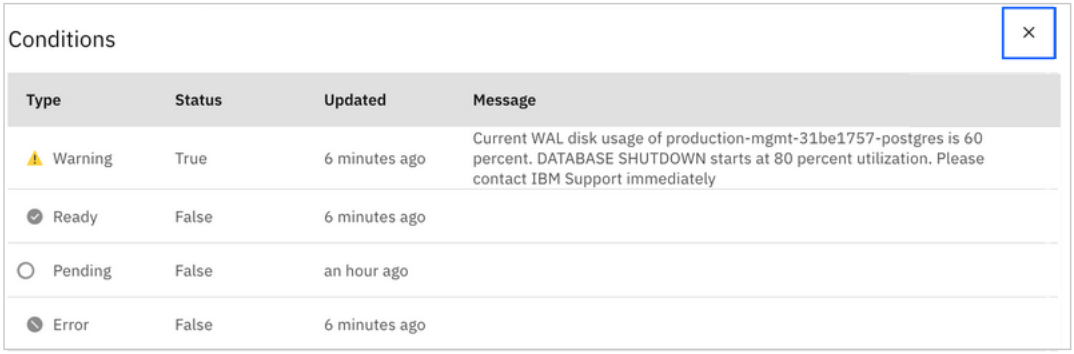
  ```
  NAME              READY   STATUS    VERSION        RECONCILED VERSION   AGE
  production-mgmt   18/18   Warning   10.0.1.5-eus   10.0.1.5-3394-eus    43h

  Current WAL disk usage of m1-ed60c42d-postgres is 51 percent. DATABASE SHUTDOWN starts at 80 percent utilization. Please
  contact IBM Support immediately
  ```

To view the status in IBM Cloud Pak Platform UI, click the Integration instances tab to see the status displayed next to the instance name



Click the status value (Warning, for this example) to display the Conditions list where a detailed message explains why the condition was set:



Error condition is populated at 80% usage

When one of the Postgres components uses 80% of its allocated space, the operator changes the overall status of the **`ManagementCluster`** to **`Error`** and brings down Postgres avoid problems that can occur if the disk becomes completely filled.

Attention: If you encounter the **`Error`** condition, contact IBM Support for help correcting the root cause.
To view the status from the command line, run the following command:

- **`APIConnectCluster`** CR:

  `oc get apiconnect`

  The following example response shows the error status:

  ```
  NAME          READY
  STATUS    VERSION         RECONCILED VERSION    AGE
  production    Current disk usage is more than 80 percent. DATABASE will be shutdown. Please contact IBM Support
  immediately.    Error     10.0.1.5-eus    10.0.1.5-3394-eus     11d
  ```

- **`ManagementCluster`** CR:

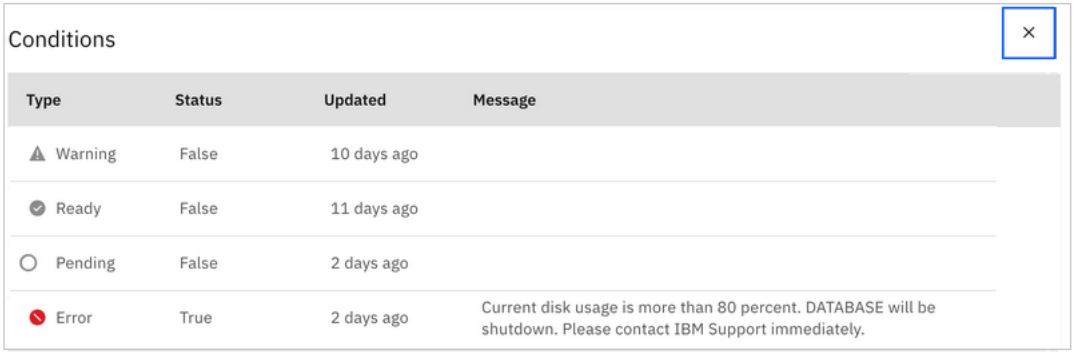
  `oc get mgmt`

  The following example response shows the warning status:

  ```
  NAME                READY    STATUS    VERSION         RECONCILED VERSION    AGE
  production-mgmt     9/9      Error     10.0.1.5-eus    10.0.1.5-3394-eus     11d
  ```

To view the status in the Platform UI, click the Integration instances tab to see the status displayed next to the instance name

Click the status value (Error in this example) to display the Conditions list where a detailed message explains why the condition was set:



Obtaining simple health check data of Developer Portal sites by using a REST API call

Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

About this task

You can use the site health REST API to determine whether a particular Developer Portal site is running. The site health API returns the current system time of the site if both the database and web server are running. This API is fast and puts no load on the system, so it is ideal for use with load balancers to help them determine where to route traffic.

Procedure

To call the site health REST API, append `/health` to the end of your Developer Portal site URL in your web browser, as follows:

`site_url/health`

Where `site_url` is the URL of the Developer Portal site that you want to check.
If both the database and web server of the site are running, the web browser returns the current system time. For example:

```
1511367695
```

If either the database or the web server of the site is not running, the web browser returns an error that the site can't be reached.

Logging

Configure logging for your deployment on Kubernetes.

See:

- **Gathering post-mortem logs**
  The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.

- **Changing logging levels**
  You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

Gathering post-mortem logs

The **generate_postmortem.sh** script gathers all logs for troubleshooting and diagnostics.

About this task

When you contact IBM Support, API Connect pod logs and associated Kubernetes or OpenShift environment data are normally required to help in diagnostics. The **generate_postmortem.sh** script gathers all the required logs and data.

The logs that are gathered by the **generate_postmortem.sh** script include the logs of the current running API Connect containers. The container logs have a maximum size, and older log messages are not retained when the maximum size is reached. To ensure that the logs gathered cover the time when the problem occurred, it is recommended to reproduce the problem and then immediately gather the logs. Also, to ensure that you have logs of previous failed containers, the recommended best practice is to offboard your logs to a remote server for long-term storage. Use ELK, or another logging infrastructure, to gather logs that include terminated pods and processes. For more information, see https://www.elastic.co/elk-stack

Procedure

1. Download the v10 **generate_postmortem.sh** script from https://github.com/ibm-apiconnect/v10-postmortem.
2. Run the script in your Kubernetes or OpenShift environment, following the instructions on https://github.com/ibm-apiconnect/v10-postmortem.
3. Upload the generated output file with your IBM support case.

What to do next

If the logs do not cover far enough back in time, or conversely if they are too large, adjust the log retention size. For further information, see: https://docs.docker.com/config/containers/logging/json-file/.

If you are not able to run the **generate_postmortem.sh** script, the API Connect container logs can be gathered manually with the following command:

```
kubectl logs -n <namespace> <pod name> [-c <container name>]
```

Redirect the output of the **logs** command to a file that you can upload to the support case, for example:

```
kubectl logs -n apic-ns apic-apim-77fdf47c55-vgnr2 > apimpod.log
```

Changing logging levels

You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

About this task

For apim-v2 pods, the default logging settings do not include entry and exit trace and logging of large payloads.

Logging of large payloads is typically needed if you are logging **apim:webhookPayload** or other processes that log large variables.

You can also set the debug level without needing to restart the pods.

You can enable the settings through either the APIM deployment YAML file, the toolkit, or the REST APIs. Note, you must use the toolkit or REST API to set the debug level without restarting the pods.

Procedure

- Updating the settings in the APIM deployment YAML file
  Note: This action causes a pod restart.
  - The DEBUG variable works the same as prior releases.

    ```
    - env:
        - name: DEBUG
          value:
    audit,bhendi:error,bhendi:probe,bhendi:flags,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:
    *
    ```

    To enable entry and exit trace, add **trace:*** to the start of the debug string:

    ```
    - env:
        - name: DEBUG
          value: trace:*,audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:webhookAudit,bhendi:cassandra-
    transactions,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*,apim:taskmanager:info
    ```

  - To enable large object logging:

    ```
    - env:
        - name: VELOX_LOG_FULL_PAYLOAD
          value: "true"
    ```

- Updating the settings by using the toolkit
  Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

  ```
  apic log-spec:get
  apic log-spec:update  LOG_SPEC_FILE
  ```

  Where the spec file contains:

  ```
  {"specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}
  ```

- Updating the settings by using the REST API
  Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

  ```
  GET /cloud/api/log-spec
  PUT /cloud/api/log-spec
  ```

  For example, to set debug level and large objects logging:

  ```
  curl -k https://172.16.140.212:3003/api/cloud/log-spec -X PUT -H "Authorization: Bearer $BEARER"
      -H "Accept: application/json" -d '{"specification":
  "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error","large_objects": true}'
      -H "Content-Type: application/json"
  ```

  The command responds with:

  ```
  {
      "specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error",
      "large_objects": true,
      "message": "Successfully changed the log specification on all apim-v2 pods. Success on IP(s): 172.16.140.212,
  172.16.140.213"
  }
  ```

  Note: The response might include the following warning, which can be ignored:

  ```
  WARNING: Could not change the log specification on all apim-v2 pods. Success on IP(s): 4.5.6.7  Failed on IP(s): 1.2.3.4
  ```

  To view the REST APIs for logging, go to API Connect REST APIs, and select IBM API Connect Platform - Cloud Management API 2.0.0 reference > Resource: Log Spec.

Troubleshooting

Troubleshooting problems with your API Connect subsystems.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
For common operational problems with API Connect, such as UI login failure, or published APIs not running on your gateways, see: Troubleshooting API Connect.

For problems with the management subsystem database and PVC resizing, see:

- Troubleshooting the management subsystem on Kubernetes
- Troubleshooting the management subsystem on OpenShift and Cloud Pak for Integration

For problems with the analytics subsystem, see Troubleshooting analytics.

For problems with the portal subsystem, see Troubleshooting the developer portal.

To run a power-cycling check on OpenShift and Cloud Pak for Integration, see Power-cycling check on OpenShift and Cloud Pak for Integration.

- **Troubleshooting the management subsystem on Kubernetes**
  Troubleshoot problems with the management subsystem and the management subsystem database

Troubleshooting the management subsystem on Kubernetes

Troubleshoot problems with the management subsystem and the management subsystem database

See:

- **Troubleshooting the management database**
  You can troubleshoot the API Connect management database
- **Increasing the PostgreSQL archive_timeout on Kubernetes**
  Increase the `archive_timeout` to `3600` (seconds) so that accumulated wal files do not cause a disk-space issue during a network outage.
- **Recovering when disks are filled by the management database**
  Resize a PersistentVolumeClaim (PVC) to recover when disks are filled by the management database.

Troubleshooting the management database

You can troubleshoot the API Connect management database

Database Replica Pods stuck in Unknown or Pending state

In certain scenarios, a postgres replica pod may not recover to a healthy state when a restore completes, a node outage occurs, or after a fresh install or upgrade. In these cases, a postgres pod remains in a **Unknown** or a **Pending** state after a number of minutes. The pod fail to get into a **Running** state.

This situation occurs when the replicas do not initialize properly. You can use the **patronictl reinit** command to reinitialize the replica. Note that this command syncs the replica's volume data from the current Primary pod.

Use the following steps to get the pod back into a working state:

1. Exec onto the failing pod:

   ```
   kubectl exec -it <postgres_replica_pod_name> -n <namespace> -- bash
   ```

2. List the cluster members:

   ```
   patronictl list
   + Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+--------------+----+-----------+
   |                         Member                          |      Host      |  Role  |    State     | TL | Lag in MB |
   +---------------------------------------------------------+----------------+--------+--------------+----+-----------+
   |    fxpk-management-01191b80-postgres-586f899fdf-6s25b   | 172.16.172.244 |        | start failed |    |   unknown |
   | fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader |   running    |  3 |           |
   |  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        |   running    |  3 |         0 |
   +---------------------------------------------------------+----------------+--------+--------------+----+-----------+
   ```

   In the example shown above **fxpk-management-01191b80-postgres-586f899fdf-6s25b** is not in running state.

   Note the **clusterName** and **replicaName** which are not up:

   - **clusterName** - **fxpk-management-01191b80-postgres**
   - **replicaName** - **fxpk-management-01191b80-postgres-586f899fdf-6s25b**

3. Run:

   ```
   patronictl reinit <clusterName> <replicaName-which-is-not-running>
   ```

   Example:

   ```
   patronictl reinit fxpk-management-01191b80-postgres fxpk-management-01191b80-postgres-586f899fdf-6s25b
   + Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+--------------+----+-----------+
   |                         Member                          |      Host      |  Role  |    State     | TL | Lag in MB |
   +---------------------------------------------------------+----------------+--------+--------------+----+-----------+
   |    fxpk-management-01191b80-postgres-586f899fdf-6s25b   | 172.16.172.244 |        | start failed |    |   unknown |
   | fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader |   running    |  3 |           |
   |  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        |   running    |  3 |         0 |
   +---------------------------------------------------------+----------------+--------+--------------+----+-----------+
   Are you sure you want to reinitialize members fxpk-management-01191b80-postgres-586f899fdf-6s25b? [y/N]: y
   Success: reinitialize for member fxpk-management-01191b80-postgres-586f899fdf-6s25b
   ```

4. Run **patronictl list** again.
   You may also observe that the replica is on a different Timeline (TL) and possibly have a Lag in MB. It may take a few minutes for the pod to switch onto the same TL as the others and the Lag should slowly go to 0.

   For example:

   ```
   bash-4.2$ patronictl list
   + Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+---------+----+-----------+
   |                         Member                          |      Host      |  Role  |  State  | TL | Lag in MB |
   +---------------------------------------------------------+----------------+--------+---------+----+-----------+
   |    fxpk-management-01191b80-postgres-586f899fdf-6s25b   | 172.16.172.244 |        | running |  1 |     23360 |
   | fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader | running |  3 |           |
   |  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        | running |  3 |         0 |
   +---------------------------------------------------------+----------------+--------+---------+----+-----------+
   ```

5. The pod that previously was in an **Unknown** or **Pending state** or **(0/1) Running** state is now in **(1/1) Running** state.

Increasing the PostgreSQL archive_timeout on Kubernetes

Increase the **archive_timeout** to **3600** (seconds) so that accumulated wal files do not cause a disk-space issue during a network outage.

About this task

PostgreSQL sends its wal archives to the backup location (S3 or local PVC) whenever the configured **archive_timeout** period elapses. By default, the **archive_timeout** is set to 60 seconds. During a network outage, the files cannot be transferred and instead accumulate on the current server, and could cause a disk-space issue. Increasing the **archive_timeout** value helps to mitigate this issue by creating archive files less frequently.

For information on tracking the Postgres disk space, see Monitoring Postgres disk usage.

Complete the following steps to increase the PostgreSQL **archive_timeout** value.

Procedure

1. Get the name of the **pgha** config map by running the following command:

   ```
   kubectl -n <namespace> get cm -l pgha-config='true'
   ```

The response looks like the following example:

```
NAME                                          DATA   AGE
apis-produ-d18f3f0-0d18f3f0-postgres-pgha-config   5      22d
```

2. Edit the config map by running the following command:

   ```
   kubectl -n <namespace> edit configmap <config-map-name>
   ```

   In the command, replace *<config-map-name>* with the **NAME** returned in step 1.

3. Change the `archive_timeout` value to `3600`.
   The value must be an integer, and represents the number of seconds that must elapse before the archive file is generated.

4. Save the file and exit the editor.
   The configuration is updated automatically; archives will be generated and pushed every **3600** seconds.

Recovering when disks are filled by the management database

Resize a PersistentVolumeClaim (PVC) to recover when disks are filled by the management database.

There are two methods to resize a PVC:

- Expand the PVC.
- Create a new, larger PVC, and copy the PVC contents.

Expansion of the PVC is easier and quicker than creating a new PVC and copying contents. However, some storage classes do not support PVC volume expansion. For these classes, you must create a new PVC.

Note: If you are using local storage, the only way to support increased data size is to add a disk

1. Determine if the StorageClass which provisioned the PVC supports VolumeExpansion.
   You can only expand a PVC if its storage class **allowVolumeExpansion** field is set to **true**.

   ```
   $ kubectl get sc

   NAME              PROVISIONER
   rook-ceph-block   rook-ceph.rbd.csi.ceph.com

   $ kubectl describe sc/rook-ceph-block | grep "AllowVolumeExpansion"

   AllowVolumeExpansion:  True
   ```

2. Choose a resizing method for the storage class:
   - If `AllowVolumeExpansion:` is **true**, go to Resizing a PersistentVolumeClaim for Postgres by volume expansion
   - If `AllowVolumeExpansion:` is not **true**, you cannot expand the PVC. Go to Resizing a PersistentVolumeClaim for Postgres by moving content to a new PVC.

- **Resizing a PersistentVolumeClaim for Postgres by volume expansion**
  Resize a PersistentVolumeClaim (PVC) for Postgres that supports volume expansion, on native Kubernetes.
- **Resizing a PersistentVolumeClaim for Postgres by moving content to a new PVC**
  Resize a PersistentVolumeClaim (PVC) for Postgres by creating a new, larger PVC, and moving content between the PVCs, on native Kubernetes.

Resizing a PersistentVolumeClaim for Postgres by volume expansion

Resize a PersistentVolumeClaim (PVC) for Postgres that supports volume expansion, on native Kubernetes.

Before you begin

Determine whether your storage class supports volume expansion. See Recovering when disks are filled by the management database.

About this task

You can expand a PVC if your storage provisioner supports volume expansion. This procedure is for use on native Kubernetes.

Note: This procedure is for use only with Postgres.

Procedure

1. Determine the primary Postgres pod.

   ```
   kubectl get pods --selector role=master | grep -v bootstrapselector=role=master
   ```

2. Gracefully shutdown Postgres pods.
   a. Exec into the Postgres primary pod.

      ```
      kubectl exec -it <postgres-pod> -- bash
      ```

   b. Pause Patroni process. Note: you can skip this step if using the one replica profile.

```
patronictl pause
```

c. Stop the Postgres process gracefully.

```
pg_ctl stop -D /pgdata/<cluster-name>
```

For example:

- ***cluster-name*** is usually the name of the cluster. If primary pod name is **m1-1b12bf81-postgres-58dfcc5f97-fsvvt**, ***cluster-name*** is **m1-1b12bf81-postgres**.
- There will be a folder named ***cluster-name*** located under **/pgdata/**.
- In this example, the command is:

```
pg_ctl stop -D /pgdata/m1-1b12bf81-postgres
```

3. Determine the PVC linked to the primary Postgres pod, and obtain the **claimName** of the PVC.

```
kubectl get pod <postgres-pod> -o json | jq '.spec.volumes[] | select ( has ("persistentVolumeClaim"))'
```

4. Scale down the Postgres deployment.

```
kubectl get deploy | grep postgres | grep -v bouncer | grep -v bootstrap | grep -v backrest | grep -v operator
```

If you are using **n3** profile then you find 3 deployments. Scale them down:

```
kubectl scale deploy <deployment-name> --replicas=0
```

5. Edit the PVC you want to increase.

```
kubectl edit pvc <claimName>
```

6. Update **spec.resources.requests.storage** field value with new size. For example:

```
spec:
  resources:
    requests:
      storage: 20Gi
```

7. Scale up the Postgres deployment.

```
kubectl get deploy | grep postgres | grep -v bouncer | grep -v bootstrap | grep -v backrest | grep -v operator
```

If you are using the **n3** profile then you find 3 deployments. Scale them up:

```
kubectl scale deploy <deployment-name> --replicas=1
```

8. If using the **n3** profile, resume the Patroni process. If using the **n1** profile, skip this step.
   a. Determine the new primary Postgres pod.

```
kubectl get pods --selector role=master | grep -v bootstrapselector=role=master
```

   b. Exec into the new Postgres primary pod.

```
kubectl exec -it <postgres-pod> -- bash
```

   c. Resume Patroni.

```
patronictl resume
```

Resizing a PersistentVolumeClaim for Postgres by moving content to a new PVC

Resize a PersistentVolumeClaim (PVC) for Postgres by creating a new, larger PVC, and moving content between the PVCs, on native Kubernetes.

Before you begin

Determine whether your storage class supports volume expansion. See Recovering when disks are filled by the management database.

About this task

Use this procedure when the storage class does not support volume expansion. This procedure is for use on native Kubernetes.

Note: This procedure is for use only with Postgres.

Procedure

1. Create a new temporary PVC. Ensure the requested storage size is more than the original PVC. For example:

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: temp-pvc
spec:
  storageClassName: rook-ceph-block
  accessModes:
    - ReadWriteOnce
  resources:
```

```
    requests:
      storage: 10Gi
```

2. Determine the primary Postgres pod.

```
kubectl get pods --selector role=master | grep -v bootstrapselector=role=master
```

3. Gracefully shutdown Postgres pods.
   a. Exec into the Postgres primary pod.

```
kubectl exec -it <postgres-pod> -- bash
```

   b. Pause the Patroni process. Note: you can skip this step if using the one replica profile.

```
patronictl pause
```

   c. Stop the Postgres process gracefully.

```
pg_ctl stop -D /pgdata/<cluster-name>
```

   For example:

   - ***cluster-name*** is usually the name of the cluster. If primary pod name is **m1-1b12bf81-postgres-58dfcc5f97-fsvvt**, ***cluster-name*** is **m1-1b12bf81-postgres**.
   - There will be a folder named ***cluster-name*** located under **/pgdata/**.
   - In this example, the command is:

```
pg_ctl stop -D /pgdata/m1-1b12bf81-postgres
```

4. Determine the PVC linked to the primary Postgres pod, and obtain the **claimName** of the PVC.

```
kubectl get pod <postgres-pod> -o json | jq '.spec.volumes[] | select ( has ("persistentVolumeClaim"))'
```

5. Scale down the Postgres deployment.

```
kubectl get deploy | grep postgres | grep -v bouncer | grep -v bootstrap | grep -v backrest | grep -v operator
```

   If you are using **n3** profile then you find 3 deployments. Scale them down:

```
kubectl scale deploy <deployment-name> --replicas=0
```

6. Start a BusyBox pod with the source and destination PVC volumes mounted, to swap the content between PVCs. For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: swap-pvc
spec:
  volumes:
    - name: volume-source
      persistentVolumeClaim:
        claimName: m1-mgmt-35817114-postgres-wal
    - name: volume-destination
      persistentVolumeClaim:
        claimName: temp-pvc
  containers:
    - name: debug
      image: busybox
      command: ['sleep', '3600']
      volumeMounts:
        - name: volume-source
          mountPath: /data-source
        - name: volume-destination
          mountPath: /data-destination
```

7. Exec to the BusyBox pod, and

```
kubectl exec -it <busybox-pod-name> -- sh
```

```
cp -r data-source/ data-destination/
```

8. Copy content to the temporary PVC. For example, using the **mountPath** values shown in Step 6:

```
cp -r data-source/ data-destination/
```

9. Delete the BusyBox pod.

```
kubectl delete pod <busybox-pod-name>
```

10. Delete the original PVC.

```
kubectl delete pvc <claimName>
```

11. Create an original PVC with the same name but with increased size. For example:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: m1-mgmt-35817114-postgres-wal
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 20Gi
```

```
  storageClassName: rook-ceph-block
  volumeMode: Filesystem
```

12. Start the BusyBox pod again and this time copy the content from destination to source PVC.

    ```
    kubectl exec -it <busybox-pod> -- sh
    ```

    ```
    cp -r data-destination/ data-source/
    ```

13. Delete the BusyBox pod.

    ```
    kubectl delete pod <busybox-pod>
    ```

14. Delete the temporary PVC that you created for swapping the content.

    ```
    kubectl delete pvc temp-pvc
    ```

15. Scale up the Postgres deployment.

    ```
    kubectl get deploy | grep postgres | grep -v bouncer | grep -v bootstrap | grep -v backrest | grep -v operator
    ```

    If you are using the `n3` profile then you find 3 deployments. Scale them up:

    ```
    kubectl scale deploy <deployment-name> --replicas=1
    ```

16. If using the `n3` profile, resume the Patroni process. If using the `n1` profile, skip this step.
    a. Determine the new primary Postgres pod.

    ```
    kubectl get pods --selector role=master | grep -v bootstrapselector=role=master
    ```

    b. Exec into the new Postgres primary pod.

    ```
    kubectl exec -it <postgres-pod> -- bash
    ```

    c. Resume Patroni.

    ```
    patronictl resume
    ```

Troubleshooting the management subsystem on OpenShift and Cloud Pak for Integration

Troubleshoot problems with the management subsystem and the management subsystem database.

See:

Troubleshooting the management database on OpenShift and Cloud Pak for Integration

You can troubleshoot the API Connect management database by complete the following tasks.

Database Replica Pods stuck in Unknown or Pending state

In certain scenarios, a postgres replica pod may not recover to a healthy state when a restore completes, a node outage occurs, or after a fresh install or upgrade. In these cases, a postgres pod remains in a **`Unknown`** or a **`Pending`** state after a number of minutes. The pod fail to get into a **`Running`** state.

This situation occurs when the replicas do not initialize properly. You can use the **`patronictl reinit`** command to reinitialize the replica. Note that this command syncs the replica's volume data from the current Primary pod.

Use the following steps to get the pod back into a working state:

1. Exec onto the failing pod:

   ```
   oc exec -it <postgres_replica_pod_name> -n <namespace> -- bash
   ```

2. List the cluster members:

   ```
   patronictl list
   + Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+--------------+----+-----------+
   |                      Member                      |      Host      |  Role  |    State     | TL | Lag in MB |
   +--------------------------------------------------+----------------+--------+--------------+----+-----------+
   |    fxpk-management-01191b80-postgres-586f899fdf-6s25b   | 172.16.172.244 |        | start failed |    |   unknown |
   | fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader |   running    |  3 |           |
   |  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        |   running    |  3 |         0 |
   +--------------------------------------------------+----------------+--------+--------------+----+-----------+
   ```

   In the example shown above **`fxpk-management-01191b80-postgres-586f899fdf-6s25b`** is not in running state.

   Note the **`clusterName`** and **`replicaName`** which are not up:

   - **`clusterName`** - **`fxpk-management-01191b80-postgres`**
   - **`replicaName`** - **`fxpk-management-01191b80-postgres-586f899fdf-6s25b`**

3. Run:

```
patronictl reinit <clusterName> <replicaName-which-is-not-running>
```

Example:

```
patronictl reinit fxpk-management-01191b80-postgres fxpk-management-01191b80-postgres-586f899fdf-6s25b
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+--------------+----+-----------+
|                          Member                          |      Host      |  Role  |    State     | TL | Lag in MB |
+----------------------------------------------------------+----------------+--------+--------------+----+-----------+
|    fxpk-management-01191b80-postgres-586f899fdf-6s25b    | 172.16.172.244 |        | start failed |    |   unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader |   running    |  3 |           |
|  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        |   running    |  3 |         0 |
+----------------------------------------------------------+----------------+--------+--------------+----+-----------+
Are you sure you want to reinitialize members fxpk-management-01191b80-postgres-586f899fdf-6s25b? [y/N]: y
Success: reinitialize for member fxpk-management-01191b80-postgres-586f899fdf-6s25b
```

4. Run `patronictl list` again.
   You may also observe that the replica is on a different Timeline (TL) and possibly have a Lag in MB. It may take a few minutes for the pod to switch onto the same TL as the others and the Lag should slowly go to 0.

   For example:

```
bash-4.2$ patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+---------+----+-----------+
|                          Member                          |      Host      |  Role  |  State  | TL | Lag in MB |
+----------------------------------------------------------+----------------+--------+---------+----+-----------+
|    fxpk-management-01191b80-postgres-586f899fdf-6s25b    | 172.16.172.244 |        | running |  1 |     23360 |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader | running |  3 |           |
|  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        | running |  3 |         0 |
+----------------------------------------------------------+----------------+--------+---------+----+-----------+
```

5. The pod that previously was in an `Unknown` or `Pending state` or `(0/1) Running` state is now in `(1/1) Running` state.

Increasing the PostgreSQL `archive_timeout` on OpenShift and Cloud Pak for Integration

Increase change the `archive_timeout` to `3600` (seconds) so that accumulated wal files do not cause a disk-space issue during a network outage.

About this task

PostgreSQL sends its wal archives to the backup location (S3 or local PVC) whenever the configured `archive_timeout` period elapses. By default, the `archive_timeout` is set to 60 seconds. During a network outage, the files cannot be transferred and instead accumulate on the current server, and could cause a disk-space issue. Increasing the `archive_timeout` value helps to mitigate this issue by creating archive files less frequently.

For information on tracking the Postgres disk space, see Monitoring Postgres disk usage.

Complete the following steps to increase the PostgreSQL `archive_timeout` value.

Procedure

1. Get the name of the `pgha` config map by running the following command:

   ```
   oc -n <APIC_namespace> get cm -l pgha-config='true'
   ```

   The response looks like the following example:

   ```
   NAME                                              DATA   AGE
   apis-produ-d18f3f0-0d18f3f0-postgres-pgha-config   5      22d
   ```

2. Edit the config map by running the following command:

   ```
   oc -n <APIC_namespace> edit configmap <config-map-name>
   ```

   In the command, replace *<config-map-name>* with the `NAME` returned in step 1.

3. Change the `archive_timeout` value to `3600`.
   The value must be an integer, and represents the number of seconds that must elapse before the archive file is generated.

4. Save the file and exit the editor.
   The configuration is updated automatically; archives will be generated and pushed every `3600` seconds.

Recovering on OpenShift and Cloud Pak for Integration when disks are filled by the management database

Resize a PersistentVolumeClaim (PVC) on OpenShift to recover when disks are filled by the API Connect management database.

There are two methods to resize a PVC:

- Expand the PVC.
- Create a new, larger PVC, and copy the PVC contents.

Expansion of the PVC is easier and faster than creating a new PVC and copying contents. However, some storage classes do not support PVC volume expansion. For these classes, you must create a new PVC.

Note: If you are using local storage, the only way to support increased data size is to add a disk.

1. Determine if the StorageClass which provisioned the PVC supports VolumeExpansion.
   You can only expand a PVC if its storage class **allowVolumeExpansion** field is set to **true**.

   ```
   oc get sc

   NAME               PROVISIONER
   rook-ceph-block    rook-ceph.rbd.csi.ceph.com

   oc describe sc/rook-ceph-block | grep "AllowVolumeExpansion"

   AllowVolumeExpansion:  True
   ```

2. Choose a resizing method for the storage class:
   - If **AllowVolumeExpansion:** is **true**, see Resizing a PVC for Postgres on OpenShift by using volume expansion
   - If **AllowVolumeExpansion:** is not **true**, you cannot expand the PVC. See Resizing a PVC for Postgres on OpenShift by moving content.

Resizing a PVC for Postgres on OpenShift by using volume expansion

Resize a Persistent Volume Claim (PVC) for Postgres that supports volume expansion.

Before you begin

This task only applies to the PVC used by Postgres. To determine whether your storage class supports volume expansion, see Recovering on OpenShift and Cloud Pak for Integration when disks are filled by the management database.

About this task

You can expand a PVC if your storage provisioner supports volume expansion.

Procedure

1. Determine the primary Postgres pod.

   ```
   oc get pods --selector role=master | grep -v bootstrapselector=role=master
   ```

2. Gracefully shutdown Postgres pods.
   a. Exec into the Postgres primary pod.

      ```
      oc exec -it <postgres-pod> -- bash
      ```

   b. Pause Patroni process. Note: you can skip this step if using the one replica profile.

      ```
      patronictl pause
      ```

   c. Stop the Postgres process gracefully.

      ```
      pg_ctl stop -D /pgdata/<cluster-name>
      ```

      For example:

      - ***cluster-name*** is usually the name of the cluster. If primary pod name is **m1-1b12bf81-postgres-58dfcc5f97-fsvvt**, ***cluster-name*** is **m1-1b12bf81-postgres**.
      - There will be a folder named ***cluster-name*** located under **/pgdata/**.
      - In this example, the command is:

        ```
        pg_ctl stop -D /pgdata/m1-1b12bf81-postgres
        ```

3. Determine the PVC linked to the primary Postgres pod, and obtain the **claimName** of the PVC.

   ```
   oc get pod <postgres-pod> -o json | jq '.spec.volumes[] | select ( has ("persistentVolumeClaim"))'
   ```

4. Scale down the Postgres deployment.

   ```
   oc get deploy | grep postgres | grep -v bouncer | grep -v bootstrap | grep -v backrest | grep -v operator
   ```

   If you are using **n3** profile then you find 3 deployments. Scale them down:

   ```
   oc scale deploy <deployment-name> --replicas=0
   ```

5. Edit the PVC you want to increase.

   ```
   oc edit pvc <claimName>
   ```

6. Update **spec.resources.requests.storage** field value with new size. For example:

   ```
   spec:
     resources:
       requests:
         storage: 20Gi
   ```

7. Scale up the Postgres deployment.

   ```
   oc get deploy | grep postgres | grep -v bouncer | grep -v bootstrap | grep -v backrest | grep -v operator
   ```

   If you are using the **n3** profile then you find 3 deployments. Scale them up:

   ```
   oc scale deploy <deployment-name> --replicas=1
   ```

8. If you are using the **n3** profile, resume the Patroni process. If using the **n1** profile, skip this step.
   a. Determine the new primary Postgres pod.

      ```
      oc get pods --selector role=master | grep -v bootstrapselector=role=master
      ```

   b. Exec into the new Postgres primary pod.

      ```
      oc exec -it <postgres-pod> -- bash
      ```

   c. Resume Patroni.

      ```
      patronictl resume
      ```

Resizing a PVC for Postgres on OpenShift by moving content

Resize a Persistent Volume Claim (PVC) for Postgres on OpenShift by creating a new, larger PVC, and then moving content between the PVCs.

Before you begin

This task only applies to the PVC used by Postgres.

About this task

Use this procedure when the storage class does not support volume expansion.

Procedure

1. Create a new temporary PVC. Ensure the requested storage size is more than the original PVC. For example:

   ```
   apiVersion: v1
   kind: PersistentVolumeClaim
   metadata:
     name: temp-pvc
   spec:
     storageClassName: rook-ceph-block
     accessModes:
       - ReadWriteOnce
     resources:
       requests:
         storage: 10Gi
   ```

2. Determine the primary Postgres pod.

   ```
   oc get pods --selector role=master | grep -v bootstrapselector=role=master
   ```

3. Gracefully shutdown Postgres pods.
   a. Exec into the Postgres primary pod.

      ```
      oc exec -it <postgres-pod> -- bash
      ```

   b. Pause the Patroni process. Note: you can skip this step if using the one replica profile.

      ```
      patronictl pause
      ```

   c. Stop the Postgres process gracefully.

      ```
      pg_ctl stop -D /pgdata/<cluster-name>
      ```

      For example:

      - ***cluster-name*** is usually the name of the cluster. If primary pod name is **m1-1b12bf81-postgres-58dfcc5f97-fsvvt**, ***cluster-name*** is **m1-1b12bf81-postgres**.
      - There will be a folder named ***cluster-name*** located under **/pgdata/**.
      - In this example, the command is:

        ```
        pg_ctl stop -D /pgdata/m1-1b12bf81-postgres
        ```

4. Determine the PVC linked to the primary Postgres pod, and obtain the **claimName** of the PVC.

   ```
   oc get pod <postgres-pod> -o json | jq '.spec.volumes[] | select ( has ("persistentVolumeClaim"))'
   ```

5. Scale down the Postgres deployment.

   ```
   oc get deploy | grep postgres | grep -v bouncer | grep -v bootstrap | grep -v backrest | grep -v operator
   ```

   If you are using **n3** profile then you find 3 deployments. Scale them down:

   ```
   oc scale deploy <deployment-name> --replicas=0
   ```

6. Start a BusyBox pod with the source and destination PVC volumes mounted, to swap the content between PVCs. For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: swap-pvc
spec:
  volumes:
    - name: volume-source
      persistentVolumeClaim:
        claimName: m1-mgmt-35817114-postgres-wal
    - name: volume-destination
      persistentVolumeClaim:
        claimName: temp-pvc
  containers:
    - name: debug
      image: busybox
      command: ['sleep', '3600']
      volumeMounts:
        - name: volume-source
          mountPath: /data-source
        - name: volume-destination
          mountPath: /data-destination
```

7. Exec to the BusyBox pod, and run the following commands:

```
oc exec -it <busybox-pod-name> -- sh

cp -r data-source/ data-destination/
```

8. Copy content to the temporary PVC. For example, using the `mountPath` values shown in Step 6:

```
cp -r data-source/ data-destination/
```

9. Delete the BusyBox pod.

```
oc delete pod <busybox-pod-name>
```

10. Delete the original PVC.

```
oc delete pvc <claimName>
```

11. Create an original PVC with the same name but with increased size. For example:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: m1-mgmt-35817114-postgres-wal
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 20Gi
  storageClassName: rook-ceph-block
  volumeMode: Filesystem
```

12. Run the following commands to start the BusyBox pod again and copy the content from the destination to the source PVC:

```
oc exec -it <busybox-pod> -- sh

cp -r data-destination/ data-source/
```

13. Delete the BusyBox pod.

```
oc delete pod <busybox-pod>
```

14. Delete the temporary PVC that you created for swapping the content.

```
oc delete pvc temp-pvc
```

15. Scale up the Postgres deployment.

```
oc get deploy | grep postgres | grep -v bouncer | grep -v bootstrap | grep -v backrest | grep -v operator
```

If you are using the `n3` profile then you find 3 deployments. Scale them up:

```
oc scale deploy <deployment-name> --replicas=1
```

16. If using the `n3` profile, resume the Patroni process. If using the `n1` profile, skip this step.
    a. Determine the new primary Postgres pod.

    ```
    oc get pods --selector role=master | grep -v bootstrapselector=role=master
    ```

    b. Exec into the new Postgres primary pod.

    ```
    oc exec -it <postgres-pod> -- bash
    ```

    c. Resume Patroni.

    ```
    patronictl resume
    ```

Power-cycling check on OpenShift and Cloud Pak for Integration

If you cycle the power on an API Connect cluster that is deployed on OpenShift or Cloud Pak for Integration, you might need to reset the IP address for the **kubernetes.io/hostname**.

About this task

You will know there is a problem if you cycle the power for the cluster and receive an error, or find that the deployment remains in the **pending** state indefinitely because some of the pods failed to start. Complete the following steps to resolve the problem:

Procedure

1. Run the following command to check the label on the worker nodes:

   ```
   oc get nodes -l kubernetes.io/hostname=localhost
   ```

   If the response shows the following message, then the power cycle did not cause a problem and you can skip the rest of this task:

   ```
   No resources found
   ```

   If the response looks like the following example (the IP address will be different), proceed to the next step:

   ```
   NAME                                         STATUS   ROLES    AGE   VERSION
   ip-233.252.0.0.us-west-1.compute.internal    Ready    worker   27h   v1.19.0+8d12420
   ```

2. Run the following command to correct the problem:

   ```
   for i in $(oc get nodes -l kubernetes.io/hostname=localhost|grep worker|awk '{print $1}'); do echo $i;  oc label nodes $i
   kubernetes.io/hostname=`echo $i|awk -F'.' '{print $1}'` --overwrite=true; done
   ```

Uninstalling API Connect

You can uninstall a Kubernetes deployment of API Connect.

About this task

You can choose to uninstall individual API Connect subsystems or you can uninstall the complete API Connect deployment. You can delete Custom Resource Definitions, Persistent Volumes, service accounts, secrets, operators and the namespace. Use one of the following topics.
Note: For information about how to maintain a two data center deployment, see Maintaining a two data center deployment.

- **Uninstalling API Connect subsystems**
  You can individually uninstall API Connect subsystems that have been deployed on Kubernetes.
- **Removing API Connect**
  You can remove all parts of the API Connect deployment on Kubernetes.
- **Removing API Connect on OpenShift or Cloud Pak for Integration**
  Remove your entire API Connect deployment on OpenShift or Cloud Pak for Integration.

Uninstalling API Connect subsystems

You can individually uninstall API Connect subsystems that have been deployed on Kubernetes.

Before you begin

If you want to disable the analytics subsystem without uninstalling it, see Shutting down the analytics subsystem.

About this task

- To delete the API Connect deployment in a Kubernetes runtime environment, you must use the Kubernetes command-line tool, kubectl.
- The API Connect operator and DataPower operator pods are needed to uninstall subsystems individually.
- If need to retain data to re-use during a re-installation later, follow the backup and restore procedures:
  - Configuring backup settings for fresh install of the Management subsystem
  - Backing up and restoring the Developer Portal in a Kubernetes environment
- If you want to delete **all** of API Connect, do not use this topic. Instead, see Removing API Connect.

Procedure

1. Uninstall the Management subsystem
   a. Save the management subsystem name:

      ```
      kubectl get mgmt -n <namespace> -o yaml
      ```

      This command returns the YAML format of the management custom resource. Make a note of the name.

b. Delete the Management Subsystem.

```
kubectl delete mgmt --all -n <namespace>
```

Important:
If your deployment uses default namespaces be cautious when using **kubectl delete <entity> --all** commands. There can be other pods, services, and more in the default namespace. When using the default namespace, keep in mind that using **kubernetes delete <entity> --all**, where <entity> can delete non-APIC entities, such as **sa** (Service Accounts), **secrets**, **rolebindings**, etc.

The Management CR deletion will take some time because the apiconnect operator must delete the Postgres cluster.

c. Manually delete secrets and PVCs:
   i. Get all of the secrets that use the management subsystem name (which you determined in Step 1.a):

   ```
   kubectl get secrets -n <namespace> | grep <management-subsystem-name>
   ```

   ii. For each secret that uses the management subsystem name, run the following command to delete the secret:

   ```
   kubectl delete secrets <secret_name> -n <namespace>
   ```

   iii. Get all the PVCs that use the management subsystem name:

   ```
   kubectl get pvc -n <namespace> | grep <management-subsystem-name>
   ```

   iv. For each PVC that uses the management subsystem name, run the following command to delete the PVC:

   ```
   kubectl delete pvc <pvc_name> -n <namespace>
   ```

d. If management subsystem backup and restore CRs are left stale, delete them also:
   i. Get the name of the backup CR:

   ```
   kubectl get mgmtb -n <namespace>
   ```

   ii. Delete the backup CR:

   ```
   kubectl delete mgmtb <backup_cr_name> -n <namespace>
   ```

   iii. Get the name of the restore CR:

   ```
   kubectl get mgmtr -n <namespace>
   ```

   iv. Delete the restore CR:

   ```
   kubectl delete mgmtr <restore_cr_name> -n <namespace>
   ```

2. Uninstall Analytics subsystem
   a. Delete the Analytics subsystem, the Analytics backup, and the Analytics restore CRs.

   ```
   kubectl delete a7s --all -n <namespace>
   kubectl delete a7b --all -n <namespace>
   kubectl delete a7r --all -n <namespace>
   ```

   b. Manually delete the Analytics secrets:

   ```
   kubectl delete secrets <secret_name> -n <namespace>
   ```

   for each of the following secrets:

   ```
   analytics-ai-endpoint
   analytics-ca
   analytics-client
   analytics-server
   ```

   c. Manually delete analytics Persistent Volume Claims (PVCs):

   ```
   kubectl delete pvc <pvc_name> -n <namespace>
   ```

   for PVCs with the following naming pattern:

   ```
   data-analytics-storage
   ```

3. Uninstall the Developer Portal subsystem
   a. Delete the Developer Portal subsystem, and the Portal backup and restore CRs.

   ```
   kubectl delete ptl --all -n <namespace>
   kubectl delete pb --all -n <namespace>
   kubectl delete pr --all -n <namespace>
   ```

   b. Manually delete Developer Portal secrets:

   ```
   kubectl delete secrets <secret_name> -n <namespace>
   ```

   for secrets with the following naming pattern:

   ```
   portal-admin
   portal-admin-client
   portal-ca
   portal-client
   portal-db-ca
   portal-encryption-key-...
   portal-server
   portal-web
   ```

c. Manually delete these Developer Portal PVCs:

```
kubectl delete pvc <pvc_name> -n <namespace>
```

for PVCs with the following naming pattern:

```
admin-portal-...-www-...
backup-portal-...-www-...
db-portal-...-db-...
dblogs-portal-...-db-...
web-portal-...-www-...
```

4. Delete the DataPower Gateway subsystem.

```
kubectl delete gw --all -n <namespace>
```

Note: The following entries include both Multi-Protocol Gateway Service (v5-compatible) and API Gateway settings. Names that include "gwv5" refer to the Multi-Protocol Gateway Service (v5-compatible), and names that include "gwv6" refer to the API Gateway.

a. Delete Service Accounts.

```
kubectl delete sa <service_account> -n <namespace>
```

for each of the following Service Accounts:

```
gwv5-datapower
gwv6-datapower
```

b. Delete Secrets.

```
kubectl delete secrets <secret_name> -n <namespace>
```

for secrets with the following naming pattern:

```
gwv5-datapower-token-...
gwv5-dpm-sa-token-...
gwv5-endpoint
gwv5-manager-endpoint
gwv6-datapower-token-...
gwv6-dpm-sa-token-...
gwv6-endpoint.
gwv6-manager-endpoint
```

c. Delete PVCs.

```
kubectl delete pvc <pvc_name> -n <namespace>
```

for PVCs with the following naming pattern:

```
gwv5...
gwv6...
```

- **Removing Management subsystem postgres resources on Kubernetes**
  When you remove the API Connect Management subsystem by deleting its files, some postgres resources from Crunchy Data remain, and must be deleted manually before you attempt to re-install the Management subsystem.

Removing Management subsystem postgres resources on Kubernetes

When you remove the API Connect Management subsystem by deleting its files, some postgres resources from Crunchy Data remain, and must be deleted manually before you attempt to re-install the Management subsystem.

About this task

Sometimes when you remove the Management subsystem, some postgres resources remain and must be deleted manually.

To determine whether you need to delete any postgres resources, use the **kubectl get** command and specify **vendor=crunchydata**; as shown in the following example.

```
$ kubectl get pods -n apic -l vendor=crunchydata
NAME                                                  READY   STATUS      RESTARTS   AGE
backrest-backup-production-mgmt-mymgmtsite123-postgres-k77xj      0/1     Completed   0          17h
production-mgmt-mymgmtsite123-postgres-backrest-shared-repk4kzc   1/1     Running     0          2d21h
production-mgmt-mymgmtsite123-postgres-full-sch-backup-9ktp5      0/1     Completed   0          164m

$ kubectl get deployments -n apic -l vendor=crunchydata
NAME                                                READY   UP-TO-DATE   AVAILABLE   AGE
production-mgmt-mymgmtsite123-postgres-backrest-shared-repo   1/1     1            1           2d21h

$ kubectl get sa -n apic -l vendor=crunchydata
No resources found in apic namespace.

$ kubectl get jobs -n apic -l vendor=crunchydata
NAME                                                COMPLETIONS   DURATION   AGE
backrest-backup-production-mgmt-mymgmtsite123-postgres   1/1           10s        17h
production-mgmt-mymgmtsite123-postgres-full-sch-backup   1/1           37s        164m
production-mgmt-mymgmtsite123-postgres-rmdata-cemg       1/1           20s        14m

$ kubectl get roles -n apic -l vendor=crunchydata
No resources found in apic namespace.
```

```
$ kubectl get rolebindings -n apic -l vendor=crunchydata
No resources found in apic namespace.

$ kubectl get secrets -n apic -l vendor=crunchydata
NAME                                                    TYPE     DATA   AGE
production-mgmt-7bc754c7-postgres-backrest-repo-config  Opaque   9      6d23h
production-mgmt-7bc754c7-postgres-postgres-secret       Opaque   2      6d23h
production-mgmt-7bc754c7-postgres-primaryuser-secret    Opaque   2      6d23h
production-mgmt-7bc754c7-postgres-testuser-secret       Opaque   2      6d23h
production-mgmt-8aac6b4e-postgres-backrest-repo-config  Opaque   9      6d22h
production-mgmt-8aac6b4e-postgres-postgres-secret       Opaque   2      6d22h
production-mgmt-8aac6b4e-postgres-primaryuser-secret    Opaque   2      6d22h
production-mgmt-8aac6b4e-postgres-testuser-secret       Opaque   2      6d22h
production-mgmt-mymgmtsite123-postgres-backrest-repo-config  Opaque   9      2d21h
production-mgmt-mymgmtsite123-postgres-postgres-secret  Opaque   2      2d21h
production-mgmt-mymgmtsite123-postgres-primaryuser-secret  Opaque   2      2d21h
production-mgmt-mymgmtsite123-postgres-testuser-secret  Opaque   2      2d21h

$ kubectl get cm -n apic -l vendor=crunchydata
NAME                                                DATA   AGE
production-mgmt-mymgmtsite123-postgres-config       0      2d21h
production-mgmt-mymgmtsite123-postgres-leader       0      2d21h
production-mgmt-mymgmtsite123-postgres-pgbouncer-cm  2      2d21h
production-mgmt-mymgmtsite123-postgres-pgha-config  5      2d21h
```

Procedure

For each type of postgres resource, check to see if any resources are available and if so, delete the resources:

- pods:

  `kubectl get pods -n <namespace> -l vendor=crunchydata`

  `kubectl delete pods -n <namespace> -l vendor=crunchydata`

- deployments:

  `kubectl get deployments -n <namespace> -l vendor=crunchydata`

  `kubectl delete deployments -n <namespace> -l vendor=crunchydata`

- service accounts:

  `kubectl get sa -n <namespace> -l vendor=crunchydata`

  `kubectl delete sa -n <namespace> -l vendor=crunchydata`

- jobs:

  `kubectl get jobs -n <namespace> -l vendor=crunchydata`

  `kubectl delete jobs -n <namespace> -l vendor=crunchydata`

- roles:

  `kubectl get roles -n <namespace> -l vendor=crunchydata`

  `kubectl delete roles -n <namespace> -l vendor=crunchydata`

- rolebindings:

  `kubectl get rolebindings -n <namespace> -l vendor=crunchydata`

  `kubectl delete rolebindings -n <namespace> -l vendor=crunchydata`

- secrets:

  `kubectl get secrets -n <namespace> -l vendor=crunchydata`

  `kubectl delete secrets -n <namespace> -l vendor=crunchydata`

- cm:

  `kubectl get cm -n <namespace> -l vendor=crunchydata`

  `kubectl delete cm -n <namespace> -l vendor=crunchydata`

- pgtasks:

  `kubectl get pgtasks.crunchydata.com -n <namespace> -l vendor=crunchydata`

  `kubectl delete pgtasks.crunchydata.com -n <namespace>`

- pgreplica:

  `kubectl get pgreplica -n <management_namespace> -l vendor=crunchydata`

  `kubectl delete pgreplica -n <management_namespace> -l vendor=crunchydata`

Removing API Connect

You can remove all parts of the API Connect deployment on Kubernetes.

About this task

These instructions completely remove API Connect, including PVCs and secrets.

- To delete the API Connect deployment in a Kubernetes runtime environment, you must use the Kubernetes command-line tool, kubectl.
- You must run the commands in the order shown in the procedure on this page. If you run commands out of order, you might encounter a problem where the deletion of namespaces hangs.
- If you want to retain the PVCs, which contain some of the data you built up when using the application, you must also keep the associated secret used to decrypt the data. To do this, you must backup each subsystem, and then uninstall the subsystems individually. In this case, do not use the instructions on this page. Instead, see Uninstalling API Connect subsystems.

Procedure

1. Delete all API Connect systems.

   ```
   kubectl delete apic --all -n <namespace>
   ```

   This command is the equivalent of deleting each of the individual subsystems one at a time, and also deleting all of their backup and restore CRs. The commands that run during this step are:

   - Subsystem CRs. For example:

     ```
     kubectl delete mgmt --all -n <namespace>
     kubectl delete a7s --all -n <namespace>
     kubectl delete ptl --all -n <namespace>
     kubectl delete gwv6 --all -n <namespace>
     ```

   - Backup and restore CRs:

     ```
     kubectl delete mgmtb --all -n <namespace>
     kubectl delete mgmtr --all -n <namespace>
     kubectl delete pb --all -n <namespace>
     kubectl delete pr --all -n <namespace>
     kubectl delete a7b --all -n <namespace>
     kubectl delete a7r --all -n <namespace>
     ```

2. Delete the Operator deployments.

   ```
   kubectl delete deployment datapower-operator ibm-apiconnect -n <namespace>
   ```

3. Delete all Service Accounts in the namespace.
   Important:
   If your deployment uses default namespaces be cautious when using **`kubectl delete <entity> --all`** commands. There can be other pods, services, and more in the default namespace. When using the default namespace, keep in mind that using **`kubernetes delete <entity> --all`**, where <*entity*> can delete non-APIC entities, such as **`sa`** (Service Accounts), **`secrets`**, **`rolebindings`**, etc.

   ```
   kubectl delete sa --all -n <namespace>
   ```

4. Delete all Secrets in the namespace.

   ```
   kubectl delete secrets --all -n <namespace>
   ```

5. Delete all Rolebindings in the namespace.

   ```
   kubectl delete rolebindings --all -n <namespace>
   ```

6. Delete all Roles in the namespace.

   ```
   kubectl delete roles --all -n <namespace>
   ```

7. Clean up any remaining jobs.

   ```
   kubectl delete jobs --all -n <namespace>
   ```

8. Delete all PVCs in the namespace.

   ```
   kubectl delete pvc --all -n <namespace>
   ```

9. Delete Issuers in the namespace.
   Note that there might be none found.

   ```
   kubectl delete issuer --all -n <namespace>
   ```

10. Delete certificates in the namespace.
    Note that there might be none found.

    ```
    kubectl delete certificates --all -n <namespace>
    ```

11. If you are not using the default namespace, delete the Namespace
    Important: If your deployment uses the default namespace, do not delete it. There can be other pods, services, and more in the default namespace.

    ```
    kubectl delete ns <namespace>
    ```

12. Delete **`validatingwebhookconfiguration`**

    a. **`kubectl get validatingwebhookconfiguration | awk /<ns>/'{print $1}' | xargs kubectl delete validatingwebhookconfiguration`**

b. `kubectl delete validatingwebhookconfiguration managements.validator.subsystem.apiconnect.ibm.com`

13. Delete `mutatingwebhookconfiguration`

    a. `kubectl get mutatingwebhookconfiguration | awk /$NS/'{print $1}' | xargs kubectl delete mutatingwebhookconfiguration`

    b. `kubectl get mutatingwebhookconfiguration | awk /apicop-management-defaulter/'{print $1}' | xargs kubectl delete mutatingwebhookconfiguration`

14. Delete the Apiconnect CRDs (custom resource definitions)

```
kubectl delete crd analyticsbackups.analytics.apiconnect.ibm.com
kubectl delete crd analyticsclusters.analytics.apiconnect.ibm.com
kubectl delete crd analyticsrestores.analytics.apiconnect.ibm.com
kubectl delete crd datapowerservices.datapower.ibm.com
kubectl delete crd gatewayclusters.gateway.apiconnect.ibm.com
kubectl delete crd managementbackups.management.apiconnect.ibm.com
kubectl delete crd managementclusters.management.apiconnect.ibm.com
kubectl delete crd managementrestores.management.apiconnect.ibm.com
kubectl delete crd natsclusters.nats.io
kubectl delete crd natsserviceroles.nats.io
kubectl delete crd natsstreamingclusters.streaming.nats.io
kubectl delete crd portalbackups.portal.apiconnect.ibm.com
kubectl delete crd portalclusters.portal.apiconnect.ibm.com
kubectl delete crd portalrestores.portal.apiconnect.ibm.com
```

15. Delete Crunchy CRDs

```
kubectl delete crd pgclusters.crunchydata.com
kubectl delete crd pgpolicies.crunchydata.com
kubectl delete crd pgreplicas.crunchydata.com
kubectl delete crd pgtasks.crunchydata.com
```

16. If you installed Cert-manager and want to remove it now, complete the following steps:
    Warning: If you are using shared clusters for API Connect with a common cert manager, be aware that this step removes the components of the cert manager from cluster wide scope.

    a. Delete the Cert-manager

```
kubectl delete deploy --all -n cert-manager
kubectl delete service --all -n cert-manager
kubectl delete sa -n cert-manager --all
kubectl delete secrets -n cert-manager --all
kubectl delete APIService v1beta1.webhook.cert-manager.io -n cert-manager
kubectl delete MutatingWebhookConfiguration cert-manager-webhook -n cert-manager
kubectl delete ValidatingWebhookConfiguration cert-manager-webhook -n cert-manager
kubectl delete ns cert-manager
```

    b. Delete cert-manager CRDs

    - Delete the cert-manager CRDs with the following:

```
kubectl delete crd issuers.cert-manager.io
kubectl delete crd certificaterequests.cert-manager.io
kubectl delete crd certificates.cert-manager.io
kubectl delete crd challenges.cert-manager.io
kubectl delete crd clusterissuers.cert-manager.io
kubectl delete crd orders.cert-manager.io
```

    - Older API Connects versions may have cert-manager CRDs from an older version of cert-manager which had a different name, delete these CRDs with the following:

```
kubectl delete crd certificaterequests.certmanager.k8s.io
kubectl delete crd certificates.certmanager.k8s.io
kubectl delete crd challenges.acme.certmanager.k8s.io
kubectl delete crd clusterissuers.certmanager.k8s.io
kubectl delete crd issuers.certmanager.k8s.io
kubectl delete crd orders.acme.certmanager.k8s.io
```

- **Removing postgres resources on Kubernetes after removing API Connect**
  When you remove API Connect by deleting its files, some of the postgres resources from Crunchy Data remain and must be deleted manually before you attempt to re-install API Connect.

Removing postgres resources on Kubernetes after removing API Connect

When you remove API Connect by deleting its files, some of the postgres resources from Crunchy Data remain and must be deleted manually before you attempt to re-install API Connect.

About this task

Sometimes when you remove API Connect, some postgres resources remain and must be deleted manually.

To determine whether you need to delete any postgres resources, use the **kubectl get** command and specify **vendor=crunchydata** as shown in the following example.

```
$ kubectl get pods -n apic -l vendor=crunchydata
NAME                                                READY   STATUS      RESTARTS   AGE
backrest-backup-production-mgmt-mymgmtsite123-postgres-k77xj       0/1     Completed   0          17h
production-mgmt-mymgmtsite123-postgres-backrest-shared-repk4kzc    1/1     Running     0          2d21h
```

```
production-mgmt-mymgmtsite123-postgres-full-sch-backup-9ktp5      0/1     Completed   0          164m

$ kubectl get deployments -n apic -l vendor=crunchydata
NAME                                                READY   UP-TO-DATE   AVAILABLE   AGE
production-mgmt-mymgmtsite123-postgres-backrest-shared-repo   1/1     1            1           2d21h

$ kubectl get sa -n apic -l vendor=crunchydata
No resources found in apic namespace.

$ kubectl get jobs -n apic -l vendor=crunchydata
NAME                                                COMPLETIONS   DURATION   AGE
backrest-backup-production-mgmt-mymgmtsite123-postgres   1/1           10s        17h
production-mgmt-mymgmtsite123-postgres-full-sch-backup   1/1           37s        164m
production-mgmt-mymgmtsite123-postgres-rmdata-cemg       1/1           20s        14m

$ kubectl get roles -n apic -l vendor=crunchydata
No resources found in apic namespace.

$ kubectl get rolebindings -n apic -l vendor=crunchydata
No resources found in apic namespace.

$ kubectl get secrets -n apic -l vendor=crunchydata
NAME                                                TYPE     DATA   AGE
production-mgmt-7bc754c7-postgres-backrest-repo-config         Opaque   9      6d23h
production-mgmt-7bc754c7-postgres-postgres-secret              Opaque   2      6d23h
production-mgmt-7bc754c7-postgres-primaryuser-secret           Opaque   2      6d23h
production-mgmt-7bc754c7-postgres-testuser-secret              Opaque   2      6d23h
production-mgmt-8aac6b4e-postgres-backrest-repo-config         Opaque   9      6d22h
production-mgmt-8aac6b4e-postgres-postgres-secret              Opaque   2      6d22h
production-mgmt-8aac6b4e-postgres-primaryuser-secret           Opaque   2      6d22h
production-mgmt-8aac6b4e-postgres-testuser-secret              Opaque   2      6d22h
production-mgmt-mymgmtsite123-postgres-backrest-repo-config    Opaque   9      2d21h
production-mgmt-mymgmtsite123-postgres-postgres-secret         Opaque   2      2d21h
production-mgmt-mymgmtsite123-postgres-primaryuser-secret      Opaque   2      2d21h
production-mgmt-mymgmtsite123-postgres-testuser-secret         Opaque   2      2d21h

$ kubectl get cm -n apic -l vendor=crunchydata
NAME                                                DATA   AGE
production-mgmt-mymgmtsite123-postgres-config          0      2d21h
production-mgmt-mymgmtsite123-postgres-leader          0      2d21h
production-mgmt-mymgmtsite123-postgres-pgbouncer-cm    2      2d21h
production-mgmt-mymgmtsite123-postgres-pgha-config     5      2d21h
```

Procedure

For each type of postgres resources, check to see if any resources are available and if so, delete the resources:

- pods:

  ```
  kubectl get pods -n <namespace> -l vendor=crunchydata

  kubectl delete pods -n <namespace> -l vendor=crunchydata
  ```

- deployments:

  ```
  kubectl get deployments -n <namespace> -l vendor=crunchydata

  kubectl delete deployments -n <namespace> -l vendor=crunchydata
  ```

- Jobs:

  ```
  kubectl get jobs -n <namespace> -l vendor=crunchydata

  kubectl delete jobs -n <namespace> -l vendor=crunchydata
  ```

- roles:

  ```
  kubectl get roles -n <namespace> -l vendor=crunchydata

  kubectl delete roles -n <namespace> -l vendor=crunchydata
  ```

- rolebindings:

  ```
  kubectl get rolebindings -n <namespace> -l vendor=crunchydata

  kubectl delete rolebindings -n <namespace> -l vendor=crunchydata
  ```

- secrets:

  ```
  kubectl get secrets -n <namespace> -l vendor=crunchydata

  kubectl delete secrets -n <namespace> -l vendor=crunchydata
  ```

- cm:

  ```
  kubectl get cm -n <namespace> -l vendor=crunchydata

  kubectl delete cm -n <namespace> -l vendor=crunchydata
  ```

- pgtasks:

  ```
  kubectl get pgtasks.crunchydata.com -n <namespace> -l vendor=crunchydata

  kubectl delete pgtasks.crunchydata.com -n <namespace>
  ```

- pgreplica:

  ```
  kubectl get pgreplica -n <management_namespace> -l vendor=crunchydata
  ```

  ```
  kubectl delete pgreplica -n <management_namespace> -l vendor=crunchydata
  ```

Removing API Connect on OpenShift or Cloud Pak for Integration

Remove your entire API Connect deployment on OpenShift or Cloud Pak for Integration.

About this task

These instructions completely remove API Connect, including PVCs and secrets.

Attention: Run the commands in the sequence shown on this page. If you run commands out of sequence, you might encounter a problem where the deletion of namespaces hangs.

Procedure

1. If Event Endpoint Management is installed, run the following command to determine the name of your Event Endpoint Management instance:

   ```
   oc get eem -n <APIC-namespace>
   ```

2. If you are using a top-level CR, run the following command to determine the name of your API Connect instance:

   ```
   oc get apiconnectcluster -n <APIC-namespace>
   ```

3. If you are using a top-level CR, run the following command to delete the API Connect operands (subsystems):

   ```
   oc delete apiconnectcluster <name_of_apic_instance> -n <APIC-namespace>
   ```

4. Run the following command to delete the API Connect backup and restore CRs:

   ```
   oc delete apic --all -n <APIC-namespace>
   ```

5. Run the following command to delete the secrets that are associated with your deleted API Connect cluster:

   ```
   oc get secrets --no-headers -n <APIC-namespace> | cut -d' ' -f1 | grep "^<first_10_characters_of_apic_instance_name>-" |
   xargs oc delete secret -n <APIC-namespace>
   ```

   Where *<first_10_characters_of_apic_instance_name>* refers to the name of your API Connect instance.

   Note: This step assumes that any secrets that you want to keep in your namespace do not have a name that starts with the same 10 first characters of the API Connect Cluster name.
6. If Event Endpoint Management is installed, run the following command to delete the secrets that are associated with your deleted Event Endpoint Management instance:

   ```
   oc get secrets --no-headers -n <APIC-namespace> | cut -d' ' -f1 | grep "^<first_10_characters_of_eem_instance_name>-" |
   xargs oc delete secret -n <APIC-namespace>
   ```

   Where *<first_10_characters_of_eem_instance_name>* refers to the name of your Event Endpoint Manager instance.

   Note: This step assumes that any secrets that you want to keep in your namespace do not have a name that starts with the same 10 first characters of the Event Endpoint Manager name.
7. If the only software that is deployed in your namespace is API Connect, run the following command to delete the PVCs associated with your deleted API Connect cluster:

   ```
   oc delete pvc -n <APIC-namespace> -l app.kubernetes.io/managed-by=ibm-apiconnect
   ```

8. If you have no other software in your namespace that uses a CrunchyData Postgres cluster, delete the CrunchyData Postgres cluster:

   ```
   oc delete pvc -n <APIC-namespace> -l vendor=crunchydata
   ```

9. Check for and remove any other Crunchy data: Removing postgres resources on OpenShift and Cloud Pak for Integration.
10. Run the following commands to delete the API Connect secret rotation CRs for the cluster:

    ```
    oc delete mgmtsr -n <APIC-namespace>  --all
    oc delete ptlsr -n <APIC-namespace> --all
    ```

11. Optional: If you created a namespace specifically for API Connect, and are not using it for anything else, you can delete the namespace. If your API Connect operators are installed in this namespace, instead of in a shared global namespace, they are also deleted.

    ```
    oc delete ns <APIC-namespace>
    ```

    Deleting the namespace removes any remaining certificates and secrets.
    Note: Namespace deletion can get stuck, check that the namespace is deleted with:

    ```
    oc get ns <APIC-namespace>
    ```

    If the namespace is still present, to see why deletion is stuck, run:

    ```
    oc describe ns <APIC-namespace>
    ```

12. Optional: Delete the API Connect operator deployments.
    If your API Connect operator deployments are in a global namespace they are not deleted when your API Connect namespace is deleted. To delete the API Connect operators:

a. Open the OpenShift web console and go to Installed Operators, in the namespace where the API Connect operators are installed.
b. For each operator, click the options menu, and select Uninstall Operator.

API Connect operator might have created a number of operand requests with IBM Cloud Pak foundational services (previously called Common Services) to deploy services such as Cert-Manager. In addition, API Connect requires the use of a DataPower Gateway, so the DataPower operator might be installed in the API Connect namespace. If those artifacts are no longer needed, uninstall them individually.

Note: DataPower can be deployed on its own without API Connect. It is possible that the DataPower operator was installed for another purpose and not for use with API Connect, so check with your organization before you delete it.

Deleting the operators from the web console ensures that related subscriptions, CSVs, and install plans are also removed.

Removing postgres resources on OpenShift and Cloud Pak for Integration

When you remove API Connect by deleting its files, some of the postgres resources from Crunchy Data remain and must be deleted manually before you attempt to re-install API Connect.

About this task

Sometimes when you remove API Connect, some postgres resources remain and must be deleted manually.

To determine whether you need to delete any postgres resources, use the **oc get** command and specify **vendor=crunchydata** as shown in the following example.

```
$ oc get pods -n apic -l vendor=crunchydata
NAME                                                    READY   STATUS      RESTARTS   AGE
backrest-backup-production-mgmt-mymgmtsite123-postgres-k77xj      0/1     Completed   0          17h
production-mgmt-mymgmtsite123-postgres-backrest-shared-repk4kzc   1/1     Running     0          2d21h
production-mgmt-mymgmtsite123-postgres-full-sch-backup-9ktp5      0/1     Completed   0          164m

$ oc get deployments -n apic -l vendor=crunchydata
NAME                                                   READY   UP-TO-DATE   AVAILABLE   AGE
production-mgmt-mymgmtsite123-postgres-backrest-shared-repo   1/1     1            1           2d21h

$ oc get sa -n apic -l vendor=crunchydata
No resources found in apic namespace.

$ oc get jobs -n apic -l vendor=crunchydata
NAME                                                COMPLETIONS   DURATION   AGE
backrest-backup-production-mgmt-mymgmtsite123-postgres   1/1           10s        17h
production-mgmt-mymgmtsite123-postgres-full-sch-backup   1/1           37s        164m
production-mgmt-mymgmtsite123-postgres-rmdata-cemg       1/1           20s        14m

$ oc get roles -n apic -l vendor=crunchydata
No resources found in apic namespace.

$ oc get rolebindings -n apic -l vendor=crunchydata
No resources found in apic namespace.

$ oc get secrets -n apic -l vendor=crunchydata
NAME                                                  TYPE     DATA   AGE
production-mgmt-7bc754c7-postgres-backrest-repo-config        Opaque   9      6d23h
production-mgmt-7bc754c7-postgres-postgres-secret             Opaque   2      6d23h
production-mgmt-7bc754c7-postgres-primaryuser-secret          Opaque   2      6d23h
production-mgmt-7bc754c7-postgres-testuser-secret             Opaque   2      6d23h
production-mgmt-8aac6b4e-postgres-backrest-repo-config        Opaque   9      6d22h
production-mgmt-8aac6b4e-postgres-postgres-secret             Opaque   2      6d22h
production-mgmt-8aac6b4e-postgres-primaryuser-secret          Opaque   2      6d22h
production-mgmt-8aac6b4e-postgres-testuser-secret             Opaque   2      6d22h
production-mgmt-mymgmtsite123-postgres-backrest-repo-config   Opaque   9      2d21h
production-mgmt-mymgmtsite123-postgres-postgres-secret        Opaque   2      2d21h
production-mgmt-mymgmtsite123-postgres-primaryuser-secret     Opaque   2      2d21h
production-mgmt-mymgmtsite123-postgres-testuser-secret        Opaque   2      2d21h

$ oc get cm -n apic -l vendor=crunchydata
NAME                                               DATA   AGE
production-mgmt-mymgmtsite123-postgres-config          0      2d21h
production-mgmt-mymgmtsite123-postgres-leader          0      2d21h
production-mgmt-mymgmtsite123-postgres-pgbouncer-cm    2      2d21h
production-mgmt-mymgmtsite123-postgres-pgha-config     5      2d21h
```

Procedure

For each type of postgres resource, check to see if any resources are available and if so, delete the resources:

- pods:

  `oc get pods -n <APIC_namespace> -l vendor=crunchydata`

  `oc delete pods -n <APIC_namespace> -l vendor=crunchydata`

- deployments:

  `oc get deployments -n <APIC_namespace> -l vendor=crunchydata`

  `oc delete deployments -n <APIC_namespace> -l vendor=crunchydata`

- Jobs:

  `oc get jobs -n <APIC_namespace> -l vendor=crunchydata`

```
oc delete jobs -n <APIC_namespace> -l vendor=crunchydata
```

- roles:

  ```
  oc get roles -n <APIC_namespace> -l vendor=crunchydata
  ```

  ```
  oc delete roles -n <APIC_namespace> -l vendor=crunchydata
  ```

- rolebindings:

  ```
  oc get rolebindings -n <APIC_namespace> -l vendor=crunchydata
  ```

  ```
  oc delete rolebindings -n <APIC_namespace> -l vendor=crunchydata
  ```

- secrets:

  ```
  oc get secrets -n <APIC_namespace> -l vendor=crunchydata
  ```

  ```
  oc delete secrets -n <APIC_namespace> -l vendor=crunchydata
  ```

- cm:

  ```
  oc get cm -n <APIC_namespace> -l vendor=crunchydata
  ```

  ```
  oc delete cm -n <APIC_namespace> -l vendor=crunchydata
  ```

- pgtasks

  ```
  oc get pgtasks.crunchydata.com -n <APIC_namespace> -l vendor=crunchydata
  ```

  ```
  oc delete pgtasks.crunchydata.com -n <APIC_namespace>
  ```

- pgreplica:

  ```
  oc get pgreplica -n <APIC_namespace> -l vendor=crunchydata
  ```

  ```
  oc delete pgreplica -n <APIC_namespace> -l vendor=crunchydata
  ```

VMware

Use the instructions in this section to install, upgrade, and maintain API Connect on VMware.

Attention:
Although API Connect 10.0.5.0 is not supported to run on VMware, support for VMware is available from API Connect 10.0.5.1 and later.

- **Planning your deployment**
  Before you install API Connect, understand deployment options and requirements for endpoints, load balancing, certificates, and firewalls.
- **Installing API Connect**
  Use these instructions to install or upgrade a deployment of API Connect on VMware.
- **Upgrading API Connect**
  Upgrade API Connect on VMware to a newer version.
- **Maintaining API Connect**
  You can use utilities to complete maintenance tasks such as backup, restore, and certificate management in a VMware environment.

Planning your deployment

Before you install API Connect, understand deployment options and requirements for endpoints, load balancing, certificates, and firewalls.

- **Deployment overview for endpoints and certificates**
  When deploying API Connect, you will create one or more endpoints for the subsystems and then configure certificates or mutual TLS for most endpoints.
- **Planning your deployment topology and profiles**
  When you install on VMware, API Connect provides a choice of deployment configurations for capacity and high availability (HA). These configurations are named 'deployment profiles' and there are several pre-defined profiles to choose from.
- **Enable JWT instead of mTLS**
- **Firewall requirements on VMware**
  Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on VMware.
- **Load balancer configuration in a VMware deployment**
  When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect OVA deployment.
- **A two data center deployment strategy on VMware**
  An overview of the two data center disaster recovery deployment strategy in API Connect.
- **Planning your analytics deployment**
  Plan your API Connect analytics deployment by reviewing options for topology, data modifications, and storage.
- **Working with certificates**
  Use the `certs` command included in the APICUP installer to set and manage certificates for each subsystem. Default certificates are automatically applied, but defaults can be overridden by user-supplied custom certificates.
- **Tips and tricks for using APICUP**
  The APICUP installer contains built-in time saving functions.

Deployment overview for endpoints and certificates

When deploying API Connect, you will create one or more endpoints for the subsystems and then configure certificates or mutual TLS for most endpoints.

Configuring endpoints

Subsystem	Endpoints	Description	Certificates	
Management	cloud-admin-ui	Configured using APICUP installer. Endpoint on the management server for communication with the Cloud Manager user interface.	cloud-admin-ui	
	api-manager-ui	Configured using APICUP installer. API Manager URL endpoint on the management server for communication with the API Manager user interface.	api-manager-ui	
	consumer-api	Configured using APICUP installer. Platform REST API endpoint for running consumer APIs on the management server.	consumer-api	
	platform-api	Configured using APICUP installer. Platform REST API endpoint for running admin and provider APIs on the management server.	platform-api	
	hub	Automated Testing Behavior UI and API endpoint. External Frontend/Ingress, port 443	hub-endpoint	
	turnstile	Automated Testing Behavior UI and API endpoint. External Frontend/Ingress, port 443	turnstile-endpoint	
Portal	portal-admin	Configured using APICUP installer. Corresponds to Management Endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS.	mutual TLS	
	portal-www	Configured using APICUP installer. Portal Web site URL entered in Cloud Manager. Used publicly to access Portal.	portal-www-ingress	
Analytics	analytics-client	This is a legacy certificate, it is not used from v10.0.5 onwards.	mutual TLS	
	analytics-ingestion	Configured using APICUP installer. The analytics-ingestion endpoint must be entered in the Cloud Manager UI when registering the analytics service. It is also used by the Gateway service to push data to the Analytics service. Requires a TLS profile configured with mutual TLS.	mutual TLS	
Gateway	apic-gw-service	Configured using APICUP installer. This is the endpoint the gateway uses for network communication. Enter this endpoint as the Management Endpoint entered in Cloud Manager.	apic-gw-service-ingress	
	api-gateway	Configured using APICUP installer. This is the endpoint the gateway uses for API traffic. Enter this endpoint as the API Invocation Endpoint in Cloud Manager.	api-gateway-ingress	

The endpoints are configured by the installation Operator. They are set for each subsystem. Endpoints are also entered when configuring the Topology for the Gateway, Portal, and Analytics subsystems in Cloud Manager.

For instructions on configuring endpoints and installing into an OVA environment, see Installing API Connect.

Configuring certificates

The certificates are configured using the **apicup** command. The certificates for the endpoints are usually configured as custom certificates as described in Setting custom certificates.

Configuring mutual TLS

Mutual TLS is configured for TLS profiles in Cloud Manager. See Creating a TLS Server Profile.

Configuring a proxy

If a Developer Portal is deployed externally to the management server zone, it does not have access to the consumer and product APIs. You need to configure a proxy to enable communication. For more information, see Configuring a proxy.

Planning your deployment topology and profiles

When you install on VMware, API Connect provides a choice of deployment configurations for capacity and high availability (HA). These configurations are named 'deployment profiles' and there are several pre-defined profiles to choose from.

High availability versus disaster recovery

High availability focuses on minimizing the loss of service that is experienced by users during a hardware or software failure. Disaster recovery (DR) focuses on the procedures for recovering a system after a catastrophic hardware, software, or operator failure. Consider the following two metrics:

Recovery Time Objective (RTO)
: The RTO is the time that it is acceptable for a system to be unavailable after a disaster.

Recovery Point Objective (RPO)
: DR solutions are usually based on restoring from a backup. This means that the system can only be recovered to the state it was in when the last backup was taken, and not to the state it was in at the instant the disaster occurred. The RPO measures how far back in time the recovery point is, and therefore how much new data is lost. An RPO of zero would assert that no data is lost, but such a solution is often a compromise against the cost and performance of the system.

To achieve high availability in your API Connect VMware deployment, the three replica deployment profiles should be used, where each API Connect component is distributed across three virtual machines (VMs). However, this topology requires a low network latency between the VMs that is often unachievable between geographically separated data centers. To overcome this limitation, API Connect provides a two data center deployment solution that has both a low Recovery Time Objective (RTO), and a low Recovery Point Objective (RPO).

Deployment options

API Connect is composed of three components: Management, Portal, and Analytics, and the DataPower Gateway supporting program, see API Connect components. Each of these components includes a set of deployment profiles to cover different capacity and availability requirements.
Note: Throughout this document, the Management, Portal, and Analytics components, and the Gateway supporting program are also referred to as "subsystems".
The naming convention of the deployment profiles is **`nAxcB.mC`** where:

- **nA** indicates the number (A) of VMs (nodes) that are deployed to support the profile. The term "node" is used to refer to a VM instance (n1 means one node, n3 means three nodes).
- **cB** indicates the minimum number of virtual cores (B) required on the VM to deploy the profile.
- **mC** indicates the minimum amount of memory (C) in GB required by the profile on the VM.

API Connect components have two profile types: one replica and three replica:

- The one replica profile is a single node profile and is also known as the **`n1`** profile. It consists of a single VM for each component. This deployment type is recommended for development or testing where high availability is not a requirement.
- The three replica profiles consist of a cluster of three VMs for each component. This profile is also referred to as the **`n3`** profile. Each VM runs a replica of the component's microservices, and if a VM fails, the replicas on the other two VMs continue serving requests.

The available profiles for the Management, Portal, and Analytics components are:

- **Management**
  `n1xc4.m16`, **`n3xc4.m16`**.
- **Portal**
  `n1xc2.m8`, **`n1xc4.m16`**, **`n1xc8.m16`**, **`n3xc3.m8`**, **`n3xc4.m8`**, **`n3xc8.m16`**.
- **Analytics**
  `n1xc2.m16`, **`n1xc4.m32`**, **`n1xc6.m48`**, **`n3xc4.m16`**, **`n3xc6.m48`**, **`n3xc8.m64`**.

For information about gateway CPU and memory, refer to *Deploying the OVA on a VMware hypervisor* in the appropriate version of the DataPower documentation.

Additional points:

- Deployment profiles do not have to be the same for each component. For example, you can have a three replica deployment of the Management component that is configured with a one replica deployment of the Portal component.
- It is possible to change the deployment profile of an existing installation, but all endpoints in your deployment must remain the same. This means that you should use a load-balancer or logical DNS records when you do the initial one replica deployment. For example, if you installed a one replica deployment and used the portal VM hostname as the portal management registration endpoint, this endpoint cannot change when you move it to a three replica deployment. For more information, see Changing deployment profiles on VMware. If you want to change the deployment profile and the endpoints, you can use the form factor migration procedure: Migrating from v10 to v10 on a different form factor.
- Multiple Portal, Analytics, and Gateway component instances can be added with either configuration. For example, you can have a one replica Management component that is configured with two Portal services: a three replica Portal component, and a one replica Portal component.

Two data center disaster recovery

API Connect deployments can operate across two data centers in an active/warm-standby configuration. Each data center has a complete API Connect installation. The active data center processes all user operations. The warm-standby data center does not process user operations but maintains its management and portal component databases in synchronization with the active data center. If a failure occurs at the active data center, the warm-standby data center can become active with a manual failover operation. For more information on the two data center disaster recovery configuration, see: A two data center deployment strategy on VMware.

Enable JWT instead of mTLS

If your network infrastructure requires that load-balancers implement TLS termination, then mTLS between API Connect subsystems can be disabled and JSON Web Token (JWT) security can be used instead.
Note: Although mTLS is disabled, the network communication is still secured with standard TLS, which does not require passthrough to be enabled on load-balancers.
The following communication flows can be secured with JWT:

- Management initiated communication to portal, analytics, and gateway subsystems.
- Analytics ingestion: The flow of API event records from the gateway to the analytics subsystem.
  Note: If the gateway is under a high transaction load and sending many API events to the analytics subsystem, the enablement of JWT might impact the performance of your analytics subsystem. It is recommended to run performance tests under your expected analytics load before you decide to use JWT for the analytics ingestion path.

With JWT enabled, the portal, gateway, and analytics subsystems verify the JSON Web Token (JWT) sent from the management subsystem when it initiates communication with them. The analytics subsystem verifies the JWT sent from the gateway with incoming API event data. The subsystems that receive the token contact a JSON Web Key Set (JWKS) URL to verify it. The JWKS URL is hosted by the management subsystem, in a subpath of the management subsystem's platform REST API.

You can configure JWT instead of mTLS during installation, as documented in Installing API Connect, or you can configure JWT after installation: Use JWT security instead of mTLS between subsystems.

If you disable mTLS, you must enable JWT. It is not possible to configure API Connect with both mTLS and JWT disabled.

Firewall requirements on VMware

Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on VMware.

Required Ports between zones

The following network diagram example helps to explain which ports must be configured in an API Connect network. Specific ports must be configured to enable the communication between the various zones, both public and private, in a network.

The ports specified in the diagram are default ports. Check your deployment to understand which communication, if any, is configured to use non-default ports.

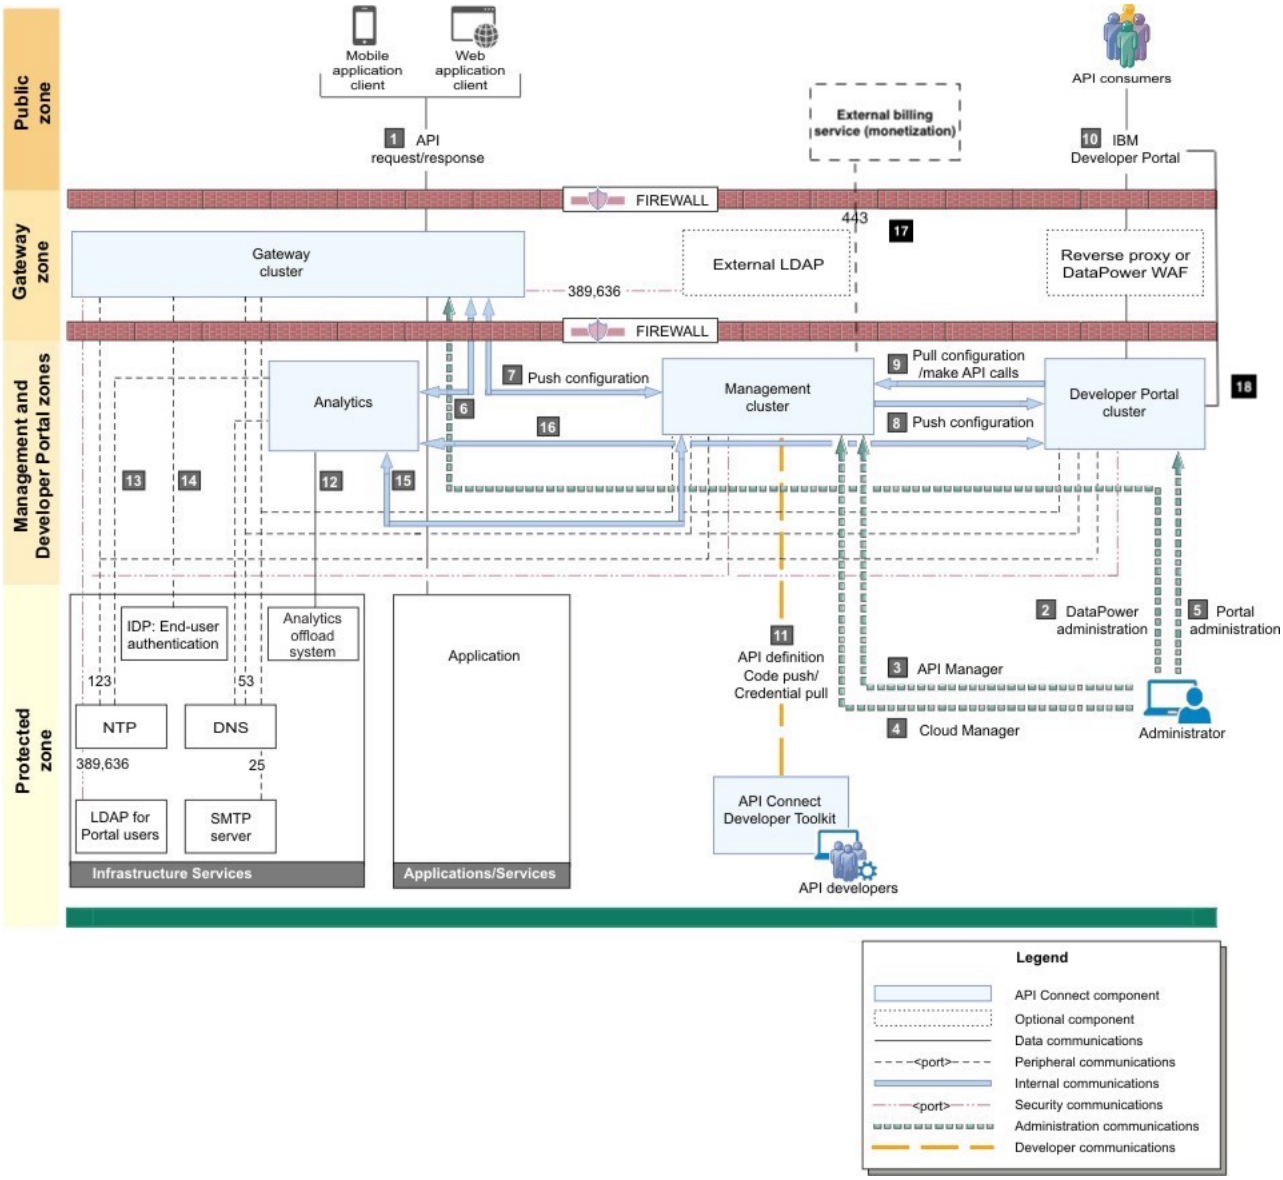


Table 1. Key for the network diagram example.
The following table lists the port numbers with a usage description.

	Usage description	Default port number
1	API request/response – Users invoking the provided APIs.	443 HTTPS from Public zone to Gateway zone
2	DataPower® administration – Internal operators who are managing the Gateway servers.	22 SSH, 9090 HTTPS from Protected zone to Gateway zone
3	API Manager – Internal business users who are defining and monitoring APIs.	443 HTTPS from Protected zone to Management zone
4	Cloud Manager – Internal operators who are administering the Cloud.	22 SSH, 443 HTTPS from Protected zone to Management zone
5	Developer Portal administration – Internal operators who are managing the Portal servers.	22 SSH, 443 HTTPS from Protected zone to Management zone
6	Gateway servers post traffic to Analytics service.	443 HTTPS from Gateway servers to Analytics service
7	Push configuration – Management servers communicate bi-directionally with Gateway servers.	3000 and 443 HTTPS Management servers to and from Gateway servers for webhook delivery. Port 3000 is the default port for apic-gw-service, and this is the port Management uses to communicate with Gateway. Port 443 is the default port for the platform-api endpoint, which apic-gw-service uses to communicate with Management.
8	Push configuration/webhooks – Management servers push configuration and webhooks to the Developer Portal.	443 HTTPS Management servers to Developer Portal servers for webhook delivery
9	Pull configuration/make API calls – Developer Portal servers pull configuration and call REST APIs.	443 HTTPS from Developer Portal servers to Management servers within Management zone

	Usage description	Default port number
10	Developer Portal – External developers who are accessing the Developer Portal.	443 HTTPS from Public zone to Developer Portal management zone. The reverse proxy/DataPower WAF for incoming web traffic to the Developer Portal cluster must be a transparent proxy - no modification of the portal URL, port, host name or path is allowed.
11	Push API definition to Management server. Pick up credential for microservice code push.	443 HTTPS from Protected zone to Management zone
12	Analytics offload	Port will depend on type of plugin and protocol used for the offload. Some possible protocols are: HTTP, HTTPS, TCP, UDP, KAFKA
13	Analytics accesses NTP	Standard NTP
14	Analytics access DNS	Standard DNS
15	Management service queries Analytics service	443 HTTPS within Management zone
16	The Portal service invokes an API (GET) on the Analytics service to retrieve data.	443 HTTPS within Management zone
17	External billing service – Management cluster connecting to external billing service (when configured for billing). If you are using Stripe as your external billing service, you must enable connections with the Stripe API at: https://stripe.com/files/ips/ips_api.json. You can also view the Stripe IP addresses at the following URL: https://stripe.com/docs/ips.	443 HTTPS from Management zone to Public zone
18	Developer Portal cluster must be able to access its own site endpoints.	443 HTTPS from Portal zone to Public zone

Firewall port requirements on VMware

The following tables lists ports that must be open in both cluster and non-clustered deployments.

Note that clustered VMware environment deployments require additional ports. See Firewall enabled ports for clustered OVA deployments

Table 2. Firewall port requirements common to all subsystems

Subsystem	Ports and description
Ports that must be open on all API Connect subsystems	The following ports must be open on the Management Server, Analytics, and Developer Portal subsystems, whether in a cluster or not. • 53 (outbound) DNS • 123 (outbound) NTP • 179 (inbound and outbound) BIRD routing daemon - VMware environments (OVA) deployments. Used for communication over TCP between servers either within the same subsystem or across different subsystems. • 443 (inbound and outbound) Used by all subsystems for communication with other subsystems • 2020 (inbound) status request. Used for communication over TCP between servers within the same subsystem. • 9177 (inbound and outbound) Member list (group membership) for API Connect`apic` daemon communication. Used for communication over both TCP and UDP, between servers within the same subsystem. • 9178 (inbound and outbound) API server, for API Connect `apic` daemon communication. Used for communication over TCP from between servers, both within the same subsystem and across different subsystems. Also used for communication between the `apicup` configuration utility and servers (this is the only port used by `apicup`).

Each subsystem uses ports in addition to the ports in Table 2. See the following table.

Table 3. Additional firewall port requirements for each subsystem

Subsystem	Ports and description
Management Service	Management Service uses the ports in Table 2 plus: • 22 remote backup server port (inbound, configurable) If backups are configured to use another port, ensure that the port is open. See Backing up the management subsystem in VMware environments. Note: this port does not have to be open between the management server and the portal server. • SMTP server port (outbound), typically 25 • 161 (inbound) SNMP. Over UDP. • LDAP server port (if using LDAP user registry), typically 389 (outbound) • In a clustered deployment, the Management Services uses additional ports. See Firewall enabled ports for clustered OVA deployments. The Automated test behavior application must be able to invoke (outbound) any port that a test system might present an API on. It can be bound to a particular port (if it is the same in all environments) or to a range of ports (to cover all of the ports it might invoke).
Developer Portal	The Developer Portal uses the ports listed in Table 2, plus: • 22 - A remote backup server port (inbound, configurable) If backups are configured to use another port, ensure that the port is open. See Backing up and restoring the Developer Portal in a Kubernetes environment. Note: this port does not have to be open between the management server and the portal server. • In a clustered deployment, the Developer Portal uses additional ports. See Firewall enabled ports for clustered OVA deployments.
Analytics	The Analytics subsystem uses the ports listed in Table 2, plus: • 161 for SNMP is required for both non-clustered and clustered deployments. UDP, inbound only. • In a non-clustered deployment, no additional ports are required. • Analytics supports an optional configuration for offload of data. This configuration might require additional outbound ports to be open. • In a clustered deployment, the Analytics subsystem uses additional ports. See Firewall enabled ports for clustered OVA deployments.

Subsystem	Ports and description
Gateway Server	The Gateway Server uses these ports in both non-clustered and clustered deployments: • 161 (inbound) SNMP. UDP protocol. Not needed if SNMP not enabled. • 162 (outbound) SNMP traps • 3000 (inbound) Gateway Service local port (configurable) • 5550 (inbound) XML management port (configurable) • 5554 (inbound) REST management port (if enabled; configurable) • 9022 (inbound) Gateway SSH (if enabled; configurable) • 9090 (inbound) Web GUI console (if enabled; configurable) • 9443 (inbound) Gateway local port (configurable) • In a clustered deployment, the Gateway Server uses additional ports. See Firewall enabled ports for clustered OVA deployments.

Communications inside the Gateway cluster

There are a number of important points to note regarding the communications within the Gateway cluster.

- We advise that you use the same port for all Gateway servers within a cluster.
- Gateway servers communicate with each other to synchronize invocation counts.
- All Gateway servers in a Gateway cluster must be able to reach all of the other Gateway servers in the same Gateway cluster.
- Gateway servers in a Gateway cluster do not directly communicate with Gateway servers in a different Gateway cluster.
- All Gateway servers must be able to reach the management subsystem platform API endpoint, which was configured during the installation of your API Connect environment.

Ethernet interface usage

To separate network traffic, you can use two or more Ethernet interfaces on the DataPower appliance on which a Gateway server is installed. For example, you can use one interface for internal IBM API Connect communications, and another for processing incoming API calls.

Port requirement for Stripe billing service

All Management servers and Developer Portal servers must be able to communicate HTTPS content with the external billing service when billing is configured. If you are using Stripe as your external billing service, you must enable HTTPS communication on port 443 with the Stripe API: https://stripe.com/files/ips/ips_api.json.
Note: API Connect does not support using webhooks with Stripe. You can see a list of the Stripe IP addresses at: https://stripe.com/docs/ips.

- **Firewall enabled ports for clustered OVA deployments**
  In a clustered OVA deployment of API Connect, specific ports must be configured for communication between members of each API Connect subsystem.
- **Load balancer ports for clustered OVA deployments**
  When you deploy a load balancer with a clustered deployment, in a VMware environment, you must ensure that the necessary ports are open.

Related concepts

- Firewall enabled ports for clustered OVA deployments
- Load balancer ports for clustered OVA deployments

Firewall enabled ports for clustered OVA deployments

In a clustered OVA deployment of API Connect, specific ports must be configured for communication between members of each API Connect subsystem.

OVA deployments require the common ports that are listed in Firewall requirements on Kubernetes. When the VMs are clustered, additional ports are used for communication between the members of the subsystems in the cluster.

All ports must be enabled inbound and outbound.

Table 1. Firewall enabled ports for clustered VMware environment deployments

Subsystem	Ports
Ports that must be open between all subsystem VMs	442, 2379, 2380, 6443, 6444, 9099, 10248, 10249, 10250,10251, 10252, 10254, 10256,10257, 10259 These ports must be open between all servers within a given subsystem. For example, from management server to management server, or from portal server to portal server, or from analytics server to analytics server. These ports are not used for communication between subsystems. You might need additional ports for Kubernetes-proxied services. The default range is **30000 – 32767**. Since the ports in use can change dynamically, ensure that the default range is open.
Additional ports that must be open between Management Service VMs	Port 8088 is required if the Automated testing behavior application is deployed for the Management Service VMs.
Additional ports that must be open between Developer Portal VMs	3009, 3010, 3306, 3307, 4443, 4444, 4567, 4568, 30865
Additional ports that must be open between Gateway Service VMs	16380, 16381, 26380, 26381
Additional ports that must be open between Analytics VMs	No additional ports are needed.

These internal ports are not used for communication between VMs. Ensure that they are open on the VM server locally.

Table 2. Internal ports reserved by API Connect

Subsystem	Ports
Reserved local ports on all subsystem VMs	8383, 8686, 8080, 8443, 30000:59999
Management Service VMs	2000, 2001, 2002, 2005, 2006, 2007, 2008, 2022, 3003, 3004, 3006, 3007, 3011, 3023, 4150, 4151, 4171, 4222, 5432, 6222, 7777, 8084, 8222, 8404
Portal Service VMs	3058, 3059, 3060, 3061
Analytics VMs	4443, 5000, 5601, 9200, 9300

Note: The ports should support IP-in-IP (protocol 4), per https://docs.projectcalico.org/getting-started/kubernetes/requirements.

Load balancer ports for clustered OVA deployments

When you deploy a load balancer with a clustered deployment, in a VMware environment, you must ensure that the necessary ports are open.

The load balancer needs port 443 for all API Connect subsystems (Management, Analytics, Developer Portal, DataPower Gateway).

Load balancer configuration in a VMware deployment

When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect OVA deployment.

About this task

API Connect can be deployed on a single node cluster. In this case the ingress endpoints are host names for which the DNS resolution points to the single IP address of the corresponding node hosting a particular subsystem, and no load balancer is required. For high availability, it is recommended to have at least a three node cluster. With three nodes, the ingress endpoints cannot resolve to a single IP address. A load balancer should be placed in front of an API Connect subsystem to route traffic.

Because it is difficult to add nodes once endpoints are configured, a good practice is to configure a load balancer even for single node deployments. With the load balancer in place, you can easily add nodes when needed. Add the node to the list of servers pointed to by the load balancer to avoid changing the ingress endpoints defined during the installation of API Connect.

To support Mutual TLS communication between the API Connect subsystems, configure the load balancer with **SSL Passthrough** and **Layer 4** load balancing. In order for Mutual TLS to be performed directly by the API Connect subsystems, the load balancer should leave the packets unmodified, as is accomplished by Layer 4. Following is a description of the communication between the endpoints that are configured with Mutual TLS:

- API Manager (with the client certificate portal-client) communicates with the Portal Admin endpoint portal-admin (with the server certificate portal-admin-ingress)
- API Manager (with the client certificate analytics-ingestion-client) communicates with the Analytics Ingestion endpoint analytics-ingestion (with the server certificate analytics-ingestion-ingress)

Note: From v10.0.5.3, it is possible to disable mTLS and use JWT instead, which allows the load-balancers to do TLS termination. For more information, see Enable JWT instead of mTLS.

Set endpoints to resolve to the load balancer
: When configuring a load balancer in front of the API Connect subsystems, the ingress endpoints are set to host names that resolve to a load balancer, rather than to the host name of any specific node. For an overview of endpoints, see Deployment overview for endpoints and certificates.

Use this example configuration as a guideline to determine the best way to configure the load balancer for your deployment.

Procedure

- **Appliance deployment**
  In this example configuration, the API Connect Management, Portal, Analytics and Gateway subsystems are deployed as three node clusters in Standard mode. An HAProxy load balancer is used. The load balancer is configured with ssl-passthrough and with upstream selection based on SNI. DNS resolution is configured to resolve the endpoints to the IP address of the load balancer. If a single HAProxy node is used, then all endpoints must resolve to the IP address of the single HAProxy. The following example endpoints require DNS resolution for this example:
  - api-manager-ui.sample.example.com
  - cloud-admin-ui.sample.example.com
  - consumer-api.sample.example.com
  - platform-api.sample.example.com
  - admin.portal.sample.example.com
  - web.portal.sample.example.com
  - analytics.ingestion.sample.example.com
  - api-gateway.sample.example.com
  - apic-gw-service.sample.example.com

  Following is an example HAProxy configuration for one HAProxy node distributing traffic to Management and Portal clusters:

  Note:
  - When you configure a load balancer in front of a Management subsystem, specify timeouts of at least 240 seconds. Note that large deployments might need larger values.

    The default timeout is typically 50 or 60 seconds, which is not long enough to avoid `409 Conflict` or `504 Gateway Timeout` errors. The `409 Conflict` error can occur when the time needed to complete an operation is sufficiently long that a

second request gets issued.

For example, to specify 240 seconds when using HAProxy as a load balancer, set **timeout client** and **timeout server** to **240000**.

- Ensure that the load balancer is configured to support the cipher **TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)**.
  When the Developer Portal, as a client, calls back to platform-api-endpoint or consumer-api-endpoint of the management subsystem, it sends only a single cipher in the Client Hello. The cipher is **TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)**. The SSL Handshake will fail if this cipher is not configured (supported) on the client's load balancer.

```
# This sample HAProxy configuration file configures one HAProxy node to distribute traffic to
# Management, Portal, Analytics, and Gateway clusters. Another option is to configure one HAproxy
# node per cluster.

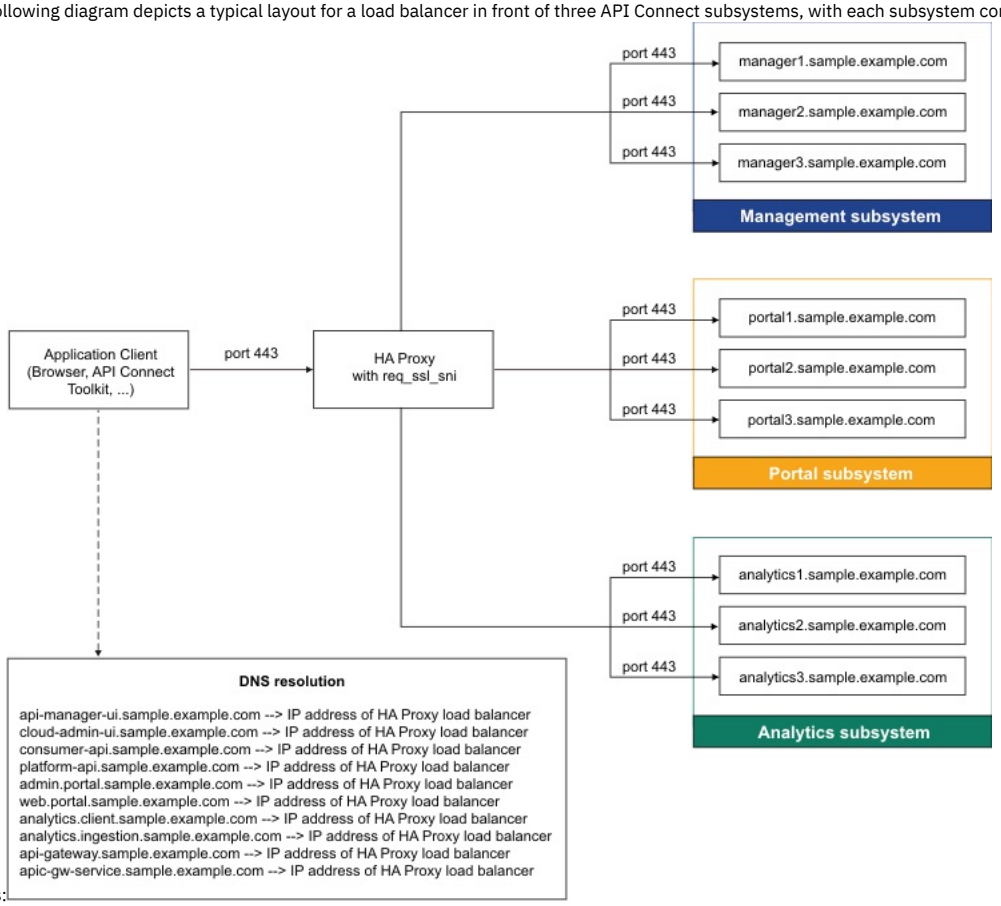
- The following diagram depicts a typical layout for a load balancer in front of three API Connect subsystems, with each subsystem containing three Appliance/OVA nodes:



A two data center deployment strategy on VMware

An overview of the two data center disaster recovery deployment strategy in API Connect.

Key points of the two data center disaster recovery (DR) solution

- Two data center DR is an active/warm-standby deployment for the API Manager and Developer Portal services, and must use manual failover.
- Two DataPower® Gateway subsystems must be deployed to provide high availability for the gateway service. However, this scenario doesn't provide high availability for the analytics service.
- If high availability is required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration Developer Portal analytics isn't possible.
- Data consistency is prioritized over data availability.
- Latency between the two data centers must be less than 80 ms.
- Replication of the API Manager is asynchronous, so it is possible that the most recent updates do not transfer to the warm-standby data center if there is an active data center failure.
- Replication of the Developer Portal is synchronous, and therefore the latency is limited to 80 ms or less.
- The API Manager and the Developer Portal services in the two data centers must use the same deployment profile.
- The deployment in each data center is effectively an instance of the same API Connect deployment - therefore, the endpoints and certificates must all be the same.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a two data center disaster recovery configuration.

Deployment architecture

A two data center deployment model is optimized for data consistency ahead of data availability, and must use manual failover when a fault occurs. For high availability of Management and Portal subsystems ensure that you use a three replica deployment profile. For more information on deployment profiles, see: Planning your deployment topology and profiles.

To achieve high availability for the DataPower Gateway, you must deploy two gateway subsystems. One subsystem in the active data center, and a separate subsystem in the warm-standby data center. Publish all Products and APIs to both gateway subsystems. The gateway subsystems are independent, and so are insulated if an issue occurs in one of them. A global dynamic router can then be used to route traffic to one gateway subsystem or the other. If high availability is also required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration Developer Portal analytics isn't possible.

Dynamic routing

Note: A dynamic routing device, such as a load balancer, is required to route traffic to either data center. However, neither this device nor its configuration is part of the API Connect offering. Contact IBM Services if you require assistance with configuring a dynamic router.

The dynamic router configuration must handle the traffic between the subsystems and between the data centers. For example, the consumer API calls from the Developer Portal to API Manager must transfer through a dynamic router so that the Developer Portal can use a single endpoint regardless of which data center API Manager is active in. The same is needed for calls to the Platform and Admin APIs from the other subsystems, as well as for incoming UI traffic for the Developer Portal UI, Cloud Manager UI, and API Manager UI.

The dynamic router must support SSL passthrough, so that it routes the Mutual TLS (mTLS) connections between API Manager and the Developer Portal, and between API Manager and the DataPower Gateway. The router should not do TLS termination, it should do layer 4 based routing by using SNI.
Note: From v10.0.5.3, it is possible to disable mTLS and use JWT instead, which allows the load-balancers to do TLS termination. For more information, see Enable JWT instead of mTLS.

Service status
: When a failure occurs, it is common practice to display an interstitial system outage web page. The dynamic router can be configured to display this web page when there is a failure, while the manual failover to the warm-standby data center is taking place.

Deployment profiles
: Both one replica and three replica deployment profiles can be used with two data center DR, but they must be the same at each data center. For more information about the deployment profiles, see Requirements for initial deployment on VMware.

For more information about a two data center DR deployment, see the following topics:

VMware

- Installing a two data center deployment
- Maintaining a two data center deployment (including information about normal operation data flows)
  - Failure handling of a two data center deployment
  - Recovering from a failover of a two data center deployment
  - Backup and restore considerations for a two data center deployment
  - Upgrading a two data center deployment

Planning your analytics deployment

Plan your API Connect analytics deployment by reviewing options for topology, data modifications, and storage.

Deployment profile

The first decision that you must make is which **`deployment-profile`** you want to use. The available deployment profiles for analytics are: **`n1xc2.m16`**, **`n1xc4.m32`**, **`n1xc6.m48`**, **`n3xc4.m16`**, **`n3xc6.m48`**, **`n3xc8.m64`**. For more information about deployment profiles, see Deployment profiles.

For a typical production deployment, choose a three replica profile. A one replica profile is only sufficient if you expect a low API transaction rate and do not plan to retain much analytics data.

Storage space

Based on your expected API transaction rate, you can estimate how much storage space your analytics subsystem requires. See Estimating storage requirements.

Firewall requirements

The analytics firewall requirements are documented here: Firewall requirments.

Inter-subsystem communication security

If your network infrastructure requires that load-balancers implement TLS termination, then mTLS between API Connect subsystems can be disabled and JSON Web Token (JWT) security can be used instead.
Note: Although mTLS is disabled, the network communication is still secured with standard TLS, which does not require passthrough to be enabled on load-balancers.
For more information about configuring JWT for network security, see: Enable JWT security.

Disabling internal storage

If you are offloading your analytics data to a third-party system, you can choose to not store your API event data in your API Connect analytics subsystem by disabling local analytics storage. With local storage disabled, the CPU, memory, and storage requirements of your analytics subsystem are greatly reduced, but you lose the ability to view your analytics data in the API Connect UIs.
Important: It is not possible to enable or disable local storage after installation.

Working with certificates

Use the **`certs`** command included in the APICUP installer to set and manage certificates for each subsystem. Default certificates are automatically applied, but defaults can be overridden by user-supplied custom certificates.

About this task

- **Certificate management: Read This First**
  Requirements and best practices for managing API Connect certificates.

- **Setting and managing certificates**
  Default certificates are automatically applied, but defaults can be overridden by custom certificates.
- **Reference for certificates, commands, and validations**
  This section contains the reference information for certificates, commands for working with certificates, and validations.

Certificate management: Read This First

Requirements and best practices for managing API Connect certificates.

Important: Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
For management purposes, API Connect certificates can be grouped by type (default, custom, and common) and by usage (public, public and user-facing, and internal). Understand each type and usage before you change any certificates.

- A default certificate is a private certificate that is uniquely generated by the installer for the current project directory, and will pass validation. Default certificates are automatically generated for each subsystem by the **`apicup subsys install`** command, unless the certificates were explicitly set by using the **`apicup certs set`** command. Note that the default certificates are self-signed, so they might not provide a level of trust suitable for external communication.
- For optimal trust levels, we recommend that you explicitly set all public and user-facing certificates by creating custom certificates.
- Some certificates are common across subsystems. Subsystems require the common certificates to allow them to register with the management subsystem. When installing any one subsystem, the common certificates are set for that subsystem and for all the other subsystems. If you use custom certificates for the common certificates, the custom certificates must be set prior to setting any other custom certificates.
- We do not recommend the explicit setting of internal certificates. The changing of internal certificates creates a risk of incompatibility with other internal certificates.

To review the usage (public, public and user-facing, or internal) of each certificate, see the following Certificate management best practice table.

Table 1. Certificate management best practice

Certificate usage	Certificate name	Best practice management
Public and User-facing	• platform-api, api-manager-ui, cloud-admin-ui • consumer-api • portal-www-ingress • hub-endpoint • turnstile-endpoint • management-replication-ingress • portal-replication-ingress	For optimal trust levels, set these explicitly. Recommended to be explicitly set as custom certificates because they are presented to an end user through a browser or Command Line Interface (CLI).
Internal	• root-ca, ingress-ca • portal-admin-ingress, portal-client • analytics-ingestion-ingress, analytics-ingestion-client For VMware appliance deployments only: k8s-ca, appliance-client	Do not change. Accept the default certificates. It is possible to change these certificates (except ingress-ca) but is strongly discouraged because you risk creating incompatibilities that can block internal communications. Each intermediate cert is used to generate other internal certs. If, for example, you change an intermediate cert, the certs generated from it might not work with internal certs generated from other intermediate certs. Note that ingress-ca is auto-generated and cannot be set using the `apicup certs set` command.

- Setting and managing certificates
- Reference for certificates, commands, and validations.

Setting and managing certificates

Default certificates are automatically applied, but defaults can be overridden by custom certificates.

About this task

- **Setting default certificates**
  Default certificates are automatically generated by APICUP when the subsystem is installed.
- **Setting custom certificates**
  Use the APICUP installer **`certs`** commands to set custom certificates.
- **Replacing custom certificates**
  Use the APICUP installer **`certs`** commands to replace existing certificates.
- **Setting common certificates**
  Common certificates are set for one subsystem, but are applied to all subsystems. Use the APICUP installer **`certs`** commands to set the common certificates.
- **Setting the encryption-secret for the management database**
  Use the APICUP installer **`certs`** commands to set the encryption-secret for the management database.
- **Clearing certificates**
  Certificates can be cleared in order to set new certificates.

Setting default certificates

Default certificates are automatically generated by APICUP when the subsystem is installed.

About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see Certificate management: Read This First. For details on each certificate, see Certificate reference.

Default certificates are generated for each subsystem by the **apicup subsys install** command. If certificates are not explicitly set by using the **apicup certs set** command, then default certificates are automatically generated by APICUP. The default certificates are self-signed, so they might not provide a level of trust suitable for external communication.

Procedure

1. Enter the settings for the subsystem by using **apicup subsys set <SUBSYS>** and validate the subsystem settings by using **apicup subsys get <SUBSYS> --validate**. The subsystem must pass validation before setting the certificates.
2. Install the subsystem by using the **apicup subsys install** command.
3. The default certificates are created for the subsystem. A default certificate is a private certificate that is uniquely generated by the installer for this project directory, they are self-signed and always pass validation.
4. List all certificates that are set for a subsystem by using the **apicup certs list** command.

```
apicup certs list -help

List all configured certificates

Usage:
  apicup certs list SUBSYS [flags]

Flags:
  -h, --help   help for list

Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Following is example output from the **apicup certs list** ***<SUBSYS>*** command:

```
Common certificates

```

Setting custom certificates

Use the APICUP installer **certs** commands to set custom certificates.

About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see Certificate management: Read This First. For details on each certificate, see Certificate reference.

The APICUP installer can be used to set certificates for each subsystem during installation. If certificates are not explicitly set by using the **apicup certs set** command, then default certificates are generated by APICUP. The default certificates are self-signed, so they might not provide a level of trust suitable for external communication.

Requirements for custom certificates:

- Extended Key Usage (EKU), either serverAuth or clientAuth depending upon the type of certificate. Certificates of type *Server* must have an Extended Key Usage with serverAuth purpose. Certificates of type *Client* must have an Extended Key Usage with clientAuth purpose.
- Subject Alternative Name (SAN) for the required hosts
- Any custom common certificates that are being used must be set prior to setting any custom certificates for a subsystem.

See Certificate reference to view the list of common certificates and to determine whether an EKU is needed for a certificate and which type of EKU (serverAuth or clientAuth).

Certificates and identical endpoints:

The Management subsystem has four public endpoints: *api-manager-ui, cloud-admin-ui, platform-api,* and *consumer-api.* Distinct TLS certificates can be set for each endpoint. However, if any two endpoints are identical, only one TLS certificate will be effective. When 2 or more endpoints are set to the same host, the secrets associated with the endpoints should be the same or contain the same certificate files.

Note: Once API Connect has been installed (meaning that the **apicup subsys install SUBSYS** command has been executed) with a given set of certificates, only the certificates for the public ingress endpoints (portal-www, api-manager-ui, cloud-admin-ui, platform-api, consumer-api) can be modified. The TLS certificates involved in mutual authentication (portal-admin-ingress, portal-client, analytics-ingestion-ingress, analytics-ingestion-client) cannot be modified after the install command has been executed.

Procedure

1. Set up and validate the subsystem. Enter the settings for the subsystem using **apicup subsys set <SUBSYS>** and validate the subsystem settings using **apicup subsys get <SUBSYS> --validate**. The subsystem must pass validation before setting the certificates.
2. Generate the custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (platform-api-example) with an EKU serverAuth and SAN using openssl:

   ```
   openssl x509 -req -days 360 -in platform-api-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
   platform-api-cert -sha256
   -extfile <(cat /etc/ssl/openssl.cnf <(printf
   "\n[SAN]\nsubjectAltName=DNS:fqdn.myserver.com\nextendedKeyUsage=serverAuth"))
   -extensions SAN
   ```

   where
   - **DNS:fqdn.myserver.com** is the fully qualified domain name of the endpoint the certificate applies to. This matches the endpoints entered in the APICUP installer. See Deploying the Management virtual appliance
   - **platform-api-example.csr** is the file name for the certificate signing request

   Following is an example for how to generate a certificate (portal-client) with an EKU clientAuth and SAN using openssl:

   ```
   openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
   portal-client-cert
   -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,
   digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,
   CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
   ```

3. Once the certificate has been created, set the certificate by entering the following command:
   ```
   apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [KEY_FILE] [flags]
   ```

   If the certificate is signed by an intermediate CA, the **CA_File** argument must point to a file that concatenates the intermediate CA, followed by the root CA, in that order.

   You can find definitions for commands at the following location: Command reference

   If the certificate was generated with an EKU serverAuth, it must be assigned to a server certificate. If the certificate was generated with an EKU clientAuth, it must be assigned to a client certificate.

4. Repeat for additional custom certificates.
5. After setting the custom certificates, you can optionally generate the remaining default certificates prior to installation by entering the **apicup certs generate** command. The **generate** command generates any certificates that have not been set, so it will create default certificates for all remaining certificates. It will not overwrite any custom certificates you have set. You can review the certificates prior to installation.
6. List all certificates with **apicup certs list SUBSYS**. The results will include the generated default certificates and the custom certificates that you set. Following is example output from the **apicup certs list** command:

```
Common certificates
===================

                    SubjectKeyId: AC:EF:88:78:01:A1:4D:8E:95:95:7D:3E:C5:43:F9:48
                    AuthorityKeyId: 6E:5A:6C:82:BA:F2:62:CF:B3:85:54:23:B6:26:9A:3F
```

7. Install the subsystem with the certificates using **apicup subsys install SUBSYS**. Any missing certificates will be generated. The installation will not proceed if there are any validation issues with the certificates. See Validation reference.
8. Repeat for other subsystems.
9. If necessary, you can replace custom certificates after installation is complete. See Replacing custom certificates.

Replacing custom certificates

Use the APICUP installer **certs** commands to replace existing certificates.

About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see Certificate management: Read This First. For details on each certificate, see Certificate reference.

The APICUP installer can be used to update certificates for each subsystem after installation.

Requirements for custom certificates:

- Extended Key Usage (EKU), either serverAuth or clientAuth depending upon the type of certificate. Certificates of type *Server* must have an Extended Key Usage with serverAuth purpose. Certificates of type *Client* must have an Extended Key Usage with clientAuth purpose.
- Subject Alternative Name (SAN) for the required hosts
- Any custom common certificates that are being used must be set prior to setting any custom certificates for a subsystem.

See Certificate Reference to view the list of common certificates and to determine whether an EKU is needed for a certificate and which type of EKU (serverAuth or clientAuth).

Certificates and identical endpoints:
The Management subsystem has four public endpoints: *api-manager-ui, cloud-admin-ui, platform-api,* and *consumer-api*. Distinct TLS certificates can be set for each endpoint. However, if any two endpoints are identical, only one TLS certificate will be effective. When 2 or more endpoints are set to the same host, the secrets associated with the endpoints should be the same or contain the same certificate files.

Procedure

1. Generate the custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (platform-api-example) with an EKU serverAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in platform-api-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
platform-api-cert -sha256
-extfile <(cat /etc/ssl/openssl.cnf <(printf
"\n[SAN]\nsubjectAltName=DNS:fqdn.myserver.com\nextendedKeyUsage=serverAuth"))
-extensions SAN
```

where

- `DNS:fqdn.myserver.com` is the fully qualified domain name of the endpoint the certificate applies to. This matches the endpoints entered in the APICUP installer.
- `platform-api-example.csr` is the file name for the certificate signing request

Following is an example for how to generate a certificate (portal-client) with an EKU clientAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
portal-client-cert
-sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,
digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,
CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

2. Once the certificate has been created, set the certificate by entering the following command:
   `apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE]`

   You can find definitions for commands at the following location: Command reference

   If the certificate is signed by an intermediate CA, the `CA_File` argument must point to a file that concatenates the intermediate CA, followed by the root CA, in that order.

   If the certificate was generated with an EKU serverAuth, it must be assigned to a server certificate. If the certificate was generated with an EKU clientAuth, it must be assigned to a client certificate.

3. Install the subsystem with the new certificate using `apicup subsys install SUBSYS`. Any missing certificates will be generated. The installation will not proceed if there are any validation issues with the certificates.
   See Validation reference.
4. Repeat for other subsystems requiring new certificates.

Setting common certificates

Common certificates are set for one subsystem, but are applied to all subsystems. Use the APICUP installer `certs` commands to set the common certificates.

About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see Certificate management: Read This First. For details on each certificate, see Certificate reference.

The common certificates are identical across subsystems. Subsystems require the common certificates to allow them to register with the management subsystem. When installing any one subsystem, the common certificates will be set for that subsystem and for all the other subsystems. If you are using custom certificates for the common certificates, they must be set prior to setting any custom certificates. See Certificate reference for a description of the common certificates.

Common certificates cannot be changed between subsystem installs. For example, you cannot set a common certificate for the management subsystem, install the management subsystem, then change a common certificate for the analytics subsystem, then install the analytics subsystem. This scenario will result in a failed installation because the common certificates are not identical.

Procedure

Follow these steps to set custom common certificates. If using default certificates, the common certificates will be set for you. See Setting default certificates.

1. Set up and validate all subsystems. Enter the settings for the subsystem using `apicup subsys set <SUBSYS>` and validate the subsystem settings using `apicup subsys get <SUBSYS> --validate`. The subsystem must pass validation before setting the certificates.
2. Generate a custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (platform-api) with an EKU serverAuth and SAN using openssl:

   ```
   openssl x509 -req -days 360 -in platform-api.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out platform-api
   -sha256
   -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nsubjectAltName=DNS:ac-msntest.myserver.com,DNS:ac2-
   msntest.myserver.com\nextendedKeyUsage=serverAuth"))
   -extensions SAN
   ```

   Following is an example for how to generate a certificate (portal-client) with an EKU clientAuth and SAN using openssl:

   ```
   openssl x509 -req -days 360 -in portal-client.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out portal-
   client-cert
   -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,
   digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,
   CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
   ```

3. Once the certificate has been created and you have a *.pem* file, set the custom common certificates in one of your subsystems. After setting the custom certificates for one subsystem, they will take effect for all subsystems. The command is targeted at a specific subsystem, but the common certificates are copied to all subsystems regardless of which subsystem they are originally set in. Following is an example for setting the `portal-client` certificate:
   ```
   apicup certs set mgmt portal-client myCertFile.pem myKeyFile.key
   myCAFile.crt
   ```
4. Set the remaining certificates for each subsystem, default or custom. See Setting default certificates and Setting custom certificates.
5. List and validate the certificates for each subsystem. See Validation reference.
6. Install each subsystem using `apicup subsys install SUBSYS`.

Setting the encryption-secret for the management database

Use the APICUP installer **certs** commands to set the encryption-secret for the management database.

About this task

The encryption-secret is a secure random bytes password used for field level encryption in the management database. You can generate 128 random bytes using the following command in openssl:

```
openssl rand -out /path/to/secret/encryption-secret.bin 128
```

Procedure

1. Enter the **apicup certs set SUBSYS CERT_NAME [KEY_FILE]** command and complete the following values:
   - SUBSYS - The subsystem for the **encryption-secret** is the name of your management subsystem, because it is used for field-level encryption for the management database.
   - CERT_NAME - The certificate name is **encryption-secret**.
   - KEY_FILE - Enter the file name for a secure random bytes string that is 128 bytes in length, for example **encryption-secret.bin**.
2. Set the remaining certificates if using custom certificates and install the management subsystem.

Clearing certificates

Certificates can be cleared in order to set new certificates.

About this task

Existing certificates must be cleared in order to set new certificates. When using default certificates, new certificates are created only for those certificates that are not set. Some of the use cases for clearing certificates are: expired certificates and configuration changes. For example, of endpoints are changed, the existing certificates must be cleared and new certificates created.

Procedure

1. Enter the **apicup certs set SUBSYS CERT_NAME --clear** command and complete the following values:
   - SUBSYS - The name of the subsystem
   - CERT_NAME - The name of the certificate that you want to clear.
2. The certificate will be cleared and can be reset, either as a default or custom certificate.

Reference for certificates, commands, and validations

This section contains the reference information for certificates, commands for working with certificates, and validations.

About this task

- **Certificate reference**
  The Certificate reference provides a description of all the certificates required in API Connect.
- **Command reference**
  The APICUP installer includes the **certs** commands to set and manage certificates.
- **Validation reference**
  Certificates are validated using several parameters.

Certificate reference

The Certificate reference provides a description of all the certificates required in API Connect.

Before you begin

APICUP sets default certificates for each subsystem during installation. The default certificates are self-signed so may not provide a level of trust suitable for external communication. Custom certificates can be set and managed following the steps described in Setting custom certificates.
The Certificates reference topic lists all certificates that are set by the **apicup certs** commands. The default certificates can be used for the majority of these certificates. The certificates that are marked as *public and user-facing* are recommended to be explicitly set as custom certificates because they are presented to an end user through a browser or Command Line Interface (CLI).

The certificates that are described as *TLS certificate used by ingress* are also considered *public* in the sense that they interact with a client that sits outside of an API Connect cluster.

Certificates that are listed as *auto-generated* cannot be set using the **apicup certs set** command. For example, the common certificate **ingress-ca** is auto-generated and used as an intermediate CA for all default ingress certificates. If you set an ingress certificate as a custom certificate, you will need to configure an intermediate CA if desired.

Important:
When setting custom certificates, additional steps must be taken to provide an Extended Key Usage (EKU) serverAuth and ClientAuth and a Subject Alternative Name (SAN) for the required hosts. These certificates are generated automatically by the **apicup certs** command when using the default certificates.

- For custom certificates of type *server*, an additional extended key usage client authentication (EKU serverAuth) certificate is required.
- For custom certificates of type *client*, an additional extended key usage server authentication (EKU clientAuth) certificate is required.

Procedure

1. **Common certificates -** The following certificates are common to all subsystems in a deployment. Subsystems require the common certificates to allow them to register with the management subsystem. The common certificates are identical across subsystems. When installing any one subsystem, the common certificates will be set for that subsystem and for all the other subsystems. Custom common certificates must be set prior to setting any custom subsystem certificates. Common certificates cannot be changed between subsystem installs. For example, you cannot set a common certificate for the management subsystem, install the management subsystem, then change a common certificate for the analytics subsystem, then install the analytics subsystem. This scenario will result in a failed installation because the common certificates are not identical.

Table 1. Common certificates

Certificate name (value used in `apicup certs`)	Usage	Requirements	Description
root-ca	CA		CA certificate which forms the root of the certificate chain
ingress-ca	CA	signed by: root-ca	Auto-generated intermediate certificate used to generate certificates for subsystem ingress endpoints if not provided by user. The ingress-ca intermediate certificate cannot be set explicitly, it is always only generated. TLS certificates for the ingresses are not required to use ingress-ca as an intermediate certificate, but if a given ingress TLS certificate remains to be auto-generated then it will be signed by this ingress-ca.
portal-client	Client	Must be signed by the same authority as the one used for the matching ingress TLS certificate **portal-admin-ingress**. For a two data center deployment, both data centers must have an identical subject name. For example, both data centers subject name could be **CN=portal-admin-client**, or they could both be **CN=ptl-adm-client, O=cert-manager**, but they must be identical.	Client certificate used by management subsystem to authenticate with the Portal admin endpoint. Requires EKU clientAuth.
analytics-client-client	Client	This is a legacy certificate, it is not used from v10.0.5 onwards	
analytics-ingestion-client	Client	Must be signed by the same authority as the one used for the matching ingress TLS certificate **analytics-ingestion-ingress** . For a two data center deployment, both data centers must have an identical subject name. For example, both data centers subject name could be **CN=a7s-ingestion-client**, or they could both be **CN=a7s-ingestion-client, O=cert-manager**, but they must be identical.	Client certificate used by management subsystem to authenticate with analytics client endpoint. Requires EKU clientAuth. Also used by gateway subsystem to authenticate with analytics ingestion endpoint.

2. **Management certificates**
These certificates apply to a single Management subsystem.

The Management subsystem has four public endpoints: *api-manager-ui, cloud-admin-ui, platform-api,* and *consumer-api.* Distinct TLS certificates can be set for each endpoint. However, if any two endpoints are identical, only one TLS certificate will be effective. When 2 or more endpoints are set to the same host, the secrets associated with the endpoints should be the same or contain the same certificate files.

The encryption-secret certificate is unique in that it is a secure random number. It is used to provide field level encryption in management (Cassandra) database. To set the encryption secret for the management database, use the following command: **apicup certs set SUBSYS CERT_NAME [KEY_FILE]** For example: **apicup certs set mgmt1 encryption-secret /path/to/keyfile**. See Setting the encryption-secret for the management database

Table 2. Management certificates

Certificate name	Usage	Requirements	Description
encryption-secret	secure random bytes	length: 128 bytes	Encryption secret used to do field level encryption in management (Cassandra) database
platform-api	Server	The host names for which the certificate is valid must include the platform-api endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for host names matching **.acme.com*.	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
consumer-api	Server	The host names for which the certificate is valid must include the consumer-api endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for host names matching **.acme.com*.	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.

Certificate name	Usage	Requirements	Description
api-manager-ui	Server	The host names for which the certificate is valid must include the api-manager-ui endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for host names matching **.acme.com*.	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
cloud-admin-ui	Server	The host names for which the certificate is valid must include the cloud-admin-ui endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for host names matching **.acme.com*.	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
hub-endpoint	Server		Automated Testing Behavior UI and API endpoint
turnstile-endpoint	Server		Automated Testing Behavior UI and API endpoint

3. **Portal certificates**
   These certificates apply to a single portal subsystem.

Table 3. Portal certificates

Certificate name	Usage	Requirements	Description
portal-admin-ingress	Server	host must match admin endpoint	TLS certificate used by ingress. The **`portal-client`** common certificate must be set prior to setting the **`portal-admin-ingress`** certificate. Requires EKU serverAuth. The **`portal-admin-ingress`** TLS certificate does not have any specific requirement on the authority signing it. If the certificate is auto-generated, it is signed by the **`ingress-ca`**.
portal-www-ingress	Server	host must match www endpoint	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.

4. **Analytics certificates**
   These certificates apply to a single analytics subsystem.

Table 4. Analytics certificates

Certificate name	Usage	Requirements	Description
analytics-ingestion-ingress	Server	Required hosts: • ingestion ingress endpoint • *.<namespace> • *.<namespace>.svc • *.<namespace>.svc.cluster.local	TLS certificate used by ingress. The **`analytics-ingestion-client`** common certificate must be set prior to setting the **`analytics-ingestion-ingress`** certificate. Requires EKU serverAuth. The **`analytics-ingestion-ingress`** TLS certificate does not have any specific requirement on the authority signing it. If the certificate is auto-generated, it is signed by the **`ingress-ca`**.

5. **OVA/Appliance certificates**
   These certificates apply only to an appliance in a VMware environment. The **`k8s-ca`** and **`appliance-client`** certificates are auto-generated and cannot be set as custom certificates. These are used to set up the Kubernetes cluster in an OVA/Appliance.

Table 5. OVA/Appliance certificates

Certificate name	Usage	Requirements	Description
k8s-ca	CA		Auto-generated CA certificate that forms the root of the certificate chain for the Appliance/Kubernetes cluster components
appliance-client	Client	signed by: k8s-ca	Auto-generated client certificate used to communicate with the Appliance API server. Requires EKU clientAuth.

Command reference

The APICUP installer includes the **`certs`** commands to set and manage certificates.

About this task

The APICUP installer can be used to set certificates for each subsystem during installation. If certificates are not explicitly set using the **`apicup certs set`** command, then default certificates are generated by APICUP. We recommend that certificates be set at installation time only (or carried over from an upgrade). The default certificates are self-signed, so they may not be optimal for external communication.

For a description of the certificates that can be set, see Certificate reference. We recommend that all public and user-facing certificates be explicitly set, including *portal-www-ingress* and *api-gateway-ingress*, and the four management endpoints (*platform-api, consumer-api, api-manager-ui*, and *cloud-admin-ui*). Following is the help reference for the **`apicup certs set`** command:

```
apicup certs set --help
Set or clear certificates and keys
```

```
Usage:
  apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [KEY_FILE] [flags]

Flags:
      --clear   Clear out a certificate or key entry
  -h, --help    help for set

Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Procedure

To set and clear certificates, complete the following steps:

1. Enter the `apicup certs set` command and complete the following values:

Table 1. apicup certs set

Command	Values	Result
`apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [flags]`	Parameters are: • SUBSYS - name of the subsystem to which the certificate applies • CERT_NAME - name of the certificate; see Certificate reference for a list of certificates that can be set for each subsystem. • CERT_FILE - Path to the certificate file in PEM format. • KEY_FILE - Path to the private key file in PEM format. • CA_FILE - Path to the Certificate Authority (CA) file. The contents of the file may be the concatenation of an intermediate CA and the root CA (in that order). **Note:** When setting the `root-ca` certificate, omit the CA_FILE parameter.	Applies the certificate when the subsystem is installed.
`apicup certs set SUBSYS CERT_NAME [KEY_FILE] [flags]`	KEY_FILE - The file containing the encryption-secret for field level encryption in the management database. Applies only to the management subsystem. The certificate name is `encryption-secret`. The type is secure random bytes with a length of 128 bytes. For example, `apicup certs set mgmt1 encryption-secret /path/to/encryption-secret.bin`. **Note:** Do not specify any of the [CERT_FILE KEY_FILE CA_FILE] parameters when setting the encryption-secret.	Applies the `encryption-secret` when the management subsystem is installed.
`flags` • `--clear` • `--help`	Flags are: • --clear - Clears the specified certificate. For example, `apicup certs set mgmt1 encryption-secret --clear` • --help - Displays help for the command.	The specified certificate will be cleared. When making configuration changes such as changing endpoints, the corresponding certificate must be cleared so that a new certificate can be set.

2. The `apicup certs get` command retrieves a specific certificate for the specified subsystem.

```
apicup certs get --help
Get a certificate

Usage:
  apicup certs get SUBSYS CERT_NAME [flags]

Flags:
  -h, --help            help for get
  -o, --output string   output to file or - (stdout) (default "-")
  -t, --type string     type of object to return: cert, key, ca (default "cert")

Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Table 2. apicup certs get

Command	Values	Result
`apicup certs get SUBSYS CERT_NAME [flags]`	Parameters are: • SUBSYS - name of the subsystem to which the certificate applies • CERT_NAME - name of the certificate to retrieve; see Certificate reference for a list of certificates	Returns the specified certificate for the specified subsystem.
`flags` • `--output string` • `--type string` • `--help`	Flags are: • --output string- Specify a file for the retrieved values, or specify "-" to send to stdout. Default is "-" to send to stdout. For example, `apicup certs get mgmt1 --output myCertsFile` • --type string - Returns only the specified type. If not specified, the type is cert. For example, `apicup certs get mgmt1 --type ca` • --help - Displays help for the command.	• For --output: The specified certificate will be retrieved and sent to stdout or saved to the specified file • For --type: Certificates will be retrieved that match the type specified. .

3. List all certificates that have been set for a subsystem using the `apicup certs list` command. You can list the certificates at any time to summarize the certificates that have been set.

```
apicup certs list -help

List all configured certificates

Usage:
  apicup certs list SUBSYS [flags]

Flags:
  -h, --help   help for list

Global Flags:
```

```
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Table 3. apicup certs list

Command	Values	Result
`apicup certs list SUBSYS [flags]`	Parameters are: • SUBSYS - name of the subsystem for which you want to list certificates	Returns a list of certificates that are configured for the subsystem.
`flags` • `--help`	Flags are: • --help - Displays help for the command.	Help text is displayed.

Following is example output from the `apicup certs list` command:

```
Common certificates
===================

Name                        Summary                                                 Validation errors
----                        -------                                                 -----------------

                   SubjectKeyId: 6D:E7:60:21:81:7E:F6:40:A4:9A:2F:88:35:D1:18:04
                   AuthorityKeyId: 0B:37:61:5F:81:B3:67:5B:E0:F1:05:A6:6E:08:D5:8E
```

4. The **`apicup certs generate`** command generates and sets default certificates. The **`generate`** command only generates and sets a certificate if it is not already set; it only sets the missing default certificates that have not been explicitly set using the **`set`** command. Execute the **`generate`** command before running the **`apicup subsys install <SUBSYS>`** command to confirm the certificates are correct before installing. It allows you to validate all certificates before performing the installation. The **`generate`** command is used as a tool to assist you when entering a combination of default and custom certificates. If you need to set specific certificates you can set them upfront (using **`set`**) and then generate the missing ones with default certificates. Or you can generate all certificates upfront and then override specific certificates to set custom certificates. Using generate helps to avoid validation errors during the installation procedure. Note that you must configure the subsystems and pass the **`--validate`** option before generating the default certificates.

```
apicup certs generate -help
Generate all unset certificates

Usage:
  apicup certs generate SUBSYS [flags]

Flags:
  -h, --help   help for generate
Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Table 4. apicup certs generate

Command	Values	Result
`apicup certs generate SUBSYS [flags]`	Parameters are: • SUBSYS - name of the subsystem for which you want to generate certificates	Generates certificates that have not been set for the subsystem. Generates self-signed certificates.
`flags` • `--help`	Flags are: • --help - Displays help for the command.	Help text is displayed.

Validation reference

Certificates are validated using several parameters.

The validations described in the following table are applied for all certificates, but are most helpful for custom certificates. For default certificates, the certificate validations will always pass, as the required elements are generated by APICUP. However, with custom certificates, some of the required elements may be missing or incorrect.

Validation	Messages	Error	See also/Action
Verify the certificate is set properly.	`certificate <cert> not set`	The certificate is not set.	
	`unable to load cert <cert>`	The certificate is set but cannot be read.	
Verify certificate key usage (Extended Key Usage).	`unable to verify cert <cert>: missing key usage <n>`	The certificate is missing the required key usage.	See Certificates Reference to see more information, including the type, for all certificates. See Setting custom certificates for tips on how to generate the EKUs for custom certificates.
Verify the certificate signing CA. If available, the CA file is loaded. Then the certificate is verified against the provided CA file, including enforcement of Extended Key Usage.	`unable to parse CA to verify cert <cert>`	The CA file could not be parsed and loaded.	
	`unable to verify cert <cert>`	The certificate failed verification against the provided CA file.	One possible reason for receiving this error is that the correct EKU is missing. For a custom certificate, see Setting custom certificates for information on generating EKUs.
Verify certificate hosts. The certificate must be valid for the hosts listed for the certificate in the Requirements column in the Certificates Reference.	`unable to verify cert <cert>: missing <host>`	The certificate is not valid for the required host.	See Certificate reference for the required hosts.
Verify that a certificate that is being used as a CA is actually a CA.	`unable to verify cert <cert>: certificate is not a CA`	The certificate is not a valid CA.	
Verify client certificate match. The `portal-client`, and `analytics-ingestion-client` certificates are verified against the CA of, respectively, `portal-admin-ingress`, and `analytics-ingestion-ingress`.	`a CA certificate must be provided for this certificate`	The CA certificate is missing for one of the `portal-admin-ingress`, and `analytics-ingestion-ingress`.	The common certificates `portal-client`, and `analytics-ingestion-client` must be set prior to setting any custom certificates.
	`client cert cannot be verified against provided CA certificate`	The verification failed.	

Tips and tricks for using APICUP

The APICUP installer contains built-in time saving functions.

Introduction

This section describes tips and techniques for working with the APICUP installation commands. The APICUP installer creates charts and secrets that are then managed by Helm.

- APICUP commands for the rotation of secrets on the Developer Portal subsystem
- Running Tiller with APICUP
- Entering multiple settings per command
- Entering multiple values
- Viewing the settings for a subsystem
- Validating the settings for a subsystem
- Output an installation plan
- Getting help for commands
- Getting help on a specific command

APICUP commands for the rotation of secrets on the Developer Portal subsystem

To rotate the Developer Portal subsystem secrets, certificates, or both, run the following command:

```
apicup subsys rotate-secrets portal
```

Where:

- ***portal*** is the name of your Developer Portal subsystem.
- **`--certs`** (optional) is the list of certificates that you want to rotate. Listing an issuer will rotate all of the certificates that were issued by that issuer, for example, listing **`portal-ca`** will rotate the **`portal-ca`**, **`portal-client`**, and **`portal-server`** certificates.
- **`--encryption-secret`** (optional) is the value to set the encryption secret to, if the supplied secret exists in the environment. If not supplied, the rotated secret will be random.
- **`--rotate-encryption-secret`** (optional) determines whether the encryption secret is rotated. Can be set to **`true`** or **`false`**.
- **`--wait`** (optional) determines whether the command waits for the operation to complete or fail. Can be set to **`true`** or **`false`**.
- **`--wait-timeout`** (optional) is the duration in seconds of the command timeout. Default is 1m0s.

For example, to rotate the encryption secret to a random value run the following command:

```
apicup subsys rotate-secrets portal --rotate-encryption-secret true
```

The following example rotates the encryption secret to a named secret (note that first you must exec into the Developer Portal OVA to create the secret):

```
apicup subsys rotate-secrets portal --rotate-encryption-secret --encryption-secret my-new-secret
```

The following example rotates all of the Developer Portal certificates:

```
apicup subsys rotate-secrets portal --certs portal-ca
```

The following example rotates just the server and client certificates:

```
apicup subsys rotate-secrets portal --certs portal-server,portal-client
```

To list any Developer Portal secret rotations that were created by using the `rotate-secrets` command:

```
apicup subsys list-rotate-secrets portal --timeout 30
```

Where:

- *portal* is the name of your Developer Portal subsystem.
- `--timeout` (optional) is the duration in seconds of the command timeout. Default is 40 seconds.

To delete any Developer Portal secret rotations that were created by using the `rotate-secrets` command:

```
apicup subsys delete-rotate-secret portal --rotate-secret-name secret_name --wait true --wait-timeout 80
```

Where:

- *portal* is the name of your Developer Portal subsystem.
- `--rotate-secret-name` is the name of the Developer Portal secret rotation CR that you want to delete. You can find this name by running the `list-rotate-secrets` command.
- `--wait` (optional) determines whether the command waits for the operation to complete or fail. Can be set to `true` or `false`.
- `--wait-timeout` (optional) is the duration in seconds of the command timeout. Default is 1m0s.

Running Tiller with APICUP

To run Tiller in a namespace:

```
export TILLER_NAMESPACE=apic
```

Entering multiple settings per command

To configure multiple settings per command, enter a space between each setting and enter an equals sign (=) to configure the setting.

In the following examples, be sure to replace [spc] with an actual space.

You can set multiple database parameters on one line:

```
apicup subsys set mgmt cassandra-max-memory-gb=9[spc]cassandra-cluster-size=3[spc]cassandra-volume-size-gb=16[spc]cassandra-backup-protocol=sftp
```

You can set all endpoints on one line:

```
apicup subsys set mgmt platform-api=my.platform.com[spc]api-manager-ui=my.apim.com[spc]cloud-admin-ui=my.cloud.com[spc]consumer-api=my.consumer.com
```

Entering multiple values

Separate multiple values for a key/value pair with commas.

```
apicup subsys set mgmt dns-servers=8.8.8.8,4.4.4.4 search-domains=a.com,b.com
```

Viewing the settings for a subsystem

To view the current values that are set for a subsystem, enter the following command: `apicup subsys get <subsys_name>`. For example: `apicup subsys get mgmt` outputs the current values for the subsystem named `mgmt` and provides a description of each value. is organized into Kubernetes settings and Subsystem settings. Following is an example of the output from the `get` command

Figure 1. Output for the get command

```
Endpoints
=========

Name                                Value          Description
----                                -----          ------
api-manager-ui                                     FQDN of API manager UI endpoint
cloud-admin-ui                                     FQDN of Cloud admin endpoint
consumer-api                                       FQDN of consumer API endpoint
platform-api                                       FQDN of platform API endpoint

Error: Subsystem validation failure. Run with --validate to see details
```

Validating the settings for a subsystem

The values set for a subsystem can be validated for syntax by entering the **--validate** option for the **get** command: **apicup subsys get <subsys_name> --validate**. For example: **apicup subsys get mgmt --validate** validates the current values for the subsystem named **mgmt**. In the following example of the output for the **--validate** option, the check mark indicates a valid setting. The x indicates an invalid setting with an error message provided.

Figure 2. Output for the --validate option

```
Endpoints
=========

Name                                Value
----                                -----
api-manager-ui                      ✘  api-manager-ui is not a valid hostname
cloud-admin-ui                      ✘  cloud-admin-ui is not a valid hostname
consumer-api                        ✘  consumer-api is not a valid hostname
platform-api                        ✘  platform-api is not a valid hostname
```

Output an installation plan

Using APICUP, you can generate an installation plan and confirm it is correct prior to running the installation. You can then install the subsystem from the plan.

To output an installation plan, enter the following command:

```
apicup subsys install SUBSYS --out=install-plan
```

where <install-plan> is the name of the directory where the installation plan will be stored.

In the example, a directory named install-plan is created in the project directory. The myProject/install-plan directory contains the configuration parameters for the subsystem.

To install the subsystem from the install-plan, enter the following command from the project directory:

```
apicup subsys install SUBSYS --plan-dir=<full-path-to-plan-directory>
```

where <full-path-to-plan-directory> is the full qualified path to the plan directory.

Following are general rules for installing from the installation plan:

- Never edit the files in the output directory directly. Instead, if changes are needed, update the parameters using APICUP and generate a new plan.
- Always run APICUP commands from the original project directory created during the initial product installation. The project directory contains the apiconnect-up.yml file.
- You can generate the plan in any location, but the install command must be run from the project directory. Enter the full path to the plan as the argument to **--plan-dir** to perform an installation.

The plan must be current with the project and the certificates. If the plan is older than the last modification date of the project or certificates, you will receive an error message such as:

```
the project was modified since the plan was generated, regenerate plan or skip this check
with a --skip-health-check flag in the command
```

or

```
the certs were changed since the plan was generated, regenerate plan or skip this check with
 a --skip-health-check flag in the command
```

Getting help for commands

You can get help for all commands by entering: **apicup --help**. Following is an example of the output:

Figure 3. Help for apicup commands

```
APIConnect Install Assist
Usage:
  apicup [command]

Available Commands:
  certs           Subsystem certificates
  completion      Generates bash or zsh completion scripts
  help            Help about any command
  hosts           Commands to configure subsystem hosts
  iface           Commands to configure hosts interfaces
  init            Create a new APIConnect UP project
  registry-upload Retag and upload images to custom registry
  server          Starts the APIConnect cluster operator
  subsys          Subsystem commands
  version         Get the APIConnect UP version

Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
  -h, --help             help for apicup

Use "apicup [command] --help" for more information about a command.
```

Getting help on a specific command

For help on a specific command, enter **--help** after the command. For example, **apicup subsys get *mgmt* --help** prints out the usage and flags for the **get** command. For example:

Figure 4. Help for get command

```
Get subsystem properties

Usage:
  apicup subsys get SUBSYS [flags]

Flags:
      --endpoints   List endpoints (default true)
  -h, --help        help for get
      --platform    List platform settings (default true)
      --subsystem   List subsystem settings (default true)
      --validate    Validate settings

Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Installing API Connect

Use these instructions to install or upgrade a deployment of API Connect on VMware.

- **IBM API Connect Version 10 software product compatibility requirements**
  Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.
- **Requirements for initial deployment on VMware**
  Review the requirements and considerations for deploying in a VMware environment.
- **API Connect licenses**
  When you install a new version of API Connect on VMware, you must accept a new license.
- **What's new for v10 installation**
  Summary of installation changes for API Connect v10 on VMware.
- **First steps for deploying in a VMware environment**
  The first steps in deploying in a VMware environment are to obtain the API Connect distribution files and to create a project directory.
- **Signature verification by using PGP**
  You can verify the integrity of files to ensure that they originated from IBM and are not modified.
- **Deploying the Management virtual appliance**
  You can create a virtual server by deploying the relevant IBM API Connect OVA file on a VMWare virtual server. Create all of the virtual servers that you want to use in your cloud.
- **Deploying the Analytics virtual appliance**
  Define your analytics subsystem, create an ISO file for each analytics node, and deploy the analytics nodes using the analytics OVA file on a VMware virtual server.
- **Deploying the Developer Portal virtual appliance**
  You create a Developer Portal node by deploying the Developer Portal OVA template. After you deploy the Developer Portal OVA template, you can install the Developer Portal.
- **Deploying DataPower Gateway virtual appliance**
  API Connect uses IBM DataPower® Gateway to provide the gateway service.
- **Post-deployment steps**
  When all subsystems are deployed, use the admin account to access the Cloud Manager administrative console and begin configuration. Optionally, take VMware snapshots of the VMs.
- **Installing a two data center deployment**
  How to install a two data center disaster recovery (2DCDR) deployment on VMware.

IBM API Connect Version 10 software product compatibility requirements

Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.

Generating a Software Product Compatibility Report

To generate an API Connect requirements report, complete the following steps:

1. Open the Detailed system requirements for a specific product page on the IBM Software Product Compatibility Reports site.
2. Search for the IBM API Connect product.
3. In the Search results list, select IBM API Connect.
4. From the Version list, select the required version.
5. Use the Filters to refine the contents of the requirements report.
6. Click Submit to generate your requirements report.

Important: When reviewing the report to determine your deployment needs, you should treat the stated CPU and memory requirements as reserved VMware capacity. For example, if the system requirements are 4 CPU and 16GB RAM, then those resources should be available at all times from the underlying hardware and should not be coming from an over-committed pool of resources.

Requirements for initial deployment on VMware

Review the requirements and considerations for deploying in a VMware environment.

Deployment requirements on VMware

- Ensure you have supported software requirement versions. See IBM API Connect Version 10 software product compatibility requirements
  Attention: API Connect is not supported on a FIPS-enabled environment.
- Do not change the hardware version of the OVA during installation. Do not attempt to use an unsupported version, even if VMware indicates compatibility with other versions. For example, when deploying API Connect, the VMware UI for the APIC OVAs might show information like:

  Table 1.

Property	Value
Guest OS	`Ubuntu Linux (64-bit)`
Compatibility	`ESXi 5.5 and later (VM version 10)`
VMware Tools	`Yes`
CPUs	`4`
Memory	`16 GB`

  Although the **Compatibility** field shows `ESXi 5.5 and later (VM version 10)`, API Connect supports only the versions listed in IBM API Connect Version 10 software product compatibility requirements. Do not change the VM version of the OVA. Ensure that the **Compatibility** field values are not changed, and remain `ESXi 5.5 and later (VM version 10)`.

  Attempts to modify the VMware compatibility may typically result in failure to boot the OVA, as per https://kb.vmware.com/s/article/52683.

- Ensure that your operating system has one of the supported utilities for creating ISOs. The apicup installer uses `mkisofs` on Linux, and `hdiutil` on macOS. For Windows, you need software that creates ISO files using `mkisofs`, such as CDRTools. Verify that the utility you will use is located in a directory that is referenced by the PATH environment setting for your operating system. When creating the ISO, if you encounter the message `Error: unable to create config ISO for host`, verify that you have sufficient permissions to run the command.
- **Important**: Use a single `apicup` project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

  The original project directory created with `apicup` during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. A good practice is to back up the original project directory to a location from where it can always be retrieved.

  Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.

- For each subsystem, gather the following networking settings, which you will need to supply during configuration:

  Table 2.

Required information	Value for your system
IP address of the server	
Domain of the server	
IP addresses of the name servers	
IP address of the network gateway (not DataPower® gateway) for the server	
Name of the Ethernet interface	
VLAN	

  Some virtualization environments require additional information when you create and configure virtual machines. For example, it might be necessary to assign a specific VLAN ID, Resource Pool, or Datastore. Please refer to information provided by your virtualization environment administrators.

Disk space requirements

- For Version 10, the data disk requirement for the management server is 200 GB. The boot disk requires 100 GB, so a minimum of 300 GB is needed for the management subsystem. You specify the data disk size in Deploying the Management subsystem OVA file when you deploy the OVF template in the VMware vSphere Web Client.
- The Developer Portal disk requirements vary with usage scenarios. See Table 1.
- Before you install, review all the minimum hardware requirements listed on the Hardware tab in the Software Product on the Compatibility Reports for API Connect. Follow the instructions in IBM API Connect Version 10 software product compatibility requirements.

API Connect configuration on VMware

- API Connect cannot be deployed on NFS.
- The timezone for API Connect pods is set to UTC. In API Connect deployments on VMware, the operating system timezone is also set to UTC. Do not change the timezone for the pods or the operating system.
- Ensure that the time settings match (within a few seconds) between the machine running `apicup` and the VMware `Host` clock. To verify the VMware host clock setting, see https://kb.vmware.com/s/article/1003736.

If the clocks are too different, the installation can fail because of invalid certificates due to time discrepancies.

- Deploying multiple similar subsystems in a single namespace is not supported. For example, deploying two management subsystems, **mgmt1**, **mgmt2** in a single namespace where apiconnect operator is installed.
- API Connect requires a dedicated IP range for deployment of the Kubernetes pod and Kubernetes service networks. These IP addresses cannot conflict with IP addresses used by other resources in your deployment, such as SMTP servers or user registries. The default values are 172.16.0.0/16 and 172.17.0.0/16, respectively. If a /16 subnet overlaps with existing IPs on the network, a CIDR as small as /22 is acceptable.
  If the default ranges conflict with other programs, you can modify the API Connect ranges during initial installation. Note that you cannot modify them once an appliance has been deployed. Follow the instructions for your subsystem if you want to modify either of the IP ranges.

- Only static IP addresses that are specified during the **apicup** project configuration before the installation of the OVAs are supported.
- Designated host names must have wildcard aliases or host aliases, which ensures that the different endpoints work together. For example, **.hostname.mycompany.com*.
- Endpoints cannot contain the underscore character **"_"** or uppercase characters.
- Host names that are used to create endpoints cannot contain the underscore character **"_"** or uppercase letters.
- Kubernetes ingress limits the character set for DNS names to not support the underscore character **"_"**. This means you cannot specify underscores in domain names that are used as endpoints. For example, **my_domain.bar.com** and **my.domain_abc.com** are not supported for **<xxx>.<hostname>.<domainname>**, and will cause an error. For example:

  ```
  Invalid value: "my_domain.bar.com": a DNS-1123 subdomain must consist of lowercase alphanumeric characters, '-' or '.',
  and must start and end with an alphanumeric character (e.g. 'example.com', regex used for validation is
   '[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*')
  ```

- Note that you cannot change host names or DNS names on a running cluster.
- For Analytics, the installer specifies a default value of 16 GB for **es-max-memory-gb**. The minimum value for this setting is 12 GB.
- Decide the *deployment-profile* to use for the installation. See Planning your deployment topology and profiles.
  Use of three replica deployment-profile is supported only on installations with three or more nodes. Installations with less than three nodes must use a one replica deployment-profile.

  Note that a deployment-profile is set for each subsystem type: Management, Analytics, and Developer Portal.

- For additional considerations for configuring clusters, see Configuring API Connect subsystems in a cluster.
  Important: For best performance it is recommended that the network latency between any 2 nodes be as low as possible. Do not configure nodes from the same subsystem cluster across multiple data centers with a high latency network. A high latency network is one that experiences more than 30ms latency between nodes.
- Configure a remote server for logging. Follow these instructions: Configuring remote logging for a VMware deployment. Pods are terminated during an upgrade, and the logs will be lost if not stored remotely.

Passwords and certificates

- When creating configuration files for use in generating an ISO image for VMware, ensure that your working directories are secure. The VMware configuration requires an ISO image that contains a plain text password to be used to unlock the VMware data disk. This means that the API Connect project configuration file apiconnect-up-v10.yml, and the /user-data directory for each host, contain the passwords you specified. This configuration information is used to create the ISO image that you combine with the ..ova distribution files when deploying (unlocking) the VMware data disk.
- You can use **apicup** to specify an **ssh** keyfile that contains a public certificate for using **ssh** to log in to a virtual machine. Logging in through **ssh** is preferred because it is more secure than password-based login.
- Default certificates are generated for each subsystem by the `apicup subsys install` command. If certificates are not explicitly set using the `apicup certs set` command, then default certificates are automatically generated by **apicup**. The default certificates are self-signed, so they may not provide a level of trust suitable for external communication. See Working with certificates.

Setting and using a hashed default password

During configuration of the Management, Analytics, and Developer Portal subsystems, you create a password to use to log in to the management console for the first time. You must use a password hashing utility to hash the password. You then use **apicup** to assign this hashed password to the subsystem. These configuration steps ensure that the password in not stored in plain text on the data disk.

The syntax of the **apicup** command is:

apicup subsys set *mgmt* **default-password='***hashed_password***'**

Usage notes:

- The **default-password** is for the **apicadm** user account on the Appliance.
- The password for **apicadm** can be used **only** to log in through the VMware console. You cannot use it to **ssh** into the Appliance as an alternative to using the **ssh-keyfiles**. Interactive login for **ssh** is disabled.
- The **default-password** value configured is only used during initial installation (first boot) of each virtual appliance. Changing the value, then regenerating the ISO, and attaching the new ISO to the virtual appliance does not change the **apicadm** password.
- The **default-password** must be hashed. If it is plain text, you will not be able to log into the Appliance through the VMware console. When you use **apicup** to set or get **default-password**, **apicup** ensures that the hash type of the password is one of the following:
  - MD5
  - SHA1
  - SHA256
  - SHA512
  - BCRYPT
  - MD5-Crypt
- When using **apicup** to set a default password for a subsystem, be aware of syntax differences between operating systems. Windows requires double-quotes. Linux and OSX require single quotes.

Operating system	Command syntax
Linux or OSX	**apicup subsys set** *mgmt* **default-password='***hashed_password***'**
Windows	**apicup subsys set** *mgmt* **default-password="***hashed_password***"**

- You can use the **passwd** command (on the appliance) to change the **apicadm** password.

- When using the VMware Remote console to login to the appliance, be aware that the keyboard layout is English. This can cause a problems with hashed passwords, if you created the ISO on a system with a different keyboard layout and you used special characters or symbols. Passwords are hashed when you set the password that you enter to log into your Management appliance for the first time, and when you create hosts.

DataPower Gateway for API Connect on VMware

- Installation and configuration of DataPower Gateway on an appliance (physical or virtual) is completed after you install the API Connect subsystems. For the gateway service in a VMware environment, use the instructions in Deploying DataPower Gateway virtual appliance.
- Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.
  Note:
  You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

  Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

API Connect licenses

When you install a new version of API Connect on VMware, you must accept a new license.

Setting the License ID on VMware

Each license has a unique identifier called a **`License ID`**. Use **`apicup`** to accept the license. License acceptance is stored in **`apiconnect-up-v10.yml`**. Each accepted **`License ID`** is passed into subsystem CRs.

```
apicup licenses accept <License_ID>
```

For example:

```
apicup licenses accept L-KZXM-S7SNCU
```

- Use **`apicup licenses list`** displays licenses available for current version. Also shows all accepted licenses, including prior versions. **`apicup licenses list`** has a **`-o yaml|json`** flag to make script based usage easier.
- If an invalid value is passed to **`apicup licenses accept`**, an error is displayed showing the valid values:

  ```
  Error: Must run `apicup licenses accept ID` with one of [L-GVEN-GFUPVE, L-BYRR-EEASJ3, .....]
  ```

- If you run other **`apicup`** commands, such as **`apicup subsys get <subsystem_name>`** from within a project directory, without first accepting a license, those commands will fail. Once you accept the license, the commands will succeed.

You accept the license during First steps for deploying in a VMware environment.

For API Connect 10.0.6.0 and later, the licenses in Table 1 will be used as the master mod-level license for all Fix Pack and security roll-up releases in this stream. There are no changes to license terms, only updates to open-source notices documented in the notes for each.

Table 1. API Connect 10.0.6 licenses

License ID	Program Name	URL
L-KZXM-S7SNCU	IBM API Connect Enterprise V10.0.6.0 If you are upgrading from 10.0.5.0 or 10.0.5.1, this ID replaces the ID for "IBM API Connect Enterprise PVU V10.0.5"	https://ibm.biz/BdPJsn
L-NRHE-WFD7EY	IBM Cloud Pak for Integration - API Calls 2023.2.1	https://ibm.biz/BdPJse
L-TBPQ-X87AGB	IBM API Connect Enterprise Add-on for IBM Products V10.0.6.0	https://ibm.biz/BdPJsb
L-FNPP-MXMAH5	IBM API Connect Professional V10.0.6.0	https://ibm.biz/BdPJsp

What's new for v10 installation

Summary of installation changes for API Connect v10 on VMware.

- Changes to **`apicup`** settings:
  - **`license-use`**. Values changed: **`Production`** is now **`production`**. **`Nonproduction`** is now **`nonproduction`**.
  - **`licenses accept`** added for setting Program license. See API Connect licenses
  - **`mode`** is deprecated and replaced by **`deployment-profile`**. Each subsystem (Management, Analytics, Portal) has separate values for one replica profiles and three replica profiles.
  - v2018 settings that are deprecated:
    - az-name - no longer used with the Management subsystem
    - cross-az-peers- no longer used with the Management subsystem
    - cassandra-max-memory-gb - no longer used with the Management subsystem
    - es-memory-gb - no longer used with the Analytics subsystem.
    - All cassandra-backup-* settings are no longer used with the Management subsystem. The Cassandra database is deprecated and replaced by Postgres.
      - cassandra-backup-auth-pass
      - cassandra-backup-auth-user
      - cassandra-backup-host

    - cassandra-backup-path
    - cassandra-backup-port
    - cassandra-backup-protocol
    - cassandra-backup-schedule
- The minimum size data disk for the Management system increases from 150 GB in v2018 to 200 GB in v10. When combined with the 100 GB requirement for the root disk (unchanged), you need 300 GB for the Management subsystem.
- Upon reboot, any extra disk that was added to the VM is picked up and added to the secure storage (data disk).

First steps for deploying in a VMware environment

The first steps in deploying in a VMware environment are to obtain the API Connect distribution files and to create a project directory.

Before you begin

- Review Requirements for initial deployment on VMware.
- See What's new for v10 installation
- See also Configuring API Connect subsystems in a cluster.

About this task

In these First Steps, you will use the **apicup** command to create a project directory that contains the configuration file **apiconnect-up-v10.yml**. When you configure the first subsystem, such as the Management Service, the subsystem configuration settings are placed in the file.

When you want to configure a second subsystem, it is important that you reuse the same project directory. This means that you only need to download **apicup** once, and create a project directory once. The configuration settings for the second subsystem are added to the existing **apiconnect-up-v10.yml**. In this way, the second subsystem, such as Developer Portal, can access the configuration information needed to interact with the first subsystem.

After completing these First Steps, follow the links to instructions for configuring your subsystem. You will specify configuration settings, create an ISO of the subsystem configuration, and then use VMware to deploy the distribution file (.ova file) for the subsystem with your ISO. Note that you create a separate ISO for each subsystem.

Installation and configuration of DataPower® Gateway on an appliance (physical or virtual) is completed after you install the API Connect subsystems. For the gateway service in a VMware environment, use the instructions in Deploying DataPower Gateway virtual appliance.

Note:

- For upgrades, do not use the procedures on this page. See Upgrading API Connect.
- Some **apicup** commands have changed from previous versions of API Connect. See What's new for v10 installation.
- When maintaining API Connect, do not use **kubectl exec** commands to access API Connect pods unless advised by IBM.
  Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

Procedure

1. Obtain the API Connect files.
   The following files are used for initial deployment on VMware:

   IBM® API Connect *<version>* Management for VMware
   : Management subsystem files

   IBM® API Connect *<version>* Developer Portal for VMware
   : Developer Portal subsystem files

   IBM® API Connect *<version>* Analytics for VMware
   : Analytics subsystem files

   IBM® API Connect *<version>* Install Assist (apicup) for *<operating_system_type>*
   : The apicup installation utility. Required for all installations on VMware.

   IBM® API Connect *<version>* Toolkit for *<operating_system_type>*
   : Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:
     - IBM® API Connect *<version>* Toolkit for *<operating_system_type>*
     - IBM® API Connect *<version>* Toolkit with Loopback for *<operating_system_type>*
     - IBM® API Connect *<version>* Toolkit Designer with Loopback for *<operating_system_type>*

     Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See Installing the toolkit.

   IBM® API Connect *<version>* Local Test Environment
   : Optional test environment. See Testing an API with the Local Test Environment

   IBM® API Connect *<version>* Security Signature Bundle File
   : Checksum files that you can use to verify the integrity of your downloads.

   Note: The Fix Pack page contains two copies of the files for each subsystem. One copy is for new installations and one is for upgrades of existing installations. For new installations, do not use files with *Upgrade* in the file name.
2. Select one of the following actions:
   - If you are configuring your first subsystem, go to step 3.
   - If you have already configured a subsystem, go to step 5.
3. Install the installation utility.
   a. Locate the apicup installation utility file for your operating system,.and download it:
   b. Rename the file for your OS type to **apicup**. Note that the instructions in this documentation refer to **apicup**.
   c. OSX and Linux® only: Make the apicup file an executable file by entering the following command:

      ```
      chmod +x apicup
      ```

d. Set your path to the location of your apicup file.
   - For the OSX and Linux operating systems:

     ```
     export PATH=$PATH:/Users/your_path/
     ```

   - For the Windows operating system:

     ```
     set PATH=c:\your_path;%PATH%
     ```

4. Create a project called *myProject* and copy the **apicup** executable into the project directory:
   a. Create a project:

      ```
      apicup init myProject
      ```

   b. Copy the **apicup** executable into the *myProject* directory or folder created by the **apicup init** command.
   c. From within your project directory, specify the API Connect license:

      ```
      apicup licenses accept <License_ID>
      ```

      The <*License_ID*> is specific to the API Connect Program Name you purchased. To view the supported license IDs, see API Connect licenses.

   Important:
   Use a single APICUP project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

   The original project directory created with APICUP during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. A good practice is to backup the original project directory to a location from where it can always be retrieved.

   Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.

   The apiconnect-up-v10.yml file is created in that directory.

   Important: The apiconnect-up-v10.yml file must be in a secure and permanent location. The file contains password information and other information that is exposed in text format. Ensure that the project directory is secure.
5. Continue with the configuration steps for your subsystem:
   - Deploying the Management virtual appliance
   - Deploying the Analytics virtual appliance
   - Deploying the Developer Portal virtual appliance

Signature verification by using PGP

You can verify the integrity of files to ensure that they originated from IBM and are not modified.

About this task

You can use code signatures to verify that a downloaded file was created by IBM and that no bits in the file were changed. The signature files that are used are ***.asc**. The key/cert file is **PRD0003216key.pub.pgp**.

Procedure

1. Import the public key.

   ```
   $ gpg --import PRD0003216key.pub.pgp
   gpg: key 020ED6B5DBE65F3B: public key "APIConnect <psirt@us.ibm.com>" imported
   gpg: Total number processed: 1
   gpg:               imported: 1

   $ gpg --list-key --fingerprint APIConnect
   pub   rsa4096 2023-02-28 [SCE]
         39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
   uid           [ unknown] APIConnect <psirt@us.ibm.com>
   ```

   When the key is imported, it does not need to be imported again. It is not signed, but you should make a note of the fingerprint so you can compare to make sure that the key is IBM's:

   ```
   39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
   ```

2. Verify the files.

   ```
   $ $ gpg --verify helper_files.zip.asc
   gpg: assuming signed data in 'helper_files.zip'
   gpg: Signature made Mon 28 Sep 17:35:17 2020 PDT
   gpg:                using RSA key 39ED16345FCDEDB5D6EDE860020ED6B5DBE65F3B
   gpg: Good signature from "APIConnect <psirt@us.ibm.com>" [unknown]
   gpg: WARNING: This key is not certified with a trusted signature!
   gpg:          There is no indication that the signature belongs to the owner.
   Primary key fingerprint: 39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
   ```

   The verification shows that the key matches the signature and that shows the fingerprint of the key, which should match the import:

   ```
   39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
   ```

Deploying the Management virtual appliance

You can create a virtual server by deploying the relevant IBM® API Connect OVA file on a VMWare virtual server. Create all of the virtual servers that you want to use in your cloud.

Before you begin

Before you deploy:

- Review the Deployment requirements on VMware.
- Review the API Connect configuration on VMware.
- Review What's new for v10 installation
- For information on deploying a cluster, see Configuring API Connect subsystems in a cluster
- If you are upgrading from a previous version, see Upgrading API Connect.

About this task

You must deploy the API Connect OVA template to create each Management virtual server that you want in your cloud.

Attention: The following settings apply to features that are currently not supported, and should not be modified:

- Subsystem settings: test-and-monitor-enabled
- Certificate settings: hub, turnstile

Procedure

Complete each of the following tasks in order:

1. Configuring the Management subsystem
2. Deploying the Management subsystem OVA file
3. Verify installation of the Management subsystem

What to do next

If you want to deploy an API Connect Analytics OVA file, continue with Deploying the Analytics virtual appliance.

If you want to deploy an API Connect Developer Portal OVA file, continue with Deploying the Developer Portal virtual appliance.

Identify the DataPower® appliances to be used as gateway servers in the API Connect cloud and obtain the IP addresses.

- **Configuring the Management subsystem**
  Specify configuration properties for your management subystem, and create an ISO.
- **Deploying the Management subsystem OVA file**
  After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.
- **Verify installation of the Management subsystem**
  Verify that deployment of the management subsystem OVA file succeeded.

Configuring the Management subsystem

Specify configuration properties for your management subystem, and create an ISO.

Before you begin

Review Deploying the Management virtual appliance

About this task

Use the **apicup** installation utility to specify configuration settings for your management subsystem.

Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in First steps for deploying in a VMware environment.
2. Change to the project directory.

   ```
   cd myProject
   ```

3. Create a management subsystem.

   ```
   apicup subsys create mgmt management
   ```

   Where:
   - *mgmt* is the name of your management server that you are creating. You can assign it any name, as long as the identifier consists of lowercase alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.

- **management** indicates that you are creating a management microservice.

The API Connect Helm charts are deployed into the default namespace. You do not need to specify a namespace.

Tip: At any time, you can view the current management subsystem values in the apiconnect-up-v10.yml by running the **apicup subsys get** command:

```
apicup subsys get mgmt
```

If you have not yet configured the subsystem, the command might return errors. Also, if you have not updated the value, a default value is listed, if there is one that is available.

After configuration is complete, you can view output similar to the following sample:

```
Appliance settings
==================

Name                          Value
Description
----                          -----
------
additional-cloud-init-file
(Optional) Path to additional cloud-init yml file
data-device                   sdb
VM disk device (usually `sdb` for SCSI or `vdb` for VirtIO)
default-password
$6$rounds=4096$vtcqpAVK$dzqrOeYP33WTvTug38Q4Rld5l8TmdQgezzTnkX/PFwkzTiZ2S0CqNRr1S4b08tOc4p.OEg4BtzBe/r8RAk.gW/
(Optional) Console login password for `apicadm` user, password must be pre-hashed
dns-servers                   [8.8.8.8]
List of DNS servers
extra-values-file
(Optional) Path to additional configuration yml file
k8s-pod-network               172.16.0.0/16
(Optional) CIDR for pods within the appliance
k8s-service-network           172.17.0.0/16
(Optional) CIDR for services within the appliance
public-iface                  eth0
Device for API/UI traffic (Eg: eth0)
search-domain                 [subnet1.example.com]
List for DNS search domains
ssh-keyfiles                  [/home/vsphere/.ssh/id_rsa.pub]
List of SSH public keys files
traffic-iface                 eth0
Device for cluster traffic (Eg: eth0)

Subsystem settings
==================

Name                          Value
Description
----                          -----
------
deployment-profile            n1xc4.m16
Deployment profile (n1xc2.m16/n3xc4.m16) for analytics, (n1xc4.m16/n3xc4.m16) for management, (n1xc2.m8/n3xc4.m8) for
portal
license-use                   production
License use (production/nonproduction)
multi-site-ha-enabled         false
Multi site HA enabled
multi-site-ha-mode            active
Multi site HA mode (active/passive)
replication-peer-fqdn
Replication peer fully qualified name (replication endpoint of active mode site)
site-name
Site name, used in k8s resource names
test-and-monitor-enabled      false
Test and Monitor enabled

Endpoints
=========

Name                          Value
Description
----                          -----
------
api-manager-ui                api-manager-ui.testsrv0231.subnet1.example.com
FQDN of API manager UI endpoint
cloud-admin-ui                cloud-admin-ui.testsrv0231.subnet1.example.com
FQDN of Cloud admin endpoint
consumer-api                  consumer-api.testsrv0231.subnet1.example.com
FQDN of consumer API endpoint
hub
FQDN of Test and Monitor hub endpoint, only required if Test and Monitor is enabled
management-replication
FQDN of Management replication endpoint, only required if HA is enabled
platform-api                  platform-api.testsrv0231.subnet1.example.com
FQDN of platform API endpoint
turnstile
FQDN of Test and Monitor turnstile endpoint, only required if Test and Monitor is enabled
```

4. Specify your deployment profile, the available profiles are described here: Planning your deployment topology and profiles.

```
apicup subsys set mgmt deployment-profile=n1xc4.m16
```

Note: The deployment profiles that are shown in the **Description** column of the **apicup get** output are not correct. The available profiles are documented in Planning your deployment topology and profiles.

5. Specify the API Connect license information:
   a. Specify the license ID:

      ```
      apicup licenses accept <License_ID>
      ```

      The <*License_ID*> is specific to the API Connect Program Name you purchased. To view the supported license IDs, see API Connect licenses.

   b. Specify the license type:

      ```
      apicup subsys set mgmt
      license-use=<license_type>
      ```

      The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

6. Optional: Configure scheduled backups for your management database. Follow the instructions in Configure your Management subsystem backup.
   Important: It is highly recommend that you configure backups and also take additional steps to ensure that your configuration and data can be restored in the event of a disaster event. See Disaster recovery of the management subsystem on VMware.
7. Optional: Configure your logging.
   Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.
   a. Complete the procedure at Configuring remote logging for a VMware deployment.
   b. Enter the following command to create the log file:

      ```
      apicup subsys set mgmt additional-cloud-init-file=config_file.yml
      ```

8. Enter the following commands to update the apiconnect-up-v10.yml with the information for your environment:
   a. Set your search domain. Multiple search domains should be separated by commas.

      ```
      apicup subsys set mgmt search-domain=your_search_domain
      ```

      Where *your_search_domain* is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is *mycompany.example.com*.

      Ensure that the value for *your_search_domain* is resolved in the system's /etc/resolv.conf file to avoid "502" errors when accessing the Cloud Manager web site. For example:

      ```
      # Generated by resolvconf
      search your_search_domain ibm.com other.domain.com
      ```

   b. Set your domain name servers (DNS).
      Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

      ```
      apicup subsys set mgmt dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
      ```

   c. Use **apicup** to set your endpoints.
      You can use wildcard aliases or host aliases with your endpoints.
      Optionally, you can specify all endpoints with one **apicup** command.

      Note: You cannot specify the underscore character "_" in domain names that are used in endpoints. See API Connect configuration on VMware.

      Table 1. Management subsystem endpoints

Setting	Endpoint host description
platform-api	Platform API endpoint. The host where your platform API calls are routed. **apicup subsys set *mgmt* platform-api=*platform-api.hostname.domain***
consumer-api	Consumer API endpoint. The host where your consumer API calls are routed. **apicup subsys set *mgmt* consumer-api=*consumer-api.hostname.domain***
cloud-admin-ui	Cloud admin user interface API endpoint. The host where your cloud administrator user-interface API calls are routed. **apicup subsys set *mgmt* cloud-admin-ui=*cloud-admin-ui.hostname.domain***
api-manager-ui	API Manager user interface endpoint. The host where your API Manager API calls are routed. **apicup subsys set *mgmt* api-manager-ui=*api-manager-ui.hostname.domain***
hub	The core microservice components for the Automated API behavior testing capability. This is an optional component and can be left unset if not used. **apicup subsys set *mgmt* hub *hub.hostname.domain*** Note: Automated API behavior testing is not supported in two data center disaster recovery configurations.
turnstile	Allows for communication between the Test pods and the API Management subsystem. This is part of the Automated API behavior testing capability. This is an optional component and can be left unset if not used. **apicup subsys set *mgmt* turnstile *turnstile.hostname.domain*** Note: Automated API behavior testing is not supported in two data center disaster recovery configurations.

9. Set a Public key.

   ```
   apicup subsys set mgmt ssh-keyfiles=path_to_public_ssh_keyfile
   ```

   Setting this key enables you to use **ssh** with this key to log in to the virtual machine to check the status of the installation. You will perform this check in later in Deploying the Management subsystem OVA file.

10. Set the password that you enter to log into your Management appliance for the first time.
    a. **Important**: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.
    b. If you do not have a password hashing utility, install one.

Operating system	Command

Operating system	Command
Ubuntu, Debian, OSX	If the **mkpasswd** command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: `gem install mkpasswd` .
Windows, Red Hat	If necessary, a password hashing utility for the Windows operating system, like OpenSSL

c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	`mkpasswd --method=sha-512 --rounds=4096 password`
Windows, Red Hat	For example, using OpenSSL: `openssl passwd -1 password`. Note that you might need to add your password hashing utility to your path; for example, on Windows: `set PATH=c:\cygwin64\bin;%PATH%`

d. Set the hashed password for your subsystem:

```
apicup subsys set mgmt default-password='hashed_password'
```

11. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.
You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See API Connect configuration on VMware.
    a. Update the IP range for the Kubernetes pod

    ```
    apicup subsys set mgmt k8s-pod-network='new_pod_range'
    ```

    Where *new_pod_range* is the new value for the range.

    b. Update the IP range for Service networks.

    ```
    apicup subsys set mgmt k8s-service-network='new_service_range'
    ```

    Where *new_service _range* is the new value for the range.

12. Add your hosts.

    ```
    apicup hosts create mgmt hostname.domainname hd_password
    ```

    Where the following are true:
    - *hostname.domainname* is the fully qualified name of the server where you are hosting your Management service, including the domain information.
    - *hd_password* is the password that the Linux Unified Key Setup uses to encrypt the storage for your Management service. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in `apiconnect-up-v10.yml`.

    Repeat this command for each host that you want to add.

    Note: Host names cannot be changed on a cluster after the initial installation.
13. Create your interfaces.

    ```
    apicup iface create mgmt hostname.domainname physical_network_id host_ip_address/subnet_mask network_gateway_ip_address
    ```

    Where *physical_network_id* is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where `x` is a number identifier.
    The format is similar to this example: `apicup iface create mgmt myHostname.domain eth0 192.0.2.10/255.255.255.0 192.0.2.1`.

    Note: The `network_gateway_ip_address` is the network gateway (not a DataPower Gateway). If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway.
14. Optional: Use **apicup** to view the configured hosts:

    ```
    apicup hosts list mgmt
    testsrv0231.subnet1.example.com
        Device  IP/Mask                  Gateway
        eth0    1.2.152.231/255.255.254.0  1.2.152.1
    ```

    Note: This command might return the following messages, which you can ignore:

    ```
    * host is missing traffic interface
    * host is missing public interface
    ```

    Note: If you are configuring two data center deployment, continue with the installation instructions in Installing a two data center deployment.

15. Optional: Verify that the configuration settings are valid.

    ```
    apicup subsys get mgmt --validate
    ```

    The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

    ```
    Appliance settings
    ==================

    Name                          Value

16. Create your ISO file.

    ```
    apicup subsys install mgmt --out mgmtplan-out
    ```

    The `--out` parameter and value are required.

    In this example, the ISO file is created in the myProject/*mgmt*plan-out directory.
    If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
Ubuntu, Debian, OSX	`export PATH=$PATH:/Users/your_path/`
Windows, Red Hat	`set PATH="c:\Program Files (x86)\cdrtools";%PATH%`

17. Deploy the subsystem ISO. Continue with Deploying the Management subsystem OVA file.

Deploying the Management subsystem OVA file

After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.

Before you begin

You must have completed the configuration of the project file entries for the management subsystem, in Configuring the Management subsystem.

About this task

Procedure

1. Log into the VMWare vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
    a. Select the Management subsystem .OVA file template by navigating to the location where you downloaded the file in First steps for deploying in a VMware environment.
    b. Enter a name and location for your file.
    c. Select a resource for your template.
    d. Review the details for your template.
    e. Select the size of your configuration.
    f. Select the storage settings.
    Important: Select at least 200 GB for the data disk size. Note that the boot disk needs 100 GB, so you need a total of 300 GB for the API Connect management subsystem.
    g. Select the networks.
    h. Customize the Template, if necessary.
    i. Review the details to ensure that they are correct.
    j. Select Finish to deploy the virtual machine.

    Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See Requirements for initial deployment on VMware.

    The template creation appears in your Recent Tasks list.
5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO file.
    a. Select the Navigate to the datastore file browser icon in the icon menu.
    b. Select the Upload a file to the Datastore icon in the icon menu.
    c. Navigate to the ISO file that you created in your project.
    It is the myProject/*mgmt*plan-out
    d. Upload the ISO file to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....
    a. On the Virtual Hardware tab, select CD/DVD Drive 1.
    b. For the Client Device, select Datastore ISO File.
    c. Find and select your datastore in the Datastores category.
    d. Find and select your ISO file in the Contents category.
    e. Select OK to commit your selection and exit the Select File window.
    f. Ensure that the Connect At Power On check box is selected.
    Tip:
        - Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
        - Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On
    g. Select OK to commit your selection and close the window.
12. Start the virtual machine by selecting the play button on the icon bar.
    The installation might take several minutes to complete, depending on the availability of the system and the download speed.
13. Verify the API Connect installation. Continue with Verify installation of the Management subsystem

Verify installation of the Management subsystem

Verify that deployment of the management subsystem OVA file succeeded.

Before you begin

You must have completed Deploying the Management subsystem OVA file.

About this task

After you configure an ISO and deploy it with the management subsystem ova, as described in Deploying the Management subsystem OVA file, verify that the subsystem installed correctly and is functional.

Procedure

1. Log in to the virtual machine by using an SSH tool to check the status of the installation:
    a. Enter the following command to connect to *mgmt* using SSH:

    ```
    ssh ip_address -l apicadm
    ```

    You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.
    b. Select Yes to continue connecting.
    Your host names are automatically added to your list of hosts.
    c. Run the **apic status** command to verify that the installation completed and the system is running correctly.

Note that after installation completes, it can take several minutes for all servers to start. If you see the error message **Subsystems not running**, wait a few minutes, try the command again, and review the output in the **Status** column.

The command output for a correctly running Management system is similar to the following lines:

```
apicadm@testsys0181:~$ sudo apic status

INFO[0001] Log level: info
Cluster members:

2. Ensure that you have saved all the necessary artifacts to enable you to restore the management subsystem in case of a disaster event. See Preparing the management subsystem for disaster recovery on VMware.
3. Verify you can access the API Connect Cloud Manager UI. Enter the URL in your browser.
   The syntax is `https://<hostname.domain>/admin`. For example:

   ```
   https://cloud-admin-ui.testsrv0231.subnet1.example.com/admin
   ```

   The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See Accessing the Cloud Manager user interface.
4. If you configured an S3 backup during installation, verify that the configuration succeeded. See Verify configuration for s3 backup.

Deploying the Analytics virtual appliance

Define your analytics subsystem, create an ISO file for each analytics node, and deploy the analytics nodes using the analytics OVA file on a VMware virtual server.

Before you begin

Before you deploy:

- Review the Deployment requirements on VMware.
- Review the API Connect configuration on VMware.
- Review What's new for v10 installation
- For information on deploying a cluster, see Configuring API Connect subsystems in a cluster
- If you are upgrading from a previous version, see Upgrading API Connect.

About this task

You must deploy the API Connect OVA template to create each analytics virtual server that you want in your cloud.

- **Configuring the Analytics subsystem**
  Specify configuration properties for your analytics subsystem, and create the ISO files.
- **Deploying the Analytics subsystem OVA file**
  After you have specified configuration settings and created your ISO files, deploy the subsystem OVA into an appliance VM.
- **Verifying deployment of the Analytics subsystem**
  Verify that deployment of the analytics subsystem and configure scheduled backups.

Configuring the Analytics subsystem

Specify configuration properties for your analytics subsystem, and create the ISO files.

Before you begin

Review Planning your analytics deployment and decide on the following:

- Deployment profile for your analytics subsystem.
- Storage space requirement for your analytics data.
- If you want to offload analytics data to a third-party system and disable local storage, you must configure storage disablement before you create the deployment ISO files. See: Disable local storage.

About this task

Use the **apicup** installation utility to specify configuration settings for your analytics subsystem.

Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in First steps for deploying in a VMware environment.

2. Change to the project directory.

```
cd myProject
```

3. Create an analytics subsystem.

```
apicup subsys create analyt analytics
```

Where:

- *analyt* is the name of the analytics server that you are creating. You can assign it any name, as long as the identifier consists of lowercase alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
- **analytics** indicates that you want it to create an analytics subsystem.

The apiconnect-up-v10.yml file that is in that directory is updated to add the analytics-related entries.
Tip: At any time, you can view the current analytics subsystem values in the apiconnect-up-v10.yml by running the **apicup get** command:

```
apicup subsys get analyt
```

If you have not updated the value, a default value is listed, if there is one that is available.
Sample output from **apicup subsys get**:

```
 Appliance settings
==================

Name                                    Value           Description
----                                    -----           ------
additional-cloud-init-file                              (Optional) Path to additional cloud-init yml file
data-device                             sdb             VM disk device (usually `sdb` for SCSI or `vdb` for VirtIO)
default-password                                        (Optional) Console login password for `apicadm` user, password
must be pre-hashed
dns-servers                             []              List of DNS servers
extra-values-file                                       (Optional) Path to additional configuration yml file
k8s-pod-network                         172.16.0.0/16   (Optional) CIDR for pods within the appliance
k8s-service-network                     172.17.0.0/16   (Optional) CIDR for services within the appliance
public-iface                            eth0            Device for API/UI traffic (Eg: eth0)
search-domain                           []              List for DNS search domains
ssh-keyfiles                            []              List of SSH public keys files
traffic-iface                           eth0            Device for cluster traffic (Eg: eth0)

Subsystem settings
==================

Name                                    Value           Description
----                                    -----           ------
analytics-backup-auth-pass                              (Optional) Server password for analytics backups
analytics-backup-auth-user                              (Optional) Server username for analytics backups
analytics-backup-certs                                  (Optional) Backup certs which are used for TLS communication
between APIC and backup server. Currently only supported for s3 backups.
analytics-backup-chunk-size             1GB             analytics-backup-chunk-size
analytics-backup-host                                   (Optional) FQDN for analytics backups server
analytics-backup-path                                   (Optional) path for analytics backups server
analytics-backup-schedule               0 0 * * *       (Optional) Cron schedule for analytics backups
analytics-enable-compression            true            (Optional) Determines whether metadata files are stored in
compressed format
analytics-enable-server-side-encryption    false        (Optional) Determines whether files are encrypted. When set to
true, files are encrypted on the server side using AES256
deployment-profile                      n1xc2.m16       Deployment profile (n1xc2.m16/n3xc4.m16) for analytics,
(n1xc2.m16/n1xc4.m16/n3xc2.m16/n3xc4.m16) for management, (n1xc2.m8/n1xc4.m16/n1xc8.m16/n3xc4.m8/n3xc8.m16) for portal
license-use                             nonproduction   License use (production/nonproduction)

Endpoints
=========

Name                                    Value           Description
----                                    -----           ------
analytics-ingestion                                     FQDN of Analytics ingestion endpoint
```

4. Specify your **deployment-profile**.

```
apicup subsys set analyt deployment-profile=<profile name>
```

For example, to deploy with a three replica profile, run the following command:

```
apicup subsys set analyt deployment-profile=n3xc4.m16
```

Note: The deployment profiles that are shown in the **Description** column of the **apicup get** output are not correct. The available profiles are documented in Planning your deployment topology and profiles.

5. Specify your license type.

```
apicup subsys set analyt license-use=license_type
```

The ***license_type*** must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

6. Optional: Configure your logging.
Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.
   a. Complete the procedure at Configuring remote logging for a VMware deployment.
   b. Enter the following command to create the log file:

```
apicup subsys set analyt additional-cloud-init-file=config_file.yml
```

7. Set your ingestion endpoint.

   ```
   apicup subsys set analyt analytics-ingestion=unique_hostname.domain
   ```

   The ingestion endpoint must be a unique host name that points to the IP address of the OVA (single node deployment), or to the IP of a load balancer configured in front of the OVA nodes. You will use the ingestion endpoint when registering the analytics service in the Cloud Manager UI.
8. Set your search domain. Multiple search domains should be separated by commas.

   ```
   apicup subsys set analyt search-domain=your_search_domain
   ```

   Where *your_search_domain* is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is *mycompany.example.com*.

   Ensure that the value for *your_search_domain* is resolved in the system's /etc/resolv.conf file to avoid "502" errors when accessing the Cloud Manager web site. For example:

   ```
   # Generated by resolvconf
   search your_search_domain ibm.com other.domain.com
   ```

9. Set your domain name servers (DNS).
   Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

   ```
   apicup subsys set analyt dns-servers=ip_address_of_dns_server
   ```

   DNS entries may not be changed on a cluster after the initial installation.
10. Set a Public key.

    ```
    apicup subsys set analyt ssh-keyfiles=path_to_public_ssh_keyfile
    ```

    Setting this key enables you to use **ssh** with this key to log in to the virtual machine to check the status of the installation. You will perform this check later in Verifying deployment of the Analytics subsystem.

11. You can set the password that you enter to log into your analytics server for the first time.
    a. Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.
    b. If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the **mkpasswd** command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: `gem install mkpasswd` .
Windows, Red Hat	If necessary, a password hashing utility for the Windows operating system, like OpenSSL

    c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	`mkpasswd --method=sha-512 --rounds=4096 password`
Windows, Red Hat	For example, using OpenSSL: `openssl passwd -1 password`. Note that you might need to add your password hashing utility to your path; for example, on Windows: `set PATH=c:\cygwin64\bin;%PATH%`

    d. Set the hashed password for your subsystem:

    ```
    apicup subsys set analyt default-password='hashed_password'
    ```

    Notes:

    - The password is hashed. If it is in plain text, you cannot log into the VMWare console.
    - Note that the password can only be used to login through the VMware console. You cannot use it to SSH into the Appliance as an alternative to using the `ssh-keyfiles`.
    - On Linux or OSX, use single quotes around *hashed_password*. For Windows, use double quotes.
    - If you are using a non-English keyboard, understand the limitations with using the remote VMware console. See Requirements for initial deployment on VMware.

12. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.
    You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See API Connect configuration on VMware.
    a. Update the IP range for the Kubernetes pod

    ```
    apicup subsys set analyt k8s-pod-network='new_pod_range'
    ```

    Where *new_pod_range* is the new value for the range.

    b. Update the IP range for Service networks.

    ```
    apicup subsys set analyt k8s-service-network='new_service_range'
    ```

    Where *new_service _range* is the new value for the range.

13. Define the hostname for each subsystem node you are deploying:

    ```
    apicup hosts create analyt hostname.domainname hd_password
    ```

    Where the following are true:
    - *hostname.domainname* is the fully qualified name of the server where you are hosting your analytics service, including the domain information.

- *hd_password* is the password of the Linux Unified Key Setup uses to encrypt the storage for your analytics service. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in **apiconnect-up-v10.yml**.

Repeat this command for each subsystem VM in your deployment. For example, if you are deploying a single node one replica profile then do this once, for a three replica profile you will define three VMs.

Note: Host names and DNS entries may not be changed on a cluster after the initial installation.

14. Define the network interface for each subsystem node you are deploying:

```
apicup iface create analyt hostname.domainname physical_network_id host_ip_address/subnet_mask gateway_ip_address
```

Where *physical_network_id* is the network interface ID of your physical server. The value is most often **eth0**. The value can also be **ethx**, where ***x*** is a number identifier.
The format is similar to this example: **apicup iface create analyt myHostname.domain eth0 192.0.2.1/255.255.1.1 192.0.2.1**
Repeat this command for each subsystem VM in your deployment. For example, if you are deploying a single node one replica profile then do this once, for a three replica profile you will define three VMs.

15. Optional: Use **apicup** to view the configured hosts:

```
apicup hosts list analyt
testsrv0233.subnet1.example.com
    Device  IP/Mask                 Gateway
    eth0    1.2.152.233/255.255.254.0  1.2.152.1
```

16. Optional: Enable JWT security instead of mTLS for communication from management and gateway to your analytics subsystem.
JWT security provides application layer security and can be used instead of mTLS when there are load-balancers located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.
To enable JWT and disable mTLS, first identify the JWKS URL from the management subsystem:

```
apicup subsys get <management subsystem>

...
jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
validate JWT -- this is unsettable and is generated based on the platform-api endpoint
...
```

Disable mTLS and enable JWT by setting the jwks-url with **apicup**:

```
apicup subsys set analyt mtls-validate-client=false
apicup subsys set analyt jwks-url=https://appliance1.apic.acme.com/api/cloud/oauth2/certs
```

Note: Do not disable mTLS without enabling JWT.
JWT for gateway to analytics communication requires an additional step during gateway registration. Enable the Use JWT switch when you register the gateway in the Cloud Manager UI.

17. Verify that the configuration settings are valid.

```
apicup subsys get analyt --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

```
 apicup subsys get analyt --validate
Appliance settings

Endpoints
=========
```

```
Name                          Value
----                          -----
analytics-ingestion           a7s-in.testsrv0233.subnet1.example.com                    ✔
```

18. If you configured additional deployment options in an extra-values file, run the following command to make the file available during installation:

    ```
    apicup subsys set analyt extra-values-file path/analytics-extra-values.yaml
    ```

    where ***analytics-extra-values*.yaml** is the name of the file containing your deployment settings.

19. Create your ISO files:

    ```
    apicup subsys install analyt --out analytplan-out
    ```

    The **--out** parameter and value are required. In this example, the ISO files are created in the myProject/analytplan-out directory.

    There will be one ISO file for each VM host you defined in step 13.
    If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
Ubuntu, Debian, OSX	`export PATH=$PATH:/Users/your_path/`
Windows, Red Hat	`set PATH="c:\Program Files (x86)\cdrtools";%PATH%`

20. Continue with Deploying the Analytics subsystem OVA file.

Deploying the Analytics subsystem OVA file

After you have specified configuration settings and created your ISO files, deploy the subsystem OVA into an appliance VM.

About this task

Repeat this procedure for each analytics VM you are deploying. Use the ISO files created in Configuring the Analytics subsystem.

Procedure

1. Log into the VMWare vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
   a. Select the analytics subsystem .OVA file template by navigating to the location where you downloaded the file in First steps for deploying in a VMware environment.
   b. Enter a name and location for your file.
   c. Select a resource for your template.
   d. Review the details for your template.
   e. Select the size of your configuration.
   f. Select the storage settings.
      Note: Ensure you specify a storage size large enough for your estimated analytics data usage: Estimating storage requirements. If in doubt, set size to 500GB.
   g. Select the networks.
   h. Customize the Template, if necessary.
   i. Review the details to ensure that they are correct.
   j. Select Finish to deploy the virtual machine.

   Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See Requirements for initial deployment on VMware.
   The template creation appears in your Recent Tasks list.
5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO file.
   a. Select the Navigate to the datastore file browser icon in the icon menu.
   b. Select the Upload a file to the Datastore icon in the icon menu.
   c. Navigate to the ISO file that you created in your project.
      It is the myProject/*analyt*plan-out
   d. Upload the ISO file to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....
    a. On the Virtual Hardware tab, select CD/DVD Drive 1.
    b. For the Client Device, select Datastore ISO File.
    c. Find and select your datastore in the Datastores category.
    d. Find and select your ISO file in the Contents category.
    e. Select OK to commit your selection and exit the Select File window.
    f. Ensure that the Connect At Power On check box is selected.
       Tip:
       - Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
       - Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On
    g. Select OK to commit your selection and close the window.

12. Start the virtual machine by selecting the play button on the icon bar.
    The installation might take several minutes to complete, depending on the availability of the system and the download speed.
13. Next, verify the deployment. Continue with Verifying deployment of the Analytics subsystem.

Verifying deployment of the Analytics subsystem

Verify that deployment of the analytics subsystem and configure scheduled backups.

Before you begin

Complete Deploying the Analytics subsystem OVA file.

About this task

After you configure an ISO and deploy it with the analytics subsystem OVA, as described in Deploying the Analytics subsystem OVA file, verify that the subsystem installed correctly and is functional, and configure the scheduled backups.

Procedure

1. Log in to the virtual machine by using an SSH tool to check the status of the installation:
   a. Enter the following command to connect to *analyt* using SSH:

      ```
      ssh ip_address -l apicadm
      ```

      You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.
   b. Select Yes to continue connecting.
      Your host names are automatically added to your list of hosts.
   c. Run the **apic status** command to verify that the installation completed and the system is running correctly.
      The command output for a correctly running analytics system is similar to the following:

      ```
      #sudo apic status
      INFO[0000] Log level: info

      Cluster members:
      - apimdev0239.subnet1.example.com (9.20.152.239)

      apimdev0239         kube-system         ingress-nginx-ingress-controller-96k8k              1/1           Running
      apimdev0239         kube-system         kube-apiserver-apimdev0239                          1/1           Running
      apimdev0239         kube-system         kube-apiserver-proxy-apimdev0239                    1/1           Running
      apimdev0239         kube-system         kube-controller-manager-apimdev0239                 1/1           Running
      apimdev0239         kube-system         kube-proxy-j4lbz                                    1/1           Running
      apimdev0239         kube-system         kube-scheduler-apimdev0239                          1/1           Running
      ```

```
apimdev0239        kube-system        local-volume-provisioner-rlfjs                  1/1          Running
apimdev0239        kube-system        metrics-server-d9fffcbc9-nmcgr                  1/1          Running
```

2. If you have now installed all subsystems, continue to Post-deployment steps.
3. Configure backups of the subsystem. Follow the instructions in Backing up and restoring the Analytics database on VMware.
   Important: It is highly recommend that you configure backups and also take additional steps to ensure that your configuration and data can be restored in the event of a disaster event. See Preparing the Analytics subsystem for disaster recovery on VMware.

Deploying the Developer Portal virtual appliance

You create a Developer Portal node by deploying the Developer Portal OVA template. After you deploy the Developer Portal OVA template, you can install the Developer Portal.

Before you begin

Before you deploy:

- Review the Deployment requirements on VMware.
- Review the API Connect configuration on VMware.
- Review What's new for v10 installation
- For information on deploying a cluster, see Configuring API Connect subsystems in a cluster
- If you are upgrading from a previous version, see Upgrading API Connect.

Note:
Ensure that your kernel or Kubernetes node has the value of its **`inotify`** watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a **`non-ready`** state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of **`inotify`** watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take **`inotify`** watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.

About this task

You must deploy the Developer Portal OVA template to create each Developer Portal node that you want in your cloud. Each node has a separate CLI password account that is required to log in through a Secure Shell (SSH) to complete specific administrative actions for only that node.

Important deployment information for Developer Portal:

- You must deploy the Developer Portal OVA template by using a version of the VMware vSphere Client that supports the SHA-512 Cryptographic Hash Algorithm.
- The Developer Portal node is initially configured with a default password of `7iron-hide`, with the user name of `admin`. For security reasons, change the default password by completing one the following actions:
  - During deployment, if the feature is available in your VMware instance, enter a new password. If you specify a password during deployment, the password for the Developer Portal command line interface (CLI) is modified. Use the new password when you log into the CLI. You cannot modify the admin user name for the CLI.
  - After deployment, log in to the CLI for each virtual appliance and run the command to change the default password for that specific node. The CLI command is **passwd**.

  Note that this console uses a US keyboard configuration, in which the `@` symbol can be in a different place to other keyboard configurations. If you are not using a US keyboard, ensure that you typed the password correctly.
- Only static IP addresses that are specified during the **`apicup`** project configuration before the installation of the OVAs are supported.
- To enable effective high availability for your Portal service, you need a latency that is less than 50ms between all OVAs to avoid the risk of performance degradation. Servers with uniform specifications are required, as any write actions occur at the speed of the slowest OVA, as the write actions are synchronous across the cluster of OVAs. It is recommended that there are three servers in each cluster of OVAs for the high availability configuration. The three servers can be situated in the same data center, or across three data centers to ensure the best availability. However, you can configure high availability with two data centers.

Procedure

Complete the following steps in order:

Note: The following steps apply to VMware only. Depending on the VMware version that you are using, some of the steps might vary. For example, you might not be able to change the user name and password during deployment.

1. Specify configuration settings for the Developer Portal subsystem and create an ISO. See Configuring the Developer Portal subsystem
2. Deploy the subsystem OVA into an appliance VM. See Deploying the Developer Portal subsystem OVA file.
3. Verify the deployment. See Verifying deployment of the Developer Portal subsystem
4. Optional: Define multiple Developer Portal endpoints. See Defining multiple portal endpoints for a VMware environment

What to do next

If you want to deploy an API Connect Analytics OVA file, continue with Deploying the Analytics virtual appliance.

If you did not specify a new password during deployment in VMware, then after deployment, log in to the command-line interface (CLI) for each appliance and run the command **passwd** to change the password.

- **Configuring the Developer Portal subsystem**
  Specify configuration properties for your Developer Portal subystem, and create an ISO.
- **Deploying the Developer Portal subsystem OVA file**
  After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.

- **Verifying deployment of the Developer Portal subsystem**
  Verify that deployment of the Developer Portal OVA file succeeded.
- **Configuring two NICs on the Developer Portal**
  Configure the Developer Portal to use two network interface cards.
- **Specifying a range of allowable client IP addresses for Developer Portal**
  Specify the range of client IP addresses to be allowed in a deployment of the Developer Portal
- **Defining multiple portal endpoints for a VMware environment**
  Multiple public facing endpoints (`portal-www`) can be defined for the Developer Portal.

Configuring the Developer Portal subsystem

Specify configuration properties for your Developer Portal subystem, and create an ISO.

Before you begin

Review the requirements and important deployment information for Developer Portal. See Deploying the Developer Portal virtual appliance.

About this task

Use the `apicup` installation utility to specify configuration settings for your Developer Portal subsystem.

Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in First steps for deploying in a VMware environment.
2. Change to the project directory.

   ```
   cd myProject
   ```

3. Create a portal subsystem.

   ```
   apicup subsys create port portal
   ```

   Where:
   - *port* is the name of the Developer Portal server that you are creating. You can assign it any name, as long as the identifier consists of lowercase alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
   - `portal` indicates that you want it to create a Developer Portal microservice.

   Note: Unless you are installing a two data center deployment, leave `multi-site-ha-enabled` as false, and ignore `multi-site-ha-mode`, `replication-peer-fqdn`, `site-name`, and the `portal-replication` endpoint, as these options are all related to that feature. For more information, see Installing a two data center deployment.
   The apiconnect-up-v10.yml file that is in that directory is updated to add the portal-related entries.
   Tip: At any time, you can view the current developer portal subsystem values in the apiconnect-up-v10.yml by running the `apicup get` command:

   ```
   apicup subsys get port
   ```

   If you have not yet configured the subsystem, the command might return errors. Also, if you have not updated the value, a default value is listed, if there is one that is available.
   After configuration is complete, you can view output similar to the following sample:

   ```
   Appliance settings
   ==================

   Name                          Value
   Description
   ----                          -----
   ------
   additional-cloud-init-file
   (Optional) Path to additional cloud-init yml file
   data-device                   sdb
   VM disk device (usually `sdb` for SCSI or `vdb` for VirtIO)
   default-password
   $6$rounds=4096$vtcqpAVK$dzqrOeYP33WTvTug38Q4Rld5l8TmdQgezzTnkX/PFwkzTiZ2S0CqNRr1S4b08tOc4p.OEg4BtzBe/r8RAk.gW/
   (Optional) Console login password for `apicadm` user, password must be pre-hashed
   dns-servers                   [192.168.1.201]
   List of DNS servers
   extra-values-file
   (Optional) Path to additional configuration yml file
   k8s-pod-network               172.16.0.0/16
   (Optional) CIDR for pods within the appliance
   k8s-service-network           172.17.0.0/16
   (Optional) CIDR for services within the appliance
   public-iface                  eth0
   Device for API/UI traffic (Eg: eth0)
   search-domain                 [subnet1.example.com]
   List for DNS search domains
   ssh-keyfiles                  [/home/vsphere/.ssh/id_rsa.pub]
   List of SSH public keys files
   traffic-iface                 eth0
   Device for cluster traffic (Eg: eth0)

   Subsystem settings

Replication peer fully qualified name (replication endpoint of active mode site)
site-name
Site name, used in k8s resource names

Endpoints
=========

Name                            Value
Description
----                            -----
------
portal-admin                    portal-api.example.com
FQDN of Portal admin endpoint
portal-replication
FQDN of Portal replication endpoint, only required if HA is enabled
portal-www                      portal-www.example.com
FQDN of Portal web endpoint
```

4. Specify **deployment-profile**.

   ```
   apicup subsys set port deployment-profile=n3xc4.m8
   ```

   The **deployment-profile** parameter indicates that you are deploying a three replica or one replica environment. For more information, see Planning your deployment topology and profiles.

   Note: The deployment profiles that are shown in the **Description** column of the **apicup get** output are not correct. The available profiles are documented in Planning your deployment topology and profiles.
5. Specify the license version you purchased.
   apicup subsys set *port*
   license-use=<*license_type***>**

   The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

6. Optional: Configure scheduled backups of the subsystem. This step is optional but is recommended.
   Refer to the instructions in Backing up and restoring the Developer Portal.

7. Optional: Configure your logging.
   Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.
   a. Complete the procedure at Configuring remote logging for a VMware deployment.
   b. Enter the following command to create the log file:

      ```
      apicup subsys set port additional-cloud-init-file=config_file.yml
      ```

8. Enter the following commands to update the apiconnect-up-v10.yml with the information for your environment:
   a. Use **apicup** to set your endpoints.
      You can use wildcard aliases or host aliases with your endpoints.
      Optionally, you can specify all endpoints with one **apicup** command.

      Note: You cannot specify the underscore character "_" in domain names that are used in endpoints. See API Connect configuration on VMware.
      The endpoints must be unique hostnames which both point to the IP address of the OVA (single node deployment), or to the IP of a load balancer configured in front of the OVA nodes. See examples in the sample output in step 3.

Setting	Endpoint host description
portal-admin	This is the *unique_hostname* for communication between your Cloud Manager and API Manager, and your Developer Portal. The values for the portal-admin and portal-www must be different. **apicup subsys set port portal-admin=*unique_hostname.domain***
portal-www	This is the *unique_hostname* for the Developer Portal Internet site that is created for the Developer Portal. Multiple portal-www endpoints may be configured, as described here: Defining multiple portal endpoints for a VMware environment. **apicup subsys set port portal-www=*unique_hostname.domain***

   b. Set your search domain. Multiple search domains should be separated by commas.

      ```
      apicup subsys set port search-domain=your_search_domain
      ```

      Where *your_search_domain* is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is *mycompany.example.com*.

      Ensure that the value for *your_search_domain* is resolved in the system's /etc/resolv.conf file to avoid "502" errors when accessing the Cloud Manager web site. For example:

      ```
      # Generated by resolvconf
      search your_search_domain ibm.com other.domain.com
      ```

   c. Set your domain name servers (DNS).

Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set port dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
```

DNS entries may not be changed on a cluster after the initial installation.

9. Set a Public key.

```
apicup subsys set port ssh-keyfiles=path_to_public_ssh_keyfile
```

Setting this key enables you to use **ssh** with this key to log in to the virtual machine to check the status of the installation. You will perform this check in Verifying deployment of the Developer Portal subsystem.

10. If there are multiple Management subsystems in the same project, set the Portal subsystem's `platform-api` and `consumer-api` certificates to match those used by the appropriate Management subsystem to ensure that the Portal subsystem is correctly associated with that Management subsystem.
This step only applies if you installed more than one Management subsystem into a single project.

A Portal subsystem can be associated with only one Management subsystem. To associate the new Portal subsystem with the appropriate Management subsystem, manually set the `mgmt-platform-api` and `mgmt-consumer-api` certificates to match the ones used by the Management subsystem.

a. Run the following commands to get the certificates from the Management subsystem:

```
apicup certs get mgmt-subsystem-name platform-api -t cert > platform-api.crt
apicup certs get mgmt-subsystem-name platform-api -t key > platform-api.key
apicup certs get mgmt-subsystem-name platform-api -t ca > platform-api-ca.crt

apicup certs get mgmt-subsystem-name consumer-api -t cert > consumer-api.crt
apicup certs get mgmt-subsystem-name consumer-api -t key > consumer-api.key
apicup certs get mgmt-subsystem-name consumer-api -t ca > consumer-api-ca.crt
```

where *mgmt-subsystem-name* is the name of the specific Management subsystem that you want to associate the new Portal subsystem with.

b. Run the following commands to set the Portal's certificates to match those used by the Management subsystem:

```
apicup certs set ptl-subsystem-name mgmt-platform-api Cert_file_path Key_file_path CA_file_path

apicup certs set ptl-subsystem-name mgmt-consumer-api Cert_file_path Key_file_path CA_file_path
```

For more information on `apicup` certificate commands, see Command reference.

11. You can set a hashed password that you enter to log in to your Developer Portal server for the first time.
a. **Important**: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.
b. If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the **mkpasswd** command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: `gem install mkpasswd` .
Windows, Red Hat	If necessary, a password hashing utility for the Windows operating system, like OpenSSL

c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	`mkpasswd --method=sha-512 --rounds=4096 password`
Windows, Red Hat	For example, using OpenSSL: `openssl passwd -1 password`. Note that you might need to add your password hashing utility to your path; for example, on Windows: `set PATH=c:\cygwin64\bin;%PATH%`

d. Set the hashed password for your subsystem:

```
apicup subsys set port default-password="hashed_password"
```

Notes:

- The password is hashed. If it is in plain text, you cannot log into the VMWare console.
- Note that the password can only be used to login through the VMware console. You cannot use it to SSH into the Appliance as an alternative to using the `ssh-keyfiles`.
- On Linux or OSX, use single quotes around *hashed_password*. For Windows, use double quotes.
- If you are using a non-English keyboard, understand the limitations with using the remote VMware console. See Requirements for initial deployment on VMware.

12. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.
You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See API Connect configuration on VMware.

a. Update the IP range for the Kubernetes pod

```
apicup subsys set port k8s-pod-network='new_pod_range'
```

Where *new_pod_range* is the new value for the range.

b. Update the IP range for Service networks.

```
apicup subsys set port k8s-service-network='new_service_range'
```

Where *new_service _range* is the new value for the range.

13. Add your hosts.

    ```
    apicup hosts create port hostname.domainname hd_password
    ```

    Where the following are true:
    - *hostname.domainname* is the fully qualified name of the server where you are hosting your Developer Portal, including the domain information.
    - *hd_password* is the password of the Linux Unified Key Setup uses to encrypt the storage for your Developer Portal. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in `apiconnect-up-v10.yml`.
      Repeat this command for each host that you want to add.

      Note: Host names and DNS entries may not be changed on a cluster after the initial installation.
14. Create your interfaces.

    ```
    apicup iface create port hostname.domainname physical_network_id host_ip_address/subnet_mask gateway_ip_address
    ```

    Where *physical_network_id* is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where `x` is a number identifier.
    The format is similar to this example: `apicup iface create port myHostname.domain eth0 192.0.2.1/255.255.1.1 192.0.2.1`

    Note: You can optionally configure a second network interface (NIC) card for use with Developer Portal. In this scenario, one NIC is used for internal traffic between the Portal and APIM, and the second is used as a public interface. If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway. For information on configuring two NICs for Developer Portal, see Configuring two NICs on the Developer Portal.
15. Optional: You can specify a range of allowable client IP addresses.
    You can optionally restrict which IP addresses can access any of the ingresses by creating an allowlist annotation, which then will only allow the specified IP addresses to access the ingress and will deny all other source IP addresses. See Specifying a range of allowable client IP addresses for Developer Portal.

    Note: One usage of this restriction is the scenario where you split traffic between your private and public networks in 2 NIC configuration.
16. Optional: Use **apicup** to view the configured hosts:

    ```
    apicup hosts list port
    apimdev0232.hursley.ibm.com
     Device  IP/Mask                    Gateway
     eth0    1.2.152.232/255.255.254.0   1.2.152.1
    ```

    Note: If you are configuring a two data center deployment, continue with the installation instructions in Installing a two data center deployment.

17. Optional: Enable JWT security instead of mTLS for communication from management to your portal subsystem.
    JWT security provides application layer security and can be used instead of mTLS when there are load-balancers located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS. To enable JWT and disable mTLS, first identify the JWKS URL from the management subsystem:

    ```
    apicup subsys get <management subsystem>

    ...
    jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
    validate JWT -- this is unsettable and is generated based on the platform-api endpoint
    ...
    ```

    Disable mTLS and enable JWT by setting the jwks-url with **apicup**:

    ```
    apicup subsys set port mtls-validate-client=false
    apicup subsys set port jwks-url=https://appliance1.apic.acme.com/api/cloud/oauth2/certs
    ```

    Note: Do not disable mTLS without enabling JWT.
18. Leave `multi-site-ha-enabled` set to `false`.
19. Optional: Verify that the configuration settings are valid.

    ```
    apicup subsys get port --validate
    ```

    The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

    ```
    Appliance settings
    ==================

    Name                          Value

20. Create your ISO file.

    ```
    apicup subsys install port --out portplan-out
    ```

    The **--out** parameter and value are required. In this example, the ISO file is created in the myProject/portplan-out directory.

    If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
Ubuntu, Debian, OSX	`export PATH=$PATH:/Users/your_path/`
Windows, Red Hat	`set PATH="c:\Program Files (x86)\cdrtools";%PATH%`

21. Next, use the ISO to deploy the subsystem OVA. Continue with Deploying the Developer Portal subsystem OVA file.

Deploying the Developer Portal subsystem OVA file

After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.

Before you begin

You must have completed the configuration of the project file entries for the Developer Portal subsystem, in Configuring the Developer Portal subsystem.

Procedure

1. Log into the VMWare vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
   a. Select the Portal subsystem .OVA file template by navigating to the location where you downloaded the file in First steps for deploying in a VMware environment.
   b. Enter a name and location for your file.
   c. Select a resource for your template.
   d. Review the details for your template.
   e. Select the size of your configuration.
   f. Select the storage settings.
   Note that the number of Central Processing Units, RAM, and size of disk that you need for the Developer Portal varies depending on the number of sites that are hosted and the number of concurrent users you expect your site to have:

Table 1. Developer Portal hardware requirements

Number of sites	Number of concurrent users	Number of CPUs	Amount of RAM (GB)	Data Disk Size (GB)++
1	1	2**	4	50
20	5	4	16	70
100	20	8	32	100
100	100	16	64	500

Important:

- ++The data disk size is extra to the main disk of the OVA. The main disk of the OVA is sized at 100GB, and should not be changed. Therefore, the total disk size of the OVA is 100GB plus the data disk size. The default data disk size is 200GB. If you want to select a different value, then you need to do

this by using the OVF Tool, or the VMware GUI, before you power on the VM. Note that certain versions of the VMware GUI may not allow you to resize the data disk, and in this case you should use the OVF Tool.
- **The requirement of 2 CPUs is suitable only for proof-of-concept work, and non-high availability deployments. For example, this configuration is suitable for the demo mode of the apicup installation, which is set by using the command `apicup subsys set port deployment-profile=n1xc2.m8`.
- It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a Portal site for every Catalog, for example Catalogs that are only for API Developers don't need a Portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services; see Registering a Portal service.

g. Select the networks.
h. Customize the Template, if necessary.
i. Review the details to ensure that they are correct.
j. Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See Requirements for initial deployment on VMware.

The template creation appears in your Recent Tasks list.

5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO file.
   a. Select the Navigate to the datastore file browser icon in the icon menu.
   b. Select the Upload a file to the Datastore icon in the icon menu.
   c. Navigate to the ISO file that you created in your project.
      It is the myProject/*port*plan-out
   d. Upload the ISO file to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....
    a. On the Virtual Hardware tab, select CD/DVD Drive 1.
    b. For the Client Device, select Datastore ISO File.
    c. Find and select your datastore in the Datastores category.
    d. Find and select your ISO file in the Contents category.
    e. Select OK to commit your selection and exit the Select File window.
    f. Ensure that the Connect At Power On check box is selected.
       Tip:
       - Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
       - Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On
    g. Select OK to commit your selection and close the window.
12. Start the virtual machine by selecting the play button on the icon bar.
    The installation might take several minutes to complete, depending on the availability of the system and the download speed.
13. Continue with Verifying deployment of the Developer Portal subsystem.

Verifying deployment of the Developer Portal subsystem

Verify that deployment of the Developer Portal OVA file succeeded.

Before you begin

You must have completed Deploying the Developer Portal subsystem OVA file.

About this task

After you configure an ISO and deploy it with the Developer Portal subsystem OVA, as described in Deploying the Developer Portal subsystem OVA file, verify that the subsystem installed correctly and is functional.

Procedure

1. Log in to the virtual machine by using an SSH tool to check the status of the installation:
   a. Enter the following command to connect to *port* using SSH:

      ```
      ssh ip_address -l apicadm
      ```

      You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.
   b. Select Yes to continue connecting.
      Your host names are automatically added to your list of hosts.
   c. Run the **apic status** command to verify that the installation completed and the system is running correctly.
      The command output for a correctly running Developer Portal system is similar to the following lines:

      ```
      $ sudo apic status
      INFO[0000] Log level: info

      Cluster members:
      - testsrv1251.subnet1.example.com (1.2.3.4)
        Type: BOOTSTRAP_MASTER
        Install stage: DONE
        Upgrade stage: NONE
        Docker status:
          Systemd unit: running
        Kubernetes status:
      ```

```
    Systemd unit: running
    Kubelet version: testsrv1251 (4.4.0-137-generic) [Kubelet v1.10.6, Proxy v1.10.6]
  Etcd status: pod etcd-testsrv1251 in namespace kube-system has status Running
  Addons: calico, dns, helm, kube-proxy, metrics-server, nginx-ingress,
Etcd cluster state:

```

2. Optional: Define multiple Developer Portal endpoints. See Defining multiple portal endpoints for a VMware environment.
3. If you have now installed all subsystems, continue to Post-deployment steps.

   Note:
   When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the **portal-www** pod, admin container logs, if the endpoint cannot be reached:

   ```
   An error occurred contacting the provided portal web endpoint: example.com
   The provided Portal web endpoint example.com returned HTTP status code 504
   ```

   In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully.
   To disable the endpoint check, complete the following update:

   On VMware

   In your **apicup** project, create a file called ptl-extra-values.yaml (or edit the file if one already exists), and add the following section:

   ```
   spec:
     template:
     - containers:
       - env:
         - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
           value: "true"
         name: admin
       name: www
   ```

   Run the following commands:

   ```
   apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>

   apicup subsys install <ptl_subsys>
   ```

Configuring two NICs on the Developer Portal

Configure the Developer Portal to use two network interface cards.

About this task

When deploying the Developer Portal, you can optionally separate network traffic such that the portal has network interface in your private network, where the communications to the APIM manager take places, and another network interface in your public network, where the end users can access the Portal web sites.

You can do this by using the iface on eth0 for your traffic and defining an extra iface definition (eth1) for your public interface. Do this as part of the initial configuration of the Developer Portal. Note the following requirements:

- iface eth0 and eth1 must have different subnets. This means that you cannot test the configuration by using two IP addresses on the same subnet, due to the routing table produced by the OVA at bootup.
- The hostname of the machine must be reachable via eth0 and you must use eth0 as the traffic (private interface) and eth1 as the public interface.

Procedure

1. Verify that you have created a first interface, by following the instructions in Step 13 of Configuring the Developer Portal subsystem.
2. Use `apicup` to add an extra iface definition as follows for your public interface:

   ```
   apicup iface create test-stack-portal test0094.test.example.com eth1 1.2.3.232/255.255.254.0 1.2.3.1
   ```

3. Set the hostname of your portal-www ingress to the hostname that is associated with the IP address given on `eth1`.

   ```
   apicup subsys set my-portal portal-www portal.myhost0232.company.com
   ```

4. When configuring the second NIC during initial installation, return to Step 14 of Configuring the Developer Portal subsystem. Follow the remaining steps in the configuration instructions, and then create the Portal OVA and deploy it as usual.
   Notes:
   - If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway.
   - Before powering on the Portal, use the VMware GUI to add a second network card to the VM, with the correct settings for your public network.

Specifying a range of allowable client IP addresses for Developer Portal

Specify the range of client IP addresses to be allowed in a deployment of the Developer Portal

About this task

Use an extra-values-file, which serves as a portal CR override, to provide an allowable addresses annotation.

Procedure

In your `apicup` project, create a file called `ptl-extra-values.yaml` with the necessary content. For example:

```
spec:
  portalUIEndpoint:
      annotations:
        ingress.kubernetes.io/whitelist-source-range: 1.2.88.0/24
```

In this example, `1.2.88.0/24` is the acceptable range of client IP addresses.

Note: Depending on your network configuration for the forwarding of client IP addresses, you might need to run several test iterations to work out which client IP addresses to include in the list.

Defining multiple portal endpoints for a VMware environment

Multiple public facing endpoints (`portal-www`) can be defined for the Developer Portal.

About this task

You can override the single endpoint definition for `portal-www`, and the associated `portal-www-ingress` TLS certificate, to support multiple `portal-www` endpoints.

For information about the endpoints for the Developer Portal, see Configuring the Developer Portal subsystem.

The task requires accessing your portal virtual appliance and creating Kubernetes secrets. Two methods are available for creating Kubernetes secrets:

- The recommended method uses a tool that exists on the portal appliance VM called cert-manager. To use the cert-manager method, skip step 5.
- If you do not want to use the cert-manager method, you can create your Kubernetes secrets manually. Follow step 5 instead of steps 3 and 4.

Procedure

Create `portal-www` endpoint certificates with cert-manager.

1. Log in to your portal virtual appliance with an SSH client, as `apicadm` user

   ```
   ssh apicadm@<subsystem hostname>
   ```

2. Switch to the root user: `sudo -i`
3. Create a file called ingress-issuer.yaml and paste in the following content:

   ```
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: ingress-ca
   spec:
   ```

```
  secretName: ingress-ca
  commonName: "ingress-ca"
  usages:
  - digital signature
  - key encipherment
  - cert sign
  isCA: true
  duration: 87600h # 10 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
  issuerRef:
    name: selfsigning-issuer
    kind: Issuer
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
spec:
  ca:
    secretName: ingress-ca
```

Run `kubectl apply -f ingress-issuer.yaml`.

4. Create cert-manager certificate objects for each `portal-www` endpoint.
   a. Create a file called portal-web-certs.yaml, and paste in a `Certificate` entry for each `portal-www` endpoint. In this example, two endpoints are created, so the example file contains two certificates:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  labels:
    app.kubernetes.io/instance: portal
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: web-endpoint
  name: portal-web-host1
  namespace: default
spec:
  dnsNames:
  - <FQDN of portal web endpoint 1>
  duration: 17520h0m0s
  issuerRef:
    group: cert-manager.io
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: portal-web-host1
  usages:
  - digital signature
  - key encipherment
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  labels:
    app.kubernetes.io/instance: portal
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: web-endpoint
  name: portal-web-host2
  namespace: default
spec:
  dnsNames:
  - <FQDN of portal web endpoint 2>
  duration: 17520h0m0s
  issuerRef:
    group: cert-manager.io
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: portal-web-host2
  usages:
  - digital signature
  - key encipherment

---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  labels:
    app.kubernetes.io/instance: portal
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: web-endpoint
  name: portal-web-host3
  namespace: default
spec:
  dnsNames:
  - <FQDN of portal web endpoint 3>
  duration: 17520h0m0s
  issuerRef:
    group: cert-manager.io
```

```
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: portal-web-host3
  usages:
  - digital signature
  - key encipherment
```

b. Apply the file:

```
kubectl apply -f portal-web-certs.yaml
```

Create `portal-www` without cert-manager.

5. Create Kubernetes secrets with OpenSSL. Follow this step instead of steps 3 and 4.
   To create the secrets and certificates for each `portal-www` endpoint, complete the following steps:
   a. If you are using self-signed certificates, create the TLS secrets for each `portal-www` endpoint by generating the certificates. The following example shows how to generate certificates for each `portal-www` endpoint by using OpenSSL:

```
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host1-tls.key -out ptl.host1-tls.crt -subj
"/CN=ptl.host1.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host2-tls.key -out ptl.host2-tls.crt -subj
"/CN=ptl.host2.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host3-tls.key -out ptl.host3-tls.crt -subj
"/CN=ptl.host3.example.com"
```

   b. Store the SSL certificates in a secret:
      i. Copy the certificates to the Portal virtual appliance, for example:

```
scp ptl.host1-tls.key ptl.host1-tls.crt ptl.host2-tls.key ptl.host2-tls.crt ptl.host3-tls.key ptl.host3-tls.crt
apicadm@portal-vm-address
```

      ii. Log in to your portal virtual appliance with an SSH client, as `apicadm` user
      iii. Switch to the root user: `sudo -i`
      iv. Create the Kubernetes secrets:

```
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host1 --key ptl.host1-tls.key --
cert ptl.host1-tls.crt
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host2 --key ptl.host2-tls.key --
cert ptl.host2-tls.crt
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host3 --key ptl.host3-tls.key --
cert ptl.host3-tls.crt
```

Add `portal-www` endpoints and secrets to your `ptl-extra-values.yaml` file.

6. Exit from the portal VM, and in your `apicup` project directory, create a file called `ptl-extra-values.yaml` with the content:

```
spec:
    portalUIEndpoint:
        annotations: # Remove if cert-manager not used
          cert-manager.io/issuer: ingress-issuer # Remove if cert-manager not used
        hosts:
        - name: ptl.host1.example.com
          secretName: portal-web-host1
        - name: ptl.host2.example.com
          secretName: portal-web-host2
        - name: ptl.host3.example.com
          secretName: portal-web-host3
```

   Note: If you followed step 5 and did not use cert-manager to create your secrets, then delete the `annotations` section, so your `ptl-extra-values.yaml` contains:

```
spec:
    portalUIEndpoint:
        hosts:
        - name: ptl.host1.example.com
          secretName: portal-web-host1
        - name: ptl.host2.example.com
          secretName: portal-web-host2
        - name: ptl.host3.example.com
          secretName: portal-web-host3
```

   Run the commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>

apicup subsys install <ptl_subsys>
```

7. SSH back into your portal virtual appliance, and confirm that multiple hosts exist for your `ptl-portal-web` ingress:

```
sudo kubectl get ingress
NAME                 HOSTS                                                          ADDRESS   PORTS     AGE
ptl-portal-director  api.ptl.example.com                                                      80, 443   25m
ptl-portal-web       ptl.host1.example.com,ptl.host2.example.com,ptl.host3.example.com           80, 443   25m
```

Deploying DataPower Gateway virtual appliance

API Connect uses IBM® DataPower® Gateway to provide the gateway service.

The instructions in this section describe how to deploy IBM DataPower Gateway from files obtained from Passport Advantage®, and apply to the following API Connect scenarios:

- API Connect deployments for the VMware environment
- API Connect deployments for Kubernetes, with a DataPower Gateway in a *non-Kubernetes* environment.

For these scenarios, continue with Installing DataPower Gateway.

Note: Do not use these instructions if you are deploying API Connect deployments for Kubernetes, with DataPower Gateway in a *Kubernetes* environment. In this case, you can use DataPower Gateway files that are packaged with API Connect, on the API Connect section of Fix Central, and configured by using the API Connect `apicup` commands. Follow the instructions in Obtaining product files.

- **Installing DataPower Gateway**
  Install and configure IBM DataPower Gateway in a non-Kubernetes environment for use with API Connect.
- **Configuring DataPower Gateway for API Connect**
  You can configure the IBM DataPower Gateway to prepare for a registration with the API Connect Management server.
- **Sample configuration for multiple peering objects on gateway services external to Kubernetes**
  Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

Installing DataPower Gateway

Install and configure IBM® DataPower® Gateway in a non-Kubernetes environment for use with API Connect.

Before you begin

Do not use these instructions for either of the following deployment scenarios:

- Both API Connect and DataPower Gateway in a Kubernetes environment.
  In this scenario, use the instructions in Obtaining product files.
- An existing DataPower Gateway in a non-Kubernetes environment, and you want to install a newer Fix Pack.
  In this scenario, complete an *upgrade* rather than a new installation. See Upgrading DataPower Gateway Service.

To review the installation and configuration scenarios, see Deploying DataPower Gateway virtual appliance.

Procedure

1. Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.
   Note:
   You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

   Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.
2. Obtain your DataPower files from IBM Passport Advantage®.
   Note that the DataPower files from Passport Advantage have entitled services for API Connect users.

   See also Download the firmware image from Passport Advantage.
3. Follow the DataPower Gateway installation information: https://www.ibm.com/docs/en/datapower-gateway.
   Note: Set the timezone to UTC on all DataPower installations for use with API Connect.
4. Continue with Configuring DataPower Gateway for API Connect.

Configuring DataPower Gateway for API Connect

You can configure the IBM® DataPower® Gateway to prepare for a registration with the API Connect Management server.

About this task

API Connect and DataPower supports two different types of gateway configurations. The DataPower Gateway (v5 compatible) provides the same support as the gateway support that was available with API Connect version 5.x. The DataPower API Gateway is an enhanced gateway that is performance-focused. See API Connect gateway types for more information about the differences between the gateway types.
Continue with the instructions for the type of Gateway Service you are configuring:

- **Configuring DataPower API Gateway**
  Configure the DataPower API Gateway to prepare for registration with the API Connect Management server.
- **Configuring DataPower Gateway (v5 compatible)**
  You can configure the DataPower Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

Configuring DataPower API Gateway

Configure the DataPower® API Gateway to prepare for registration with the API Connect Management server.

Before you begin

- These instructions are for DataPower API Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower API Gateway Service also in the Kubernetes environment. To review deployment scenarios, see Deploying DataPower Gateway virtual appliance.
- Ensure you have installed a version of DataPower API Gateway that is compatible with the version of the API Connect Management server. See Installing DataPower Gateway.
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower API Gateway is set to UTC.

About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See *Gateway peering* in the DataPower documentation for more information about configuring additional gateways for peering. See *Providing the gateway service to API Connect* in the DataPower documentation for more details about the DataPower settings and procedures.

Procedure

To configure a DataPower API Gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower API Gateway . If you are configuring DataPower Gateway (v5 compatible) see Configuring DataPower Gateway (v5 compatible).

1. Open the DataPower WebGUI interface.
   Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Optional: Enable the XML management interface in the default domain.
   The XML management interface is optional for DataPower API Gateway. If enabled, this interface allows you to send status and configuration requests to the DataPower appliance through a standard SOAP interface, using SOAP messages.
   a. Search for XML management interface in the navigation search bar, and select it.
   b. Set the Administrative state to enabled.
   c. You can specify a different port number if you do not want to use the default of `5550`.
   d. Select Apply to make the changes
   e. Save changes to the default domain by selecting Save Configuration.
3. Optional: Enable the REST management interface in the default domain.
   The REST management interface is required if you want to enable to the Trace feature in the assembly Test tab in the API Manager.
   a. Search for REST management interface in the navigation search bar, and select it.
   b. Set the Administrative state to enabled.
   c. You can specify a different port number if you do not want to use the default of `5554`.
   d. Select Apply to make the changes
   e. Save changes to the default domain by selecting Save Configuration.
4. Create an application domain.
   This domain receives your traffic. The name of the DataPower domain where you configure the API Connect Gateway Service must be the same on each DataPower Gateway.
   a. Search for Application domain in the navigation search bar, and select it.
   b. Select Add to create the application domain.
   c. Enter a unique name for your domain.
   d. Ensure that enabled is selected for the Administrative state.
   e. Ensure that the default domain is listed in the Visible application domain list.
   f. Select Apply.
   g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
   h. Select Save changes and switch domains.
   All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
   i. Save changes to the domain by selecting Save Configuration.
5. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
   See *Managing the NTP service* in the DataPower documentation.
6. Ensure that you have set a unique `System Identifier` for each v10 DataPower gateway. See *Initializing the DataPower Gateway* in the DataPower documentation.
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
   a. Search for Crypto key in the navigation search bar, and select it.
   b. Select Add to create a key object.
   c. Create a unique name for the key object in the Name field.
   d. Select Upload....
   e. Browse for the key file (which must be a .pem or .p12 file) and select it.
   f. If you want to rename it, enter a new name for the file.
   g. Select Upload to move it to the server in the cert:// folder.
   h. Select Apply to save the changes.
9. Upload your crypto certificate file to the domain.
   Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.

a. Search for Crypto certificate in the navigation search bar, and select it.
b. Select Add to create a certificate object.
c. Create a unique name for the certificate object in the Name field.
d. Select Upload....
e. Browse for the key file (which must be a .pem or .p12 file) and select it.
f. If you want to rename it, enter a new name for the file.
g. Select Upload to move it to the server in the cert:// folder.
h. Select Apply to save the changes.

10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
    a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a name for your credential.
    d. Ensure that the Administrative state has a value of enabled.
    e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
    f. In the Certificate object field, select the name of the certificate object that you created from the drop-down menu.
    g. Select Apply to commit your changes.
11. Create your TLS Client profile.
    a. Search for TLS Client profile in the navigation search bar, and select it.
    b. Select Add to create a client profile.
    c. Create a unique name for the profile in the Name field.
    d. Select your Identification credential from the drop-down list.
    e. Ensure that the value of Validate server certificate is set to off.
    f. Ensure that the value of Use SNI is set to on.
    g. Select Apply to save the changes.
12. Create your TLS Server profile.
    a. Search for TLS Server Profile in the navigation search bar, and select it.
    b. Select Add to create a server profile.
    c. Create a unique name for the profile in the Name field.
    d. Select your Identification credential from the drop-down list.
    e. Ensure that the value of Request client authentication is set to off.
       Disabling the request for client authentication for the TLS client profile and the validation of server certificates for the TLS server profile disables security for the ease of configuring the gateway. To enable the secure communication using mutual TLS between IBM API Connect and Gateway, see Binding a TLS server profile to a gateway service.

       If mTLS is disabled it is recommended to use JWT application layer security instead. See Enable JWT instead of mTLS.

    f. Select Apply to save the changes.
13. Define a configuration sequence.
    The configuration sequence specifies how DataPower implements the APIs that are defined in API Connect.

    a. Search for Configuration sequence in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a name for your configuration sequence.
       The name **`apic-config`** is not allowed because it is already used internally.

    d. Ensure that the Administrative state has a value of enabled.
    e. Ensure that the value in the Location profiles field is set to local:///
       This is the default value, so you might not need to change it.
    f. Select the Access profile.
       For instructions on creating access profiles, see *Configuring the access profile for a configuration sequence* in the appropriate version of the DataPower documentation.

    g. Change the value of the Configuration execution interval field to `3000`.
       The other fields can retain their default settings.
    h. Select Apply to commit your changes.
14. Configure your gateway peering object for the API Connect Gateway Service.
    This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
       You can use the default value of 16380.
    g. Select a monitor port for the communication.
       You can use the default value of 26380.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
    i. Clear the Enable TLS check box. TLS is not needed for a single peer.
    j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
    k. Select Apply to commit your changes.
15. Configure your gateway peering object for rate limit information.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
       Use a unique port, different than the ports used for communication by other gateway peering objects.
    g. Select a monitor port for the communication.
       Use a unique port, different than the ports used for monitoring by other gateway peering objects.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.

i. Clear the Enable TLS check box. TLS is not needed for a single peer.
j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
k. Select Apply to commit your changes.

16. Optional: If you are using the ratelimit module described in the DataPower documentation, configure your gateway peering object for GatewayScript rate limiting information.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
    Use a unique port, different than the ports used for communication by other gateway peering objects.
    g. Select a monitor port for the communication.
    Use a unique port, different than the ports used for monitoring by other gateway peering objects.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
    i. Clear the Enable TLS check box. TLS is not needed for a single peer.
    j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
    k. Select Apply to commit your changes.
17. Configure your gateway peering object for subscription information.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
    Use a unique port, different than the ports used for communication by other gateway peering objects.
    g. Select a monitor port for the communication.
    Use a unique port, different than the ports used for monitoring by other gateway peering objects.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
    i. Clear the Enable TLS check box. TLS is not needed for a single peer.
    j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
    k. Select Apply to commit your changes.
18. Configure the gateway peering object for the API probe.
    In order for API Connect to receive trace data in the Test tab's debugger, the DataPower API Gateway must be configured to support the API probe.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
    Use a unique port, different than the ports used for communication by other gateway peering objects.
    g. Select a monitor port for the communication.
    Use a unique port, different than the ports used for monitoring by other gateway peering objects.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
    i. Clear the Enable TLS check box. TLS is not needed for a single peer.
    j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
    k. Select Apply to commit your changes.
19. Configure the gateway peering manager.
    a. Search for Gateway Peering Manager in the navigation search bar, and select it.
    b. Set the Administrative state to enabled.
    c. In the pull-down menu next to API Connect Gateway Service, select the gateway peering object configured in Step 14 for the API Connect Gateway Service.
    d. In the pull-down menu next to Rate Limit, select the gateway peering object configured in Step 15 for rate limit information.
    e. In the pull-down menu next to Subscription, select the gateway peering object configured in Step 17 for subscription.
    f. In the pull-down menu next to API Probe, select the gateway peering object that you configured in Step 18 for the API probe.
    g. If you are using the ratelimit module described in the DataPower documentation, then for Gateway rate limiting, select the gateway peering object that you configured in Step 16 for rate limit information.
    h. Select Apply to commit your changes.
20. Configure the API probe settings object.
    a. Search for API probe settings in the navigation search bar, and select it.
    b. Set the Administrative state to enabled.
    c. Set the maximum number of records to `1000`.
    d. Set the expiration to `60` minutes.
    e. In the pull-down menu next to Gateway Peering, select the gateway peering object that you configured in Step 18 for the API probe.
    f. Select Apply to commit your changes.
21. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
    a. Search for API Connect Gateway service in the navigation search bar, and select it.
    b. Ensure that the Administrative state is set to enabled.
    c. In the Local address field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
    d. Specify a value for Local port. You can use the default value of 3000, or specify a different port value.
    Note: The Local port specifies the port through which API Connect connects to manage the API Connect Gateway Service. Use this port when you configure a Gateway Service on API Connect. Beyond this port, the gateway service uses two additional consecutive ports after the defined local port to bind to a loopback address. Therefore, you must ensure that there are no conflicts on all three consecutive ports that start from the defined local port.
    e. In the TLS client field drop-down list, select the name of the TLS client profile that you created.
    f. In the TLS server field drop-down list, select the name of the TLS server profile that you created.
    g. In the API gateway address field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
    h. Use the default port value of 9443 for the API gateway port.
    If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
    i. For DataPower API Gateway, set the Gateway Peering to **`(none)`**.

When no gateway peering object is configured for the DataPower API Gateway, the peering configuration defined in the Gateway Peering Manager configuration is used.

j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.
When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway. Clear it to enable a DataPower API Gateway.

22. Optional: Enable JWT security instead of mTLS for communication from management to gateway. JWT security provides application layer security and can be used instead of mTLS when load-balancers are located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.
To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the DataPower documentation. The JWKS URL required to enable JWT security can be found in the management subsystem settings:

```
apicup subsys get <management subsystem>

...
jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
validate JWT -- this is unsettable and is generated based on the platform-api endpoint
...
```

23. Register the gateway service in the API Connect Cloud Manager console:
    a. Open the API Connect Cloud Manager console.
    b. Navigate to Configure Topology.
    c. Select Register Service.
    d. Select DataPower API Gateway for the DataPower API Gateway.
    e. Add a title, name, and summary for the gateway connection.
    f. Optional: Configure the OAuth Shared Secret.
    This setting allows OAuth tokens to be shared across multiple gateway services.
    g. Enter one of the following values in the API Invocation Endpoint field:
        - IP address of the load balancer for the API transactions
        - IP address or host name of one of the gateways

    For example:`https://192.0.2.0:9443/`
    h. Enter the one of the following values in the Management Endpoint field:
        - IP address of the load balancer for the management server traffic set to port 3000
        - IP address or hostname of one of the gateways

    For example:`https://192.0.2.0:3000/`
24. Select the default TLS Client Profile
25. Optional: Configure Server Name Indication (SNI) profiles.
SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.

Configuring DataPower Gateway (v5 compatible)

You can configure the DataPower® Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

Before you begin

- These instructions are for DataPower API Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower API Gateway Service also in the Kubernetes environment. To review deployment scenarios, see Deploying DataPower Gateway virtual appliance.
- Ensure you have installed a version of DataPower API Gateway that is compatible with the version of the API Connect Management server. See Installing DataPower Gateway.
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower API Gateway is set to UTC.

About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See *Gateway peering* in the DataPower documentation for more information about configuring additional gateways for peering. See *Providing the gateway service to API Connect* in the DataPower documentation for more details about the DataPower settings and procedures.

Procedure

To configure a DataPower gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower Gateway (v5 compatible). If you are configuring DataPower API Gateway, see Configuring DataPower API Gateway.

1. Open the DataPower WebGUI interface.
Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Enable the XML management interface in the **default** domain, if required. The XML management interface is required for DataPower Gateway (v5 compatible). The XML management interface is optional for DataPower API Gateway.
    a. Search for **XML management interface** in the navigation search bar, and select it.
    b. Set the Administrative state to enabled.
    c. You can specify a different port number if you do not want to use the default of `5550`.
    d. Select Apply to make the changes
    e. Save changes to the default domain by selecting Save Configuration.
3. Create an application domain.

This domain receives your traffic. The name of the DataPower domain where you configure the API Connect Gateway Service must be the same on each DataPower Gateway.
    a. Search for Application domain in the navigation search bar, and select it.
    b. Select Add to create the application domain.
    c. Enter a unique name for your domain.
    d. Ensure that enabled is selected for the Administrative state.
    e. Ensure that the default domain is listed in the Visible application domain list.
    f. Select Apply.
    g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
    h. Select Save changes and switch domains.
    All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
    i. Save changes to the domain by selecting Save Configuration.
4. For the DataPower Gateway (v5 compatible) only: Enable statistics in the domain you created for **API Connect**.
    a. Search for and select Statistics settings in the navigation search.
    b. Select enabled for the Administrative state.
    c. Select Apply.
5. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
See Managing the NTP service.
6. Ensure that you have set a unique **`System Identifier`** for each v10 DataPower gateway. See Initializing the DataPower Gateway.
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
    a. Search for Crypto key in the navigation search bar, and select it.
    b. Select Add to create a key object.
    c. Create a unique name for the key object in the Name field.
    d. Select Upload....
    e. Browse for the key file (which must be a .pem or .p12 file) and select it.
    f. If you want to rename it, enter a new name for the file.
    g. Select Upload to move it to the server in the cert:// folder.
    h. Select Apply to save the changes.
9. Upload your crypto certificate file to the domain.
Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.
    a. Search for Crypto certificate in the navigation search bar, and select it.
    b. Select Add to create a certificate object.
    c. Create a unique name for the certificate object in the Name field.
    d. Select Upload....
    e. Browse for the key file (which must be a .pem or .p12 file) and select it.
    f. If you want to rename it, enter a new name for the file.
    g. Select Upload to move it to the server in the cert:// folder.
    h. Select Apply to save the changes.
10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
    a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a name for your credential.
    d. Ensure that the Administrative state has a value of enabled.
    e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
    f. In the Certificate object field, select the name of the certificate object that you created from the drop-down menu.
    g. Select Apply to commit your changes.
11. Create your TLS Client profile.
    a. Search for TLS Client profile in the navigation search bar, and select it.
    b. Select Add to create a client profile.
    c. Create a unique name for the profile in the Name field.
    d. Select your Identification credential from the drop-down list.
    e. Ensure that the value of Validate server certificate is set to off.
    f. Ensure that the value of Use SNI is set to on.
    g. Select Apply to save the changes.
12. Create your TLS Server profile.
    a. Search for TLS Server Profile in the navigation search bar, and select it.
    b. Select Add to create a server profile.
    c. Create a unique name for the profile in the Name field.
    d. Select your Identification credential from the drop-down list.
    e. Ensure that the value of Request client authentication is set to off.
    Disabling the request for client authentication for the TLS client profile and the validation of server certificates for the TLS server profile disables security for the ease of configuring the gateway. To enable the secure communication using mutual TLS between IBM API Connect and Gateway, see Binding a TLS server profile to a gateway service.

    If mTLS is disabled it is recommended to use JWT application layer security instead. See Enable JWT instead of mTLS.

    f. Select Apply to save the changes.
13. Configure your gateway peering object for the API Connect Gateway Service.
This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
    You can use the default value of 16380.
    g. Select a monitor port for the communication.

You can use the default value of 26380.

h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
i. Clear the Enable TLS check box. TLS is not needed for a single peer.
j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
k. Select Apply to commit your changes.

14. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
    a. Search for API Connect Gateway service in the navigation search bar, and select it.
    b. Ensure that the Administrative state is set to enabled.
    c. In the Local address field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
    d. Use the default port value of 3000 for the Local port.
    e. In the TLS client field drop-down list, select the name of the TLS client profile that you created.
    f. In the TLS server field drop-down list, select the name of the TLS server profile that you created.
    g. In the API gateway address field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
    h. Use the default port value of 9443 for the API gateway port.
       If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
    i. For DataPower Gateway (v5 compatible), select the gateway peering object that you created in Step 13.
    j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.
       When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway.
15. Optional: Enable JWT security instead of mTLS for communication from management to gateway. JWT security provides application layer security and can be used instead of mTLS when load-balancers are located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.
    To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the DataPower documentation. The JWKS URL required to enable JWT security can be found in the management subsystem settings:

```
apicup subsys get <management subsystem>

...
jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
validate JWT -- this is unsettable and is generated based on the platform-api endpoint
...
```

16. Register the gateway service in the API Connect Cloud Manager console:
    a. Open the API Connect Cloud Manager console.
    b. Navigate to Configure Topology.
    c. Select Register Service.
    d. Select DataPower Gateway (v5 compatible) for the gateway that was available in version 5.
    e. Add a title, name, and summary for the gateway connection.
    f. Optional: Configure the OAuth Shared Secret.
       This setting allows OAuth tokens to be shared across multiple gateway services.
    g. Enter one of the following values in the API Invocation Endpoint field:
       - IP address of the load balancer for the API transactions
       - IP address or host name of one of the gateways

       For example:**https://192.0.2.0:9443/**
    h. Enter the one of the following values in the Management Endpoint field:
       - IP address of the load balancer for the management server traffic set to port 3000
       - IP address or hostname of one of the gateways

       For example:**https://192.0.2.0:3000/**
17. Select the default TLS Client Profile
18. Optional: Configure Server Name Indication (SNI) profiles.
    SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.

Sample configuration for multiple peering objects on gateway services external to Kubernetes

Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

- This reference shows how to configure API Connect domain configuration with gateway-peering configuration. To review domain configuration settings, see Configuring DataPower Gateway for API Connect.
- This sample applies only to gateway services that are deployed external to Kubernetes, on either a physical or virtual appliance. This sample does not apply to gateway services that are deployed on Kubernetes.

The following examples show sample configuration for 3 different gateways, listed here with sample IP addresses of 1.1.1.1, 2.2.2.2, and 3.3.3.3. Note the following:

- The priority should be set differently on each of the three gateways. Set the lowest priority for the gateway that will run as primary.
- **persistence** should be set to **memory** for all configured peering objects.
- Optionally, add SSL configuration.

Configuration on gateway 1 (1.1.1.1)

```
top; configure terminal;
    domain apiconnect; visible default; exit;

    sw apiconnect;

    loglevel debug;
    logging target gwd-log
      type file
      format text
      timestamp syslog
      size 50000
      local-file logtemp:///gwd-log
```

```
    event apic-gw-service debug
  exit

  config-sequence "apiconnect"
    location "local:///"
    watch "on"
    delete-unused "on"
    match "(.*)\.cfg$"
    summary "Toolkit Reboot configuration"
    run-sequence-interval 3000
    optimize-for-apic on
  exit

  crypto
    key sth_apic sharedcert:///sth_apic-privkey.cer

Post-deployment steps

When all subsystems are deployed, use the admin account to access the Cloud Manager administrative console and begin configuration. Optionally, take VMware snapshots of the VMs.

About this task

When you have deployed all required API Connect components, and all subsystems are running, complete the following:

Procedure

1. If you have not previously accessed the Cloud Manager, verify you can access the API Connect Cloud Manager. Enter the URL in your browser.
   The syntax is **`https://<hostname.domain>/admin`**. For example:

   `https://cloud-admin-ui.testsrv0231.subnet1.example.com/admin`

   The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See Accessing the Cloud Manager user interface.
2. Define your API Connect configuration by using the API Connect Cloud Manager. See Cloud Manager configuration checklist.
3. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see Using VM snapshots for infrastructure backup and disaster recovery for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.
   Important: VM snapshots are not an alternative to the standard API Connect backups. You should have completed an API Connect backup of each subsystem when verifying initial deployment, as advised in:
   - Verify installation of the Management subsystem
   - Verifying deployment of the Developer Portal subsystem
   - Verifying deployment of the Analytics subsystem

Installing a two data center deployment

How to install a two data center disaster recovery (2DCDR) deployment on VMware.

Before you begin

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see A two data center deployment strategy on VMware.

Review the information in Requirements for initial deployment on VMware and, if appropriate, What's new for v10 installation from previous versions.

Familiarize yourself with the instructions in First steps for deploying in a VMware environment. Complete these instructions with the additional steps in this topic that are specific to installing a 2DCDR deployment.

Restriction: It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration.

About this task

Installing API Connect as a 2DCDR deployment is similar to a single installation. The deployment in each data center is effectively an instance of the same API Connect deployment. The following endpoints must be the same on both data centers:

Management subsystem endpoints

- **`platform-api`**
- **`consumer-api`**
- **`cloud-admin-ui`**
- **`api-manager-ui`**

Portal subsystem endpoints

- **`portal-admin`**
- **`portal-www`**

To install a 2DCDR deployment, you follow the normal stand-alone API Connect installation steps, but before you generate the ISO files you must set some additional 2DCDR properties.

The 2DCDR properties are described in the following table.

Table 1. 2DCDR properties

Setting	Description
`multi-site-ha-enabled`	Indicates whether 2DCDR deployment is enabled. Set to **`true`** to enable 2DCDR. Set to **`false`** to disable 2DCDR. The default value is **`false`**.
`multi-site-ha-mode`	The 2DCDR mode of the data center. Possible values are: • **`active`** - indicates the primary data center. • **`passive`** - indicates the warm-standby data center.
`management-replication`	Required only for the management subsystem. The external ingress name for the management subsystem in the current data center in the 2DCDR deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`portal-replication`	Required only for the portal subsystem. The external ingress name for the portal subsystem in the current data center in the 2DCDR deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`replication-peer-fqdn`	The ingress hostname for the other data center in the 2DCDR deployment. This information is required so that the two data centers can communicate with each other.
`siteName`	Unique descriptive name for the API Connect data center. Must be different in each data center. This name is used in the hostnames, and so can contain only **`a-z`** and **`0-9`** characters. You can set a **`siteName`** only when the subsystems are first deployed, and you cannot change the name after deployment. If you don't set **`siteName`** at first deployment, the **`siteName`** is autogenerated.

Important:

- Use a single APICUP project for all subsystems so that the API Connect deployments in both data centers have the same certificate chains. If network access to both data centers from the same APICUP project location is not possible, you can copy the project directory across to the other data center. If you are copying the project directory to your other data center, ensure that you keep backups of both project directories.
- The original project directory that is created with APICUP during the initial product installation is required to both restore the database and to upgrade your deployment. You cannot restore the database or complete an upgrade without the initial project directory because it contains pertinent information about the cluster.
- Subsystem endpoints for the components cannot be changed.
- The subsystem name of the management and portal subsystems must consist of lowercase alphanumeric characters or '-', contain no spaces, start with an alphabetic character, and end with an alphanumeric character.

Procedure

- **Installing on the active data center**
  The following example shows how to configure the 2DCDR settings for deploying on the active data center (DC). In this example, the active data center is called **`dallas`** (DC1), and the warm-standby data center is called **`raleigh`** (DC2).

  1. Complete the steps in Configuring the Management subsystem up to and including step 14 to configure the standard (non-2DCDR) settings for the management subsystem in Dallas (DC1).
  2. Configure the 2DCDR values to set Dallas to be active for the management subsystem in DC1.
     Run the following commands:

     ```
     apicup subsys set mgmt_dallas multi-site-ha-enabled=true

     apicup subsys set mgmt_dallas multi-site-ha-mode=active

     apicup certs set mgmt_dallas management-replication-ingress --clear

     apicup subsys set mgmt_dallas management-replication=mgrreplicationdallas.cluster1.example.com

     apicup subsys set mgmt_dallas replication-peer-fqdn=mgrreplicationraleigh.cluster2.example.com

     apicup subsys set mgmt_dallas site-name=dallas
     ```

     where
     - **`mgmt_dallas`** is the name of the management subsystem that you are configuring.
     - **`mgrreplicationdallas.cluster1.example.com`** is the ingress hostname for the current data center in the two data center deployment.
     - **`mgrreplicationraleigh.cluster2.example.com`** is the ingress hostname for the other data center in the two data center deployment.
     - **`dallas`** is the name of the site in the current data center.
  3. Complete the remainder of the steps in Configuring the Management subsystem from step 15 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
  4. Complete the steps in Configuring the Developer Portal subsystem up to and including step 16 to configure the standard (non-2DCDR) settings for the portal subsystem in Dallas (DC1).
  5. Configure the 2DCDR values to set Dallas to be active for the portal subsystem in DC1.
     Run the following commands:

     ```
     apicup subsys set port_dallas multi-site-ha-enabled=true

     apicup subsys set port_dallas multi-site-ha-mode=active

     apicup certs set port_dallas portal-replication-ingress --clear

     apicup subsys set port_dallas portal-replication=ptlreplicationdallas.cluster1.example.com

     apicup subsys set port_dallas replication-peer-fqdn=ptlreplicationraleigh.cluster2.example.com

     apicup subsys set port_dallas site-name=dallas
     ```

     where
     - **`port_dallas`** is the name of the portal subsystem that you are configuring.
     - **`ptlreplicationdallas.cluster1.example.com`** is the ingress hostname for the current data center in the two data center deployment.
     - **`ptlreplicationraleigh.cluster2.example.com`** is the ingress hostname for the other data center in the two data center deployment.
     - **`dallas`** is the name of the site in the current data center.
  6. Complete the remainder of the steps in Configuring the Developer Portal subsystem from step 19 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
  7. Log in to the virtual machine subsystems on DC1 by using an SSH tool, and check the status of the installation by running the **`apic status`** command.
  8. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

     Management subsystem endpoints
     - **`platform-api`**
     - **`consumer-api`**
     - **`cloud-admin-ui`**
     - **`api-manager-ui`**

     Portal subsystem endpoints
     - **`portal-admin`**
     - **`portal-www`**

- **Installing on the warm-standby data center**
  The following example shows how to set the 2DCDR values for the remote data center called **`raleigh`** (DC2), which is being installed as the warm-standby location.

  Important: Remember to use the same APICUP project directory as for the active data center. If you cannot use the same project directory because its location does not have network access to both data centers, you can copy the project directory over. Ensure that backups are kept of both project directories in each data center.

  1. Complete the steps in Configuring the Management subsystem up to and including step 14 to configure the standard (non-2DCDR) settings for the management subsystem in Raleigh (DC2).

2. Configure the 2DCDR values to set the management subsystem to be the warm-standby in the Raleigh (DC2) data center.
   Run the following commands:

   ```
   apicup subsys set mgmt_raleigh multi-site-ha-enabled=true

   apicup subsys set mgmt_raleigh multi-site-ha-mode=passive

   apicup certs set mgmt_raleigh management-replication-ingress --clear

   apicup subsys set mgmt_raleigh management-replication=mgrreplicationraleigh.cluster2.example.com

   apicup subsys set mgmt_raleigh replication-peer-fqdn=mgrreplicationdallas.cluster1.example.com

   apicup subsys set mgmt_raleigh site-name=raleigh
   ```

   where
   - `mgmt_raleigh` is the name of the management subsystem that you are configuring.
   - `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
   - `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
   - `raleigh` is the name of the site in the current data center.
3. Set the encryption key manually for Raleigh (DC2) by copying it from Dallas (DC1).
   Run the following commands:

   ```
   apicup certs get mgmt_dallas encryption-secret -t key > mgmt-encryption-secret

   apicup certs set mgmt_raleigh encryption-secret mgmt-encryption-secret
   ```

4. Check that the management encryption key is set the same on both DC1 and DC2.
   Run the following commands, and verify that the outputs match:

   ```
   apicup certs get mgmt_dallas encryption-secret -t key

   apicup certs get mgmt_raleigh encryption-secret -t key
   ```

5. Complete the remainder of the steps in Configuring the Management subsystem from step 15 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
6. Complete the steps in Configuring the Developer Portal subsystem up to and including step 16 to configure the standard (non-2DCDR) settings for the portal subsystem in Raleigh (DC2).
7. Configure the 2DCDR values to set Raleigh to be warm-standby for the portal subsystem on DC2.
   Run the following commands:

   ```
   apicup subsys set port_raleigh multi-site-ha-enabled=true

   apicup subsys set port_raleigh multi-site-ha-mode=passive

   apicup certs set port_raleigh portal-replication-ingress --clear

   apicup subsys set port_raleigh portal-replication=ptlreplicationraleigh.cluster2.example.com

   apicup subsys set port_raleigh replication-peer-fqdn=ptlreplicationdallas.cluster1.example.com

   apicup subsys set port_raleigh site-name=raleigh
   ```

   where
   - `port_raleigh` is the name of the portal subsystem that you are configuring.
   - `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
   - `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
   - `raleigh` is the name of the site in the current data center.
8. Copy the encryption key for the portal subsystem on DC1 over to the portal subsystem on DC2.
   Run the following command to get the encryption key for the portal subsystem on DC1, and put it into a file that is called port-encryption-secret:

   ```
   apicup certs get port_dallas encryption-secret -t key > port-encryption-secret
   ```

   Run the following command to use the port-encryption-secret file to set the same encryption key on DC2:

   ```
   apicup certs set port_raleigh encryption-secret port-encryption-secret
   ```

   Where `port_dallas` is the name of the portal subsystem on DC1, and `port_raleigh` is the name of the portal subsystem on DC2.
   To check that the encryption key is set the same on both DC1 and DC2, you can run the following commands and verify that the outputs match:

   ```
   apicup certs get port_dallas encryption-secret -t key

   apicup certs get port_raleigh encryption-secret -t key
   ```

9. Complete the remainder of the steps in Configuring the Developer Portal subsystem from step 19 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
10. Log in to the virtual machine subsystems on DC2 by using an SSH tool, and check the status of the installation by running the `apic status` command.

- **Converting a single data center deployment to two data centers**
  Important:
  - Use the existing deployment as the active site. The new site must be set to warm-standby. If you set your existing deployment to warm-standby then all your management and portal data is erased.
  - The ingress endpoint values from the existing deployment become the global ingress endpoints for the two center deployment. The following endpoints must be set the same on your new deployment, as they are on your existing deployment:

    Management subsystem endpoints
    - `platform-api`
    - `consumer-api`
    - `cloud-admin-ui`
    - `api-manager-ui`

    Portal subsystem endpoints

        - `portal-admin`
        - `portal-www`
    - Configure your network to be able to route the endpoints to either data center, depending on which is the active.
    - You cannot configure a `site-name` for the existing management or portal cluster because the `site-name` property can be configured only at first deployment.

The following example shows how to update the 2DCDR values to make the existing data center `Dallas` the active, and for installing and setting the new remote data center `Raleigh` as warm-standby.

1. Configure the 2DCDR values to set Dallas to be active for the API Manager subsystem on DC1.
   Run the following commands:

   ```
   apicup subsys set mgmt_dallas multi-site-ha-enabled=true

   apicup subsys set mgmt_dallas multi-site-ha-mode=active

   apicup certs set mgmt_dallas management-replication-ingress --clear

   apicup subsys set mgmt_dallas management-replication=mgrreplicationdallas.cluster1.example.com

   apicup subsys set mgmt_dallas replication-peer-fqdn=mgrreplicationraleigh.cluster2.example.com
   ```

   where
   - `mgmt_dallas` is the name of the management subsystem that you are configuring.
   - `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the current data center in the two data center deployment.
   - `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the other data center in the two data center deployment.

   Note: As the API Manager subsystem already exists, you cannot set the `site-name` property.
2. Configure the 2DCDR values to set Dallas to be active for the portal subsystem on DC1.
   Run the following commands:

   ```
   apicup subsys set port_dallas multi-site-ha-enabled=true

   apicup subsys set port_dallas multi-site-ha-mode=active

   apicup certs set port_dallas portal-replication-ingress --clear

   apicup subsys set port_dallas portal-replication=ptlreplicationdallas.cluster1.example.com

   apicup subsys set port_dallas replication-peer-fqdn=ptlreplicationraleigh.cluster2.example.com
   ```

   where
   - `port_dallas` is the name of the portal subsystem that you are configuring.
   - `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the current data center in the two data center deployment.
   - `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the other data center in the two data center deployment.

   Note: As the portal subsystem already exists, you cannot set the `site-name` property.
3. Run `apicup` to update the settings in each subsystem, for example:

   ```
   apicup subsys install subsystem_name
   ```

   where `subsystem_name` is the name of the management or portal subsystem that you want to update, for example `mgmt_dallas`.
4. Log in to the virtual machine subsystems on DC1 by using an SSH tool, and check the status of the installation by running the `apic status` command.
5. Add the new DC, Raleigh (DC2) by completing the steps in Configuring the Management subsystem up to and including step 14 to create a management subsystem in Raleigh (DC2).
   Note:
   - Remember to use the same APICUP project directory as for the active data center.
   - Remember to set the same endpoints as for DC1:

     Management subsystem endpoints
     - `platform-api`
     - `consumer-api`
     - `cloud-admin-ui`
     - `api-manager-ui`

     Portal subsystem endpoints
     - `portal-admin`
     - `portal-www`
6. Configure the 2DCDR values to set Raleigh to be warm-standby for the API Manager subsystem on DC2.
   Run the following commands:

   ```
   apicup subsys set mgmt_raleigh multi-site-ha-enabled=true

   apicup subsys set mgmt_raleigh multi-site-ha-mode=passive

   apicup certs set mgmt_raleigh management-replication-ingress --clear

   apicup subsys set mgmt_raleigh management-replication=mgrreplicationraleigh.cluster2.example.com

   apicup subsys set mgmt_raleigh replication-peer-fqdn=mgrreplicationdallas.cluster1.example.com

   apicup subsys set mgmt_raleigh site-name=raleigh
   ```

   where
   - `mgmt_raleigh` is the name of the management subsystem that you are configuring.
   - `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
   - `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
   - `raleigh` is the name of the site in the current data center.

   Note: As this is a new deployment of the API Manager subsystem, you can set the `site-name` property.
7. Set the encryption key manually for Raleigh (DC2) by copying it from Dallas (DC1).
   Run the following commands:

```
apicup certs get mgmt_dallas encryption-secret -t key > mgmt-encryption-secret

apicup certs set mgmt_raleigh encryption-secret mgmt-encryption-secret
```

8. Check that the management encryption key is set the same on both DC1 and DC2.
   Run the following commands, and verify that the outputs match:

   ```
   apicup certs get mgmt_dallas encryption-secret -t key

   apicup certs get mgmt_raleigh encryption-secret -t key
   ```

9. Complete the remainder of the steps in Configuring the Management subsystem from step 15 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
10. Complete the steps in Configuring the Developer Portal subsystem up to and including step 16 to create a portal subsystem in Raleigh (DC2).
11. Configure the 2DCDR values to set Raleigh to be warm-standby for the portal subsystem on DC2.
    Run the following commands:

    ```
    apicup subsys set port_raleigh multi-site-ha-enabled=true

    apicup subsys set port_raleigh multi-site-ha-mode=passive

    apicup certs set port_raleigh portal-replication-ingress --clear

    apicup subsys set port_raleigh portal-replication=ptlreplicationraleigh.cluster2.example.com

    apicup subsys set port_raleigh replication-peer-fqdn=ptlreplicationdallas.cluster1.example.com

    apicup subsys set port_raleigh site-name=raleigh
    ```

    where
    - *port_raleigh* is the name of the portal subsystem that you are configuring.
    - *ptlreplicationraleigh.cluster2.example.com* is the ingress hostname for the current data center in the two data center deployment.
    - *ptlreplicationdallas.cluster1.example.com* is the ingress hostname for the other data center in the two data center deployment.
    - *raleigh* is the name of the site in the current data center.
12. Run the following command to generate the default portal certificates on the warm-standby site:

    ```
    apicup certs generate port_raleigh
    ```

13. Copy the encryption key for the portal subsystem on DC1 over to the portal subsystem on DC2.
    Run the following command to get the encryption key for the portal subsystem on DC1, and put it into a file that is called port-encryption-secret:

    ```
    apicup certs get port_dallas encryption-secret -t key > port-encryption-secret
    ```

    Run the following command to use the port-encryption-secret file to set the same encryption key on DC2:

    ```
    apicup certs set port_raleigh encryption-secret port-encryption-secret
    ```

    Where *port_dallas* is the name of the portal subsystem on DC1, and *port_raleigh* is the name of the portal subsystem on DC2.
    To check that the encryption key is set the same on both DC1 and DC2, you can run the following commands and verify that the outputs match:

    ```
    apicup certs get port_dallas encryption-secret -t key

    apicup certs get port_raleigh encryption-secret -t key
    ```

14. Complete the remainder of the steps in Configuring the Developer Portal subsystem from step 19 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
15. Log in to the virtual machine subsystems on DC2 by using an SSH tool, and check the status of the installation by running the `apic status` command.
16. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

Management subsystem endpoints
- `platform-api`
- `consumer-api`
- `cloud-admin-ui`
- `api-manager-ui`

Portal subsystem endpoints
- `portal-admin`
- `portal-www`

- **Validating your two data center deployment**
  To validate that your two data center deployment is replicating data:
  1. Log in to your management and portal virtual appliances with an SSH client, as `apicadm` user:

     ```
     ssh apicadm@<subsystem hostname>
     ```

  2. Switch to the root user: `sudo -i`.
  3. On the management VMs, run `kubectl get mgmt`. The `STATUS` column reports `Running` when data replication is working:

     ```
     NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
     AGE
     management    n/n     Running   10.0.5.3-0   10.0.5.3-0           Management is ready.              8m59s
     ```

     If you see `HA Status Warning` in the `MESSAGE` column, then check the status details with `kubectl describe mgmt`:

     ```
     status:
       haStatus
         {
           "lastTransitionTime": "2023-03-31T19:47:08Z",
           "message": "Replication not working, install or upgrade in progress.",
           "reason": "na",
           "status": "True",
     ```

```
      "type": "Pending"
   }
```

4. On the portal VMs, run `kubectl get pods` on both the active and warm-standby data centers, and confirm that the number and names of the pods all match (the UUIDs in the names might be different on each site), and that all are in the `Ready` state.

Create test data on both management and portal subsystems, and complete a test failover:

1. Create some test data, for example, on management create a local user registry: Configuring a local user registry.
2. Complete a failover: Failure handling of a two data center deployment.
3. Verify that the test data created on the original active site, exists on the new active site. For example, login to the Cloud Manager UI on the new active site and confirm the presence of the test local user registry.
4. Delete the test data.
5. Complete another failover to return to your original active and warm-standby configuration.

Example

Example of the management subsystem values that you can view by running the `apicup subsys get mgmt_name` command:

```
apicup subsys get mgmt_dallas

Appliance settings

Related tasks

- Failure handling of a two data center deployment
- Recovering from a failover of a two data center deployment

Upgrading API Connect

Upgrade API Connect on VMware to a newer version.

After reviewing the overview, use the procedures in this section to upgrade API Connect on VMware.

Note:

- For upgrading from v5, see Migrating a version 5 deployment to version 10.0.6x.
- For information about how to maintain a two data center deployment, including upgrade considerations, see Maintaining a two data center deployment.

- **Upgrade considerations on VMware**
  Before upgrading API Connect on VMware, ensure that your deployment meets all the upgrade requirements.
- **Preparing to upgrade on VMware**
  Prepare your VMware deployment for upgrading to the newest version of API Connect.
- **Upgrading Management, Portal, and Analytics on VMware**
  Upgrade your management, portal, and analytics subsystems on VMware.
- **Upgrading DataPower Gateway Service**
  Use these instructions when upgrading DataPower Gateway Service in a non-Kubernetes environment, during upgrade of API Connect.
- **Troubleshooting upgrades on VMware**
  Review the following troubleshooting guidance if you encounter a problem while upgrading API Connect on VMware.

Upgrade considerations on VMware

Before upgrading API Connect on VMware, ensure that your deployment meets all the upgrade requirements.

- Supported upgrade paths
- Supported DataPower Gateway versions
- Upgrade requirements

Tip: After upgrade, clear your browser cache, and open a new browser window. This action avoids stale cache issues in your browser, that can result in unexpected behavior in the Cloud Manager and API Manager UIs.

Supported upgrade paths

Table 1. Supported upgrade paths

Upgrade from:	How to upgrade to 10.0.6.0:
• 10.0.5.3 • 10.0.5.2 • 10.0.5.1	See Upgrading to the latest release on VMware Note: Version 10.0.5.0 was not released on VMware.

Supported DataPower Gateway versions

You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

However, before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

Upgrade requirements

- API Connect is not supported on a FIPS-enabled environment.
- The instructions for upgrading apply to the latest version of API Connect.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order:
  1. Management
  2. Portal
  3. Analytics
  4. Gateway

  Gateway must be upgraded after Management, because upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
- When maintaining API Connect, do not use `kubectl exec` commands to access API Connect pods unless advised by IBM.
  Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

Preparing to upgrade on VMware

Prepare your VMware deployment for upgrading to the newest version of API Connect.

Before you begin

Review the Upgrade considerations on VMware to ensure that you are following a supported upgrade path and that you understand important changes that might affect your deployment.

Procedure

VM health checks:

1. Login to each of your API Connect VMs and switch to the root user:

   ```
   ssh apicadm@<hostname>
   ```

   ```
   sudo -i
   ```

2. Run the health-check command:

   ```
   apic health-check
   ```

   If no errors are reported, then continue to the next step. For more information about the **apic** health check command, see Checking cluster health on VMware.

3. Delete any stale upgrade files that might be left on the VM from previous upgrades:

   ```
   apic clean-upgrade-files
   ```

4. Remove obsolete **sources** files to ensure a clean upgrade.
   Delete any files in the directory /etc/apt/sources.list.d whose names match the format: repo-*<subsystem>*-*<version>*-*<appliance version>*.list:
   a. List the files in /etc/apt/sources.list.d:

      ```
      ls /etc/apt/sources.list.d
      ```

   b. Delete all files that match the format: repo-*<subsystem>*-*<version>*-*<appliance version>*.list

      ```
      rm /etc/apt/sources.list.d/repo-<subsystem>-<version>-<appliance version>.list
      ```

   Do not delete any other files in the /etc/apt/sources.list.d directory.
5. Verify that each VM has sufficient disk space:
   a. Check the available space on the data disk:

      ```
      df -h /data/secure
      ```

      If disk usage is higher than 70%, then add disk capacity. See Adding disk space to a VMware appliance.

   a. Check available space in "/":

      ```
      df -h /
      ```

      If disk usage is higher than 70%, delete or copy off older **/var/log/syslog*.gz** files. The **syslog** files contain your API Connect and system logs. Do not delete any syslog files that might contain log data that is needed for any active support cases. If in doubt, backup the syslog files to another system before your delete them.

6. Run the **apicops** pre-upgrade health checks:
   Attention: This is a required step. Failure to run this check before upgrading could result in problems during the upgrade.
   a. Download the latest apicops release and copy it to your VM.
   b. On all subsystem VMs, as root user, run:
      i. The VM system performance check:

         ```
         apicops appliance-checks:appliance-pre-upgrade
         ```

         If the performance check is successful, the command returns:

         ```
         Ready for upgrade
         ```

      ii. The subsystem status check:

         ```
         apicops upgrade:check-subsystem-status
         ```

         If the subsystem status check is successful, the command returns:

         ```
         All subsystems are in healthy, 'Running' state!
         ```

      If either check returns any errors, do not proceed with the upgrade.
   c. Run the apicops pre-upgrade check on your management VMs:
      Note: If you have a 2DCDR deployment, run this check only on the active management subsystem.

      ```
      apicops version:pre-upgrade
      ```

      If the **apicops** check returns:

      ```
      The original primary PVC is not attached to any pods in this namespace
      ```

      then follow the steps in The original primary PVC is not attached to any pods in this namespace.

      If the **apicops** check returns:

      ```
      Current postgres leader is not the original leader, see https://ibm.biz/BdPLWU for next steps
      ```

      then follow the steps in the linked page https://ibm.biz/BdPLWU.
7. Back up the Postgres images on one of the management VMs by running the following commands:

   ```
   postgres_operator=$(kubectl get pod -l app.kubernetes.io/name=postgres-operator -o name)

   ctr --namespace k8s.io images pull --plain-http=true `kubectl get  $postgres_operator  -o
   jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'`
   ctr --namespace k8s.io images export rmdata.tar `kubectl get  $postgres_operator  -o jsonpath='{.spec.containers[].env[?
   (@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'`
   ctr --namespace k8s.io images export backrestrepo.tar `kubectl get  $postgres_operator  -o
   ```

```
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_BACKREST_REPO")].value}'`
ctr --namespace k8s.io images export pgbouncer.tar `kubectl get  $postgres_operator  -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_PGBOUNCER")].value}'`
ctr --namespace k8s.io images export postgres-ha.tar `kubectl get  $postgres_operator  -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_POSTGRES_HA")].value}'`

postgres_pod=$(kubectl get pod -l role=master -o name)
ctr --namespace k8s.io images export k8s-init.tar `kubectl get $postgres_pod  -o
jsonpath='{.spec.initContainers[].image}'`
```

Pre-upgrade backups and preparation:

8. Optional: Setup remote logging: Configuring remote logging for a VMware deployment.
   If the upgrade process fails, it is possible that important log messages for problem diagnosis are not retained on the VMs. Configure remote logging to ensure that all API Connect logging during the upgrade is retained.
9. Complete the disaster recovery preparation steps: Preparing for a disaster.
   Follow all the disaster recovery preparation steps to ensure that you have:
   - Database backups of all your subsystems.
   - Project directory backup.
   - **Optional:** VM snapshots of all subsystems.

Download and verification of API Connect upgrade files:

10. Obtain the API Connect upgrade files:
    You can access the latest files from IBM Fix Central by searching for the API Connect product and your installed version.

    The following files are used during upgrade on VMware:

    IBM API Connect *<version>* Management Upgrade File for VMware
    : Management subsystem files for upgrade

    IBM API Connect *<version>* Developer Portal Upgrade File for VMware
    : Developer Portal subsystem files for upgrade

    IBM API Connect *<version>* Analytics Upgrade File for VMware
    : Analytics subsystem files for upgrade

    IBM API Connect *<version>* Install Assist for *<operating_system_type>*
    : The apicup installation utility. Required for all installations on VMware.

    The following files are not used during the upgrade process, but should be downloaded to replace your existing versions of them:

    IBM API Connect *<version>* Toolkit for *<operating_system_type>*
    : Toolkit command line utility (**apic** or **apic-slim**). Packaged stand-alone, or with API Designer or Loopback:
      - IBM API Connect *<version>* Toolkit for *<operating_system_type>*
      - IBM API Connect *<version>* Toolkit with Loopback for *<operating_system_type>*
      - IBM API Connect *<version>* Toolkit Designer with Loopback for *<operating_system_type>*

    IBM API Connect *<version>* Local Test Environment
    : Optional test environment. See Testing an API with the Local Test Environment

    IBM API Connect *<version>* Security Signature Bundle File
    : Checksum files that you can use to verify the integrity of your downloads.

11. If control plane files are required for your upgrade path, download them from the same IBM Fix Central page.
    Control plane files are required to support specific Kubernetes versions. The IBM API Connect *<version>* Management Upgrade File for VMware file contains the latest control plane file.

    Consult the following table to see whether your upgrade path requires one or more separate control plane files.

    Table 1. Control Plane files needed for upgrade

Version to upgrade from	Instructions for upgrading to 10.0.6.0
• 10.0.5.3	No control plane file needed.

    On the Fix Central page, type "control-plane" in the Filter fix details field to only show the list of control plane files in the results table. Then, click the Description header to sort the results so you can easily locate the control plane files that you need.

    For information about the control plane files used with older releases, see Control Plane files for earlier releases.

12. Verify that the subsystem upgrade files are not corrupted.
    a. Run the following command separately for the Management, the Developer Portal, and the Analytics upgrade files:
       - MacOS or Linux:

         ```
         sha256sum <upgrade-file-name>
         ```

         Example:

         ```
         sha256sum upgrade_management_v10.0.6.0
         ```

       - Windows:

         ```
         C:\> certUtil -hashfile C:\<upgrade-file-name> SHA256
         ```

         Example:

         ```
         C:\> certUtil -hashfile C:\upgrade_management_v10.0.6.0 SHA256
         ```

    b. Compare the result with the checksum values to verify that the files are not corrupted.
       If the checksum does not match the value for the corresponding version and subsystem, then the upgrade file is corrupted. Delete it and download a new copy of the upgrade file. The following list shows the checksum values for the current release.

       Checksum values for 10.0.6.0:

```
10.0.6 analytics : d927781a01ed2172ae978f83bc17e8b7e12994f8de6027fab2124adf2d40f09c
10.0.6 management : 876ca328aa1e411d8e3896b65e3dff925baaf85579b1ac65248749b321126436
10.0.6 portal : a2bf468ce1bc7c6104858d757088364001e8620922396b80b52657d146c303de
```

For information about the checksum files used with older releases, see Checksum values for earlier releases.

13. Setup the new **apicup** command in your project directory.
The **apicup** executable file is updated with each API Connect release. To upgrade API Connect, you must replace the **apicup** file from your current release with the new **apicup** file.
Note: If you decide to stop or delay your API Connect upgrade, then revert these steps.
    a. In your project directory, take a backup of your current apicup file, appending the current API Connect version to the name of the backup file.
    For example:

    ```
    cp apicup apicup_v10.0.6.0
    ```

    b. Replace the apicup file in your project directory with the new apicup file that you downloaded in step 10.
    c. OSX and Linux® only: Make the apicup file executable:

    ```
    chmod +x apicup
    ```

    d. Set your operating system's **PATH** variable to include your project directory:

    Table 2. Commands for setting the path to the apicup file

Operating system	Command to set the path
MacOS and Linux	`export PATH=$PATH:<project directory path>`
Windows	`set PATH=<project directory path>;%PATH%`

    e. Verify that the new **apicup** command is in your **PATH**:

    ```
    apicup version
    ```

    The version returned should be the version that you are upgrading to.

    f. Run the **apicup** command to accept the API Connect license:

    ```
    apicup licenses accept <License ID>
    ```

    <License ID> is specific to the API Connect Program Name that you purchased. To view the supported license IDs, see API Connect licenses.

14. Run the **apicup** health check command against each of your subsystems.

    ```
    apicup subsys health-check <subsystem name>
    ```

    If the health check is successful, then the command returns silently.

    If you see an IO timeout error, then it's likely that a firewall is blocking access to port 9178. For example:

    ```
    apicup subsys health-check <subsystem name>
    ...
    Error: failed to install the subsystem: unable to open file send stream:
     rpc error: code = Unavailable desc = all SubConns are in TransientFailure,
     latest connection error: connection error:
     desc = "transport: Error while dialing dial tcp 1.2.3.4:9178: i/o timeout"
    ```

    If you see this error, make sure that your firewall has port 9178 open.

15. If you are upgrading from a release earlier than 10.0.5.3, review the Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10 to ensure that any customizations to the Developer Portal are compatible with Drupal 10.
In API Connect 10.0.5.3, the Developer Portal moved from Drupal 9 to Drupal 10 (this upgrade also requires PHP 8.1). The upgrade process updates your Developer Portal sites; however, if you have any custom modules or themes, it is your responsibility to ensure their compatibility with Drupal 10 and PHP 8.1 before you start the upgrade.

Upgrading a two data center deployment

How to upgrade a two data center disaster recovery (DR) deployment on VMware.

To upgrade a two data center disaster recovery deployment, follow the API Connect on VMware upgrade procedures along with the additional procedures that are described in this topic.

Key points for two data center disaster recovery upgrade on VMware:

- Both data centers must be using the same version of API Connect, including down to the specific fix pack and interim fix level. Therefore, both data centers must be upgraded in the same maintenance window.
- Do not reboot any of the management or portal virtual machines until the end of the upgrade, even if you're instructed to do so by the **apicup subsys health-check** command during the upgrade process.
- 2DCDR is disabled on the management subsystems during the upgrade process. Keep a note of which data center had the active management subsystems when you start the upgrade process; set this same data center as the active at the end of the process.
- For the portal subsystems, 2DCDR is not disabled during upgrade, and the warm-standby data center must be upgraded first.

Upgrade steps for 2DCDR:

1. Review the Upgrade considerations on VMware.
2. Complete the Preparing to upgrade on VMware steps.
3. To upgrade the management subsystem, follow Management subsystem two data center upgrade.
4. To upgrade the portal subsystem, follow the steps in Upgrade on VMware, but ensure that the warm-standby is upgraded first.
5. Upgrade analytics and gateway subsystems as described in Upgrade on VMware.

How to upgrade when one data center is down

If you cannot get your failed data center back online and want to upgrade, you can convert your active data center to a stand-alone and upgrade it:

1. Ensure that the network links to the failed data center are removed, so that if the failed data center recovers unexpectedly, it cannot interfere with your active data center.
2. Convert the active data center to a stand-alone data center: Removing a two data center deployment.
3. Upgrade your active data center with the standard upgrade steps: Upgrade on VMware.

To restore 2DCDR, replace the API Connect deployment in your failed data center with a new installation at the same fix pack level as your upgraded active data center. Follow the steps in Installing a two data center deployment to configure 2DCDR between the data centers.

Management subsystem two data center upgrade

How to upgrade your management subsystem in a two data center deployment.

About this task

Follow the steps in this topic, along with the steps documented in Upgrading to the latest release on VMware.

The steps in this topic involve running command-line operations from several locations:

- **apicup** operations are run from your API Connect project directory.
  Note: The **apicup** command is a binary file that is included with each API Connect release. Unless stated otherwise, all operations in this topic that use the **apicup** command must use the **apicup** binary from the target release (the release that you want to upgrade to). Be careful to not use the **apicup** command from your source release.
- **apic** and **kubectl** operations are run from within your management appliance, as the root user. Login to your management virtual appliance with an SSH client and the username `apicadm`, then switch to the root user with `sudo -i`.

Procedure

1. Determine the current version and license of API Connect (the version that you are upgrading from).
   You will need to specify the correct version number and license in the next step.
   a. To get the current version, from within the management appliance run the following command:

      ```
      apic version
      ```

      In the response, the `- subsystem-<subsytem-name>` statement displays the installed version. In the following example, the response indicates that the installed version is 10.0.5.3:

      ```
      apic version

      INFO[0000] Log level: info
      Control plane: 1.26.0
      Appliance base 4.6.0
      GitCommitSha:10.0.5.2-55-gb784ac7
      Packages:
      - appliance-base:4.6.0
      - appliance-runtime-4.6.0:1.0.0
      - appliance-setup-4.6.0:1.0.0
      - subsystem-management:1:10.0.5.3
      ```

   b. To get the current license, run the following **apicup** command in your project directory:

      ```
      apicup licenses list
      ```

      in the response, the `ID` statement displays the installed license, for example:

      ```
      Accepted licenses:
              ID: <source_license>
              Product Version: <source_version>
              URL: <license_url>
      ```

      Note: If there are multiple accepted licenses, refer only to the `<source_license>` that aligns with the `<source_version>` of your system (that is the `<source_version>` that matches the version that you obtained in step 1.a).
2. Add source license and version to your extra-values.yaml file.
   Note: If you do not have an extra-values.yaml file, then create one in a directory that the `apicup` command can access.
   Add the source lines that you identified in step 1 to your extra-values.yaml as shown:

   ```
   spec:
     version: "<source_version>"
   ```

```
  license:
    license: <source_license>
  imageRegistry: 127.0.0.1:8675/<source_version>
```

<source_version> is added in two places: **version** and **imageRegistry**.

3. Apply the extra-values.yaml file.
   Run the following **apicup** command to set the **extra-values** file for both the **active** and **warm-standby** sites:

   ```
   apicup subsys set <mgmt> extra-values-file=<extra-values-file-path>
   ```

   where *<mgmt>* is the name of your management subsystem, which you can get with:

   ```
   apicup subsys list
   ```

   If you want to validate your ***<extra-values-file-path>***, and the other subsystem settings, before proceeding, you can run:

   ```
   apicup subsys get <mgmt> --validate
   ```

4. Start the upgrade process on both active and warm-standby management subsystems.

   ```
   apicup subsys install <mgmt> <mgmt_upgrade_tar_archive>
   ```

   Note: If any Control Plane files are needed for your upgrade, you must append the files to the **install** command.
5. Wait for the management subsystem status to become **Running** on both sites.
   To determine the status, login to the management appliances on both sites as root user and run:

   ```
   kubectl get mgmt
   ```

   ```
   NAME          READY   STATUS    VERSION    RECONCILED VERSION AGE
   management    n/n     Running   10.0.6.0   10.0.6.0-100   5h2m
   ```

   The **RECONCILED VERSION**/**VERSION** should be the ***source_version*** that you retrieved in step 1.

6. Disable 2DCDR on the **warm-standby** management subsystem:

   ```
   apicup subsys set <warm-standby management subsystem> multi-site-ha-enabled=false
   apicup subsys install <warm-standby management subsystem>
   ```

   Conversion from warm-standby to a stand-alone management subsystem can take some time. Run the health check to ensure that the deployment is in a good state before proceeding:

   ```
   apicup subsys health-check <warm-standby management subsystem>
   ```

   an empty response means no detected problems.
7. Disable 2DCDR on the active management subsystem.

   ```
   apicup subsys set <active management subsystem> multi-site-ha-enabled=false
   apicup subsys install <active management subsystem>
   ```

   Conversion from active to a stand-alone management subsystem can take some time. Run the health check to ensure that the deployment is in a good state before proceeding:

   ```
   apicup subsys health-check <active management subsystem>
   ```

   an empty response means no detected problems.
8. Wait for the management subsystem status to become **Running** on both sites.
   To determine the status, login to the management appliances on both sites as root user and run:

   ```
   kubectl get mgmt
   ```

   ```
   NAME          READY   STATUS    VERSION    RECONCILED VERSION AGE
   management    n/n     Running   10.0.6.0   10.0.6.0-100   5h2m
   ```

   The **RECONCILED VERSION**/**VERSION** should be the ***source_version*** that you retrieved in step 1.

9. Edit your extra-values.yaml file and delete the **version**, **license**, and **imageRegistry** properties that you added in step 2.
   If you have no other properties in your extra-values.yaml file, then unset the **extra-values-file** property:

   ```
   apicup subsys set mgmt extra-values-file=
   ```

   Apply the change to both sites by running:

   ```
   apicup subsys install <mgmt>
   ```

10. Wait for the management subsystems status to become **Running** on both sites.

    ```
    kubectl get mgmt
    NAME          READY   STATUS    VERSION    RECONCILED VERSION AGE
    management    16/16   Running   10.0.6.1   10.0.6.1-100   5h2m
    ```

    The **RECONCILED VERSION**/**VERSION** should now be the target release that you are upgrading to.

11. Run the health check on both clusters to ensure that the upgrade completed.

    ```
    apicup subsys health-check <mgmt>
    ```

    an empty response means no detected problems.
12. Enable 2DCDR on the previously **active** management subsystem.

    ```
    apicup subsys set <active management subsystem> multi-site-ha-enabled=true
    apicup subsys install <active management subsystem>
    ```

13. Wait for the management subsystem status to become **Running** on the active site.

```
kubectl get mgmt
NAME         READY   STATUS    VERSION    RECONCILED VERSION AGE
management   16/16   Running   10.0.6.1   10.0.6.1-100   5h2m
```

The **RECONCILED VERSION/VERSION** should now be the target release that you are upgrading to.

14. Enable 2DCDR on the previously warm-standby management subsystem.

```
apicup subsys set <warm-standby management subsystem> multi-site-ha-enabled=true
apicup subsys install <warm-standby management subsystem>
```

15. Wait for the management subsystem status to become **Running** on the warm-standby site.

```
kubectl get mgmt
NAME         READY   STATUS    VERSION    RECONCILED VERSION AGE
management   16/16   Running   10.0.6.1   10.0.6.1-100   5h2m
```

The **RECONCILED VERSION/VERSION** should now be the target release that you are upgrading to.

16. Verify that 2DCDR replication is working.
To validate that your two data center deployment is replicating data, login to your active management appliance as root user, run **kubectl get mgmt**:

```
kubectl get mgmt
```

```
NAME         READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management   n/n     Running   10.0.5.3-0   10.0.5.3-0           Management is ready.              8m59s
```

If you see **HA Status Warning** in the **MESSAGE** column, then check the status details with **kubectl describe mgmt**:

```
status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
   }
```

Notes:

- It takes time for the **warm-standby** site to sync with the **active** site.
- When **STATUS** shows **Running**, you can reboot (if **apicup subsys health-check** advises you to do so).

Upgrading Management, Portal, and Analytics on VMware

Upgrade your management, portal, and analytics subsystems on VMware.

Before you begin

- Complete the Pre-upgrade preparation.
- Enable keep-alive in your SSH configuration to avoid problems during the upgrade. For information, consult the documentation for your version of SSH.

About this task

You can upgrade the Management subsystem, Developer Portal subsystem, and Analytics subsystem. The Gateway subsystem remains available during the upgrade of the other subsystems.

For the optional components API Connect Toolkit and API Connect Local Test Environment, you do not need to upgrade. For these components, install the new version of each after you upgrade the subsystems.

Important notes:

- If you have a two data center disaster recovery deployment, the upgrade steps are slightly different. Refer to Upgrading a two data center deployment.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Portal, (3) Analytics, (4) Gateway. Management must be upgraded first. Gateway must be upgraded after Management because upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
- When you run the install, the program sends the compressed tar file, which contains the upgrade images, to all cluster members. The compressed tar file is about 2 GB, and transfer can take some time. When the install command exits, the compressed tar file has arrived at each member. The upgrade process is now underway, and might continue for some time depending on factors such as the size of your deployment, your network speed, and so on.
- The **apicup subsys install** command automatically runs **apicup health-check** prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade.
When troubleshooting a problem with an upgrade, you can optionally suppress the health check. See Skipping health check when re-running upgrade.

Procedure

Notes:

- Do not start an upgrade if a backup is scheduled to run within a few hours.

- Do not perform maintenance tasks such as rotating key-certificates, restoring from a backup, or starting a new backup, at any time while the upgrade process is running.
- If you encounter an issue while performing the upgrade, see Troubleshooting upgrades on VMware.

1. If some time has passed since you completed the Pre-upgrade preparation, repeat these pre-upgrade steps to be sure that your subsystems are ready for upgrade.
2. Block all external traffic to the management server.
   Upgrading API Connect requires down-time while files are transferred and updated. All external traffic to the management server from all sources (Cloud Manager UI, API Manager UI, CLI, and REST API) must be blocked. As a result, the Cloud Manager and API Manager UIs cannot be used during the upgrade. In addition, the Developer Portal cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the upgrade.

3. Verify that the new **apicup** command is in your operating system's `PATH` variable:

   ```
   apicup version
   ```

   The version returned should be the version that you are upgrading to. If not, then refer to step 13 on Preparing to upgrade on VMware.

4. Upgrade the Management subsystem:
   a. Start the upgrade of the Management subsystem:
      i. Install the Management subsystem files.
      Note: If you have a two data center disaster recovery deployment, do not follow this step, instead follow the steps in Management subsystem two data center upgrade from v10.0.6 or Management subsystem two data center upgrade.

      ```
      apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
      ```

      Notes:
      - If you are adding one or more control plane files, specify each path and file name on the command line:

        ```
        apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1> <path_to_control_plane_file_n>
        ```

      - If the upgrade gets stuck, run the following command to reboot the appliance:

        ```
        sudo systemctl restart appliance-manager
        ```

      ii. Verify that the upgrade was successful by running the **apicup** health check:

      ```
      apicup subsys health-check <subsystem_name>
      ```

      Note: If the health-check reports `Error: Cluster not in good health`, check if it is one of the known issues:
      - Original PostgreSQL primary not found.
      - Postgres primary on replica.

      iii. If the health check indicates that a reboot is needed, complete the following:
         1. Login to the VM:

            ```
            ssh apicadm@<hostname>
            ```

         2. Switch to `root` user:

            ```
            sudo -i
            ```

         3. `apic lock`
         4. `systemctl reboot`

   b. Use `apicops` to validate the certificates.
   For information on the `apicops` tool, see The API Connect operations tool: apicops.

      i. Login to the VM:

      ```
      ssh apicadm@<hostname>
      ```

      ii. Switch to `root` user:

      ```
      sudo -i
      ```

      iii. Run the following command:

      ```
      apicops upgrade:stale-certs
      ```

      iv. Delete any stale certificates that are managed by cert-manager.
      If a certificate failed the validation and it is managed by cert-manager, you can delete the stale certificate secret, and let cert-manager regenerate it.
      Run the following command:

      ```
      kubectl delete secret <stale-secret>
      ```

      v. Restart the corresponding pod so that it can pick up the new secret.
      To determine which pod to restart, see the following topics:
      - List of ingress certificates
      - List of intra-subsystem certificates

   c. Restart all nats-server pods.
      i. Login to the VM:

      ```
      ssh apicadm@<hostname>
      ```

      ii. Switch to `root` user:

      ```
      sudo -i
      ```

      iii. Restart all nats-server pods by running the following command:

      ```
      kubectl delete po -l app.kubernetes.io/name=natscluster
      ```

5. If there are multiple Management subsystems in the same project, set the Portal subsystem's **platform-api** and **consumer-api** certificates to match those used by the appropriate Management subsystem to ensure that the Portal subsystem is correctly associated with that Management subsystem.
   This step only applies if you installed more than one Management subsystem into a single project.

   A Portal subsystem can be associated with only one Management subsystem. To associate the upgraded Portal subsystem with the appropriate Management subsystem, manually set the **mgmt-platform-api** and **mgmt-consumer-api** certificates to match the ones used by the Management subsystem.

   a. Run the following commands to get the certificates from the Management subsystem:

   ```
   apicup certs get mgmt-subsystem-name platform-api -t cert > platform-api.crt
   apicup certs get mgmt-subsystem-name platform-api -t key > platform-api.key
   apicup certs get mgmt-subsystem-name platform-api -t ca > platform-api-ca.crt

   apicup certs get mgmt-subsystem-name consumer-api -t cert > consumer-api.crt
   apicup certs get mgmt-subsystem-name consumer-api -t key > consumer-api.key
   apicup certs get mgmt-subsystem-name consumer-api -t ca > consumer-api-ca.crt
   ```

   where *mgmt-subsystem-name* is the name of the specific Management subsystem that you want to associate the new Portal subsystem with.

   b. Run the following commands to set the Portal's certificates to match those used by the Management subsystem:

   ```
   apicup certs set ptl-subsystem-name platform-api Cert_file_path Key_file_path CA_file_path

   apicup certs set ptl-subsystem-name consumer-api Cert_file_path Key_file_path CA_file_path
   ```

   For more information on **apicup** certificate commands, see Command reference.

6. Upgrade the Portal subsystem.
   a. If you did not verify that your Portal customizations are compatible with Drupal 10, do that now.
   In API Connect 10.0.5.3, the Developer Portal moved from Drupal 9 to Drupal 10 (this upgrade also requires PHP 8.1). The upgrade tooling will update your Developer Portal sites; however, if you have any custom modules or themes, it is your responsibility to ensure their compatibility with Drupal 10 and PHP 8.1 before starting the upgrade. Review the Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10 to ensure that any customizations to the Developer Portal are compatible with Drupal 10 and PHP 8.1.

   b. Install the Portal subsystem files:

   ```
   apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
   ```

   Note: If you are adding one or more control plane files, specify each path and file name on the command line:

   ```
   apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1>
   <path_to_control_plane_file_n>
   ```

   c. Verify that the upgrade was successful by running a health check with the following command:

   ```
   apicup subsys health-check <subsystem_name>
   ```

   Important: If the health check indicates that a reboot is required, first complete the upgrade for all Portal sites and verify that all sites were upgraded before running the reboot command at the end of this step.
   d. Run the following toolkit commands to ensure that the Portal site upgrades are complete:
      i. Log in as an admin user:

      ```
      apic login -s <server_name> --realm admin/default-idp-1 --username admin --password <password>
      ```

      ii. Get the portal service ID and endpoint:

      ```
      apic portal-services:get -o admin -s <management_server_endpoint> \
                  --availability-zone availability-zone-default <portal-service-name> \
                  --output - --format json
      ```

      iii. List the sites:

      ```
      apic --mode portaladmin sites:list -s <management_server_endpoint> \
                  --portal_service_name <portal-service-name> \
                  --format json
      ```

      Any sites currently upgrading display the **UPGRADING** status; any site that completed its upgrade displays the **INSTALLED** status and the new platform version. Verify that all sites display the **INSTALLED** status before proceeding.

      For more information on the **sites** command, see **apic sites:list** and Using the **sites** commands.

      iv. After all sites are in **INSTALLED** state and have the new platform listed, run:

      ```
      apic --mode portaladmin platforms:list -s <server_name> --portal_service_name <portal_service_name>
      ```

      Verify that the new version of the platform is the only platform listed.

      For more information on the **platforms** command, see **apic platforms:list** and Using the **platforms** commands.

   e. If all Portal sites are upgraded and the health check indicates that a reboot is needed, then run the following command:

   ```
   systemctl reboot
   ```

7. Upgrade the Analytics subsystem
   a. Install the Analytics subsystem files:

   ```
   apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
   ```

   Note: If you are adding one or more control plane files, specify each path and file name on the command line:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1>
<path_to_control_plane_file_n>
```

b. Verify that the upgrade was successful by running a health check with the following command:

```
apicup subsys health-check <subsystem_name>
```

c. If the health check indicates that a reboot is needed, run the following commands:

i. `apic lock`

ii. `systemctl reboot`

8. If you are upgrading from 10.0.5.1 or 10.0.5.2: If you want to use JWT security instead of mTLS, enable this feature as explained in Use JWT security instead of mTLS between subsystems.
9. Complete a manual backup of the upgraded API Connect subsystems; see Backing up and restoring on VMware.
10. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see Using VM snapshots for infrastructure backup and disaster recovery for details. This action requires a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully.
11. Complete the disaster preparation steps to ensure recovery of API Connect from a disaster event. See Preparing for a disaster.

What to do next

When you have upgraded all of the API Connect subsystems, upgrade your DataPower Gateway Service. See Upgrading DataPower Gateway Service.

- **Control Plane files for earlier releases**
  If you are upgrading to an earlier version than 10.0.6.0, refer to the following tables to determine which Control Plane files are required.
- **Checksum values for earlier releases**
  If you are upgrading to an earlier version than 10.0.6.0, use the corresponding checksum values to verify your downloaded upgrade files.

Control Plane files for earlier releases

If you are upgrading to an earlier version than 10.0.6.0, refer to the following tables to determine which Control Plane files are required.

Control planes for upgrading to 10.0.6

Installs with `appliance-control-plane-1.26.x.tgz`

Table 1. Control Plane files needed for upgrading to 10.0.6

Upgrading from API Connect version	Control Plane files needed
• 10.0.5.3	No Control Plane needed.
• 10.0.5.2	Download: • `appliance-control-plane-1.25.x.tgz`
• 10.0.5.1	Download: • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz`

Checksum values for earlier releases

If you are upgrading to an earlier version than 10.0.6.0, use the corresponding checksum values to verify your downloaded upgrade files.

Version 10.0.5.0 was not released on VMware so there are no checksum values for that version.

```

Upgrading DataPower Gateway Service

Use these instructions when upgrading DataPower Gateway Service in a non-Kubernetes environment, during upgrade of API Connect.

Before you begin

Ensure you have completed the upgrade of the API Connect subsystems (Management service, Developer Portal, Analytics) before upgrading DataPower Gateway. Upgrading the Management service before the DataPower Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.

About this task

- The DataPower Gateway Service in a non-Kubernetes environment can be on either a physical appliance or in a virtual DataPower deployment.
- The upgrade of DataPower Gateway Service in a non-Kubernetes environment, for use in API Connect deployments in a VMware environment, does not use the **`apicup`** command. Use DataPower Gateway instructions in the following steps.

Note: To upgrade the DataPower Gateway Service in a Kubernetes environment, do not use this procedure. Instead, see Upgrading Gateway subsystem on native Kubernetes.

Procedure

1. Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.
   Note:
   You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

   Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

2. When upgrading a high-availability cluster, ensure that you meet the requirements:
   - Gateways must be updated one at a time.
   - Before starting the upgrade, a single gateway must be running as primary for all gateway-peering definitions.
   - When upgrading multiple gateways, the primary gateway must be upgraded last.

   To determine which gateway is running as primary, use either the **`show gateway-peering-status`** command in the DataPower CLI, or use the Gateway Peering Status display in the Web GUI in the API Connect application domain. To move the primary to the DataPower on which you're currently working, you can issue the **`gateway-peering-switch-primary <peering-object-name>`** command.

3. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
   See Managing the NTP service.
4. Ensure that you have set a unique **`System Identifier`** for each v10 DataPower gateway. See Initializing the DataPower Gateway.
5. Follow the upgrade instructions on the DataPower Gateway documentation. See Installation operations.
   Note:
   - If upgrading a cluster (high-availability) deployment, ensure that you have identified which gateway is running a primary in gateway-peering definitions, and that you upgrade that gateway last.
   - For troubleshooting help with DataPower operator deployments, see IBM DataPower Operator documentation.

Troubleshooting upgrades on VMware

Review the following troubleshooting guidance if you encounter a problem while upgrading API Connect on VMware.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

The original primary PVC is not attached to any pods in this namespace

If the **`apicops version:pre-upgrade`** check reports

`The original primary PVC is not attached to any pods in this namespace`

and you have not started the upgrade yet (you have not run the **apicup subsys install** command) then follow these steps:

1. Take a backup of your management subsystem: Backing up and restoring the Management subsystem.
2. Restore the new backup: Restoring the management subsystem.

The action of taking and restoring a management backup fixes the problem that causes the error message. If you see this error after starting upgrade, see Original PostgreSQL primary not found.

Original PostgreSQL primary not found

If you ran the **apicup subsys install <tar file>** command to start an upgrade, the upgrade does not complete, and the **apicup health-check** command returns:

```
apicup subsys health-check management
Error: Cluster not in good health:
expect member apicdev.ibm.com 'Install stage' to be 'Done'(actual: SETUP_SUBSYSTEM) | Detail: reconcile.go#apply subsystem not
ready
```

then SSH into the management appliance and switch to root user to get more details of the error:

```
ssh apicadm@<management appliance>
sudo -i
```

Run **kubectl describe mgmt**, and check the output for the following message:

```
kubectl describe mgmt

...
Original PostgreSQL primary not found, further operand upgrade will be blocked. Set apiconnect-operator/db-primary-not-found-
allow-upgrade=true annotation to unblock operand upgrade and perform db backup and restore after upgrade to restore original
primary
...
```

To fix this problem, complete the following steps:

1. Create an extra-values.yaml file and set the annotation:

   ```
   metadata:
     annotations:
       apiconnect-operator/db-primary-not-found-allow-upgrade: "true"
   ```

   Note: If you already have an extra-values.yaml file, update the existing file with above annotation.
2. Set the extra-values-file property on your management subsystem with **apicup**:

   ```
   apicup subsys set <management subsystem name> extra-values-file=<extra values filename>
   ```

3. Restart the upgrade, with the **--skip-health-check** flag:

   ```
   apicup subsys install <management subsystem name> <upgrade tar file> <control plane file - if required> --skip-health-
   check
   ```

4. When upgrade is complete:
   a. Remove the annotation from your extra-values.yaml file.
   b. Take a backup of your management subsystem: Backing up and restoring the Management subsystem.
   c. Restore the new backup: Restoring the management subsystem. The action of taking and restoring a management backup fixes the problem that causes the error message `The original primary PVC is not attached to any pods in this namespace`. Be careful to restore from the backup that is taken after the upgrade, and not from a backup taken before upgrade.

The `cloud-final.service` fails during upgrade

Sometimes during upgrade, there is an issue with the `cloud-final.service` and a node, and the appliance-manager enters a bad state.

To determine whether your upgrade encountered this problem, complete the following steps:

1. Check the output of `apic health-check` command for a result similar to the following example:

   ```
   # apic health-check
   INFO[0000] Log level: info
   FATA[0000] Unable to cluster status: rpc error: code = Unavailable desc = connection error: desc = "transport: Error while
   dialing dial tcp 9.20.153.38:9178: connect: connection refuse
   ```

2. Check the response to the `journalctl -u appliance-manager | grep cloud-final` command and see if it looks like the following example:

   ```
   # journalctl -u appliance-manager | grep cloud-final
   Nov 21 19:41:58 apimdev1040 apic[2569]: Job for cloud-final.service failed because the control process exited with error
   code.
   Nov 21 19:41:58 apimdev1040 apic[2569]: See "systemctl status cloud-final.service" and "journalctl -xe" for details.
   ```

If you determined that this was the problem, you can correct it by running each of the following commands on every node:

1. `systemctl restart cloud-final.service`
2. `apic lock`
3. `apic unlock`

Postgres replica fails to start due to permissions issue

Symptom:

```
2023-04-11 11:31:40,535 INFO: Lock owner: v10-0-5-up-ce0f24dc-site1-postgres-iszz-c5d9c4f5c-9d9fj; I am v10-0-5-up-ce0f24dc-
site1-postgres-75845474bd-kzcjl
2023-04-11 11:31:40,537 INFO: starting as a secondary
2023-04-11 11:31:41.032 UTC [151610][]FATAL:  data directory "/pgdata/v10-0-5-up-ce0f24dc-site1-postgres" has invalid
permissions
```

```
2023-04-11 11:31:41.032 UTC [151610][]DETAIL:  Permissions should be u=rwx (0700) or u=rwx,g=rx (0750).
2023-04-11 11:31:41,055 INFO: postmaster pid=151610
/tmp:5432 - no response
2023-04-11 11:31:41,091 INFO: Lock owner: v10-0-5-up-ce0f24dc-site1-postgres-iszz-c5d9c4f5c-9d9fj; I am v10-0-5-up-ce0f24dc-site1-postgres-75845474bd-kzcjl
2023-04-11 11:31:41,092 INFO: failed to start postgres
```

Resolve the issue by completing the following steps to correct the permissions and restart the replica pod:

1. Run the following command to exec into the pod:

   ```
   k exec -it <pg-primary-pod> -- bash
   ```

2. Run the following command to reset the permissions:

   ```
   chmod 0700 /pgdata/<pg-cluster-name>
   ```

3. Restart the failed pod.

Upgrade stuck with "Unable to upgrade appliance-base: exit status 100" message

This error can occur when the deployment is using an incorrect version of **containerd**. There is a known issue where upgrades from 10.0.1.7-eus or 10.0.1.8-eus to 10.0.5.1 incorrectly upgraded the **containerd** version and subsequent upgrades from 10.0.5.1 might encounter this error.

On each node, complete the following steps to determine the version of **containerd** and if necessary, downgrade it to the correct version:

1. Run the following set of commands on the healthy node to downgrade the version of **containerd**:

   ```
   systemctl stop appliance-manager
   systemctl stop kubelet
   systemctl stop containerd
   apt-get --allow-downgrades upgrade -y containerd.io
   sed -i 's/KillMode=process/KillMode=mixed/g' /lib/systemd/system/containerd.service
   systemctl daemon-reload
   systemctl restart containerd
   apic lock
   apic unlock
   ```

2. Run the following command to verify that **containerd** now displays **containerd://1.5.11** for the CONTAINER-RUNTIME:

   ```
   kubectl get nodes -o wide
   ```

Remember to complete these steps on every node.

Some containers in the kube-system namespace show a status of ErrImageNeverPull

When upgrading, some of the containers in the **kube-system** namespace might show a status of**ErrImageNeverPull**. This happens due to Docker not successfully loading all images from the upgrade .tgz file. To resolve this issue and enable the upgrade to proceed, complete the following steps:

1. Run the following command to determine which node is missing the control plane files:

   ```
   kubectl -n kube-system get pods -owide
   ```

   This command returns the names of the nodes containing pods with the **ErrImageNeverPull** status, which indicates missing control plane files.

2. On the node that is missing the control plane files, run the following command to determine which versions of the control plane are missing:

   ```
   cat /var/lib/apiconnect/appliance-control-plane-current
   ```

3. For each missing control plane, run the following command on the same node to add it, replacing *<version>* with the version of the control plane:

   ```
   docker load < /usr/local/lib/appliance-control-plane/<version>/kubernetes.tgz
   ```

Pod stuck in Pending status during upgrade

When upgrading, the scheduler might deploy a subset of the same microservice pods on the same node. This can prevent other pods with **requiredDuringSchedulingIgnoredDuringExecution** affinity rules from being deployed due to a lack of resources on a subset of nodes. To allow the pending containers to be deployed successfully, identify any pods of the same type that are scheduled on the same node and delete one of them. This will free up space and cause the deleted pod to get rescheduled. To identify pods that are eligible to be deleted, and then delete the pods, complete the following steps:

1. Run the following command and check for any pods of the same type that are on the same node:

   ```
   kubectl get po -o=custom-columns='name:.metadata.name, node:.spec.nodeName,
   antiaffinity:.spec.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution' | grep -v '<none>' | awk
   '{print $1" "$2'}
   ```

   In the following example snippet, one of the two **apim** pods on the node test0186 should be deleted:

   ```
   stv3-management-analytics-proxy-56848c8c69-phpdh test0186
   stv3-management-analytics-proxy-56848c8c69-sc45f test0187
   stv3-management-analytics-proxy-56848c8c69-scf6g test0188
   stv3-management-apim-5574796948-6lnwj test0186
   stv3-management-apim-5574796948-h9dgx test0186
   stv3-management-apim-5574796948-tsb4g test0188
   ```

2. Run the following command to delete a pod:

   ```
   kubectl delete po <pod_name>
   ```

Database replica pods stuck in Unknown or Pending state

In certain scenarios, a postgres replica pod may not recover to a healthy state when a restore completes, a node outage occurs, or after a fresh install or upgrade. In these cases, a postgres pod remains in a **Unknown** or a **Pending** state after a number of minutes. The pod fail to get into a **Running** state.

This situation occurs when the replicas do not initialize properly. You can use the **patronictl reinit** command to reinitialize the replica. Note that this command syncs the replica's volume data from the current Primary pod.

Use the following steps to get the pod back into a working state:

1. SSH into the VM as root.
2. Exec onto the failing pod:

   ```
   kubectl exec -it <postgres_replica_pod_name> -n <namespace> -- bash
   ```

3. List the cluster members:

   ```
   patronictl list
   + Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+--------------+----+-----------+
   |                         Member                          |      Host      |  Role  |    State     | TL | Lag in MB |
   +---------------------------------------------------------+----------------+--------+--------------+----+-----------+
   |    fxpk-management-01191b80-postgres-586f899fdf-6s25b   | 172.16.172.244 |        | start failed |    |   unknown |
   | fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader |   running    |  3 |           |
   |  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        |   running    |  3 |         0 |
   +---------------------------------------------------------+----------------+--------+--------------+----+-----------+
   ```

   In the example shown above **fxpk-management-01191b80-postgres-586f899fdf-6s25b** is not in running state.

   Note the **clusterName** and **replicaName** which are not up:

   - **clusterName** - **fxpk-management-01191b80-postgres**
   - **replicaName** - **fxpk-management-01191b80-postgres-586f899fdf-6s25b**

4. Run:

   ```
   patronictl reinit <clusterName> <replicaName-which-is-not-running>
   ```

   Example:

   ```
   patronictl reinit fxpk-management-01191b80-postgres fxpk-management-01191b80-postgres-586f899fdf-6s25b
   + Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+--------------+----+-----------+
   |                         Member                          |      Host      |  Role  |    State     | TL | Lag in MB |
   +---------------------------------------------------------+----------------+--------+--------------+----+-----------+
   |    fxpk-management-01191b80-postgres-586f899fdf-6s25b   | 172.16.172.244 |        | start failed |    |   unknown |
   | fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader |   running    |  3 |           |
   |  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        |   running    |  3 |         0 |
   +---------------------------------------------------------+----------------+--------+--------------+----+-----------+
   Are you sure you want to reinitialize members fxpk-management-01191b80-postgres-586f899fdf-6s25b? [y/N]: y
   Success: reinitialize for member fxpk-management-01191b80-postgres-586f899fdf-6s25b
   ```

5. Run **patronictl list** again.
   You may also observe that the replica is on a different Timeline (TL) and possibly have a Lag in MB. It may take a few minutes for the pod to switch onto the same TL as the others and the Lag should slowly go to 0.

   For example:

   ```
   bash-4.2$ patronictl list
   + Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+---------+----+-----------+
   |                         Member                          |      Host      |  Role  |  State  | TL | Lag in MB |
   +---------------------------------------------------------+----------------+--------+---------+----+-----------+
   |    fxpk-management-01191b80-postgres-586f899fdf-6s25b   | 172.16.172.244 |        | running |  1 |     23360 |
   | fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader | running |  3 |           |
   |  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        | running |  3 |         0 |
   +---------------------------------------------------------+----------------+--------+---------+----+-----------+
   ```

6. The pod that previously was in an **Unknown** or **Pending state** or **(0/1) Running** state is now in **(1/1) Running** state.

etcd pod stuck in Terminating state

During an upgrade, you might see a health-check reporting the upgrade is stuck in **ETCD** stage and that an **etcd** pod is stuck in the **Terminating** state.

Verify the issue by completing the following steps:

1. SSH into the VM as root.
2. Run the following command and verify that the upgrade stage is **ETCD**:

   ```
   apic status
   ```

3. Run the following command to determine whether an **etcd** pod is stuck in the **Terminating** state:

   ```
   kubectl get pods -n namespace | grep etcd
   ```

Resolve the issue by completing the following steps:

1. Run the following command to retrieve the names of the **etcd** pods:

   ```
   kubectl get pods -n namespace -o wide | grep etcd
   ```

2. On the pod that is stuck, SSH into the VM as root.
3. Run the following command to restart the pod:

```
systemctl restart kubelet
```

Skipping health check when re-running upgrade

The **apicup subsys install** command automatically runs **apicup health-check** prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade

In some scenarios, if you encounter an upgrade failure, an attempt to rerun **apicup subsys install** is blocked by errors found by **apicup health-check**. Even when you have fixed the error (such as reconfiguration of an incorrect upgrade CR), the failed upgrade can continue to cause the health check to fail.

You can workaround the problem by adding the **--skip-health-check** flag to suppress the health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

In this case, use of **--skip-health-check** allows the upgrade to rerun successfully.

Maintaining API Connect

You can use utilities to complete maintenance tasks such as backup, restore, and certificate management in a VMware environment.

Note: When maintaining API Connect, do not use **kubectl exec** commands to access API Connect pods unless advised by IBM.
Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

- **Advanced installation on VMware**
  Optionally install additional software.
- **Advanced configuration on VMware**
  Perform configuration tasks on your API Connect deployment on VMware.
- **Advanced configuration for management subsystem**
  Specify advanced configuration for the management subsystem.
- **Backing up and restoring on VMware**
  Backup and restore API Connect on VMware.
- **Disaster recovery**
  Prepare for disaster events and recover API Connect on VMware if a disaster event occurs.
- **Disabling and re-enabling the Analytics subsystem on VMware**
  Disable the Analytics subsystem by shutting down the VM that hosts it.
- **Maintaining a two data center deployment**
  How to maintain a two data center disaster recovery (DR) deployment on VMware, including information about normal operation, failure handling, and recovery.
- **Monitoring and health checks**
  Monitor your deployment and complete health checks on subsystems.
- **Logging**
  Configure logging for your deployment on VMware.
- **Troubleshooting**
  Troubleshoot your deployment on VMware.

Advanced installation on VMware

Optionally install additional software.

See:

- **Installing the IBM License Metric Tool on VMware**
  The IBM License Metric Tool (ILMT) helps you determine whether your IBM® API Connect deployment is compliant with licensing requirements.
- **Installing the toolkit**
- **Installing the Automated API behavior testing application**
  Install the Automated API behavior testing application in your IBM API Connect deployment on VMware.

Installing the IBM License Metric Tool on VMware

The IBM License Metric Tool (ILMT) helps you determine whether your IBM® API Connect deployment is compliant with licensing requirements.

About this task

>ILMT provides useful features for managing virtualized environments and measuring license utilization. ILMT discovers the software that is installed in your infrastructure, helps you to analyze the consumption data, and allows you to generate audit reports. Each report provides you with different information about your infrastructure, for example the computer groups, software installations, and the content of your software catalog.

By default, every ILMT audit report presents data from the previous 90 days. You can customize the type and amount of information displayed in a report by using filters, and save your personal settings for future use. You can also export the reports to .csv or .pdf format, and schedule report emails so that specified recipients are notified when important events occur.

For more information about ILMT, see the IBM License Metric Tool documentation.

Note: The following instructions describe the ILMT installation for API Connect deployments in a VMware environment, and apply to the Management, Developer Portal, and Analytics OVAs.

Procedure

To download the BigFix Agent for the Ubuntu operating system, complete the following steps:

1. Navigate to http://support.bigfix.com/bes/release/ and then follow the link to the latest release; for example: http://support.bigfix.com/bes/release/9.5/patch11/.
2. In the Agent section of the table, click the Download link corresponding to the following release:
   - Operating System: Ubuntu
   - Version: 16
   - Architecture: x86_64

   In this example, the direct download link is: http://software.bigfix.com/download/bes/95/BESAgent-9.5.11.191-ubuntu10.amd64.deb

Upload the BigFix Agent package to each OVA server, as follows:

3. Upload the BigFix Agent .deb package to each running OVA server. Following is an example of the command for uploading the file that was downloaded in Step 2:

   ```
   scp BESAgent-9.5.11.191-ubuntu10.amd64.deb apicadm@<OVA_Hostname>:~

   The generic command is:
   scp <BigFix_Agent_Package_File_Path> apicadm@<OVA_Hostname>:~
   ```

   The BigFix Agent .deb package will be uploaded to */home/apicadm*.

Install the BigFix client on each OVA server, as follows:

4. Log in, with a secure shell connection, to the server as the **apicadm** user.
5. Become root by entering **sudo -s**.
6. Follow IBM Bigfix installation instructions Ubuntu to install the .deb package.

What to do next

Ensure that TCP/IP port 52311 is open on your firewall.

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just to need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
   - To download the toolkit from IBM Fix Central, complete the following steps:
     - Open the IBM Fix Central site in your browser.
     - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
     - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
     - In the Text field, enter `toolkit`, then click Continue.
     - Select the toolkit file that you want to download.
     - Click Continue, then follow the instructions to complete the download operation.
   - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
     - Open the Cloud Manager or API Manager user interface.
     - On the welcome page, click the Download Toolkit tile. The two toolkit options are listed.
     - Click your platform alongside either the CLI option or the CLI + LoopBack + Designer option as required, then save the associated compressed file to your local file system.
     - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the designer_credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 6.

- To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 5.
- Close the Install API Connect Toolkit window.

2. Extract the contents of the toolkit compressed file to a folder of your choice.
   The contents of the file depend on the your chosen toolkit option and platform, as follows:

   - The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.
   - The apic or apic.exe file is the CLI for IBM API Connect including LoopBack support.
     Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.
   - The api_designer-*platform* file is the API Designer user interface application for the specified platform.

3. Optional: Delete the **`$HOME/.apiconnect/node_clis`** directory.
   You need to do this only if you replaced a version of **`apic`** or apic.exe and are using the **`apic lb4`** command. You need to delete the directory get **`apic`** to unpack the new loopback.

   On Windows, $HOME is defined by environment USERPROFILE.

4. Run the CLI.
   - For the Mac OSX or Linux® platforms, complete the following steps:
     - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Make the CLI file an executable file by entering the following command:

       `chmod +x download_name`

       Where *download_name* is the name of the toolkit file that you downloaded, either apic or apic-slim.
     - Run CLI commands as follows:

       `./apic command_name_and_parameters`

       or

       `./apic-slim command_name_and_parameters`

       For details of the CLI commands, see apic.
   - For the Windows platform, complete the following steps:
     - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Run CLI commands as follows:

       `apic command_name_and_parameters`

       or

       `apic-slim command_name_and_parameters`

       For details of the CLI commands, see apic.

   Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.

5. Install the toolkit credentials.
   If you do not install the toolkit credentials that are provided for download, as detailed previously in the toolkit credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

   `apic client-creds:set toolkit_credentials_file_path/credentials.json`

   where *credentials_file_path* is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.
   Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
   To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

   `apic client-creds:clear`

   For increased security, an administrator can remove the default credentials from the management server by completing the following steps:
   a. Log in to the management server as an administrator; see Logging in to a management server.
   b. Delete the default credentials by running the following commands:

   ```
   apic registrations:delete toolkit --server mgmt_endpoint_url
   apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
   ```

6. Install the API Designer credentials.
   If you do not install the API Designer credentials that are provided for download, as detailed previously in the API Designer credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the **`APIC_DESIGNER_CREDENTIALS`** environment variable to the credentials download location, using the mechanism appropriate for your operating system.

   After you have set the **`APIC_DESIGNER_CREDENTIALS`** environment variable, your API Designer uses the new credentials to authenticate with the management server.

   - Windows:
     If you are using Windows, create an environment variable using one of the following methods:

     - Create a permanent environment variable so that you can start API Designer from any location on your computer:
       - Open the Environment Variables page: Click Start > Settings > System and in the "Related Settings" section of the page, click Advanced System Settings.
       - On the Advanced tab of the System Properties dialog box, click Environment Variables.
       - In the "User variables" section, click New and create an environment variables with the following settings:
         - Variable: **`APIC_DESIGNER_CREDENTIALS`**

- Value: *<designer_credentials_file_path>*\designer_credentials.json where **<designer_credentials_file_path>** is the location where you stored the designer_credentials.json file.
- Click OK to save the new environment variable, and then exit the dialog box.

- If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
  - Open the Windows command prompt.
  - Run the following command to set the temporary environment variable:

    ```
    set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
    ```

    where **<designer_credentials_file_path>** is the location where you stored the designer_credentials.json file.

    Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.
  - Now run the following command to start API Designer:

    ```
    C:\"Program Files\API Designer\API Designer.exe"
    ```

    By default, API Designer is installed in the C:\"Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

- Mac:
  If you are using Mac OS X, create an environment variable using one of the following methods:

  - Run the following command to set the global environment variable:

    ```
    launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
    ```

    where **<designer_credentials_file_path>** is the location where you stored the API Designer credentials JSON file.
  - Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

    ```
    APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open
    <designer_application_file_path>/'API Designer.app'
    ```

    where:
    - **<designer_credentials_file_path>** is the location to which you downloaded the API Designer credentials JSON file.
    - **<designer_application_file_path>** is the location to which you downloaded and uncompressed the API Designer application.

7. Start the API Designer application from the location to where you stored the extracted file.
   Note:
   - To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
     - In Windows File Explorer, navigate to the USER_HOME\AppData\Local\Programs\api-designer folder.
     - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
   - To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see Developing your APIs and applications.

For information on using the toolkit CLI, see Using the developer toolkit command-line tool.

Installing the Automated API behavior testing application

Install the Automated API behavior testing application in your IBM® API Connect deployment on VMware.

About this task

Use the following steps to install the Automated API behavior testing application as part of your initial deployment, or to add it in later.
Note: It is not possible to use the Automated API behavior testing application with a two data center disaster recovery configuration (A two data center deployment strategy on VMware).

Procedure

1. Run the following **apicup** commands to install or update your deployment with the the Automated API behavior testing application:

   ```
   apicup subsys set mgmt test-and-monitor-enabled true
   apicup certs set mgmt hub --clear
   apicup certs set mgmt turnstile --clear
   apicup subsys set mgmt hub hub-endpoint
   apicup subsys set mgmt turnstile turnstile-endpoint
   apicup subsys install mgmt
   ```

   where:
   - **mgmt** is the name of your Management server (which you are either installing or updating).
   - **hub-endpoint** is an endpoint on the ingress subdomain for the API Connect stack; for example: hub.testsrv0231.subnet1.example.com.
   - **turnstile-endpoint** is an endpoint on the ingress subdomain for the API Connect stack; for example: turnstile.testsrv0231.subnet1.example.com.

   Attention: The hub and turnstile endpoints should be distinct and must not overlap with any of the 4 management endpoints.

2. Verify that the application deployed properly by completing the following steps:
    a. Log in to API Manager.
    b. On the Home page, click the Test APIs tile.
    c. Verify that the Automated API behavior testing opens.

Advanced configuration on VMware

Perform configuration tasks on your API Connect deployment on VMware.

See:

- **Adding a static route on a virtual machine**
  You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.
- **Adding disk space to a VMware appliance**
  Increase disk space on the VMware appliance.
- **Appliance boot mode configuration**
  Configure the boot mode for the appliance VMs.
- **Running commands at boot with iso-ignored boot mode**
  When `iso-ignored` boot mode is configured, complete the following steps on each appliance that should run commands at boot.
- **Changing deployment profiles on VMware**
  You can change an API Connect installation to use a different deployment profile.
- **Changing the DNS server configuration on appliances**
  Complete this task only if you must change the DNS addresses after the initial boot of the VM.
- **Configuring API Connect subsystems in a cluster**
  This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.
- **Configuring SSHD to limit access to your deployment**
  How to configure SSHD in order to limit host access to your VMware deployment.
- **Enabling Developer Portal feature flags on VMware**
  Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.
- **Managing an appliance data disk**
  You can use `apic` commands to manage appliance data disks in your VMware deployment.
- **Replica override for microservices on VMware**
  Modify the replica count for microservices by using template overrides for Custom Resources.
- **Testing a new configuration against a current cluster**
  You can use the `apicup` utility to test the validity of a new configuration before you install it.
- **Use JWT security instead of mTLS between subsystems**
  If your network requires TLS termination on load-balancers located between your API Connect subsystems, then disable mTLS and enable JWT to provide application layer security.

Adding a static route on a virtual machine

You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.

About this task

Add commands to your additional `cloud-init` file. You can do this for the Management, Analytics, and Portal subsystems.

Procedure

1. Specify an additional cloud-init file:

   ```
   apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
   ```

2. Add lines to your cloud-init file.
   Syntax:

   ```
   bootcmd:
    - ip route add <destination>/<mask> via <gateway> dev eth<n>
   ```

   Example:

   ```
   bootcmd:
    - ip route add 172.27.218.0/24 via 172.27.218.1 dev eth1
    - ip route add 172.26.203.0/24 via 172.27.218.1 dev eth1
   ```

3. Regenerate the ISO file.

   ```
   apicup subsys install <subsys> --out <plan-directory>
   ```

4. Restart the ISO, and ensure that the node(s) have this updated ISO attached at startup.

Adding disk space to a VMware appliance

Increase disk space on the VMware appliance.

About this task

For multi-node deployment of the appliance, only one VM at a time should have its disk space augmented. The subsystem should be in good health before proceeding to the next node. Health of the subsystem can be checked with **`apicup subsys health-check <subsystem-name>`**.

Restriction:
The increased disk capacity of a VMware appliance won't be reflected in the storage size of the PVCs that are hosted on the appliance, as those PVCs are immutable. This restriction doesn't impact the Portal and Analytics subsystems, as the PVC storage size isn't used to enforce any disk usage limit, so the subsystems can use all of the additional disk space. However, for the Management subsystem the PVC storage size is used in the database storage utilization computation, and that might trigger disk usage warnings.

The most common reason for the Management subsystem database to run out of disk space, is due to Write Ahead Log (WAL) file accumulation in relation to an incorrectly configured backup, or an unavailable backup server. If this type of condition arises, adding disk space might help with the health of the appliance control plane, but it won't increase the disk space that's available to the database, so you must resolve the WAL file accumulation condition. If the disk space that's available to the Management database must be increased, you should carry out a disaster recovery operation of the Management subsystem, using a larger data disk size for the new installation, so that adding disk space after the install won't be needed.

Procedure

1. Shutdown the virtual machine, either by issuing a shutdown command as root from the VM, or by using the VMware console or command line interface.
   For example, use the VMware console user interface and click the red rectangle.
2. Use either the VMware console or command line interface to add a new device to the VM, of type Hard Disk and of the desired size to be added to the appliance.
   For example, on the VMware console:
   a. Click Edit settings.
   b. Click Add new device. From the drop-down menu, select Hard Disk.
   c. Enter size in GB and click OK.
3. Use either the VMware console or the command line interface to power on the VM.
   As the VM starts it should detect the newly added disk and use it to augment the available capacity for the /data/secure mount point.
4. Optionally you may verify that a new disk **`sdc`** was added (or **`sdd`** if you already added one disk, and so on). Log in to the server and observe the new disk. For example:

```
root@apimdev1139:~# lsblk
NAME                MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
sda                   8:0    0  100G  0 disk
├─sda1                8:1    0 99.9G  0 part  /
├─sda14               8:14   0    4M  0 part
└─sda15               8:15   0  106M  0 part  /boot/efi
sdb                   8:16   0  250G  0 disk
└─apiconnect-data   252:0    0  260G  0 lvm
  └─apicSecureDisk  252:1    0  260G  0 crypt /data/secure
sdc                   8:32   0   10G  0 disk
└─apiconnect-data   252:0    0  260G  0 lvm
  └─apicSecureDisk  252:1    0  260G  0 crypt /data/secure
sr0                  11:0    1   44K  0 rom
```

Appliance boot mode configuration

Configure the boot mode for the appliance VMs.

By default every appliance node requires the presence of an ISO file attached at boot.

Version 10.0.4.0 or later: You can configure individual VMs so that they can be booted and rebooted without an ISO being attached. Each appliance VM (node) is configured individually.

You can:

- Check the current boot mode of an appliance
- Configure an appliance for iso-ignored boot mode
- Configure an appliance for iso-required boot mode
- Revert back to iso-required boot mode by booting the appliance in rescue mode

Check the current boot mode of an appliance

The default boot mode for all appliances is **`iso-required`**. To check the current boot mode:

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Use **`apic boot-mode`** to check the current boot mode of the appliance. For example:

```
root@ip-192-168-122-241:~# apic boot-mode
INFO[0000] Log level: info
INFO[0000] current boot mode is: iso-required
```

Configure an appliance for `iso-ignored` boot mode

An appliance can be configured to use the **iso-ignored** boot mode instead of the default **iso-required**. Prerequisite: The appliance must have first booted with its configuration ISO attached and in **iso-required** boot mode (default) before the boot mode can be changed to **iso-ignored**.

You can configure an appliance to use he **iso-ignored** boot mode instead of the default **iso-required**.

Prerequisite: The appliance must have first booted with its configuration ISO attached and in **iso-required** boot mode (default), before you can change the boot mode to **iso-ignored**.

Note: If you added a static route to the routing table, as documented in Adding a static route on a virtual machine, and if you are relying on a **bootcmd** from the ISO, then using the **iso-ignored** boot mode causes the **bootcmd** section being ignored or ineffective.

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Edit the file **/etc/default/grub.d/50-cloudimg-settings.cfg** to ensure that the **GRUB_TIMEOUT** and **GRUB_RECORDFAIL_TIMEOUT** are set to the value **5**. Then run the command **update-grub**. For example:

```
root@ip-192-168-122-241:~# update-grub
Sourcing file `/etc/default/grub'
Sourcing file `/etc/default/grub.d/50-cloudimg-settings.cfg'
Sourcing file `/etc/default/grub.d/init-select.cfg'
Generating grub configuration file ...
Found linux image: /boot/vmlinuz-5.4.0-84-generic
Found initrd image: /boot/initrd.img-5.4.0-84-generic
done
```

3. Set the appliance boot mode to **iso-ignored** with the command **apic boot-mode iso-ignored**. For example:

```
root@ip-192-168-122-241:~# apic boot-mode iso-ignored
INFO[0000] Log level: info
INFO[0000] current boot mode is: iso-ignored
```

4. Shutdown the VM, and remove the CD/DVD device from the VM configuration through VSphere.
For any subsequent boot of the appliance while it remains in **iso-ignored** boot mode, any ISO file attached will be ignored, and the boot will proceed as normal, whether an ISO file is attached or not.

   Warning: If the appliance was booted in **iso-ignored** boot mode, it is possible to change its boot mode to **iso-required**. However, as stated in the prerequisites, it is not possible to immediately switch back to **iso-ignored**, and the next boot of the appliance must happen with the configuration ISO attached and boot mode **iso-required**.

Configure an appliance for iso-required boot mode

The mode **iso-required** is the default boot mode for all appliances. If the appliance boot mode was changed to **iso-ignored** you can revert back to **iso-required** boot mode.

Warning:
If the appliance was booted in **iso-ignored** boot mode, it is possible to change its boot mode to **iso-required**. However, you cannot immediately switch back to **iso-ignored**, and the next boot of the appliance must happen with the configuration ISO attached and boot mode **iso-required**. After the appliance is booted with ISO attached in **iso-required** boot mode, the boot mode can then be switched to **iso-ignored** if needed.

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Set the appliance boot mode to **iso-required** with the command **apic boot-mode iso-required**. For example:

```
root@ip-192-168-122-241:~# apic boot-mode iso-required
INFO[0000] Log level: info
INFO[0000] current boot mode is: iso-required
```

   Important: For any subsequent boot of the appliance while it remains in **iso-required** boot mode, the configuration ISO file must be connected at boot and for every boot.

Revert back to iso-required boot mode by booting the appliance in rescue mode

When an appliance is configured with the **iso-ignored** boot mode, the boot sequence ignores any attached ISO. This means that it is not possible to influence the appliance configuration during its boot. In case the appliance is not booting properly and the boot mode needs to be reverted back to **iso-required**, proceed as follows:

1. Access to the VMware console for the Appliance, and after causing it to reboot, bring up a console to the appliance. You can give focus to the window by clicking the mouse into it. Press the **Esc** key to access the Linux grub boot menu. For example:

```
GNU GRUB version 2.04

*Ubuntu
Advanced options for Ubuntu
```

2. Press **e** and navigate using arrow keys to the line starting with **linux** to append **systemd.unit=rescue.target**

```
GNU GRUB version 2.04
.
.
.
```

```
insmod part_gpt
insmod ext2
if [ x$feature_platform_search_hint = xy ];  then
   search --no-floppy --fs-uuid --set=root e46da1b8-55ao-4df9-842e-\
     8d80c3a22ffc
else
   search --no-floppy --fs-uuid --set=root e46da1b8-55ao-4df9-842e-8\
     d80c3a22ffc
fi
linux      /boot/vmlinuz-5.4.0-84-generic root=LABEL=cloudimg-roo\

   =rescue.target
initrd     /boot/initrd.img-5.4.0-84-generic
```

3. Press **Ctrl+x** to boot.
4. Press **Enter** to enter maintenance mode. Run the commands:

   ```
   rm -f /etc/cloud/cloud-init.disabled
   ```

   and

   ```
   echo -n "iso-required" > /usr/local/lib/appliance-config/boot-mode
   ```

   ```

   Press Enter for maintenance:
   (or press Ctrl-D to continue):
   root#ip-192-168-122-241:~# rm -f /etc/cloud/cloud-init.disabled
   root#ip-192-168-122-241:~# echo -n "iso-required" > /usr/local/lib/appliance-config/boot-mode
   root#ip-192-168-122-241:~#
   ```

5. Reboot the appliance with correct configuration ISO attached.

Running commands at boot with `iso-ignored` boot mode

When **iso-ignored** boot mode is configured, complete the following steps on each appliance that should run commands at boot.

About this task

If you configured the appliance to boot in **iso-ignored** mode as documented in Appliance boot mode configuration, the **bootcmd** lines will be ignored. For each appliance node that should run commands at boot, complete the following steps.

Procedure

1. SSH into the appliance as root.
2. Create the /usr/local/bin/appliance-boot-commands.sh script to be executed at boot; for example:

   ```
   cat << EOF > /usr/local/bin/appliance-boot-commands.sh
   #!/bin/bash

   ip route add 172.27.218.0/24 via 192.168.122.1 dev eth0
   ip route add 172.26.203.0/24 via 192.168.122.1 dev eth0
   EOF
   ```

   This step takes the same example, and essentially achieves the same result, as the procedure in Adding a static route on a virtual machine.

3. Make the script executable by running the following command:

   ```
   chmod +x /usr/local/bin/appliance-boot-commands.sh
   ```

4. Create the following systemd service file /lib/systemd/system/appliance-boot-commands.service:

   ```
   cat << EOF > /lib/systemd/system/appliance-boot-commands.service
   [Unit]
   After=network-online.target

   [Service]
   Type=oneshot
   ExecStart=/usr/local/bin/appliance-boot-commands.sh
   RemainAfterExit=false
   StandardOutput=journal

   [Install]
   ```

```
WantedBy=multi-user.target
EOF
```

5. Enable the systemd service by running the following command:

   ```
   systemctl enable appliance-boot-commands
   ```

   Upon subsequent boots, the **/usr/local/bin/appliance-boot-command.sh** script will be executed.

Changing deployment profiles on VMware

You can change an API Connect installation to use a different deployment profile.

For information on the available deployment profiles, see Planning your deployment topology and profiles. The steps for changing deployment profile after installation depend on whether you want to change to a profile that has a different number of VMs and whether additional CPU and memory resources are required for the profile you move to.
Note: The procedures to change deployment profile that are described in this topic do not permit the endpoints to be changed. The API Connect endpoints are listed here: Deployment overview for endpoints and certificates. If you want to change a one replica deployment to a three replica deployment, and you used your VM hostnames in your endpoints, then you must configure load-balancers and logical DNS records so that your original VM hostnames route to your new VMs. Alternatively, you can change endpoints by following the form factor migration procedure: Migrating from v10 to v10 on a different form factor.

Moving to a profile that has the same number of VMs

If you are moving to a profile that requires greater CPU and memory resources, follow these steps:

1. Complete the disaster recovery preparation steps for your subsystems: Preparing for a disaster.
2. Shutdown your API Connect VMs.
3. Update the CPU and memory resources for your API Connect VMs in your VMware console, as required for your new profile.
4. Restart your VMs.
5. In your project directory, update your deployment profile:

   ```
   apicup subsys set <subsystem_name> deployment-profile=<new profile>
   ```

6. Apply the new profile:

   ```
   apicup subsys install <subsystem_name>
   ```

If you are moving to a profile that requires lower CPU and memory resources, follow these steps:

1. Complete the disaster recovery preparation steps for your subsystems: Preparing for a disaster.
2. In your project directory, update your deployment profile:

   ```
   apicup subsys set <subsystem_name> deployment-profile=<new profile>
   ```

3. Apply the new profile:

   ```
   apicup subsys install <subsystem_name>
   ```

4. Shutdown your API Connect VMs.
5. Update the CPU and memory resources for your API Connect VMs in your VMware console, as required for your new profile.
6. Restart your VMs.

If for any reason you are not able to change the CPU or memory on your VMs, redeploy them following the disaster recovery process: Recovering from a disaster.

Moving from a one replica to a three replica deployment profile

1. Complete the disaster recovery preparation steps for your subsystems: Preparing for a disaster.
   Note: You do not need to take VMware snapshots, since your existing VMs are deleted and replaced when you change deployment profile.
2. In your project directory, update your deployment profile:

   ```
   apicup subsys set <subsystem_name> deployment-profile=<three replica profile>
   ```

3. Define the hostname and network interfaces for the two new VMs in each of your subsystems. Use the `apicup hosts create` and `apicup iface create` commands. For more information, see the hosts and interface create steps in the installation instructions for each subsystem:
   - Configuring the Management subsystem.
   - Configuring the Analytics subsystem.
   - Configuring the Developer Portal subsystem.
4. Shutdown your existing API Connect VMs.
   Note: To minimize downtime, you can delay shutting down your existing deployment until you are about to deploy their replacement VMs in the next step.
5. Follow the disaster recovery steps for each subsystem: Recovering from a disaster, but note that you must create new ISO files. Do not attempt to reuse the previous ISO file for one of the VMs in your new three replica deployment.

Moving from a three replica to a one replica deployment profile

1. Complete the disaster recovery preparation steps for your subsystems: Preparing for a disaster.
   Note: You do not need to take VMware snapshots, since your existing VMs are deleted and replaced when you change deployment profile.
2. In your project directory, update your deployment profile:

   ```
   apicup subsys set <subsystem_name> deployment-profile=<one replica profile>
   ```

3. Delete two of your three VMs from your configuration with the **apicup hosts delete** command.
4. Shutdown your existing API Connect VMs.
   Note: To minimize downtime, you can delay shutting down your existing deployment until you are about to deploy their replacement VMs in the next step.
5. Follow the disaster recovery steps for each subsystem: Recovering from a disaster, but note that you must create new ISO files. Do not attempt to reuse any previous ISO files for your new one replica deployment.

Changing the DNS server configuration on appliances

Complete this task only if you must change the DNS addresses after the initial boot of the VM.

Before you begin

Verify that you have VMware console access to the VM, as well as the correct password. If you cannot **ssh** into the appliance, you can use the VMware console interactive login instead (use the **apicadm** login and the password configured as **default-password** in the **apicup** project).

About this task

This task is only valid for making changes to DNS resolution. The IP address of the VM cannot be changed at any time after the initial boot.

Procedure

1. Edit the /etc/netplan/50-cloud-init.yaml file and update the list of nameserver addresses.
   Attention: Typically, you do not edit this file manually. You should only make direct changes to the /etc/netplan/50-cloud-init.yaml file when you need to update the nameserver addresses.
   The following example shows what the list of nameserver addresses looks like in the file:

```
network:
    ethernets:
        eth0:
            addresses:
            - 192.168.122.242/24
            nameservers:
                addresses:
                - 1.1.1.1
                - 1.0.0.1
                - 8.8.8.8
                search:
                - nip.io
            routes:
            -   metric: 10
                to: 0.0.0.0/0
                via: 192.168.122.1
    version: 2
```

2. Run the following command to apply the changes:

```
sudo netplan apply
```

3. Run the following command to verify the changes:

```
cat /run/systemd/resolve/resolv.conf
```

4. Attach an updated ISO to the VM to ensure all artifacts are up-to-date in case a disaster recovery is needed.
   a. Update the **apicup** project configuration with the correct DNS values.
   b. Generate a new ISO based on the updated project.
   c. Attach the new ISO to the VM.

Configuring API Connect subsystems in a cluster

This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.

Before you begin

To create a cluster of hosts for each API Connect subsystem, use **apicup** to create a subsystem with all the required parameters, and to add as many hosts as needed to the configuration file. The configuration file is a .yml file in the project directory.

For each host of a subsystem added in the .yml file, a separate ISO file is created for the cluster member VM. Note that the ISO files for each VM must stay attached during the whole lifetime of the VM.

In an API Connect cluster in a VMware environment, the first three nodes are master nodes. Additional nodes are worker nodes.

Note: To add a new host to an existing cluster, you can create the host, regenerate the ISO and attach it to the new virtual machine, and it will automatically join the cluster.
To use these instructions, you should first review:

- Requirements for initial deployment on VMware
- Load balancer configuration in a VMware deployment
- Deployment overview for endpoints and certificates
- Firewall requirements on VMware
- Firewall enabled ports for clustered OVA deployments
- Important: For best performance it is recommended that the network latency between any 2 nodes be as low as possible. Do not configure nodes from the same subsystem cluster across multiple data centers with a high latency network. A high latency network is one that experiences more than 30ms latency between nodes.

About this task

This page presents a concise step-by-step flow, with sample commands, for the configuration of each subsystem. As you step through the flow, you might want to refer back to the detailed configuration steps for each subsystem. The detailed instructions provide additional considerations for each step, and include optional configuration tasks for backups, logging, message queues (analytics), and password hashing. Each of the subsystem pages describe how to use the VMware console to deploy the ISOs that you create here.

Detailed configuration steps:

- Deploying the Management virtual appliance
- Deploying the Analytics virtual appliance
- Deploying the Developer Portal virtual appliance

The example commands uses the following values for DNS server, internet gateway, host names and IP addresses:

Component	Host names and IP addresses
DNS Name Server	`IP: 192.168.1.1`
Internet gateway	`IP: 192.168.1.2`
Manager on VM1	`Hostname: manager1.sample.example.com` `IP: 192.168.1.101`
Manager on VM2	`Hostname: manager2.sample.example.com` `IP: 192.168.1.102`
Manager on VM3	`Hostname: manager3.sample.example.com` `IP: 192.168.1.103`
Analytics on VM4	`Hostname: analytics1.sample.example.com` `IP: 192.168.1.104`
Analytics on VM5	`Hostname: analytics2.sample.example.com` `IP: 192.168.1.105`
Analytics on VM6	`Hostname: analytics3.sample.example.com` `IP: 192.168.1.106`
Developer Portal on VM7	`Hostname: portal1.sample.example.com` `IP: 192.168.1.107`
Developer Portal on VM8	`Hostname: portal2.sample.example.com` `IP: 192.168.1.108`
Developer Portal on VM9	`Hostname: portal3.sample.example.com` `IP: 192.168.1.109`

Procedure

1. Create the Management subsystems
   a. Create the Management subsystem.

      ```
      apicup subsys create mgmt management
      ```

   b. Set deployment-profile to **`n3xc4.m16`**.

      ```
      apicup subsys set mgmt deployment-profile=n3xc4.m16
      ```

      If you omit this step, the deployment-profile defaults to **`n1xc4.16`**, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

   c. Specify the license version you purchased.
      `apicup subsys set` ***`mgmt`***
      `license-use=<`*`license_type`*`>`

      The *license_type* must be either **`production`** or **`nonproduction`**. If not specified, the default value is **`nonproduction`**.

   d. Set management endpoints
      Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
Management REST API URL	`apicup subsys set mgmt platform-api platform-api.sample.example.com`
Consumer (Portal) REST API URL	`apicup subsys set mgmt consumer-api consumer-api.sample.example.com`
Cloud Manager UI	`apicup subsys set mgmt cloud-admin-ui cloud-admin-ui.sample.example.com`
API Manager UI	`apicup subsys set mgmt api-manager-ui api-manager-ui.sample.example.com`

   e. Set the search domain for the VM.

      ```
      apicup subsys set mgmt search-domain sample.example.com
      ```

   f. Set the DNS Name Server for the VM to look up endpoints.

      ```
      apicup subsys set mgmt dns-servers 192.168.1.1
      ```

   g. Set a Public Keyfile.

This is the public key of the user account that you want to use to **ssh** from, to the appliance.

```
apicup subsys set mgmt ssh-keyfiles "id_rsa.pub"
```

h. Create the hosts for the subsystem.
You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the previous example with a strong password that meets your security requirements.

```
apicup hosts create mgmt manager1.sample.example.com password123
apicup hosts create mgmt manager2.sample.example.com password123
apicup hosts create mgmt manager3.sample.example.com password123
```

i. Set the network interface. Note that the last parameter is the Internet Gateway.

```
apicup iface create mgmt manager1.sample.example.com eth0 192.168.1.101/255.255.255.0 192.168.1.2
apicup iface create mgmt manager2.sample.example.com eth0 192.168.1.102/255.255.255.0 192.168.1.2
apicup iface create mgmt manager3.sample.example.com eth0 192.168.1.103/255.255.255.0 192.168.1.2
```

j. Set the network traffic interfaces.

```
apicup subsys set mgmt traffic-iface eth0
apicup subsys set mgmt public-iface eth0
```

k. Verify the host configuration.

```
apicup hosts list mgmt
```

Note: This command might return the following messages, which you can ignore:

```
* host is missing traffic interface
* host is missing public interface
```

l. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

```
apicup subsys set mgmt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.

m. Validate the installation.

```
apicup subsys get mgmt --validate
```

n. Create an ISO file in a plan folder. For example, **mgmtplan-out**.

```
apicup subsys install mgmt --out mgmtplan-out
```

If you have multiple nodes listed for the hosts, when you run the **--out** command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

o. To deploy the management ISOs on VMware, see Deploying the Management subsystem OVA file.

2. Create the analytics subsystems
   a. Create the subsystem:

```
apicup subsys create analyt analytics
```

   b. Set deployment-profile to **n3xc4.m16**.

```
apicup subsys set analyt deployment-profile=n3xc4.m16
```

   If you omit this step, the deployment-profile defaults to **n1xc2.16**, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

   c. Specify the license version you purchased.
   apicup subsys set *analyt*
   license-use=<*license_type*>

   The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

   d. Set analytics ingestion endpoint
   Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following value points to a sample load balancer URL.

Component	Command
analytics-ingestion	`apicup subsys set analyt analytics-ingestion=analytics-ingestion.sample.example.com`

   e. Set the search domain for the VM.

```
apicup subsys set analyt search-domain sample.example.com
```

   f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set analyt dns-servers 192.168.1.1
```

   g. Set a Public Keyfile.
   This is the public key of the user account that you want to use to **ssh** from, to the appliance

```
apicup subsys set analyt ssh-keyfiles "id_rsa.pub"
```

   h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

```
apicup subsys set analyt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.

i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the following password with a strong password that meets your security requirements.

```
apicup hosts create analyt analytics1.sample.example.com password123
apicup hosts create analyt analytics2.sample.example.com password123
apicup hosts create analyt analytics3.sample.example.com password123
```

j. Set the network interface.
Note that the last parameter is the Internet Gateway.

```
apicup iface create analyt analytics1.sample.example.com eth0 192.168.1.104/255.255.255.0 192.168.1.2
apicup iface create analyt analytics2.sample.example.com eth0 192.168.1.105/255.255.255.0 192.168.1.2
apicup iface create analyt analytics3.sample.example.com eth0 192.168.1.106/255.255.255.0 192.168.1.2
```

k. Check the host configuration for problems.

```
apicup hosts list analyt
```

l. Validate the installation.

```
apicup subsys get analyt --validate
```

m. Create an ISO file in a plan folder. For example, `analytplan-out`.

```
apicup subsys install analyt --out analytplan-out
```

If you have multiple nodes listed for the hosts, when you run the `--out` command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

n. To deploy the ISOs, see Deploying the Analytics subsystem OVA file.

3. Create the portal subsystems

a. Create the portal.

```
apicup subsys create port portal
```

b. For three replica environments, set deployment-profile to `n3xc4.m8`.

```
apicup subsys set port deployment-profile=n3xc4.m8
```

If you omit this step, the deployment-profile defaults to `n1xc4.m8`, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

c. Specify the license version you purchased.

```
apicup subsys set port
license-use=<license_type>
```

The *license_type* must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

d. Set the portal endpoints.
Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
portal-admin	`apicup subsys set port portal-admin=portal-admin.sample.example.com`
portal-www	`apicup subsys set port portal-www=portal-www.sample.example.com`

e. Set the search domain for the VM.

```
apicup subsys set port search-domain sample.example.com
```

f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set port dns-servers 192.168.1.1
```

g. Set a Public Keyfile.
This is the public key of the user account that you want to use to **ssh** from, to the appliance

```
apicup subsys set port ssh-keyfiles "id_rsa.pub"
```

h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use `apicup` to set the hashed password for your subsystem:

```
apicup subsys set port default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.

i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses.

```
apicup hosts create port portal1.sample.example.com password123
apicup hosts create port portal2.sample.example.com password123
apicup hosts create port portal3.sample.example.com password123
```

Replace the example password in the previous example with a strong password that meets your security requirements.

j. Set the network interface.
Note that the last parameter is the Internet Gateway.

```
apicup iface create port portal1.sample.example.com eth0 192.168.1.107/255.255.255.0 192.168.1.2
apicup iface create port portal2.sample.example.com eth0 192.168.1.108/255.255.255.0 192.168.1.2
apicup iface create port portal3.sample.example.com eth0 192.168.1.109/255.255.255.0 192.168.1.2
```

k. Check the host configuration for problems.

```
apicup hosts list port
```

l. Validate the installation.

```
apicup subsys get port --validate
```

m. Create an ISO file in a plan folder. For example, `portplan-out`.

```
apicup subsys install port --out portplan-out
```

If you have multiple nodes listed for the hosts, when you run the `--out` command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

n. To deploy the ISOs, see Deploying the Developer Portal subsystem OVA file.

Configuring SSHD to limit access to your deployment

How to configure SSHD in order to limit host access to your VMware deployment.

About this task

The following example shows how to configure SSHD in order to limit VMware access to a certain set of IP addresses.

Attention:

- SSHD configuration settings are not included in the IBM® API Connect backups. However, the settings are kept when you upgrade to a new fix pack.
- If you change the SSHD cipher level, and encounter issues with the new configuration, you must revert your cipher changes and retest. If after the retest you still have issues, contact IBM Support.

Procedure

1. Log in to the target virtual machine by using an SSH tool, and switch to the root user. For example, to log in to the Management subsystem, run the following commands:

   ```
   ssh ip_address -l apicadm
   sudo -i
   ```

2. Move to the following folder:

   ```
   /etc/ssh/sshd_config.d
   ```

3. Create a new configuration file with the extension .conf that contains the IP address of the host that you want to allow to access your deployment. For example, to create the file run the following command:

   ```
   vi filename.conf
   ```

   Then, edit the file by using the following format, which in this example is allowing users from IP address `123.135.1.2`:

   ```
   AllowUsers *@123.135.1.2
   ```

   Additional hosts can be added by separating the IP address patterns with a space. For example:

   ```
   AllowUsers *@123.135.1.2 *@135.168.1.2
   ```

4. Restart the SSHD service by running the following command:

   ```
   systemctl restart sshd.service
   ```

Results

Access to your VMware is now limited to a certain set of IP addresses.

What to do next

If you want to remove a cipher from your SSHD configuration, you can edit the /etc/ssh/sshd_config file. For example, if your security department decides that you must stop using the 128 bit UMAC cipher, you can remove it from your supported ciphers list by editing the `/etc/ssh/sshd_config` file and changing the following line from:

```
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
```

to:

```
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,hmac-sha2-512,hmac-sha2-256
```

Then restart the SSHD service by running the following command:

```
systemctl restart sshd.service
```

Enabling Developer Portal feature flags on VMware

Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.

About this task

You can add a template override to the Developer Portal subsystem CR to change the default behavior of the Portal subsystem, or to turn specific features on and off. Table 1 describes the available feature flags.

Table 1. List of available feature flags for the Developer Portal

Feature flag name	Default Value	Pod	Container	Description
`PORTAL_SKIP_WEB_ENDPOINT_VALIDATION`	`true`	`www`	`admin`	Controls whether the Portal subsystem checks whether the Portal web endpoint is accessible. Sometimes, the endpoint cannot be reached, for example due to the complexity of the networks. In which case the following type of error can be seen in the `portal-www` pod, and `admin` container logs: `An error occurred contacting the provided portal web endpoint: example.com` `The provided Portal web endpoint example.com returned HTTP status code 504` You can disable the check by setting this flag to `false`.
`ENABLE_TRUSTED_REVERSE_PROXY`	`false`	`www`	`admin`	Controls whether the Drupal `trusted_reverse_proxy` module can manage the reverse proxies list. If you have multiple load balancers and reverse proxies in your upstream network, and the perimeter module is triggered, the incorrect IP address might be banned rather than the intended client IP address. However, you can manage which IP addresses are banned by using the Drupal `trusted_reverse_proxy` module, and setting this feature flag to `true`. The Drupal module inspects the `x-forwarded-for` headers to identify the reverse proxies, and trusts that the first IP address found in the list is the client IP. For example, in `X-Forwarded-For: <client>, <proxy1>, <proxy2>`, the client IP `<client>` will be banned. For more information about this module, see https://www.drupal.org/project/trusted_reverse_proxy. To use this module, you must ensure that all of the proxies in your upstream network, including the ingress controller, are configured correctly so that the `x-forwarded-for` header is passed through to the `portal-www` pod. For example, the default behavior of the `nginx-ingress-controller` is to ignore the inbound `x-forwarded-for` header, and create a new one. To change this behavior, update the `nginx-ingress-controller` `configmap` with the following information: `data:` `  compute-full-forwarded-for: "true"` `  use-forwarded-headers: "true"` Warning: Enable this feature flag only if you trust your upstream reverse proxies, as it is possible to trick the `x-forwarded-for` header.

Procedure

1. Create an `extra-values.yaml` file, or open an existing `extra-values.yaml` file.
2. In the file, append the feature flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the `trusted_reverse_proxy` feature on all possible UI pages.

   ```
   spec:
     template:
     - containers:
       - env:
           - name: ENABLE_TRUSTED_REVERSE_PROXY
             value: true
         name: container
       name: pod
   ```

   Where:
   - *`container`* `is the name of the portal container.`
   - *`pod`* `is the name of the portal pod.`

   Note: You can add multiple feature flags to the file.
3. Save the file.
4. Run the following command to set the `extra-values.yaml` file:

   ```
   apicup subsys set <portal_subsystem> extra-values-file <path_to_portal_extra-values.yaml_file>
   ```

5. Apply the overrides to the portal subsystem by running the following command:

   ```
   apicup subsys install <SUBSYSTEM_NAME>
   ```

   The Developer Portal subsystem is updated to enable or disable features as specified.

Managing an appliance data disk

You can use **apic** commands to manage appliance data disks in your VMware deployment.

The API Connect deployment on VMware uses 2 partitions. The first contains the base operating system, while the second is encrypted so that any customer data that is stored on disk uses the encrypted volume. Encryption is done with Linux Unified Key Setup (LUKS) disk encryption.

During installation of each API Connect subsystem, you specify a password **HD-PASSWD** when configuring the host:

```
apicup hosts create <SUBSYS> <HOSTNAME> <HD-PASSWD>
```

If you want to force a restart of processes, without requiring a full restart of the virtual machine, you can use the command **apic lock** to stop the Kubernetes node on the virtual machine and lock the secured storage. When you are ready to restart processes, you can use **apic unlock** to restart the Kubernetes node. The command **apic**
unlock uses the password to unlock the partition so that files can be read from it and written to it. The unlock command also starts the **apic** daemon, also known as the **appliance-manager** service.

You can check that status of this service with:

```
sudo systemctl status appliance-manager
```

One **appliance-manager** daemon runs on each node, where it manages the Kubernetes cluster, processes update and upgrade requests, and gathers logs.

apic command	Description
lock	Shut down appliance services and lock the secured storage
logs	Retrieve logs from all nodes in the cluster
status	Report on cluster status
unlock	Unlock the secure storage and start the appliance
version	Get the API Connect appliance base version

Replica override for microservices on VMware

Modify the replica count for microservices by using template overrides for Custom Resources.

When API Connect is deployed, the deployment profile you select drives the number of replicas to be used for most deployment. For one replica profiles, specified by**n1x...**, the replica count is 1. For three replica profiles, specified by **n3x...**, the replica count is 3.

You can override the replica count for individual deployments by using template overrides.

- Template overrides are a piece of yaml that should be added to the Kubernetes custom resource. The examples provided in this topic show only that the **template:** element should be under the main **spec:** element of a CR. The rest of the CR is not shown.
- When applying overrides for Appliance deployments (virtual machines), the yaml sample provided as example must be added in an extra-values-file for the subsystem. To view an example of documenting a template override for an Appliance, see Setting rate limits for public APIs on the management service

Management subsystem

For a Management CR in Kubernetes or OpenShift, the following override specifies 5 replicas for the **apim** deployment:

```
spec:
  template:
  - name: apim
    replicaCount: 5
```

You can also configure replicate count through a similar template override for:

- **juhu**
- **ldap**
- **lur**

Analytics subsystem

The Analytics microservices that can be scaled using template override are:

- **ingestion**
- **mtls-gw**
- **storage-shared**
  Note that this microservice cannot be scaled below 2 replicas when using a three replica deployment profile.

Testing a new configuration against a current cluster

You can use the **apicup** utility to test the validity of a new configuration before you install it.

The **apicup** utility is used to set configuration properties for subsystems on API Connect on VMware appliances. The utility can be used for installation, upgrade, and maintenance activities such as backup and restore.

The usage pattern is to set values for each parameter you need for a subsystem, and then deploy the new values with the **apicup subsys install** command.

You can use the **--dry-run** option to test the validity of your values prior to deploying them to an existing cluster:

```
apicup subsys install <subsystem_name> --dry-run
```

Important: You cannot use `apicup subsys install <SUBSYS> --dry-run` for a fresh install or an upgrade. The `--dry-run` feature is for testing proposed configuration changes on an existing cluster.
For example, if you want to configure S3 backups for you management subsystem, the command flow is:

1. Follow the instructions for configuring S3 backupsReconfiguring backup settings for the management subsystem by issuing the required `apicup subsys set` commands:

   ```
   apicup subsys set mgmt <setting>=<value>
   apicup subsys set mgmt <second_setting>=<value>
   apicup subsys set mgmt <third_setting>=<value>
   .
   .
   .
   ```

2. Do a dry run of the install command:

   ```
   apicup subsys install mgmt --dry-run
   ```

   Example message on success:

   ```
   managementcluster.management.apiconnect.ibm.com/management configured (server dry run)
   ```

   Example message on failure:

   ```
   Error: Failed to execute dry-run:....
   ```

   The error message also contains details about the error.

3. When dry run returns success, deploy:

   ```
   apicup subsys install mgmt
   ```

Use JWT security instead of mTLS between subsystems

If your network requires TLS termination on load-balancers located between your API Connect subsystems, then disable mTLS and enable JWT to provide application layer security.

JWT security provides application layer security and can be used instead of mTLS when there are load-balancers located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.

1. To enable JWT and disable mTLS, first identify the JWKS URL from the management subsystem:

   ```
   apicup subsys get <management subsystem>

   ...
   jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
   validate JWT -- this is unsettable and is generated based on the platform-api endpoint
   ...
   ```

2. Disable mTLS and enable JWT on portal and analytics by setting the `mtls-validate-client` and `jwks-url` values with **apicup**:

   ```
   apicup subsys set <portal> mtls-validate-client=false
   apicup subsys set <portal> jwks-url=appliance1.apic.acme.com/api/cloud/oauth2/certs

   apicup subsys set <analytics> mtls-validate-client=false
   apicup subsys set <analytics> jwks-url=appliance1.apic.acme.com/api/cloud/oauth2/certs
   ```

3. Apply the change to portal and analytics with `apicup subsys install`:

   ```
   apicup subsys install <subsystem_name>
   ```

4. To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the DataPower documentation.

Note: Do not disable mTLS without enabling JWT.

Advanced configuration for management subsystem

Specify advanced configuration for the management subsystem.

Note: VMware deployments include subsystem settings that cannot be reconfigured without a complete deployment. For example, for the Management Service these settings include hosts, endpoints, interfaces (`public-iface`, `traffic-iface`), IP ranges of the Kubernetes pod and the service networks (`k8s-pod-network`, `k8s-service-network`). Before reconfiguring, review the installation instructions for your subsystem to determine which settings are optional during initial installation and thus able to be updated later.
See:

- **Setting rate limits for public APIs on the management service**
  Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.
- **Configuring maximum size of client requests to the Management subsystem on VMware**
  You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.
- **Enabling API governance on VMware**
  You can optionally configure API governance in API Connect on VMware by enabling the governance microservice.

- **Configuring monetization on VMware**
  You can optionally configure monetization in API Connect on a VMware virtual machine by enabling the billing microservice.
- **Configuring use of an external NTP server**
  You can optionally configure an external NTP server for use by API Connect when deploying on a VMware virtual machine.
- **Overriding resources for Postgres components on VMware**
  In 10.0.4.0 and greater, you can optionally override the CPU and Memory resources used by postgres database components.
- **Enabling UI feature flags on VMware**
  Use a template override to update the installation CR with settings that control UI features.

Setting rate limits for public APIs on the management service

Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.

Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software may change and this information may become outdated.
These instructions assume you have the kubectl command-line tool installed. For more information, see https://kubernetes.io.

About this task

Rate limits can be set for public APIs on the management service. Rate limits on APIs help provide protection from DDoS (distributed denial of service) attacks. Without a rate limit, API calls from public APIs are unlimited.

The rate limit configuration requires that the header contains the actual client IP address. Any load balancer or proxy (for example, HAProxy) that is installed in front of the management service must be configured to pass the actual client IP address.

This procedure must be performed on a running API Connect deployment.

Rate limits are calculated as requests per seconds per client.

Note: If the rate limit has been reached on the management subsystem, the client will get an HTTP error: **`429 Too Many Requests`**.

Procedure

- Set a rate limit:
  1. Add the following entries to the extra-values-file:

     ```
     spec:
       template:
       - name: juhu
         containers:
         - name: juhu
           env:
           - name: RATE_LIMIT_PER_CLIENT
             value: "10"
           - name: LIMIT_REQUEST_OPTION
             value: "burst=10 nodelay"
     ```

     In this example, the first option sets the rate to 10 requests per second (10r/s). The second option allows 10 requests boosted without delay within < 1 second. You can customize as needed.

     The **`rateLimitPerClient`** property sets **`rate`**, and **`limitRequestOption`** sets **`[burst=number] [nodelay | delay=number]`** in the following nginx configuration:

     ```
     limit_req_zone key zone=name:size rate=rate;
     limit_req zone=name [burst=number] [nodelay | delay=number];
     ```

     Note that **`zone`** has been pre-defined and can't be configured. For more details, see the nginx doc http://nginx.org/en/docs/http/ngx_http_limit_req_module.html.

  2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
  3. Use **`apicup`** to update the VMware **`extra-values-file`** attribute to point to the new or updated management subsystem extra-values file:

     ```
     apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
     ```

     Where:
     - *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.
     - *<extra_values_file_path_and_name>* is the fully qualified path and name of your extra-values file.

     For example:

     ```
     apicup subsys set ds10-management extra-values-file /workspace/v10012/my_extra_values.yaml
     ```

  4. Verify that the configuration settings are valid in the apiconect-up-v10.yaml by running the following command:

     ```
     apicup subsys get <mgmt_subsystem_name> --validate
     ```

     The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
  5. Run **`apicup`** to update the settings in the deployed Management subsystem.

     ```
     apicup subsys install <management-subsystem>
     ```

6. Enter the following command to connect to the management subsystem using SSH:

   ```
   ssh ip_address -l apicadm
   ```

   You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

7. Select Yes to continue connecting, and once connected:

   ```
   sudo -i
   ```

8. Validate that the juhu pod has restarted by listing the pods:

   ```
   kubectl get pods  grep juhu
   ```

9. Check the AGE column to ensure a new juhu pod has started.
10. If the older juhu pod is still running, delete it with the following command:

    ```
    kubectl delete pods <old-juhu-pod>
    ```

- Disable a rate limit:
  1. Remove the values from the extra-values-file.
  2. Run `apicup` to update the settings in the deployed Management subsystem.

     ```
     apicup subsys install <management-subsystem>
     ```

  3. Enter the following command to connect to the management subsystem using SSH:

     ```
     ssh ip_address -l apicadm
     ```

     You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

  4. Select Yes to continue connecting, and once connected:

     ```
     sudo -i
     ```

  5. Validate that the juhu pod has restarted by listing the pods:

     ```
     kubectl get pods  grep juhu
     ```

  6. Check the AGE column to ensure a new juhu pod has started.
  7. If the older juhu pod is still running, delete it with the following command:

     ```
     kubectl delete pods <old-juhu-pod>
     ```

Configuring maximum size of client requests to the Management subsystem on VMware

You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.

About this task

The default maximum size is 8 megabytes. You can increase this value.

Increasing the setting can be useful if you get errors when using the CLI to import a large API. Example error:

```
HTTP/1.1 413 Request Entity Too Large
```

Note:

- These instructions apply only to VMware installations. For Kubernetes installations, see Configuring maximum size of client requests to the Management subsystem.
- These instructions use an extra-values file. This file can be used to define CR overrides. Note that extra-values files for a CR can contain more than one override. If you already use an extra-values file, you can add the new override to it.
- All of the commands must be run in the `apicup` management project directory.

Procedure

1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

   ```
   spec:
     template:
     - name: juhu
       containers:
       - name: juhu
         env:
         - name: CLIENT_MAX_BODY_SIZE
           value: "12m"
   ```

2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
3. Use `apicup` to update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file:

   ```
   apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
   ```

   Where:

- *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.
- *<extra_values_file_path_and_name>* is the fully qualified path and name of your extra-values file.

For example:

```
apicup subsys set ds10-management extra-values-file /workspace/v10011/my_extra_values.yaml
```

4. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

   ```
   apicup subsys get <mgmt_subsystem_name> --validate
   ```

   The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
5. Update the management VMware with the updated setting.

   ```
   apicup subsys install <mgmt_subsystem_name>
   ```

6. Monitor the health-check output until the management subsystem is healthy by running the following command:

   ```
   apicup subsys health-check <mgmt_subsystem_name>
   ```

   If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

   ```
   Error: Cluster not in good health:
    ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
    ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
   ```

   When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.

Enabling API governance on VMware

You can optionally configure API governance in API Connect on VMware by enabling the governance microservice.

About this task

API governance is an optional add-on to IBM® API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process.

Note:

- These instructions apply only to VMware installations. For Kubernetes, OpenShift, and IBM Cloud Pak for Integration installations, see Enabling API governance on Kubernetes.
- API governance rulesets cannot be added to your deployment until the governance microservice is enabled.
- All of the commands must be run in the `apicup` management project directory.

To enable or disable the governance microservice, you must configure a management subsystem extra-values file. See the following instructions:

- **Enabling the governance microservice**
- **Disabling the governance microservice**

After the governance microservice is enabled, API governance resources can be created. For more information, see Configuring API governance in the Cloud Manager, and Configuring API governance in the API Manager.

Procedure

- **Enabling the governance microservice**
  1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

     ```
     spec:
       governance:
         enabled: true
     ```

  2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
  3. Update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file.
     Run the following `apicup` command to insert the location of the extra-values file:

     ```
     apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
     ```

     Where:
     - *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.
     - *<extra_values_file_path_and_name>* is the fully qualified path and name of your extra-values file.

     For example:

     ```
     apicup subsys set ds10-management extra-values-file /workspace/v10060/governance.yaml
     ```

  4. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

     ```
     apicup subsys get <mgmt_subsystem_name> --validate
     ```

     The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
  5. Update the management VMware with the updated governance value.
     Install the new setting for the governance microservice by running the following command:

```
apicup subsys install <mgmt_subsystem_name> --debug
```

Including the `--debug` option enables the debug output for the command.

6. Monitor the health-check output until the management subsystem is healthy by running the following command:

```
apicup subsys health-check <mgmt_subsystem_name>
```

If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

```
Error: Cluster not in good health:
 ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
 ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.

- **Disabling the governance microservice**
  1. Edit the management subsystem extra-values file in the `apicup` management project directory, and change the `enabled` configuration option to `false`:

```
spec:
  governance:
    enabled: false
```

  2. Save the changed extra-values file.
  3. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

```
apicup subsys get <mgmt_subsystem_name> --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

  4. Update the management VMware with the altered governance value.
Install the updated setting for the governance microservice by running the following command:

```
apicup subsys install <mgmt_subsystem_name> --debug
```

Including the `--debug` option enables the debug output for the command.

  5. Monitor the health-check output until the management subsystem is healthy by running the following command:

```
apicup subsys health-check <mgmt_subsystem_name>
```

If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

```
Error: Cluster not in good health:
 ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
 ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.
The governance microservice is now disabled.

Results

Note that when the governance microservice is enabled, there are a number of new deployments, jobs, and pods in the `ManagementCluster` namespace. These Kubernetes governance resources have names containing either `compliance-service` or `compliance-ui`. For example:

```
kubectl get pods -n apic | grep compliance
management-compliance-service-f6cdf95fc-t4qkx                     1/1     Running     0          127m
management-compliance-ui-59897fcc4-zm25v                          1/1     Running     0          126m
management-up-compliance-service-data-populate-0-to-1-t2f4d       0/1     Completed   1          132m
management-up-compliance-service-schema-0-to-1-2lkqq              0/1     Completed   0
```

Configuring monetization on VMware

You can optionally configure monetization in API Connect on a VMware virtual machine by enabling the billing microservice.

Before you begin

Important: If the optional billing microservice is enabled, you must increase the memory for the API Manager for VMware component by 0.5 GB.

About this task

API Connect includes a subscription billing microservice that allows API providers to define pricing plans in their API Products, and monetize their API offerings. If a Product contains a pricing plan, API Consumers must enter their payment information into the Developer Portal before they can subscribe to that plan. API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

Note:

- These instructions apply only to VMware installations. For Kubernetes installations, see Configuring monetization on Kubernetes.
- To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements on Kubernetes and Firewall requirements on VMware for more information about this requirement.
- Provider organizations cannot add any billing integrations until the billing microservice is enabled.

- After provider organizations have added billing integrations, the billing microservice must not be disabled.
- All of the commands must be run in the `apicup` management project directory.

To enable or disable the billing microservice, you must configure a management subsystem extra-values file. See the following instructions:

- **Enabling the billing microservice**
- **Disabling the billing microservice**

Procedure

- **Enabling the billing microservice**
  1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

     ```
     spec:
       billing:
         enabled: true
     ```

  2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
  3. Update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file.
     Run the following `apicup` command to insert the location of the extra-values file:

     ```
     apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
     ```

     Where:
     - *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.
     - *<extra_values_file_path_and_name>* is the fully qualified path and name of your extra-values file.

     For example:

     ```
     apicup subsys set ds10-management extra-values-file /workspace/v10011/monetization.yaml
     ```

  4. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

     ```
     apicup subsys get <mgmt_subsystem_name> --validate
     ```

     The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
  5. Update the management VMware with the updated billing value.
     Install the new setting for the billing microservice by running the following command:

     ```
     apicup subsys install <mgmt_subsystem_name> --debug
     ```

     Including the `--debug` option enables the debug output for the command.
  6. Monitor the health-check output until the management subsystem is healthy by running the following command:

     ```
     apicup subsys health-check <mgmt_subsystem_name>
     ```

     If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

     ```
     Error: Cluster not in good health:
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
     ```

     When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.
     The billing microservice is now enabled, and provider organization owners can create billing integration resources for API providers in the API Manager UI. For more information, see Monetizing your Products.

- **Disabling the billing microservice**
  Important: After provider organizations have added billing integrations, the billing microservice must not be disabled.
  1. Edit the management subsystem extra-values file in the `apicup` management project directory, and change the `enabled` configuration option to `false`:

     ```
     spec:
       billing:
         enabled: false
     ```

  2. Save the changed extra-values file.
  3. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

     ```
     apicup subsys get <mgmt_subsystem_name> --validate
     ```

     The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
  4. Update the management VMware with the altered billing value.
     Install the updated setting for the billing microservice by running the following command:

     ```
     apicup subsys install <mgmt_subsystem_name> --debug
     ```

     Including the `--debug` option enables the debug output for the command.
  5. Monitor the health-check output until the management subsystem is healthy by running the following command:

     ```
     apicup subsys health-check <mgmt_subsystem_name>
     ```

     If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

     ```
     Error: Cluster not in good health:
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
     ```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.
The billing microservice is now disabled.

Configuring use of an external NTP server

You can optionally configure an external NTP server for use by API Connect when deploying on a VMware virtual machine.

About this task

Secure communication between API Connect subsystems relies on the system time being in sync on all hosts. For example, time stamps are checked to ensure that certificates are valid. When API Connect is deployed behind a firewall that blocks access to the internet, the API Connect subsystems cannot by default access a Network Time Protocol (NTP) server.

You can use an additional cloud-init file to manually specify an NTP server for use by the subsystems. Complete the following steps.

Procedure

1. Create the cloud-init file extra values file, and enter the configuration details that you want to overwrite. For example:

```
ntp:
  enabled: true
  ntp_client: systemd-timesyncd
  servers:
    - time.google.com
```

2. Use `apicup` to specify the cloud-init file.
   Syntax:

```
apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
```

   Example:

```
apicup subsys set mgmt additional-cloud-init-file myCloudInitFile.yaml
```

3. Install the subsystem. Note that the output directory must be empty:

```
apicup subsys install mgmt --out mgmtplan-out
```

4. Deploy the VMware image (.ova) with the ISO file that is generated.
   To review the deployment steps, see Deploying the Management virtual appliance.

5. Verify that the correct NTP server is being used:

```
journalctl -u systemd-timesyncd
```

   Example output for the NTP server that was set in Step 1:

```
Nov 05 21:09:24 h-apicdev-4 systemd[1]: Starting Network Time Synchronization...
Nov 05 21:09:24 h-apicdev-4 systemd[1]: Started Network Time Synchronization.
Nov 05 21:09:24 h-apicdev-4 systemd-timesyncd[1697]: Synchronized to time server 216.239.35.8:123 (time.google.com).
```

Overriding resources for Postgres components on VMware

In 10.0.4.0 and greater, you can optionally override the CPU and Memory resources used by postgres database components.

About this task

There are three postgres components:

- `postgres`
- `pgBouncer`
- `pgBackRest`

The default resources used in `postgrespgBouncer` and `pgBackRest` components are:

Table 1. Postgres component default resources

Resource	Postgres DB	pgBouncer	pgBackRest
Memory Request	512Mi	24Mi	48Mi
Memory Limit	8Gi	128Mi	128Mi
CPU Request	600m	80m	80m
CPU Limit	1500m	200m	200m

Procedure

To override resources, complete the following procedure

1. Create an extra-values yaml file, or add values to an existing extra-values file.
   - Ensure that you specify the name of the container for the resource you want to override. Names:
     - `postgres`
     - `pgBouncer`
     - `pgBackRest`
