20. Create your ISO file.

    ```
    apicup subsys install port --out portplan-out
    ```

    The **--out** parameter and value are required. In this example, the ISO file is created in the myProject/portplan-out directory.

    If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
Ubuntu, Debian, OSX	`export PATH=$PATH:/Users/your_path/`
Windows, Red Hat	`set PATH="c:\Program Files (x86)\cdrtools";%PATH%`

21. Next, use the ISO to deploy the subsystem OVA. Continue with Deploying the Developer Portal subsystem OVA file.

Deploying the Developer Portal subsystem OVA file

After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.

Before you begin

You must have completed the configuration of the project file entries for the Developer Portal subsystem, in Configuring the Developer Portal subsystem.

Procedure

1. Log into the VMWare vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.

a. Select the Portal subsystem .OVA file template by navigating to the location where you downloaded the file in First steps for deploying in a VMware environment.
b. Enter a name and location for your file.
c. Select a resource for your template.
d. Review the details for your template.
e. Select the size of your configuration.
f. Select the storage settings.
Note that the number of Central Processing Units, RAM, and size of disk that you need for the Developer Portal varies depending on the number of sites that are hosted and the number of concurrent users you expect your site to have:

Table 1. Developer Portal hardware requirements

Number of sites	Number of concurrent users	Number of CPUs	Amount of RAM (GB)	Data Disk Size (GB)++
1	1	2**	4	50
20	5	4	16	70
100	20	8	32	100
100	100	16	64	500

Important:
- ++The data disk size is extra to the main disk of the OVA. The main disk of the OVA is sized at 100GB, and should not be changed. Therefore, the total disk size of the OVA is 100GB plus the data disk size. The default data disk size is 200GB. If you want to select a different value, then you need to do this by using the OVF Tool, or the VMware GUI, before you power on the VM. Note that certain versions of the VMware GUI may not allow you to resize the data disk, and in this case you should use the OVF Tool.
- **The requirement of 2 CPUs is suitable only for proof-of-concept work, and non-high availability deployments. For example, this configuration is suitable for the demo mode of the apicup installation, which is set by using the command `apicup subsys set` *`port`* `deployment-profile=n1xc2.m8`.
- It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a Portal site for every Catalog, for example Catalogs that are only for API Developers don't need a Portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services; see Registering a Portal service.

g. Select the networks.
h. Customize the Template, if necessary.
i. Review the details to ensure that they are correct.
j. Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See Requirements for initial deployment on VMware.
The template creation appears in your Recent Tasks list.
5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO file.
a. Select the Navigate to the datastore file browser icon in the icon menu.
b. Select the Upload a file to the Datastore icon in the icon menu.
c. Navigate to the ISO file that you created in your project.
It is the myProject/*port*plan-out
d. Upload the ISO file to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....
a. On the Virtual Hardware tab, select CD/DVD Drive 1.
b. For the Client Device, select Datastore ISO File.
c. Find and select your datastore in the Datastores category.
d. Find and select your ISO file in the Contents category.
e. Select OK to commit your selection and exit the Select File window.
f. Ensure that the Connect At Power On check box is selected.
Tip:
- Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
- Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On

g. Select OK to commit your selection and close the window.
12. Start the virtual machine by selecting the play button on the icon bar.
The installation might take several minutes to complete, depending on the availability of the system and the download speed.
13. Continue with Verifying deployment of the Developer Portal subsystem.

Verifying deployment of the Developer Portal subsystem

Verify that deployment of the Developer Portal OVA file succeeded.

Before you begin

You must have completed Deploying the Developer Portal subsystem OVA file.

About this task

After you configure an ISO and deploy it with the Developer Portal subsystem OVA, as described in Deploying the Developer Portal subsystem OVA file, verify that the subsystem installed correctly and is functional.

Procedure

1. Log in to the virtual machine by using an SSH tool to check the status of the installation:
   a. Enter the following command to connect to *port* using SSH:

      ```
      ssh ip_address -l apicadm
      ```

      You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.
   b. Select Yes to continue connecting.
      Your host names are automatically added to your list of hosts.
   c. Run the **apic status** command to verify that the installation completed and the system is running correctly.
      The command output for a correctly running Developer Portal system is similar to the following lines:

      ```
      $ sudo apic status
      INFO[0000] Log level: info

      Cluster members:
      - testsrv1251.subnet1.example.com (1.2.3.4)
        Type: BOOTSTRAP_MASTER
        Install stage: DONE
        Upgrade stage: NONE
        Docker status:
          Systemd unit: running
        Kubernetes status:
          Systemd unit: running
          Kubelet version: testsrv1251 (4.4.0-137-generic) [Kubelet v1.10.6, Proxy v1.10.6]
        Etcd status: pod etcd-testsrv1251 in namespace kube-system has status Running
        Addons: calico, dns, helm, kube-proxy, metrics-server, nginx-ingress,
      Etcd cluster state:
      - etcd member name: testsrv1251.subnet1.example.com, member id: 10293853252850049269, cluster id:

      Running
      ```

2. Optional: Define multiple Developer Portal endpoints. See Defining multiple portal endpoints for a VMware environment.
3. If you have now installed all subsystems, continue to Post-deployment steps.

   Note:
   When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the **portal-www** pod, admin container logs, if the endpoint cannot be reached:

   ```
   An error occurred contacting the provided portal web endpoint: example.com
   The provided Portal web endpoint example.com returned HTTP status code 504
   ```

   In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully.
   To disable the endpoint check, complete the following update:

   On VMware
   In your **apicup** project, create a file called ptl-extra-values.yaml (or edit the file if one already exists), and add the following section:

   ```
   spec:
     template:
     - containers:
       - env:
         - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
           value: "true"
   ```

```
      name: admin
    name: www
```

Run the following commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>
```

```
apicup subsys install <ptl_subsys>
```

Configuring two NICs on the Developer Portal

Configure the Developer Portal to use two network interface cards.

About this task

When deploying the Developer Portal, you can optionally separate network traffic such that the portal has network interface in your private network, where the communications to the APIM manager take places, and another network interface in your public network, where the end users can access the Portal web sites.

You can do this by using the iface on eth0 for your traffic and defining an extra iface definition (eth1) for your public interface. Do this as part of the initial configuration of the Developer Portal. Note the following requirements:

- iface eth0 and eth1 must have different subnets. This means that you cannot test the configuration by using two IP addresses on the same subnet, due to the routing table produced by the OVA at bootup.
- The hostname of the machine must be reachable via eth0 and you must use eth0 as the traffic (private interface) and eth1 as the public interface.

Procedure

1. Verify that you have created a first interface, by following the instructions in Step 13 of Configuring the Developer Portal subsystem.
2. Use `apicup` to add an extra iface definition as follows for your public interface:

   ```
   apicup iface create test-stack-portal test0094.test.example.com eth1 1.2.3.232/255.255.254.0 1.2.3.1
   ```

3. Set the hostname of your portal-www ingress to the hostname that is associated with the IP address given on `eth1`.

   ```
   apicup subsys set my-portal portal-www portal.myhost0232.company.com
   ```

4. When configuring the second NIC during initial installation, return to Step 14 of Configuring the Developer Portal subsystem. Follow the remaining steps in the configuration instructions, and then create the Portal OVA and deploy it as usual.
   Notes:
   - If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway.
   - Before powering on the Portal, use the VMware GUI to add a second network card to the VM, with the correct settings for your public network.

Specifying a range of allowable client IP addresses for Developer Portal

Specify the range of client IP addresses to be allowed in a deployment of the Developer Portal

About this task

Use an extra-values-file, which serves as a portal CR override, to provide an allowable addresses annotation.

Procedure

In your `apicup` project, create a file called `ptl-extra-values.yaml` with the necessary content. For example:

```
spec:
  portalUIEndpoint:
      annotations:
        ingress.kubernetes.io/whitelist-source-range: 1.2.88.0/24
```

In this example, `1.2.88.0/24` is the acceptable range of client IP addresses.

Note: Depending on your network configuration for the forwarding of client IP addresses, you might need to run several test iterations to work out which client IP addresses to include in the list.

Defining multiple portal endpoints for a VMware environment

Multiple public facing endpoints (`portal-www`) can be defined for the Developer Portal.

About this task

You can override the single endpoint definition for `portal-www`, and the associated `portal-www-ingress` TLS certificate, to support multiple `portal-www` endpoints.

For information about the endpoints for the Developer Portal, see Configuring the Developer Portal subsystem.

The task requires accessing your portal virtual appliance and creating Kubernetes secrets. Two methods are available for creating Kubernetes secrets:

- The recommended method uses a tool that exists on the portal appliance VM called cert-manager. To use the cert-manager method, skip step 5.
- If you do not want to use the cert-manager method, you can create your Kubernetes secrets manually. Follow step 5 instead of steps 3 and 4.

Procedure

Create **portal-www** endpoint certificates with cert-manager.

1. Log in to your portal virtual appliance with an SSH client, as **apicadm** user

   ```
   ssh apicadm@<subsystem hostname>
   ```

2. Switch to the root user: **sudo -i**
3. Create a file called ingress-issuer.yaml and paste in the following content:

   ```
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: ingress-ca
   spec:
     secretName: ingress-ca
     commonName: "ingress-ca"
     usages:
     - digital signature
     - key encipherment
     - cert sign
     isCA: true
     duration: 87600h # 10 years
     renewBefore: 720h # 30 days
     privateKey:
       rotationPolicy: Always
     issuerRef:
       name: selfsigning-issuer
       kind: Issuer
   ---
   apiVersion: cert-manager.io/v1
   kind: Issuer
   metadata:
     name: ingress-issuer
   spec:
     ca:
       secretName: ingress-ca
   ```

   Run **kubectl apply -f ingress-issuer.yaml**.

4. Create cert-manager certificate objects for each **portal-www** endpoint.
   a. Create a file called portal-web-certs.yaml, and paste in a **Certificate** entry for each **portal-www** endpoint. In this example, two endpoints are created, so the example file contains two certificates:

      ```
      apiVersion: cert-manager.io/v1
      kind: Certificate
      metadata:
        labels:
          app.kubernetes.io/instance: portal
          app.kubernetes.io/managed-by: ibm-apiconnect
          app.kubernetes.io/name: web-endpoint
        name: portal-web-host1
        namespace: default
      spec:
        dnsNames:
        - <FQDN of portal web endpoint 1>
        duration: 17520h0m0s
        issuerRef:
          group: cert-manager.io
          kind: Issuer
          name: ingress-issuer
        renewBefore: 720h0m0s
        privateKey:
          rotationPolicy: Always
        secretName: portal-web-host1
        usages:
        - digital signature
        - key encipherment
      ---
      apiVersion: cert-manager.io/v1
      kind: Certificate
      metadata:
        labels:
          app.kubernetes.io/instance: portal
          app.kubernetes.io/managed-by: ibm-apiconnect
          app.kubernetes.io/name: web-endpoint
        name: portal-web-host2
        namespace: default
      spec:
        dnsNames:
        - <FQDN of portal web endpoint 2>
        duration: 17520h0m0s
        issuerRef:
          group: cert-manager.io
          kind: Issuer
          name: ingress-issuer
        renewBefore: 720h0m0s
      ```

```
  privateKey:
    rotationPolicy: Always
  secretName: portal-web-host2
  usages:
  - digital signature
  - key encipherment

---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  labels:
    app.kubernetes.io/instance: portal
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: web-endpoint
  name: portal-web-host3
  namespace: default
spec:
  dnsNames:
  - <FQDN of portal web endpoint 3>
  duration: 17520h0m0s
  issuerRef:
    group: cert-manager.io
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: portal-web-host3
  usages:
  - digital signature
  - key encipherment
```

b. Apply the file:

```
kubectl apply -f portal-web-certs.yaml
```

Create **portal-www** without cert-manager.

5. Create Kubernetes secrets with OpenSSL. Follow this step instead of steps 3 and 4.
   To create the secrets and certificates for each **portal-www** endpoint, complete the following steps:
   a. If you are using self-signed certificates, create the TLS secrets for each **portal-www** endpoint by generating the certificates. The following example shows how to generate certificates for each **portal-www** endpoint by using OpenSSL:

```
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host1-tls.key -out ptl.host1-tls.crt -subj
"/CN=ptl.host1.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host2-tls.key -out ptl.host2-tls.crt -subj
"/CN=ptl.host2.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host3-tls.key -out ptl.host3-tls.crt -subj
"/CN=ptl.host3.example.com"
```

   b. Store the SSL certificates in a secret:
      i. Copy the certificates to the Portal virtual appliance, for example:

```
scp ptl.host1-tls.key ptl.host1-tls.crt ptl.host2-tls.key ptl.host2-tls.crt ptl.host3-tls.key ptl.host3-tls.crt
apicadm@portal-vm-address
```

      ii. Log in to your portal virtual appliance with an SSH client, as **apicadm** user
      iii. Switch to the root user: **sudo -i**
      iv. Create the Kubernetes secrets:

```
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host1 --key ptl.host1-tls.key --
cert ptl.host1-tls.crt
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host2 --key ptl.host2-tls.key --
cert ptl.host2-tls.crt
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host3 --key ptl.host3-tls.key --
cert ptl.host3-tls.crt
```

Add **portal-www** endpoints and secrets to your **ptl-extra-values.yaml** file.

6. Exit from the portal VM, and in your **apicup** project directory, create a file called **ptl-extra-values.yaml** with the content:

```
spec:
    portalUIEndpoint:
        annotations: # Remove if cert-manager not used
          cert-manager.io/issuer: ingress-issuer # Remove if cert-manager not used
        hosts:
        - name: ptl.host1.example.com
          secretName: portal-web-host1
        - name: ptl.host2.example.com
          secretName: portal-web-host2
        - name: ptl.host3.example.com
          secretName: portal-web-host3
```

Note: If you followed step 5 and did not use cert-manager to create your secrets, then delete the **annotations** section, so your **ptl-extra-values.yaml** contains:

```
spec:
    portalUIEndpoint:
        hosts:
        - name: ptl.host1.example.com
          secretName: portal-web-host1
        - name: ptl.host2.example.com
          secretName: portal-web-host2
```

```
        - name: ptl.host3.example.com
          secretName: portal-web-host3
```

Run the commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>
```

```
apicup subsys install <ptl_subsys>
```

7. SSH back into your portal virtual appliance, and confirm that multiple hosts exist for your `ptl-portal-web` ingress:

```
sudo kubectl get ingress
NAME                  HOSTS                                                          ADDRESS   PORTS     AGE
ptl-portal-director   api.ptl.example.com                                                      80, 443   25m
ptl-portal-web        ptl.host1.example.com,ptl.host2.example.com,ptl.host3.example.com        80, 443   25m
```

Deploying DataPower Gateway virtual appliance

API Connect uses IBM® DataPower® Gateway to provide the gateway service.

The instructions in this section describe how to deploy IBM DataPower Gateway from files obtained from Passport Advantage®, and apply to the following API Connect scenarios:

- API Connect deployments for the VMware environment
- API Connect deployments for Kubernetes, with a DataPower Gateway in a *non-Kubernetes* environment.

For these scenarios, continue with Installing DataPower Gateway.

Note: Do not use these instructions if you are deploying API Connect deployments for Kubernetes, with DataPower Gateway in a *Kubernetes* environment. In this case, you can use DataPower Gateway files that are packaged with API Connect, on the API Connect section of Fix Central, and configured by using the API Connect `apicup` commands. Follow the instructions in Obtaining product files.

- **Installing DataPower Gateway**
  Install and configure IBM DataPower Gateway in a non-Kubernetes environment for use with API Connect.
- **Configuring DataPower Gateway for API Connect**
  You can configure the IBM DataPower Gateway to prepare for a registration with the API Connect Management server.
- **Sample configuration for multiple peering objects on gateway services external to Kubernetes**
  Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

Installing DataPower Gateway

Install and configure IBM® DataPower® Gateway in a non-Kubernetes environment for use with API Connect.

Before you begin

Do not use these instructions for either of the following deployment scenarios:

- Both API Connect and DataPower Gateway in a Kubernetes environment.
  In this scenario, use the instructions in Obtaining product files.
- An existing DataPower Gateway in a non-Kubernetes environment, and you want to install a newer Fix Pack.
  In this scenario, complete an *upgrade* rather than a new installation. See Upgrading DataPower Gateway.

To review the installation and configuration scenarios, see Deploying DataPower Gateway virtual appliance.

Procedure

1. Ensure that the DataPower Gateway firmware version you plan to install is compatible with the API Connect management subsystem version.
   Note:
   You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

   Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

2. Obtain your DataPower files from IBM Passport Advantage®.
   Note that the DataPower files from Passport Advantage have entitled services for API Connect users.

   See also Download the firmware image from Passport Advantage.

3. Follow the DataPower Gateway installation information: https://www.ibm.com/docs/en/datapower-gateway.
   Note: Set the timezone to UTC on all DataPower installations for use with API Connect.
4. Continue with Configuring DataPower Gateway for API Connect.

Configuring DataPower Gateway for API Connect

You can configure the IBM® DataPower® Gateway to prepare for a registration with the API Connect Management server.

About this task

API Connect and DataPower supports two different types of gateway configurations. The DataPower Gateway (v5 compatible) provides the same support as the gateway support that was available with API Connect version 5.x. The DataPower API Gateway is an enhanced gateway that is performance-focused. See API Connect gateway types for more information about the differences between the gateway types.
Continue with the instructions for the type of Gateway Service you are configuring:

- **Configuring DataPower API Gateway**
  Configure the DataPower Gateway to prepare for registration with the API Connect Management server.
- **Configuring DataPower Gateway (v5 compatible)**
  You can configure the DataPower Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

Configuring DataPower API Gateway

Configure the DataPower Gateway to prepare for registration with the API Connect Management server.

Before you begin

- These instructions are for DataPower® API Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower API Gateway Service also in the Kubernetes environment. To review deployment scenarios, see Deploying DataPower Gateway virtual appliance.
- Ensure you have installed a version of DataPower API Gateway that is compatible with the version of the API Connect Management server. See Installing DataPower Gateway.
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower API Gateway is set to UTC.

About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See *Gateway peering* in the DataPower documentation for more information about configuring additional gateways for peering. See *Providing the gateway service to API Connect* in the DataPower documentation for more details about the DataPower settings and procedures.

Procedure

To configure a DataPower API Gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower API Gateway . If you are configuring DataPower Gateway (v5 compatible) see Configuring DataPower Gateway (v5 compatible).

1. Open the DataPower WebGUI interface.
   Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Optional: Enable the XML management interface in the default domain.
   The XML management interface is optional for DataPower API Gateway. If enabled, this interface allows you to send status and configuration requests to the DataPower appliance through a standard SOAP interface, using SOAP messages.
   a. Search for XML management interface in the navigation search bar, and select it.
   b. Set the Administrative state to enabled.
   c. You can specify a different port number if you do not want to use the default of **5550**.
   d. Select Apply to make the changes
   e. Save changes to the default domain by selecting Save Configuration.
3. Optional: Enable the REST management interface in the default domain.
   The REST management interface is required if you want to enable to the Trace feature in the assembly Test tab in the API Manager.
   a. Search for REST management interface in the navigation search bar, and select it.
   b. Set the Administrative state to enabled.
   c. You can specify a different port number if you do not want to use the default of **5554**.
   d. Select Apply to make the changes
   e. Save changes to the default domain by selecting Save Configuration.
4. Create an application domain.
   This domain receives your traffic. The name of the DataPower domain where you configure the API Connect Gateway Service must be the same on each DataPower Gateway.
   a. Search for Application domain in the navigation search bar, and select it.
   b. Select Add to create the application domain.
   c. Enter a unique name for your domain.
   d. Ensure that enabled is selected for the Administrative state.
   e. Ensure that the default domain is listed in the Visible application domain list.
   f. Select Apply.
   g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
   h. Select Save changes and switch domains.
   All of the remaining steps on the DataPower gateway must be done in the application domain that you created.

i. Save changes to the domain by selecting Save Configuration.

5. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
   You must configure the NTP service, the API Connect Gateway Service cannot run without it. See *Managing the NTP service* in the DataPower documentation.

6. Ensure that you have set a unique **`System Identifier`** for each v10 DataPower gateway. See *Initializing the DataPower Gateway* in the DataPower documentation.
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
   a. Search for Crypto key in the navigation search bar, and select it.
   b. Select Add to create a key object.
   c. Create a unique name for the key object in the Name field.
   d. Select Upload....
   e. Browse for the key file (which must be a .pem or .p12 file) and select it.
   f. If you want to rename it, enter a new name for the file.
   g. Select Upload to move it to the server in the cert:// folder.
   h. Select Apply to save the changes.
9. Upload your crypto certificate file to the domain.
   Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.
   a. Search for Crypto certificate in the navigation search bar, and select it.
   b. Select Add to create a certificate object.
   c. Create a unique name for the certificate object in the Name field.
   d. Select Upload....
   e. Browse for the key file (which must be a .pem or .p12 file) and select it.
   f. If you want to rename it, enter a new name for the file.
   g. Select Upload to move it to the server in the cert:// folder.
   h. Select Apply to save the changes.
10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
    a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a name for your credential.
    d. Ensure that the Administrative state has a value of enabled.
    e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
    f. In the Certificate object field, select the name of the certificate object that you created from the drop-down menu.
    g. Select Apply to commit your changes.
11. Create your TLS Client profile.
    a. Search for TLS Client profile in the navigation search bar, and select it.
    b. Select Add to create a client profile.
    c. Create a unique name for the profile in the Name field.
    d. Select your Identification credential from the drop-down list.
    e. Ensure that the value of Validate server certificate is set to off.
    f. Ensure that the value of Use SNI is set to on.
    g. Select Apply to save the changes.
12. Create your TLS Server profile.
    The TLS Server profile secures your gateway director endpoint. When you register your gateway service in the Cloud Manager UI, the gateway returns the server certificate that you configure in this TLS Server profile.
    a. Search for TLS Server Profile in the navigation search bar, and select it.
    b. Select Add to create a server profile.
    c. Create a unique name for the profile in the Name field.
    d. Select your Identification credential from the drop-down list.
    e. Select Apply to save the changes.
    Important: Do not disable Request client authentication unless you enable JWT instead of mTLS. Client authentication is essential for secure mTLS communication between your management and gateway subsystems.
13. Define a configuration sequence.
    The configuration sequence specifies how DataPower implements the APIs that are defined in API Connect.

    a. Search for Configuration sequence in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a name for your configuration sequence.
       The name **`apic-config`** is not allowed because it is already used internally.

    d. Ensure that the Administrative state has a value of enabled.
    e. Ensure that the value in the Location profiles field is set to local:///
       This is the default value, so you might not need to change it.
    f. Select the Access profile.
       For instructions on creating access profiles, see *Configuring the access profile for a configuration sequence* in the appropriate version of the DataPower documentation.

    g. Change the value of the Configuration execution interval field to `3000`.
       The other fields can retain their default settings.
    h. Select Apply to commit your changes.
14. Configure your gateway peering object for the API Connect Gateway Service.
    This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
       You can use the default value of 16380.

g. Select a monitor port for the communication.
   You can use the default value of 26380.
h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
i. Clear the Enable TLS check box. TLS is not needed for a single peer.
j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
k. Select Apply to commit your changes.

15. Configure your gateway peering object for rate limit information.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
       Use a unique port, different than the ports used for communication by other gateway peering objects.
    g. Select a monitor port for the communication.
       Use a unique port, different than the ports used for monitoring by other gateway peering objects.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
    i. Clear the Enable TLS check box. TLS is not needed for a single peer.
    j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
    k. Select Apply to commit your changes.
16. Optional: If you are using the ratelimit module described in the DataPower documentation, configure your gateway peering object for GatewayScript rate limiting information.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
       Use a unique port, different than the ports used for communication by other gateway peering objects.
    g. Select a monitor port for the communication.
       Use a unique port, different than the ports used for monitoring by other gateway peering objects.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
    i. Clear the Enable TLS check box. TLS is not needed for a single peer.
    j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
    k. Select Apply to commit your changes.
17. Configure your gateway peering object for subscription information.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
       Use a unique port, different than the ports used for communication by other gateway peering objects.
    g. Select a monitor port for the communication.
       Use a unique port, different than the ports used for monitoring by other gateway peering objects.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
    i. Clear the Enable TLS check box. TLS is not needed for a single peer.
    j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
    k. Select Apply to commit your changes.
18. Configure the gateway peering object for the API probe.
    In order for API Connect to receive trace data in the Test tab's debugger, the DataPower API Gateway must be configured to support the API probe.

    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
       Use a unique port, different than the ports used for communication by other gateway peering objects.
    g. Select a monitor port for the communication.
       Use a unique port, different than the ports used for monitoring by other gateway peering objects.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
    i. Clear the Enable TLS check box. TLS is not needed for a single peer.
    j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
    k. Select Apply to commit your changes.
19. Configure the gateway peering manager.
    a. Search for Gateway Peering Manager in the navigation search bar, and select it.
    b. Set the Administrative state to enabled.
    c. In the pull-down menu next to API Connect Gateway Service, select the gateway peering object configured in Step 14 for the API Connect Gateway Service.
    d. In the pull-down menu next to Rate Limit, select the gateway peering object configured in Step 15 for rate limit information.
    e. In the pull-down menu next to Subscription, select the gateway peering object configured in Step 17 for subscription.
    f. In the pull-down menu next to API Probe, select the gateway peering object that you configured in Step 18 for the API probe.
    g. If you are using the ratelimit module described in the DataPower documentation, then for Gateway rate limiting, select the gateway peering object that you configured in Step 16 for rate limit information.
    h. Select Apply to commit your changes.
20. Configure the API probe settings object.
    a. Search for API probe settings in the navigation search bar, and select it.
    b. Set the Administrative state to enabled.
    c. Set the maximum number of records to `1000`.
    d. Set the expiration to `60` minutes.

e. In the pull-down menu next to Gateway Peering, select the gateway peering object that you configured in Step 18 for the API probe.
f. Select Apply to commit your changes.

21. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
    a. Search for API Connect Gateway service in the navigation search bar, and select it.
    b. Ensure that the Administrative state is set to enabled.
    c. In the Local address field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
    d. Specify a value for Local port. You can use the default value of 3000, or specify a different port value.
    Note: The Local port specifies the port through which API Connect connects to manage the API Connect Gateway Service. Use this port when you configure a Gateway Service on API Connect. Beyond this port, the gateway service uses two additional consecutive ports after the defined local port to bind to a loopback address. Therefore, you must ensure that there are no conflicts on all three consecutive ports that start from the defined local port.
    e. In the TLS client field drop-down list, select the name of the TLS client profile that you created.
    f. In the TLS server field drop-down list, select the name of the TLS server profile that you created.
    g. In the API gateway address field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
    h. Use the default port value of 9443 for the API gateway port.
    If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
    i. For DataPower API Gateway, set the Gateway Peering to **(none)**.
    When no gateway peering object is configured for the DataPower API Gateway, the peering configuration defined in the Gateway Peering Manager configuration is used.
    j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.
    When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway. Clear it to enable a DataPower API Gateway.
22. Optional: Enable JWT security instead of mTLS for communication from management to gateway. JWT security provides application layer security and can be used instead of mTLS when load-balancers are located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.
    To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the DataPower documentation. The JWKS URL required to enable JWT security can be found in the management subsystem settings:

```
apicup subsys get <management subsystem>

...
jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
validate JWT -- this is unsettable and is generated based on the platform-api endpoint
...
```

23. Register the gateway service in the API Connect Cloud Manager console:
    a. Open the API Connect Cloud Manager console.
    b. Navigate to Configure Topology.
    c. Select Register Service.
    d. Select DataPower API Gateway for the DataPower API Gateway.
    e. Add a title, name, and summary for the gateway connection.
    f. Optional: Configure the OAuth Shared Secret.
    This setting allows OAuth tokens to be shared across multiple gateway services.
    g. Enter one of the following values in the API Invocation Endpoint field:
        - IP address of the load balancer for the API transactions
        - IP address or host name of one of the gateways

    For example:**https://192.0.2.0:9443/**
    h. Enter the one of the following values in the Management Endpoint field:
        - IP address of the load balancer for the management server traffic set to port 3000
        - IP address or hostname of one of the gateways

    For example:**https://192.0.2.0:3000/**
24. Select the default TLS Client Profile
25. Optional: Configure Server Name Indication (SNI) profiles.
    SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.
26. Enable logging for the gateway.
    a. Use the CLI to configure the following log target in the API Connect application domain:

```
switch domain <apiconnect_domain>
configure terminal
logging target gwd-log
type file
format text
timestamp zulu
size 50000
local-file logtemp:///gwd-log.log
event apic-gw-service debug
exit
apic-gw-service;admin-state disabled;exit
apic-gw-service;admin-state enabled;exit
write mem
exit
```

    b. Repeat this set for every gateway server in the cluster.

Configuring DataPower Gateway (v5 compatible)

You can configure the DataPower Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

Before you begin

- These instructions are for DataPower® API Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower API Gateway Service also in the Kubernetes environment. To review deployment scenarios, see Deploying DataPower Gateway virtual appliance.

- Ensure you have installed a version of DataPower API Gateway that is compatible with the version of the API Connect Management server. See Installing DataPower Gateway.
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower API Gateway is set to UTC.

About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See *Gateway peering* in the DataPower documentation for more information about configuring additional gateways for peering. See *Providing the gateway service to API Connect* in the DataPower documentation for more details about the DataPower settings and procedures.

Procedure

To configure a DataPower gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower Gateway (v5 compatible). If you are configuring DataPower API Gateway, see Configuring DataPower API Gateway.

1. Open the DataPower WebGUI interface.
   Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Enable the XML management interface in the **default** domain, if required. The XML management interface is required for DataPower Gateway (v5 compatible). The XML management interface is optional for DataPower API Gateway.
   a. Search for **XML management interface** in the navigation search bar, and select it.
   b. Set the Administrative state to enabled.
   c. You can specify a different port number if you do not want to use the default of `5550`.
   d. Select Apply to make the changes
   e. Save changes to the default domain by selecting Save Configuration.
3. Create an application domain.
   This domain receives your traffic. The name of the DataPower domain where you configure the API Connect Gateway Service must be the same on each DataPower Gateway.
   a. Search for Application domain in the navigation search bar, and select it.
   b. Select Add to create the application domain.
   c. Enter a unique name for your domain.
   d. Ensure that enabled is selected for the Administrative state.
   e. Ensure that the default domain is listed in the Visible application domain list.
   f. Select Apply.
   g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
   h. Select Save changes and switch domains.
   All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
   i. Save changes to the domain by selecting Save Configuration.
4. For the DataPower Gateway (v5 compatible) only: Enable statistics in the domain you created for **API Connect**.
   a. Search for and select Statistics settings in the navigation search.
   b. Select enabled for the Administrative state.
   c. Select Apply.
5. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
   See Managing the NTP service.
6. Ensure that you have set a unique **`System Identifier`** for each v10 DataPower gateway. See Initializing the DataPower Gateway.
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
   a. Search for Crypto key in the navigation search bar, and select it.
   b. Select Add to create a key object.
   c. Create a unique name for the key object in the Name field.
   d. Select Upload....
   e. Browse for the key file (which must be a .pem or .p12 file) and select it.
   f. If you want to rename it, enter a new name for the file.
   g. Select Upload to move it to the server in the cert:// folder.
   h. Select Apply to save the changes.
9. Upload your crypto certificate file to the domain.
   Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.
   a. Search for Crypto certificate in the navigation search bar, and select it.
   b. Select Add to create a certificate object.
   c. Create a unique name for the certificate object in the Name field.
   d. Select Upload....
   e. Browse for the key file (which must be a .pem or .p12 file) and select it.
   f. If you want to rename it, enter a new name for the file.
   g. Select Upload to move it to the server in the cert:// folder.
   h. Select Apply to save the changes.
10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
    a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a name for your credential.
    d. Ensure that the Administrative state has a value of enabled.
    e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
    f. In the Certificate object field, select the name of the certificate object that you created from the drop-down menu.

g. Select Apply to commit your changes.

11. Create your TLS Client profile.
    a. Search for TLS Client profile in the navigation search bar, and select it.
    b. Select Add to create a client profile.
    c. Create a unique name for the profile in the Name field.
    d. Select your Identification credential from the drop-down list.
    e. Ensure that the value of Validate server certificate is set to off.
    f. Ensure that the value of Use SNI is set to on.
    g. Select Apply to save the changes.
12. Create your TLS Server profile.
    The TLS Server profile secures your gateway director endpoint. When you register your gateway service in the Cloud Manager UI, the gateway returns the server certificate that you configure in this TLS Server profile.
    a. Search for TLS Server Profile in the navigation search bar, and select it.
    b. Select Add to create a server profile.
    c. Create a unique name for the profile in the Name field.
    d. Select your Identification credential from the drop-down list.
    e. Select Apply to save the changes.

    Important: Do not disable Request client authentication unless you enable JWT instead of mTLS. Client authentication is essential for secure mTLS communication between your management and gateway subsystems.
13. Configure your gateway peering object for the API Connect Gateway Service.
    This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
       You can use the default value of 16380.
    g. Select a monitor port for the communication.
       You can use the default value of 26380.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
    i. Clear the Enable TLS check box. TLS is not needed for a single peer.
    j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
    k. Select Apply to commit your changes.
14. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
    a. Search for API Connect Gateway service in the navigation search bar, and select it.
    b. Ensure that the Administrative state is set to enabled.
    c. In the Local address field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
    d. Use the default port value of 3000 for the Local port.
    e. In the TLS client field drop-down list, select the name of the TLS client profile that you created.
    f. In the TLS server field drop-down list, select the name of the TLS server profile that you created.
    g. In the API gateway address field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
    h. Use the default port value of 9443 for the API gateway port.
       If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
    i. For DataPower Gateway (v5 compatible), select the gateway peering object that you created in Step 13.
    j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.
       When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway.
15. Optional: Enable JWT security instead of mTLS for communication from management to gateway. JWT security provides application layer security and can be used instead of mTLS when load-balancers are located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.
    To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the DataPower documentation. The JWKS URL required to enable JWT security can be found in the management subsystem settings:

    ```
    apicup subsys get <management subsystem>

    ...
    jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
    validate JWT -- this is unsettable and is generated based on the platform-api endpoint
    ...
    ```

16. Register the gateway service in the API Connect Cloud Manager console:
    a. Open the API Connect Cloud Manager console.
    b. Navigate to Configure Topology.
    c. Select Register Service.
    d. Select DataPower Gateway (v5 compatible) for the gateway that was available in version 5.
    e. Add a title, name, and summary for the gateway connection.
    f. Optional: Configure the OAuth Shared Secret.
       This setting allows OAuth tokens to be shared across multiple gateway services.
    g. Enter one of the following values in the API Invocation Endpoint field:
       - IP address of the load balancer for the API transactions
       - IP address or host name of one of the gateways

       For example:**`https://192.0.2.0:9443/`**
    h. Enter the one of the following values in the Management Endpoint field:
       - IP address of the load balancer for the management server traffic set to port 3000
       - IP address or hostname of one of the gateways

       For example:**`https://192.0.2.0:3000/`**
17. Select the default TLS Client Profile
18. Optional: Configure Server Name Indication (SNI) profiles.
    SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.
19. Enable logging for the gateway.
    a. Use the CLI to configure the following log target in the API Connect application domain:

```
switch domain <apiconnect_domain>
configure terminal
logging target gwd-log
type file
format text
timestamp zulu
size 50000
local-file logtemp:///gwd-log.log
event apic-gw-service debug
exit
apic-gw-service;admin-state disabled;exit
apic-gw-service;admin-state enabled;exit
write mem
exit
```

b. Repeat this set for every gateway server in the cluster.

Sample configuration for multiple peering objects on gateway services external to Kubernetes

Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

- This reference shows how to configure API Connect domain configuration with gateway-peering configuration. To review domain configuration settings, see Configuring DataPower Gateway for API Connect.
- This sample applies only to gateway services that are deployed external to Kubernetes, on either a physical or virtual appliance. This sample does not apply to gateway services that are deployed on Kubernetes.

The following examples show sample configuration for 3 different gateways, listed here with sample IP addresses of 1.1.1.1, 2.2.2.2, and 3.3.3.3. Note the following:

- The priority should be set differently on each of the three gateways. Set the lowest priority for the gateway that will run as primary.
- **persistence** should be set to **memory** for all configured peering objects.
- Optionally, add SSL configuration.

Configuration on gateway 1 (1.1.1.1)

```
top; configure terminal;
    domain apiconnect; visible default; exit;

    sw apiconnect;

    loglevel debug;
    logging target gwd-log
      type file
      format text
      timestamp syslog
      size 50000
      local-file logtemp:///gwd-log
      event apic-gw-service debug
    exit

    config-sequence "apiconnect"
      location "local:///"
      watch "on"
      delete-unused "on"
      match "(.*)\.cfg$"
      summary "Toolkit Reboot configuration"
      run-sequence-interval 3000
      optimize-for-apic on
    exit

    ssl-client gwd_to_mgmt
  exit

  write mem
```

Post-deployment steps

When all subsystems are deployed, use the admin account to access the Cloud Manager administrative console and begin configuration. Optionally, take VMware snapshots of the VMs.

About this task

When you have deployed all required API Connect components, and all subsystems are running, complete the following:

Procedure

1. If you have not previously accessed the Cloud Manager, verify you can access the API Connect Cloud Manager. Enter the URL in your browser.
   The syntax is `https://<hostname.domain>/admin`. For example:

   ```
   https://cloud-admin-ui.testsrv0231.subnet1.example.com/admin
   ```

   The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See Accessing the Cloud Manager user interface.

2. Define your API Connect configuration by using the API Connect Cloud Manager. See Cloud Manager configuration checklist.
3. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see Using VM snapshots for infrastructure backup and disaster recovery for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.
   Important: VM snapshots are not an alternative to the standard API Connect backups. You should have completed an API Connect backup of each subsystem when verifying initial deployment, as advised in:
   - Verify installation of the Management subsystem
   - Verifying deployment of the Developer Portal subsystem
   - Verifying deployment of the Analytics subsystem

Installing a two data center deployment

How to install a two data center disaster recovery (2DCDR) deployment on VMware.

Before you begin

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see Two data center warm-standby deployment strategy on VMware.

Review the information in Requirements for initial deployment on VMware and, if appropriate, What's new for v10 installation from previous versions.

Familiarize yourself with the instructions in First steps for deploying in a VMware environment. Complete these instructions with the additional steps in this topic that are specific to installing a 2DCDR deployment.

Restriction: It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration.

About this task

Installing API Connect as a 2DCDR deployment is similar to a single installation. The deployment in each data center is effectively an instance of the same API Connect deployment. The following endpoints must be the same on both data centers:

Management subsystem endpoints

- `platform-api`
- `consumer-api`
- `cloud-admin-ui`
- `api-manager-ui`

Portal subsystem endpoints

- `portal-admin`
- `portal-www`

To install a 2DCDR deployment, you follow the normal stand-alone API Connect installation steps, but before you generate the ISO files you must set some additional 2DCDR properties.

The 2DCDR properties are described in the following table.

Table 1. 2DCDR properties

Setting	Description
`multi-site-ha-enabled`	Indicates whether 2DCDR deployment is enabled. Set to `true` to enable 2DCDR. Set to `false` to disable 2DCDR. The default value is `false`.
`multi-site-ha-mode`	The 2DCDR mode of the data center. Possible values are: • `active` - indicates the primary data center. • `passive` - indicates the warm-standby data center.
`management-replication`	Required only for the management subsystem. The external ingress name for the management subsystem in the current data center in the 2DCDR deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`portal-replication`	Required only for the portal subsystem. The external ingress name for the portal subsystem in the current data center in the 2DCDR deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`replication-peer-fqdn`	The ingress hostname for the other data center in the 2DCDR deployment. This information is required so that the two data centers can communicate with each other.
`siteName`	Unique descriptive name for the API Connect data center. Must be different in each data center. This name is used in the hostnames, and so can contain only `a-z` and `0-9` characters. You can set a `siteName` only when the subsystems are first deployed, and you cannot change the name after deployment. If you don't set `siteName` at first deployment, the `siteName` is autogenerated.

Important:

- Use a single APICUP project for all subsystems so that the API Connect deployments in both data centers have the same certificate chains. If network access to both data centers from the same APICUP project location is not possible, you can copy the project directory across to the other data center. If you are copying the project directory to your other data center, ensure that you keep backups of both project directories.
- The original project directory that is created with APICUP during the initial product installation is required to both restore the database and to upgrade your deployment. You cannot restore the database or complete an upgrade without the initial project directory because it contains pertinent information about the cluster.
- Subsystem endpoints for the components cannot be changed.
- The subsystem name of the management and portal subsystems must consist of lowercase alphanumeric characters or '-', contain no spaces, start with an alphabetic character, and end with an alphanumeric character.

Procedure

- **Installing on the active data center**
  The following example shows how to configure the 2DCDR settings for deploying on the active data center (DC). In this example, the active data center is called `dallas` (DC1), and the warm-standby data center is called `raleigh` (DC2).

  1. Complete the steps in Configuring the Management subsystem up to and including step 14 to configure the standard (non-2DCDR) settings for the management subsystem in Dallas (DC1).
  2. Configure the 2DCDR values to set Dallas to be active for the management subsystem in DC1.
     Run the following commands:

     ```
     apicup subsys set mgmt_dallas multi-site-ha-enabled=true

     apicup subsys set mgmt_dallas multi-site-ha-mode=active

     apicup certs set mgmt_dallas management-replication-ingress --clear

     apicup subsys set mgmt_dallas management-replication=mgrreplicationdallas.cluster1.example.com

     apicup subsys set mgmt_dallas replication-peer-fqdn=mgrreplicationraleigh.cluster2.example.com

     apicup subsys set mgmt_dallas site-name=dallas
     ```

     where
     - *`mgmt_dallas`* is the name of the management subsystem that you are configuring.

- ***mgrreplicationdallas.cluster1.example.com*** is the ingress hostname for the current data center in the two data center deployment.
- ***mgrreplicationraleigh.cluster2.example.com*** is the ingress hostname for the other data center in the two data center deployment.
- ***dallas*** is the name of the site in the current data center.

3. Complete the remainder of the steps in Configuring the Management subsystem from step 15 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
4. Complete the steps in Configuring the Developer Portal subsystem up to and including step 16 to configure the standard (non-2DCDR) settings for the portal subsystem in Dallas (DC1).
5. Configure the 2DCDR values to set Dallas to be active for the portal subsystem in DC1.
   Run the following commands:

   ```
   apicup subsys set port_dallas multi-site-ha-enabled=true

   apicup subsys set port_dallas multi-site-ha-mode=active

   apicup certs set port_dallas portal-replication-ingress --clear

   apicup subsys set port_dallas portal-replication=ptlreplicationdallas.cluster1.example.com

   apicup subsys set port_dallas replication-peer-fqdn=ptlreplicationraleigh.cluster2.example.com

   apicup subsys set port_dallas site-name=dallas
   ```

   where
   - ***port_dallas*** is the name of the portal subsystem that you are configuring.
   - ***ptlreplicationdallas.cluster1.example.com*** is the ingress hostname for the current data center in the two data center deployment.
   - ***ptlreplicationraleigh.cluster2.example.com*** is the ingress hostname for the other data center in the two data center deployment.
   - ***dallas*** is the name of the site in the current data center.

6. Complete the remainder of the steps in Configuring the Developer Portal subsystem from step 19 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
7. Check the status of the installation by running:

   ```
   apicup subsys status subsystem_name
   ```

8. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

   Management subsystem endpoints
   - **platform-api**
   - **consumer-api**
   - **cloud-admin-ui**
   - **api-manager-ui**

   Portal subsystem endpoints
   - **portal-admin**
   - **portal-www**

- **Installing on the warm-standby data center**
  The following example shows how to set the 2DCDR values for the remote data center called **raleigh** (DC2), which is being installed as the warm-standby location.

  Important: Remember to use the same APICUP project directory as for the active data center. If you cannot use the same project directory because its location does not have network access to both data centers, you can copy the project directory over. Ensure that backups are kept of both project directories in each data center.

  1. Complete the steps in Configuring the Management subsystem up to and including step 14 to configure the standard (non-2DCDR) settings for the management subsystem in Raleigh (DC2).
  2. Configure the 2DCDR values to set the management subsystem to be the warm-standby in the Raleigh (DC2) data center.
     Run the following commands:

     ```
     apicup subsys set mgmt_raleigh multi-site-ha-enabled=true

     apicup subsys set mgmt_raleigh multi-site-ha-mode=passive

     apicup certs set mgmt_raleigh management-replication-ingress --clear

     apicup subsys set mgmt_raleigh management-replication=mgrreplicationraleigh.cluster2.example.com

     apicup subsys set mgmt_raleigh replication-peer-fqdn=mgrreplicationdallas.cluster1.example.com

     apicup subsys set mgmt_raleigh site-name=raleigh
     ```

     where
     - ***mgmt_raleigh*** is the name of the management subsystem that you are configuring.
     - ***mgrreplicationraleigh.cluster2.example.com*** is the ingress hostname for the current data center in the two data center deployment.
     - ***mgrreplicationdallas.cluster1.example.com*** is the ingress hostname for the other data center in the two data center deployment.
     - ***raleigh*** is the name of the site in the current data center.

  3. Set the encryption key manually for Raleigh (DC2) by copying it from Dallas (DC1).
     Run the following commands:

     ```
     apicup certs get mgmt_dallas encryption-secret -t key > mgmt-encryption-secret

     apicup certs set mgmt_raleigh encryption-secret mgmt-encryption-secret
     ```

  4. Check that the management encryption key is set the same on both DC1 and DC2.
     Run the following commands, and verify that the outputs match:

     ```
     apicup certs get mgmt_dallas encryption-secret -t key

     apicup certs get mgmt_raleigh encryption-secret -t key
     ```

  5. Complete the remainder of the steps in Configuring the Management subsystem from step 15 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.

6. Complete the steps in Configuring the Developer Portal subsystem up to and including step 16 to configure the standard (non-2DCDR) settings for the portal subsystem in Raleigh (DC2).
7. Configure the 2DCDR values to set Raleigh to be warm-standby for the portal subsystem on DC2.
   Run the following commands:

   ```
   apicup subsys set port_raleigh multi-site-ha-enabled=true

   apicup subsys set port_raleigh multi-site-ha-mode=passive

   apicup certs set port_raleigh portal-replication-ingress --clear

   apicup subsys set port_raleigh portal-replication=ptlreplicationraleigh.cluster2.example.com

   apicup subsys set port_raleigh replication-peer-fqdn=ptlreplicationdallas.cluster1.example.com

   apicup subsys set port_raleigh site-name=raleigh
   ```

   where
   - *port_raleigh* is the name of the portal subsystem that you are configuring.
   - *ptlreplicationraleigh.cluster2.example.com* is the ingress hostname for the current data center in the two data center deployment.
   - *ptlreplicationdallas.cluster1.example.com* is the ingress hostname for the other data center in the two data center deployment.
   - *raleigh* is the name of the site in the current data center.
8. Copy the encryption key for the portal subsystem on DC1 over to the portal subsystem on DC2.
   Run the following command to get the encryption key for the portal subsystem on DC1, and put it into a file that is called port-encryption-secret:

   ```
   apicup certs get port_dallas encryption-secret -t key > port-encryption-secret
   ```

   Run the following command to use the port-encryption-secret file to set the same encryption key on DC2:

   ```
   apicup certs set port_raleigh encryption-secret port-encryption-secret
   ```

   Where *port_dallas* is the name of the portal subsystem on DC1, and *port_raleigh* is the name of the portal subsystem on DC2.
   To check that the encryption key is set the same on both DC1 and DC2, you can run the following commands and verify that the outputs match:

   ```
   apicup certs get port_dallas encryption-secret -t key

   apicup certs get port_raleigh encryption-secret -t key
   ```

9. Complete the remainder of the steps in Configuring the Developer Portal subsystem from step 19 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
10. Check the status of the installation by running:

    ```
    apicup subsys status subsystem_name
    ```

- **Converting a single data center deployment to two data centers**
  Important:
  - Use the existing deployment as the active site. The new site must be set to warm-standby. If you set your existing deployment to warm-standby then all your management and portal data is erased.
  - The ingress endpoint values from the existing deployment become the global ingress endpoints for the two center deployment. The following endpoints must be set the same on your new deployment, as they are on your existing deployment:

    Management subsystem endpoints
    - `platform-api`
    - `consumer-api`
    - `cloud-admin-ui`
    - `api-manager-ui`

    Portal subsystem endpoints
    - `portal-admin`
    - `portal-www`

  - Configure your network to be able to route the endpoints to either data center, depending on which is the active.
  - You cannot configure a `site-name` for the existing management or portal cluster because the `site-name` property can be configured only at first deployment.

  The following example shows how to update the 2DCDR values to make the existing data center `Dallas` the active, and for installing and setting the new remote data center `Raleigh` as warm-standby.

  1. Configure the 2DCDR values to set Dallas to be active for the API Manager subsystem on DC1.
     Run the following commands:

     ```
     apicup subsys set mgmt_dallas multi-site-ha-enabled=true

     apicup subsys set mgmt_dallas multi-site-ha-mode=active

     apicup certs set mgmt_dallas management-replication-ingress --clear

     apicup subsys set mgmt_dallas management-replication=mgrreplicationdallas.cluster1.example.com

     apicup subsys set mgmt_dallas replication-peer-fqdn=mgrreplicationraleigh.cluster2.example.com
     ```

     where
     - *mgmt_dallas* is the name of the management subsystem that you are configuring.
     - *mgrreplicationdallas.cluster1.example.com* is the ingress hostname for the current data center in the two data center deployment.
     - *mgrreplicationraleigh.cluster2.example.com* is the ingress hostname for the other data center in the two data center deployment.

     Note: As the API Manager subsystem already exists, you cannot set the `site-name` property.
  2. Configure the 2DCDR values to set Dallas to be active for the portal subsystem on DC1.
     Run the following commands:

     ```
     apicup subsys set port_dallas multi-site-ha-enabled=true

     apicup subsys set port_dallas multi-site-ha-mode=active
     ```

```
apicup certs set port_dallas portal-replication-ingress --clear

apicup subsys set port_dallas portal-replication=ptlreplicationdallas.cluster1.example.com

apicup subsys set port_dallas replication-peer-fqdn=ptlreplicationraleigh.cluster2.example.com
```

where

- `port_dallas` is the name of the portal subsystem that you are configuring.
- `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the other data center in the two data center deployment.

Note: As the portal subsystem already exists, you cannot set the `site-name` property.

3. Run `apicup` to update the settings in each subsystem, for example:

```
apicup subsys install subsystem_name
```

where `subsystem_name` is the name of the management or portal subsystem that you want to update, for example `mgmt_dallas`.

4. Check the status of the installation by running:

```
apicup subsys status subsystem_name
```

5. Add the new DC, Raleigh (DC2) by completing the steps in Configuring the Management subsystem up to and including step 14 to create a management subsystem in Raleigh (DC2).
   Note:
   - Remember to use the same APICUP project directory as for the active data center.
   - Remember to set the same endpoints as for DC1:

     Management subsystem endpoints
     - `platform-api`
     - `consumer-api`
     - `cloud-admin-ui`
     - `api-manager-ui`

     Portal subsystem endpoints
     - `portal-admin`
     - `portal-www`

6. Configure the 2DCDR values to set Raleigh to be warm-standby for the API Manager subsystem on DC2.
   Run the following commands:

```
apicup subsys set mgmt_raleigh multi-site-ha-enabled=true

apicup subsys set mgmt_raleigh multi-site-ha-mode=passive

apicup certs set mgmt_raleigh management-replication-ingress --clear

apicup subsys set mgmt_raleigh management-replication=mgrreplicationraleigh.cluster2.example.com

apicup subsys set mgmt_raleigh replication-peer-fqdn=mgrreplicationdallas.cluster1.example.com

apicup subsys set mgmt_raleigh site-name=raleigh
```

   where
   - `mgmt_raleigh` is the name of the management subsystem that you are configuring.
   - `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
   - `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
   - `raleigh` is the name of the site in the current data center.

   Note: As this is a new deployment of the API Manager subsystem, you can set the `site-name` property.

7. Set the encryption key manually for Raleigh (DC2) by copying it from Dallas (DC1).
   Run the following commands:

```
apicup certs get mgmt_dallas encryption-secret -t key > mgmt-encryption-secret

apicup certs set mgmt_raleigh encryption-secret mgmt-encryption-secret
```

8. Check that the management encryption key is set the same on both DC1 and DC2.
   Run the following commands, and verify that the outputs match:

```
apicup certs get mgmt_dallas encryption-secret -t key

apicup certs get mgmt_raleigh encryption-secret -t key
```

9. Complete the remainder of the steps in Configuring the Management subsystem from step 15 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
10. Complete the steps in Configuring the Developer Portal subsystem up to and including step 16 to create a portal subsystem in Raleigh (DC2).
11. Configure the 2DCDR values to set Raleigh to be warm-standby for the portal subsystem on DC2.
    Run the following commands:

```
apicup subsys set port_raleigh multi-site-ha-enabled=true

apicup subsys set port_raleigh multi-site-ha-mode=passive

apicup certs set port_raleigh portal-replication-ingress --clear

apicup subsys set port_raleigh portal-replication=ptlreplicationraleigh.cluster2.example.com

apicup subsys set port_raleigh replication-peer-fqdn=ptlreplicationdallas.cluster1.example.com

apicup subsys set port_raleigh site-name=raleigh
```

    where
    - `port_raleigh` is the name of the portal subsystem that you are configuring.
    - `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.

- ***ptlreplicationdallas.cluster1.example.com*** is the ingress hostname for the other data center in the two data center deployment.
- ***raleigh*** is the name of the site in the current data center.

12. Run the following command to generate the default portal certificates on the warm-standby site:

    ```
    apicup certs generate port_raleigh
    ```

13. Copy the encryption key for the portal subsystem on DC1 over to the portal subsystem on DC2.
    Run the following command to get the encryption key for the portal subsystem on DC1, and put it into a file that is called port-encryption-secret:

    ```
    apicup certs get port_dallas encryption-secret -t key > port-encryption-secret
    ```

    Run the following command to use the port-encryption-secret file to set the same encryption key on DC2:

    ```
    apicup certs set port_raleigh encryption-secret port-encryption-secret
    ```

    Where ***port_dallas*** is the name of the portal subsystem on DC1, and ***port_raleigh*** is the name of the portal subsystem on DC2.
    To check that the encryption key is set the same on both DC1 and DC2, you can run the following commands and verify that the outputs match:

    ```
    apicup certs get port_dallas encryption-secret -t key
    ```

    ```
    apicup certs get port_raleigh encryption-secret -t key
    ```

14. Complete the remainder of the steps in Configuring the Developer Portal subsystem from step 19 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
15. Check the status of the installation by running:

    ```
    apicup subsys status subsystem_name
    ```

16. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

Management subsystem endpoints
- `platform-api`
- `consumer-api`
- `cloud-admin-ui`
- `api-manager-ui`

Portal subsystem endpoints
- `portal-admin`
- `portal-www`

- **Validating your two data center deployment**
  Use the `apicup health-check` command to confirm that the management subsystems are ready and synchronized:

  ```
  apicup subsys health-check <management subsystem>
  ```

  If the management subsystem is healthy, the `health-check` command returns silently with no output.
  If you want to see more information in the `health-check` output, add the `-v` flag:

  ```
  apicup subsys health-check <management subsystem> -v
  ```

  ```
  ok(true) - Expected apicup version(10.0.7.0) to match apic version(10.0.7.0)
  ...
  ok(true) - ManagementCluster (specified multi site ha mode: active, current ha mode: active, ha status: Ready, ha message:
  Active DB is ready) is Ready | State: 17/17 | Phase: Running | Message: All services ready. HA status Ready - see HAStatus
  in CR for details
  ```

Example

Example of the management subsystem values that you can view by running the `apicup subsys get mgmt_name` command:

```
apicup subsys get mgmt_dallas
```

```
Appliance settings

Upgrading API Connect

Upgrade API Connect on VMware to a newer version.

Upgrading your API Connect deployment consists of three phases:

1. Upgrade planning. Decide on your upgrade path based on your current version.

   Review any feature changes in the new API Connect version that might impact how you use API Connect and plan for such changes.

   Upgrade planning should be started as early as possible to identify any issues that might influence when you are able to upgrade, and any actions to take before upgrade.

2. Upgrade preparation. Run pre-upgrade checks on your current deployment, download the new version of API Connect from Fix Central, backup your current deployment.

   Upgrade preparation can be done at any time, and it is worth doing early to identify and fix any potential problems before your upgrade window. If you do complete the upgrade preparation early, repeat the pre-upgrade checks just before your upgrade window to check for any new problems.

3. Upgrade process. Updating your API Connect subsystems to the new version.

   The upgrade process should be started only when all upgrade planning and preparation are completed. Interrupting and rolling back API Connect upgrades is not possible. Disaster recovery procedures must be followed to restore API Connect to the old version if problems are encountered during upgrade.

Use the procedures in this section to upgrade API Connect on VMware.

Note:

- For upgrading from v5, see Migrating a version 5 deployment to version 10.0.x.
- For information about how to maintain a two data center deployment, including upgrade considerations, see Maintaining a two data center deployment.

Important: API Connect v10.0.7.0 supports only backups to an S3 object-store for the management database. If your v10.0.6 deployment uses SFTP or local backups, then you must reconfigure your management backup settings to use an S3 object-store.
Upgrade to v10.0.7.0 is blocked if management database backups are not configured to use an S3 object-store.

If you do not require management database backups, you can enable an opt-out parameter to override the upgrade block. Support for SFTP and local backups will be provided in a future v10.0.x release.

- **Planning your API Connect upgrade on VMware**
  Before you upgrade API Connect on VMware, check that your deployment meets all the upgrade requirements.
- **Pre-upgrade preparation and checks VMware**
  Prepare your VMware deployment for upgrading to the newest version of API Connect.
- **Upgrading management, portal, and analytics on VMware**
  Upgrade your management, portal, and analytics subsystems on VMware.
- **Upgrading DataPower Gateway**
  Use these instructions to upgrade your DataPower Gateway services in a non-Kubernetes environment.
- **Troubleshooting upgrades on VMware**
  Review the following troubleshooting guidance if you encounter a problem while upgrading API Connect on VMware.

Planning your API Connect upgrade on VMware

Before you upgrade API Connect on VMware, check that your deployment meets all the upgrade requirements.

Supported upgrade paths

Table 1. Supported upgrade paths

Upgrade from:	How to upgrade to 10.0.7.0
• 10.0.6.0 • 10.0.5.5 • 10.0.5.4 • 10.0.5.3	Complete the procedure in Upgrading to the latest release on VMware.
10.0.5.2 or earlier	Complete two upgrades: 1. Upgrade to version 10.0.5.3 or later as explained in Upgrading to the latest release on VMware in the API Connect 10.0.5.x documentation. 2. Upgrade to the current release by completing the procedures in Upgrading to the latest release on VMware.

Supported DataPower Gateway versions

You can use any combination of API Connect CD releases (10.0.7.x) with DataPower CD releases (DataPower Gateway 10.5.3.x or DataPower API Gateway 10.5.3.x).

However, before you install, it is recommended to review the compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

Control planes for upgrading to 10.0.7

Installs with **`appliance-control-plane-1.27.x.tgz`**

Table 2. Control Plane files needed for upgrading to 10.0.7

Upgrading from API Connect version	Control Plane files needed
• 10.0.6.0 • 10.0.5.5 • 10.0.5.4 • 10.0.5.3	No Control Plane needed.

Upgrade requirements

- API Connect is not supported on a FIPS-enabled environment.
- The instructions for upgrading apply to the latest version of API Connect.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order:
  1. Management
  2. Portal
  3. Analytics
  4. Gateway

  Gateway must be upgraded after management so that any new policies and capabilities are available to any previously registered gateway services.

- Do not use **`kubectl exec`** commands to access API Connect pods unless advised by IBM.
  Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

Important upgrade considerations

Carefully review the following items, to plan and prepare for your upgrade.

OAuth provider resources with **`api.securityDefintions`**

If you have native OAuth providers that are configured with the **`api.securityDefintions`** field assigned, then upgrade fails. Before upgrade, remove all **`api.securityDefintions`** from all native OAuth providers that you configured in the Cloud Manager and API Manager UIs:

- Configuring a native OAuth provider in the Cloud Manager UI
- Configuring a native OAuth provider in the API Manager UI

Switch to the source view and delete any **`securityDefintions`** sections that are present.

SFTP management backups (V10.0.6.0 to V10.0.7.0 upgrade)

API Connect V10.0.7.0 supports only backups to an S3 object-store for the management database. If your V10.0.6.0 deployment uses SFTP or local backups, then you must reconfigure your management backup settings to use an S3 object-store.

Upgrade to V10.0.7.0 is blocked if management database backups are not configured to use an S3 object-store.

If you do not require management database backups, you can enable an opt-out parameter to override the upgrade block. Support for SFTP and local backups will be provided in a future V10.0.x release.

Extra backup folder appended to management database backup path

When you upgrade to V10.0.7.0 or later with S3 backups configured, an extra backup path folder /edb is appended to your backup path. The /edb path is to distinguish new EDB backups from your previous management backups.

Pre-upgrade preparation and checks VMware

Prepare your VMware deployment for upgrading to the newest version of API Connect.

Before you begin

Review the Planning your API Connect upgrade on VMware to ensure that you are following a supported upgrade path and that you understand important changes that might affect your deployment.

Procedure

VM health checks:

1. From your project directory, run the **apicup** health-check command for each of your subsystems.

   ```
   apicup subsys health-check <subsystem name>
   ```

   If the health check is successful, then the command returns silently.

   If you see an IO timeout error, then it's likely that a firewall is blocking access to port 9178. For example:

   ```
   apicup subsys health-check <subsystem name>
   ...
   Error: failed to install the subsystem: unable to open file send stream:
    rpc error: code = Unavailable desc = all SubConns are in TransientFailure,
    latest connection error: connection error:
    desc = "transport: Error while dialing dial tcp 1.2.3.4:9178: i/o timeout"
   ```

   If you see this error, make sure that your firewall has port 9178 open.

2. If you are upgrading to V10.0.7.0, and you have management database backups set to SFTP or local: Change your management database backup settings to S3.
   See Reconfiguring backup settings for the management subsystem V10.0.6.0.
   V10.0.7.0 supports only backups to an S3 object-store. If you are not able to configure an S3 object-store, then to upgrade to v10.0.7.0 you must enable the **accept-no-backups** setting before you upgrade, see step 4.a on Upgrading management, portal, and analytics on VMware.

3. Login to each of your API Connect VMs and switch to the root user:

   ```
   ssh apicadm@<hostname>
   ```

   ```
   sudo -i
   ```

4. Delete any stale upgrade files that might be left on the VM from previous upgrades:

   ```
   apic clean-upgrade-files
   ```

5. Remove obsolete **sources** files to ensure a clean upgrade.
   Delete any files in the directory /etc/apt/sources.list.d whose names match the format: repo-*<subsystem>*-*<version>*-*<appliance version>*.list:

   ```
   rm /etc/apt/sources.list.d/repo-*.list
   ```

6. Verify that each VM has sufficient disk space:
   a. Check the available space on the data disk:

      ```
      df -h /data/secure
      ```

      If disk usage is higher than 70%, then add disk capacity. See Adding disk space to a VMware appliance.

   b. Check available space in "/":

      ```
      df -h /
      ```

      If disk usage is higher than 70%, delete or copy off older **/var/log/syslog*.gz** files. The **syslog** files contain your API Connect and system logs. Do not delete any syslog files that might contain log data that is needed for any active support cases. If in doubt, backup the syslog files to another system before your delete them.

7. Run the **apicops** pre-upgrade health checks:
   Attention: Running the **apicops** pre-upgrade check is a required step. Failure to run this check before you start the upgrade might result in problems during the upgrade.
   a. Download the latest apicops release and copy it to your VM.
   b. On all subsystem VMs, as root user, run the subsystem status check:

      ```
      apicops upgrade:check-subsystem-status
      ```

      If the subsystem status check is successful, the command returns:

      ```
      All subsystems are in healthy, 'Running' state!
      ```

      If either check returns any errors, do not proceed with the upgrade.

   c. Run the **apicops** pre-upgrade check on your management VMs:
      Note: If you have a 2DCDR deployment, run this check only on the active management subsystem.

`apicops version:pre-upgrade`

If the `apicops` check returns:

`The original primary PVC is not attached to any pods in this namespace`

then follow the steps in The original primary PVC is not attached to any pods in this namespace.

If the `apicops` check returns:

`Current postgres leader is not the original leader, see https://ibm.biz/BdPLWU for next steps`

then follow the steps in the linked page https://ibm.biz/BdPLWU.

8. **Upgrading from v10.0.6:** Back up the Postgres images on one of the management VMs by running the following commands:

```
postgres_operator=$(kubectl get pod -l app.kubernetes.io/name=postgres-operator -o name)

ctr --namespace k8s.io images pull --plain-http=true `kubectl get  $postgres_operator  -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'`
ctr --namespace k8s.io images export rmdata.tar `kubectl get  $postgres_operator  -o jsonpath='{.spec.containers[].env[?
(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'`
ctr --namespace k8s.io images export backrestrepo.tar `kubectl get  $postgres_operator  -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_BACKREST_REPO")].value}'`
ctr --namespace k8s.io images export pgbouncer.tar `kubectl get  $postgres_operator  -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_PGBOUNCER")].value}'`
ctr --namespace k8s.io images export postgres-ha.tar `kubectl get  $postgres_operator  -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_POSTGRES_HA")].value}'`

postgres_pod=$(kubectl get pod -l role=master -o name)
ctr --namespace k8s.io images export k8s-init.tar `kubectl get $postgres_pod  -o
jsonpath='{.spec.initContainers[].image}'`
```

Pre-upgrade backups and preparation:

9. Optional: Setup remote logging: Configuring remote logging for a VMware deployment.
   If the upgrade process fails, it is possible that important log messages for problem diagnosis are not retained on the VMs. Configure remote logging to ensure that all API Connect logging during the upgrade is retained.

10. Backup all your subsystems. Ensure that you have:
    - Database backups of all your subsystems.
    - Project directory backup.
    - **Optional:** VM snapshots of all subsystems.

    Upgrading from V10.0.7.0 or later: see Backing up and restoring on VMware.

    Upgrading from V10.0.6.0 or earlier: see Preparing for a disaster.

Download and verification of API Connect upgrade files:

11. Obtain the API Connect upgrade files:
    You can access the latest files from IBM Fix Central by searching for the API Connect product and your installed version.

    The following files are used during upgrade on VMware:

    IBM API Connect *<version>* Management Upgrade File for VMware
    : Management subsystem files for upgrade. Filename is: upgrade_management_*<version>*.

    IBM API Connect *<version>* Developer Portal Upgrade File for VMware
    : Developer Portal subsystem files for upgrade. Filename is: upgrade_portal_*<version>*

    IBM API Connect *<version>* Analytics Upgrade File for VMware
    : Analytics subsystem files for upgrade. Filename is upgrade_analytics_*<version>*

    IBM API Connect *<version>* Install Assist for *<operating_system_type>*
    : The apicup installation utility. Required for all installations on VMware. Filename is apicup-*<platform>*_*<version>*.

    The following files are not used during the upgrade process, but should be downloaded to replace your existing versions of them:

    IBM® API Connect *<version>* Toolkit for *<operating_system_type>*
    : Toolkit command-line utility. Packaged as a stand-alone file, or with API Designer or Loopback:
      - IBM® API Connect *<version>* Toolkit for *<operating_system_type>*
      - IBM® API Connect *<version>* Toolkit with Loopback for *<operating_system_type>*
      - IBM® API Connect *<version>* Toolkit Designer with Loopback for *<operating_system_type>*

      Filename is toolkit-...*<operating system>*_*<version>*.
      Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See Installing the toolkit.

    IBM® API Connect *<version>* Local Test Environment
    : Optional test environment. See Testing an API with the Local Test Environment
      Filename is apic-lte-*<operating system>*_*<version>*.

    IBM® API Connect *<version>* Security Signature Bundle File
    : Checksum files that you can use to verify the integrity of your downloads.
      Filename is signatures_*<version>*.

      To verify the files against the signatures, see Verifying the integrity of IBM product files.

12. If control plane files are required for your upgrade path, download them from the same IBM Fix Central page.
    Control plane files are required to support specific Kubernetes versions. The IBM API Connect *<version>* Management Upgrade File for VMware file contains the latest control plane file.

    Table 1 lists the control plane files that are needed for upgrading to the current release.

Tip: On the Fix Central page, type "control-plane" in the Filter fix details field to list only the control plane files in the results table. Then, click the Description header to sort the results so you can easily locate the control plane files that you need.

Table 1. Control plane files needed for upgrade

Version to upgrade from	Control plane files that are needed for upgrading to 10.0.7.0
• 10.0.6.0 • 10.0.5.5 • 10.0.5.4 • 10.0.5.3	No control plane files needed.

For information about the control plane files that are required for upgrading from older releases, see Control Plane files for earlier releases.

13. Verify that the subsystem upgrade files are not corrupted.
    a. Run the following command separately for the management, the developer portal, and the analytics upgrade files:
       - MacOS or Linux:

         ```
         sha256sum <upgrade-file-name>
         ```

         Example:

         ```
         sha256sum upgrade_management_v10.0.7.0
         ```

       - Windows:

         ```
         C:\> certUtil -hashfile C:\<upgrade-file-name> SHA256
         ```

         Example:

         ```
         C:\> certUtil -hashfile C:\upgrade_management_v10.0.7.0 SHA256
         ```

    b. Compare the result with the checksum values to verify that the files are not corrupted.
       If the checksum does not match the value for the corresponding version and subsystem, then the upgrade file is corrupted. Delete it and download a new copy of the upgrade file. The following list shows the checksum values for the current release.

       Checksum values for 10.0.7.0:

       ```
       10.0.7 analytics : 049f6c487ab62e07307c01206ce1ec75e2f2b1279ea1aa0f084d6220f5c206a4
       10.0.7 management : c8242110f1a5789ebe6a1dc1eefc17f0463451860794febb1f18969e7537dc0a
       10.0.7 portal : 09b23e0bc98ba2ba7b2ab4306bb4755acc95fb09bf5dc4fa8d09d453793dd04b
       ```

       For information about the checksum files used with older releases, see Checksum values for earlier releases.

14. Setup the new **apicup** command in your project directory.
    The **apicup** executable file is updated with each API Connect release. To upgrade API Connect, you must replace the **apicup** file from your current release with the new **apicup** file.
    Note: If you decide to stop or delay your API Connect upgrade, then revert these steps.
    a. In your project directory, take a backup of your current apicup file, appending the current API Connect version to the name of the backup file.
       For example:

       ```
       cp apicup apicup_v10.0.6.0
       ```

    b. Replace the apicup file in your project directory with the new apicup file that you downloaded in step 11.
    c. OSX and Linux® only: Make the apicup file executable:

       ```
       chmod +x apicup
       ```

    d. Set your operating system's `PATH` variable to include your project directory:

       Table 2. Commands for setting the path to the apicup file

Operating system	Command to set the path
macOS and Linux	`export PATH=$PATH:<project directory path>`
Windows	`set PATH=<project directory path>;%PATH%`

    e. Verify that the new **apicup** command is in your `PATH`, run:

       ```
       apicup version
       ```

       The output should show the version that you are upgrading to.

    f. Run the **apicup** command to accept the API Connect license:

       ```
       apicup licenses accept <License ID>
       ```

       <License ID> is specific to the API Connect Program Name that you purchased. To view the supported license IDs, see API Connect licenses.

- **Control Plane files for earlier releases**
  If you are upgrading to an earlier version than 10.0.7.0, refer to the following tables to determine which Control Plane files are required.
- **Checksum values for earlier releases**
  If you are upgrading to an earlier version than 10.0.7.0, use the corresponding checksum values to verify your downloaded upgrade files.

Control Plane files for earlier releases

If you are upgrading to an earlier version than 10.0.7.0, refer to the following tables to determine which Control Plane files are required.

Control planes for upgrading to 10.0.7

Installs with **appliance-control-plane-1.27.x.tgz**

Table 1. Control Plane files needed for upgrading to 10.0.7

Upgrading from API Connect version	Control Plane files needed
• 10.0.6.0 • 10.0.5.5 • 10.0.5.4 • 10.0.5.3	No Control Plane needed.

Control planes for upgrading to 10.0.6

Installs with **appliance-control-plane-1.26.x.tgz**

Table 2. Control Plane files needed for upgrading to 10.0.6

Upgrading from API Connect version	Control Plane files needed
• 10.0.5.3	No Control Plane needed.
• 10.0.5.2	Download: • **appliance-control-plane-1.25.x.tgz**
• 10.0.5.1	Download: • **appliance-control-plane-1.25.x.tgz** • **appliance-control-plane-1.24.x.tgz**

Checksum values for earlier releases

If you are upgrading to an earlier version than 10.0.7.0, use the corresponding checksum values to verify your downloaded upgrade files.

```
10.0.7 analytics : 049f6c487ab62e07307c01206ce1ec75e2f2b1279ea1aa0f084d6220f5c206a4
10.0.7 management : c8242110f1a5789ebe6a1dc1eefc17f0463451860794febb1f18969e7537dc0a
10.0.7 portal : 09b23e0bc98ba2ba7b2ab4306bb4755acc95fb09bf5dc4fa8d09d453793dd04b

10.0.6 analytics : d927781a01ed2172ae978f83bc17e8b7e12994f8de6027fab2124adf2d40f09c
10.0.6 management : 876ca328aa1e411d8e3896b65e3dff925baaf85579b1ac65248749b321126436
10.0.6 portal : a2bf468ce1bc7c6104858d757088364001e8620922396b80b52657d146c303de
```

Upgrading management, portal, and analytics on VMware

Upgrade your management, portal, and analytics subsystems on VMware.

Before you begin

- Review Planning your API Connect upgrade on VMware.
- Complete the Pre-upgrade preparation.
- Enable keep-alive in your SSH client configuration to avoid disconnects during the transfer of the upgrade images to your VMs. For more information, consult the documentation for the version of SSH that is installed on your client system (where you run the **apicup** commands from).

About this task

- If you have a two data center disaster recovery deployment, the upgrade steps are slightly different. Refer to Upgrading a two data center deployment.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) management, (2) portal, (3) analytics, (4) gateway. Management must be upgraded first to ensure that any new policies and capabilities are available to previously registered gateway services.
- When you start the upgrade process on a subsystem, the **apicup install** command sends the compressed upgrade files to all subsystem VMs. The compressed files are about 2 GB, and the transfer can take some time. The **apicup install** command exits when the transfer of the upgrade files to each VM is complete, at which point the upgrade starts. The progress of the upgrade is monitored with other commands.
- The **apicup subsys install** command runs **apicup health-check** first before the upgrade process is started. If the health-check fails, then the upgrade is aborted and details of the health-check failure is displayed.
  If you are troubleshooting a problem with upgrade and want the upgrade to proceed despite a health-check failure, then you can suppress the health check. See Skipping health check when re-running upgrade.
- You do not need to upgrade the components API Connect Toolkit and API Connect Local Test Environment in the same upgrade window. These components are single executable files. Replace them the new versions downloaded from Fix Central.

Procedure

Notes:

- If a backup of any of your subsystems is scheduled to run within a few hours, do not start an upgrade.
- While the upgrade process is running, do not do any maintenance tasks such as rotating key-certificates, or restoring from a backup.

- If you encounter an issue during the upgrade, see Troubleshooting upgrades on VMware.

1. If some time has passed since you completed the Pre-upgrade preparation, repeat these pre-upgrade steps to be sure that your subsystems are ready for upgrade.
2. Block all external traffic to the management server.
   Upgrading API Connect requires downtime while files are transferred and updated. All external traffic to the management server from all sources (Cloud Manager UI, API Manager UI, CLI, and REST API) must be blocked. As a result, the Cloud Manager and API Manager UIs cannot be used during the upgrade. In addition, the developer portal cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the upgrade.

3. Verify that the new **apicup** command is in your operating system's `PATH` variable:

   ```
   apicup version
   ```

   The version that is returned should be the version that you are upgrading to. If not, then refer to step 14 on Pre-upgrade preparation and checks VMware.

4. Upgrade the management subsystem:
   a. If you are upgrading to v10.0.7.0 and are not able to configure S3 object-store backups for your management subsystem, then set `accept-no-backups` to `true` to allow upgrade to proceed:

      ```
      apicup subsys set <subsystem_name> accept-no-backups=true
      ```

      For more information about this limitation, see Planning your API Connect upgrade on VMware.
   b. Start the upgrade of the management subsystem:
      i. Install the management subsystem files.
      Note:
      If you have a two data center disaster recovery deployment and are upgrading to v10.0.7.0, all data on the warm-standby management subsystem is deleted during the upgrade, to be replaced by data from the upgraded active management subsystem.

      Include the flag `--accept-warm-standby-upgrade-data-deletion` in the `apicup subsys install <mgmt_subsystem> <upgrade_tar>` command to acknowledge this temporary data deletion.

      If you have a two data center disaster recovery deployment, and are upgrading to v10.0.6.0, do not follow this step. Instead, follow the steps in Management subsystem two data center upgrade from v10.0.5.

      For more information about two data center disaster recovery upgrade, see Upgrading a two data center deployment.

      If you are upgrading to v10.0.7.0, include the `--skip-health-check` argument:

      ```
      apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> --skip-health-check
      ```

      For all other upgrade paths, use:

      ```
      apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
      ```

      Notes:
      - If you are adding one or more control plane files, specify the file path to each control plane file:

        ```
        apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1> <path_to_control_plane_file_n>
        ```

      - If the upgrade gets stuck, run the following command to restart the appliance:

        ```
        sudo systemctl restart appliance-manager
        ```

      ii. Verify that the upgrade was successful by running the **apicup** health check:

      ```
      apicup subsys health-check <subsystem_name>
      ```

      iii. If upgrading to 10.0.7.0, verify that the health check did not return a false-positive response.
      Note: This step only applies if you upgraded to API Connect 10.0.7.0 and is due to a known issue that will be corrected in a later release.
      Run the following command to get the current version of API Connect on the upgraded subsystem:
      1. Log in to the VM:

         ```
         ssh apicadm@<hostname>
         ```

      2. Switch to `root` user:

         ```
         sudo -i
         ```

      3. Get the API Connect version:

         ```
         kubectl get apic
         ```

      If the health check indicates a successful upgrade but the subsystem is still running the older version of API Connect, skip the remaining steps in this procedure and see False positive result from health check after upgrading to 10.0.7.0 for troubleshooting instructions.

      If the subsystem is running the newer version of API Connect then the upgrade was successful; continue with the remaining steps in this procedure.

      iv. If the health check indicates that a reboot is needed, complete the following steps on all management VMs:
      1. Login to the VM:

         ```
         ssh apicadm@<hostname>
         ```

      2. Switch to `root` user:

         ```
         sudo -i
         ```

      3. `systemctl reboot`

   c. Use `apicops` to validate the certificates.
      For more information about the `apicops` tool, see The API Connect operations tool: apicops.

i. Login to the VM:

```
ssh apicadm@<hostname>
```

ii. Switch to `root` user:

```
sudo -i
```

iii. Run the following command:

```
apicops upgrade:stale-certs
```

iv. Delete any stale cert-manager certificates.
If a cert-manager certificate failed validation, delete the stale certificate secret to trigger cert-manager to regenerate it. Run the following command:

```
kubectl delete secret <stale-secret>
```

v. Restart the corresponding pod so that it can pick up the new secret.
To determine which pod to restart, see the following topics:
- List of ingress certificates
- List of intra-subsystem certificates

5. If you have multiple management subsystems in the same project, set the portal subsystem's `platform-api` and `consumer-api` certificates to match the certificates used by their corresponding management subsystems.
This step applies only if you installed more than one management subsystem into a single project.

   A portal subsystem can be associated with only one management subsystem. To associate the upgraded portal subsystem with the appropriate management subsystem, manually set the `mgmt-platform-api` and `mgmt-consumer-api` certificates to match the ones used by the management subsystem.

   a. Run the following commands to get the certificates from the management subsystem:

   ```
   apicup certs get mgmt-subsystem-name platform-api -t cert > platform-api.crt
   apicup certs get mgmt-subsystem-name platform-api -t key > platform-api.key
   apicup certs get mgmt-subsystem-name platform-api -t ca > platform-api-ca.crt

   apicup certs get mgmt-subsystem-name consumer-api -t cert > consumer-api.crt
   apicup certs get mgmt-subsystem-name consumer-api -t key > consumer-api.key
   apicup certs get mgmt-subsystem-name consumer-api -t ca > consumer-api-ca.crt
   ```

   where *`mgmt-subsystem-name`* is the name of the specific management subsystem that you want to associate the new portal subsystem with.

   b. Run the following commands to set the portal's certificates to match the certificates used by the management subsystem:

   ```
   apicup certs set ptl-subsystem-name platform-api Cert_file_path Key_file_path CA_file_path

   apicup certs set ptl-subsystem-name consumer-api Cert_file_path Key_file_path CA_file_path
   ```

6. Upgrade the portal subsystem.
Attention: If you are upgrading a two data center disaster recovery deployment, upgrade the warm-standby data center first.
For more information about two data center disaster recovery upgrade, see Upgrading a two data center deployment.

   a. Install the portal subsystem files:

   ```
   apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
   ```

   Note: If you are adding one or more control plane files, specify the file path of each control plane file:

   ```
   apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1>
   <path_to_control_plane_file_n>
   ```

   b. Verify that the upgrade was successful by running a health check with the following command:

   ```
   apicup subsys health-check <subsystem_name>
   ```

   Important: If the health check indicates that a reboot is required, do not reboot at this stage. Reboot after all sites are upgraded, see step 7.

   c. Verify that the health check did not return a false-positive response.
   Run the following command to get the current version of API Connect on the upgraded subsystem:
      i. Log in to the VM:

      ```
      ssh apicadm@<hostname>
      ```

      ii. Switch to `root` user:

      ```
      sudo -i
      ```

      iii. Get the API Connect version:

      ```
      kubectl get apic
      ```

   If the health check indicates a successful upgrade but the subsystem is still running the older version of API Connect, skip the remaining steps in this procedure and see False positive result from health check after upgrading to 10.0.7.0 for troubleshooting instructions.

   If the subsystem is running the newer version of API Connect then the upgrade was successful; continue with the remaining steps in this procedure.

   d. If you have two data center disaster recovery deployment and upgraded the portal subsystem in the warm-standby data center, then start the upgrade on the active data center.
   Note: In a two data center disaster recovery deployment, after the warm-standby is upgraded, the active data center might enter a non-READY state. If this happens, do not be concerned, proceed to upgrade the portal subsystem in the active data center.

7. Verify portal sites are upgraded.
Run the following toolkit commands to ensure that the portal site upgrades are complete:

   a. Log in as an admin user:

```
apic login -s <server_name> --realm admin/default-idp-1 --username admin --password <password>
```

b. Get the portal service ID and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
            --availability-zone availability-zone-default <portal-service-name> \
            --output - --format json
```

c. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
            --portal_service_name <portal-service-name> \
            --format json
```

Any sites currently upgrading display the **UPGRADING** status; any site that completed its upgrade displays the **INSTALLED** status and the new platform version. Verify that all sites display the **INSTALLED** status before proceeding.

For more information about the **sites** command, see **apic sites:list** and Using the **sites** commands.

d. After all sites are in **INSTALLED** state and show the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <server_name> --portal_service_name <portal_service_name>
```

Verify that the new version of the platform is the only platform listed.

For more information about the **platforms** command, see **apic platforms:list** and Using the **platforms** commands.

e. If all portal sites are upgraded and the health check indicates that a reboot is needed, then run the following command on all portal VMs:

```
systemctl reboot
```

8. Upgrade the analytics subsystem.
   a. Install the analytics subsystem files:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
```

Note: If you are adding one or more control plane files, specify the file path of each control plane file:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1>
<path_to_control_plane_file_n>
```

b. Verify that the upgrade was successful by running a health check with the following command:

```
apicup subsys health-check <subsystem_name>
```

c. If upgrading to 10.0.7.0, verify that the health check did not return a false-positive response.
Note: This step only applies if you upgraded to API Connect 10.0.7.0 and is due to a known issue that will be corrected in a later release.
Run the following command to get the current version of API Connect on the upgraded subsystem:

```
kubectl get apic
```

If the health check indicates a successful upgrade but the subsystem is still running the older version of API Connect, skip the remaining steps in this procedure and see False positive result from health check after upgrading to 10.0.7.0 for troubleshooting instructions.

If the subsystem is running the newer version of API Connect then the upgrade was successful; continue with the remaining steps in this procedure.

d. If the health check indicates that a reboot is needed, run the following commands on all analytics VMs:

```
systemctl reboot
```

9. Take a backup of your project directory, and database backups of each upgraded API Connect subsystem; see Backing up and restoring on VMware.
10. Optional: Take a virtual machine (VM) snapshot of all your VMs; see Using VM snapshots for infrastructure backup and disaster recovery for details. This action requires a brief outage while the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully.

What to do next

When your management, portal, and analytics subsystem are upgraded, upgrade your DataPower Gateway Service. See Upgrading DataPower Gateway.

Upgrading DataPower Gateway

Use these instructions to upgrade your DataPower Gateway services in a non-Kubernetes environment.

Before you begin

Complete the upgrade of the API Connect management, portal, and analytics subsystems before upgrading gateway. Upgrading the management subsystem before the gateway ensures that any new policies and capabilities are available to a previously registered gateway service.

About this task

- The DataPower Gateway Service in a non-Kubernetes environment can be on either a physical appliance or in a virtual DataPower deployment.
- The upgrade of DataPower Gateway Service in a non-Kubernetes environment, for use in API Connect deployments in a VMware environment, does not use the **apicup** command. Use DataPower Gateway instructions in the following steps.

Note: To upgrade the DataPower Gateway Service in a Kubernetes environment, do not use this procedure. Instead, see Upgrading the gateway subsystem on Kubernetes.

Procedure

1. Ensure that the DataPower Gateway firmware version you plan to install is compatible with the API Connect management subsystem version.
   Note:
   You can use any combination of API Connect CD releases (10.0.6.x) with DataPower CD releases (DataPower Gateway 10.5.1.x or DataPower API Gateway 10.5.1.x).

   Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

2. When you upgrade a high-availability cluster, check that you meet the following requirements:
   - Gateways must be updated one at a time.
   - Before you start the upgrade, a single gateway must be running as primary for all gateway-peering definitions.
   - If you are upgrading multiple gateways, the primary gateway must be upgraded last.

   To determine which gateway is running as primary, use either the **`show gateway-peering-status`** command in the DataPower CLI, or use the Gateway Peering Status display in the Web GUI in the API Connect application domain. To move the primary to the DataPower on which you are working, you can issue the **`gateway-peering-switch-primary <peering-object-name>`** command.

3. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
   See Managing the NTP service.
4. Ensure that a unique **`System Identifier`** is set for each v10 DataPower Gateway . See Initializing the DataPower Gateway.
5. Follow the upgrade instructions on the DataPower Gateway documentation. See Installation operations.
   Note:
   - If you are upgrading a cluster (high-availability) deployment, ensure that you have identified which gateway is running a primary in gateway-peering definitions, and that you upgrade that gateway last.
   - For troubleshooting help with DataPower operator deployments, see IBM DataPower Operator documentation.

Upgrading a two data center deployment

How to upgrade a two data center disaster recovery (DR) deployment on VMware.

To upgrade a two data center disaster recovery deployment, follow the API Connect on VMware upgrade procedures along with the additional procedures that are described in this topic.

Key points for two data center disaster recovery upgrade on VMware:

- Both data centers must be using the same version of API Connect, including down to the specific fix pack and interim fix level. Therefore, both data centers must be upgraded in the same maintenance window.
- Do not reboot any of the management or portal virtual machines until the end of the upgrade, even if you're instructed to do so by the **`apicup subsys health-check`** command during the upgrade process.
- The management and portal subsystems in the warm-standby data center must be upgraded first.
- Upgrades to V10.0.6.0 only: 2DCDR is disabled on the management subsystems during the upgrade process. Keep a note of which data center had the active management subsystems when you start the upgrade process; set this same data center as the active at the end of the process.

Upgrade steps for 2DCDR:

1. Review the Planning your API Connect upgrade on VMware.
2. Complete the Pre-upgrade preparation and checks VMware steps.
3. **Upgrades to v10.0.7 and later only:** Upgrade the warm-standby management subsystem first, include the **`--accept-warm-standby-upgrade-data-deletion`** flag in the upgrade command.
4. **Upgrades to v10.0.6 only:** To upgrade the management subsystem, follow Management subsystem two data center upgrade from v10.0.5.
5. To upgrade the portal subsystem, follow the steps in Upgrade on VMware, but ensure that the warm-standby is upgraded first.
6. Upgrade analytics and gateway subsystems as described in Upgrade on VMware.

How to upgrade when one data center is down

If you cannot get your failed data center back online and want to upgrade, you can convert your active data center to a stand-alone and upgrade it:

1. Ensure that the network links to the failed data center are removed, so that if the failed data center recovers unexpectedly, it cannot interfere with your active data center.
2. Convert the active data center to a stand-alone data center: Removing a two data center deployment.
3. Upgrade your active data center with the standard upgrade steps: Upgrade on VMware.

To restore 2DCDR, replace the API Connect deployment in your failed data center with a new installation at the same fix pack level as your upgraded active data center. Follow the steps in Installing a two data center deployment to configure 2DCDR between the data centers.

Related concepts

- Two data center warm-standby deployment strategy on VMware

Related tasks

- Installing a two data center deployment

Management subsystem two data center upgrade from v10.0.6

Upgrades from v10.0.6 and later: How to upgrade your management subsystem in a two data center deployment.

About this task

Follow the steps in this topic, along with the steps documented in Upgrading to the latest release on VMware.

Some steps in the upgrade process are run from the project directory with the **apicup** command. Other steps require you to login to the management VMs as root user. To login as root, follow these steps:

- Use SSH to login to the VM as the `apicadm` user:

  ```
  ssh apicadm@<hostname>
  ```

- Switch to the root user with `sudo`:

  ```
  sudo -i
  ```

Procedure

1. Review the Planning your API Connect upgrade on VMware.
2. Complete the Pre-upgrade preparation and checks VMware steps.
3. Block all external traffic to the management server.
   Upgrading API Connect requires downtime while files are transferred and updated. All external traffic to the management server from all sources (Cloud Manager UI, API Manager UI, CLI, and REST API) must be blocked. As a result, the Cloud Manager and API Manager UIs cannot be used during the upgrade. In addition, the developer portal cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the upgrade.
4. Verify that the new **apicup** command is in your operating system's `PATH` variable:

   ```
   apicup version
   ```

   The version that is returned should be the version that you are upgrading to. If not, then refer to step 14 on Pre-upgrade preparation and checks VMware.
5. Upgrade your warm-standby first. Run the upgrade command with the `--accept-warm-standby-upgrade-data-deletion` and `--skip-health-check` flags:

   ```
   apicup subsys install <subsystem name> <subsystem upgrade tar archive> --accept-warm-standby-upgrade-data-deletion --skip-health-check
   ```

   Note: If any Control Plane files are needed for your upgrade, you must append the files to the `install` command. For example:

   ```
   apicup subsys install <subsystem name> <subsystem upgrade tar archive> <path to control plane file 1> <path to control plane file 2> --accept-warm-standby-upgrade-data-deletion --skip-health-check
   ```

   The `--accept-warm-standby-upgrade-data-deletion` flag is required to acknowledge that you accept that the management subsystem data is deleted from the warm-standby during the upgrade. The deleted data is replaced when the active management subsystem is upgraded and synchronizes with the upgraded warm-standby. W
6. Login to the warm-standby VM to monitor the status. Verify that the subsystem status reaches the `Running` state.

   ```
   kubectl get mgmt
   ```

   ```
   NAME          READY   STATUS    VERSION    RECONCILED VERSION AGE
   management    n/n     Running   <current version>   <current version>   5h2m
   ```

   The `RECONCILED VERSION`/`VERSION` should still show your current version, not the version you are upgrading to.
7.
8. Run the upgrade command on both sites without the `--skip-operand-update` flag:

   ```
   apicup subsys install <subsystem name> <subsystem_upgrade_tar_archive>
   ```

9. Continue following the standard management subsystem upgrade steps, from step 5.b.ii on Upgrade on VMware.

Management subsystem two data center upgrade from v10.0.5

Upgrades to v10.0.6 from v10.0.5 only: How to upgrade your management subsystem in a two data center deployment.

About this task

Follow the steps in this topic, along with the steps documented in Upgrading to the latest release on VMware.

The steps in this topic involve running command-line operations from several locations:

- **apicup** operations are run from your API Connect project directory.
  Note: The **apicup** command is a binary file that is included with each API Connect release. Unless stated otherwise, all operations in this topic that use the **apicup** command must use the **apicup** binary from the target release (the release that you want to upgrade to). Be careful to not use the **apicup** command from your

source release.
- **apic** and **kubectl** operations are run from within your management appliance, as the root user. Login to your management virtual appliance with an SSH client and the username `apicadm`, then switch to the root user with `sudo -i`.

Procedure

1. Determine the current version and license of API Connect (the version that you are upgrading from).
   You will need to specify the correct version number and license in the next step.
   a. To get the current version, from within the management appliance run the following command:

      ```
      apic version
      ```

      In the response, the `- subsystem-<subsytem-name>` statement displays the installed version. In the following example, the response indicates that the installed version is 10.0.5.3:

      ```
      apic version

      INFO[0000] Log level: info
      Control plane: 1.26.0
      Appliance base 4.6.0
      GitCommitSha:10.0.5.2-55-gb784ac7
      Packages:
      - appliance-base:4.6.0
      - appliance-runtime-4.6.0:1.0.0
      - appliance-setup-4.6.0:1.0.0
      - subsystem-management:1:10.0.5.3
      ```

   b. To get the current license, run the following **apicup** command in your project directory:

      ```
      apicup licenses list
      ```

      in the response, the `ID` statement displays the installed license, for example:

      ```
      Accepted licenses:
              ID: <source_license>
              Product Version: <source_version>
              URL: <license_url>
      ```

      Note: If there are multiple accepted licenses, refer only to the `<source_license>` that aligns with the `<source_version>` of your system (that is the `<source_version>` that matches the version that you obtained in step 1.a).
2. Add source license and version to your extra-values.yaml file.
   Note: If you do not have an extra-values.yaml file, then create one in a directory that the `apicup` command can access.
   Add the source lines that you identified in step 1 to your extra-values.yaml as shown:

   ```
   spec:
     version: "<source_version>"
     license:
       license: <source_license>
     imageRegistry: 127.0.0.1:8675/<source_version>
   ```

   <source_version> is added in two places: `version` and `imageRegistry`.
3. Apply the extra-values.yaml file.
   Run the following `apicup` command to set the `extra-values` file for both the `active` and `warm-standby` sites:

   ```
   apicup subsys set <mgmt> extra-values-file=<extra-values-file-path>
   ```

   where *<mgmt>* is the name of your management subsystem, which you can get with:

   ```
   apicup subsys list
   ```

   If you want to validate your `<extra-values-file-path>`, and the other subsystem settings, before proceeding, you can run:

   ```
   apicup subsys get <mgmt> --validate
   ```

4. Start the upgrade process on both active and warm-standby management subsystems.

   ```
   apicup subsys install <mgmt> <mgmt_upgrade_tar_archive>
   ```

   Note: If any Control Plane files are needed for your upgrade, you must append the files to the `install` command.
5. Wait for the management subsystem status to become `Running` on both sites.
   To determine the status, login to the management appliances on both sites as root user and run:

   ```
   kubectl get mgmt

   NAME         READY   STATUS    VERSION    RECONCILED VERSION AGE
   management   n/n     Running   10.0.6.0   10.0.6.0-100   5h2m
   ```

   The `RECONCILED VERSION`/`VERSION` should be the `source_version` that you retrieved in step 1.

6. Disable 2DCDR on the `warm-standby` management subsystem:

   ```
   apicup subsys set <warm-standby management subsystem> multi-site-ha-enabled=false
   apicup subsys install <warm-standby management subsystem>
   ```

   Conversion from warm-standby to a stand-alone management subsystem can take some time. Run the health check to ensure that the deployment is in a good state before proceeding:

   ```
   apicup subsys health-check <warm-standby management subsystem>
   ```

an empty response means no detected problems.

7. Disable 2DCDR on the active management subsystem.

```
apicup subsys set <active management subsystem> multi-site-ha-enabled=false
apicup subsys install <active management subsystem>
```

Conversion from active to a stand-alone management subsystem can take some time. Run the health check to ensure that the deployment is in a good state before proceeding:

```
apicup subsys health-check <active management subsystem>
```

an empty response means no detected problems.

8. Wait for the management subsystem status to become **Running** on both sites.
To determine the status, login to the management appliances on both sites as root user and run:

```
kubectl get mgmt
```

```
NAME          READY   STATUS    VERSION    RECONCILED VERSION AGE
management    n/n     Running   10.0.6.0   10.0.6.0-100    5h2m
```

The **RECONCILED VERSION**/**VERSION** should be the ***source_version*** that you retrieved in step 1.

9. Edit your extra-values.yaml file and delete the **version**, **license**, and **imageRegistry** properties that you added in step 2.
If you have no other properties in your extra-values.yaml file, then unset the **extra-values-file** property:

```
apicup subsys set mgmt extra-values-file=
```

Apply the change to both sites by running:

```
apicup subsys install <mgmt>
```

10. Wait for the management subsystems status to become **Running** on both sites.

```
kubectl get mgmt
NAME          READY   STATUS    VERSION    RECONCILED VERSION AGE
management    16/16   Running   10.0.6.1   10.0.6.1-100    5h2m
```

The **RECONCILED VERSION**/**VERSION** should now be the target release that you are upgrading to.

11. Run the health check on both clusters to ensure that the upgrade completed.

```
apicup subsys health-check <mgmt>
```

an empty response means no detected problems.

12. Enable 2DCDR on the previously **active** management subsystem.

```
apicup subsys set <active management subsystem> multi-site-ha-enabled=true
apicup subsys install <active management subsystem>
```

13. Wait for the management subsystem status to become **Running** on the active site.

```
kubectl get mgmt
NAME          READY   STATUS    VERSION    RECONCILED VERSION AGE
management    16/16   Running   10.0.6.1   10.0.6.1-100    5h2m
```

The **RECONCILED VERSION**/**VERSION** should now be the target release that you are upgrading to.

14. Enable 2DCDR on the previously warm-standby management subsystem.

```
apicup subsys set <warm-standby management subsystem> multi-site-ha-enabled=true
apicup subsys install <warm-standby management subsystem>
```

15. Wait for the management subsystem status to become **Running** on the warm-standby site.

```
kubectl get mgmt
NAME          READY   STATUS    VERSION    RECONCILED VERSION AGE
management    16/16   Running   10.0.6.1   10.0.6.1-100    5h2m
```

The **RECONCILED VERSION**/**VERSION** should now be the target release that you are upgrading to.

16. Verify that 2DCDR replication is working.
To validate that your two data center deployment is replicating data, login to your active management appliance as root user, run **kubectl get mgmt**:

```
kubectl get mgmt
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Running   10.0.5.3-0   10.0.5.3-0           Management is ready.              8m59s
```

If you see **HA Status Warning** in the **MESSAGE** column, then check the status details with **kubectl describe mgmt**:

```
status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
   }
```

Notes:

- It takes time for the **warm-standby** site to sync with the **active** site.
- When **STATUS** shows **Running**, you can reboot (if **apicup subsys health-check** advises you to do so).

Troubleshooting upgrades on VMware

Review the following troubleshooting guidance if you encounter a problem while upgrading API Connect on VMware.

For additional issues that you might encounter when upgrading to v10.0.6.0 only, see Troubleshooting upgrades to v10.0.6.0 on VMware.

Subsystem is stuck in `Pending` state with a reason of `PreUpgradeCheckInProgress`

Before the subsystem microservices are upgraded, the operator triggers a set of pre-upgrade checks that must pass for the upgrade to proceed. If one or more of the checks fail, the subsystem status remains in **Pending** state with a reason of **PreUpgradeCheckInProgress**. Check the status condition of the subsystem CR to confirm the pre-upgrade check failed. The **status.PreUpgradeCheck** property contains a summary of the failed checks. Full logs for the checks that are carried out can be viewed in the **ConfigMap** referenced in the **status.PreUpgradeCheck** property. The pre-upgrade checks automatically retry until they successfully pass. If you are unable to rectify the problem that causes a check to fail, then open an IBM support case.

False positive result from health check after upgrading to 10.0.7.0

Sometimes an upgrade to API Connect 10.0.7.0 appears to complete successfully and the health-check reports that the upgraded subsystem is healthy, but the older version is still installed. A false positive response from the health check indicates a problem with the upgrade.

Note: This step only applies if you upgraded to API Connect 10.0.7.0 and is due to a known issue that will be corrected in a later release.
Complete the following steps to resolve the issue:

1. If you did not do so already, run the follow command on each subsystem to determine what version of API Connect is deployed:

   ```
   kubectl get apic
   ```

   If the new version of API Connect is deployed on a subsystem, then the upgrade was successful for that subsystem.

2. If the older version of API Connect is still deployed on a subsystem, run the following command to check the status of that subsystem in case there is a message about the underlying problem:

   ```
   apic status
   ```

   Sometimes the status indicates the problem and you can correct it before upgrading that subsystem again.
3. If you do not see any messages indicating the source of the problem, contact IBM Support for assistance.

V10.0.7 only: Upgrade issues a warning for management subsystem to use S3 backups

If you previously used SFTP for backups, you must configure S3 backups before upgrading to v10.0.7.0. Configuring the S3 backups requires that you use the older version of the **apicup** tool (from your current release of API Connect) to both set the values and run the **apicup install** command.

If you used the wrong version of **apicup** to configure S3 backup settings before upgrading, you might see a warning for the Management subsystem with the following message: **Please set S3 backup configs.**

Correct the problem by running the following command run the upgrade again but skip the health-check and allow the CR to be updated with the new S3 settings:

```
./apicup subsys install <mgt-subsys-name> --skip-health-check
```

Some containers in the `kube-system` namespace show a status of `ErrImageNeverPull`

When upgrading, some of the containers in the **kube-system** namespace might show a status of**ErrImageNeverPull**. This happens due to Docker not successfully loading all images from the upgrade .tgz file. To resolve this issue and enable the upgrade to proceed, complete the following steps:

1. Run the following command to determine which node is missing the control plane files:

   ```
   kubectl -n kube-system get pods -owide
   ```

   This command returns the names of the nodes containing pods with the **ErrImageNeverPull** status, which indicates missing control plane files.

2. On the node that is missing the control plane files, run the following command to determine which versions of the control plane are missing:

   ```
   cat /var/lib/apiconnect/appliance-control-plane-current
   ```

3. V10.0.7: For each missing control plane, run the following command on the same node to add it, replacing *<version>* with the version of the control plane:

   ```
   ctr -k8s.io images import /usr/local/lib/appliance-control-plane/<version>/kubernetes.tar --all-platforms
   ```

   If you have a kubernetes.tgz file instead of a kubernetes.tar file, the run this first:

   ```
   gunzip /usr/local/lib/appliance-control-plane/<version>/kubernetes.tgz
   ```

4. V10.0.6: For each missing control plane, run the following command on the same node to add it, replacing *<version>* with the version of the control plane:

   ```
   docker load < /usr/local/lib/appliance-control-plane/<version>/kubernetes.tgz
   ```

Skipping health check when re-running upgrade

The **apicup subsys install** command automatically runs **apicup health-check** prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade

In some scenarios, if you encounter an upgrade failure, an attempt to rerun **apicup subsys install** is blocked by errors found by **apicup health-check**. Even when you have fixed the error (such as reconfiguration of an incorrect upgrade CR), the failed upgrade can continue to cause the health check to fail.

You can workaround the problem by adding the **--skip-health-check** flag to suppress the health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

In this case, use of **--skip-health-check** allows the upgrade to rerun successfully.

Unexpected behavior in Cloud Manager and API Manager UIs after upgrade

Stale browser cache issues can cause problems after an upgrade. To remedy this problem, clear your browser cache, and open a new browser window.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

- **Troubleshooting upgrades to v10.0.6.0 on VMware**
  Review the following troubleshooting guidance if you encounter a problem while upgrading to API Connect 10.0.6.0 on VMware.

Troubleshooting upgrades to v10.0.6.0 on VMware

Review the following troubleshooting guidance if you encounter a problem while upgrading to API Connect 10.0.6.0 on VMware.

In addition to the issues noted in Troubleshooting upgrades on VMware, you might encounter the following issues when upgrading specifically to version 10.0.6.0. These issues do not apply when upgrading to v10.0.7.0 or later.

The original primary PVC is not attached to any pods in this namespace

Upgrading to v10.0.6.0 only:

If the **apicops version:pre-upgrade** check reports

```
The original primary PVC is not attached to any pods in this namespace
```

and you have not started the upgrade yet (you have not run the **apicup subsys install** command) then follow these steps:

1. Take a backup of your management subsystem: Backing up and restoring the Management subsystem V10.0.6.0.
2. Restore the new backup: Restoring the management subsystem V10.0.6.0.

The action of taking and restoring a management backup fixes the problem that causes the error message. If you see this error after starting upgrade, see Original PostgreSQL primary not found.

Original PostgreSQL primary not found

Upgrading to v10.0.6.0 only:

If you ran the **apicup subsys install <tar file>** command to start an upgrade, the upgrade does not complete, and the **apicup health-check** command returns:

```
apicup subsys health-check management
Error: Cluster not in good health:
expect member apicdev.ibm.com 'Install stage' to be 'Done'(actual: SETUP_SUBSYSTEM) | Detail: reconcile.go#apply subsystem not
ready
```

then SSH into the management appliance and switch to root user to get more details of the error:

```
ssh apicadm@<management appliance>
sudo -i
```

Run **kubectl describe mgmt**, and check the output for the following message:

```
kubectl describe mgmt

...
Original PostgreSQL primary not found, further operand upgrade will be blocked. Set apiconnect-operator/db-primary-not-found-
allow-upgrade=true annotation to unblock operand upgrade and perform db backup and restore after upgrade to restore original
primary
...
```

To fix this problem, complete the following steps:

1. Create an extra-values.yaml file and set the annotation:

   ```
   metadata:
     annotations:
       apiconnect-operator/db-primary-not-found-allow-upgrade: "true"
   ```

   Note: If you already have an extra-values.yaml file, update the existing file with above annotation.
2. Set the extra-values-file property on your management subsystem with **apicup**:

```
apicup subsys set <management subsystem name> extra-values-file=<extra values filename>
```

3. Restart the upgrade, with the **--skip-health-check** flag:

```
apicup subsys install <management subsystem name> <upgrade tar file> <control plane file - if required> --skip-health-check
```

4. When upgrade is complete:
   a. Remove the annotation from your extra-values.yaml file.
   b. Take a backup of your management subsystem: Backing up and restoring the Management subsystem V10.0.6.0.
   c. Restore the new backup: Restoring the management subsystem V10.0.6.0. The action of taking and restoring a management backup fixes the problem that causes the error message `The original primary PVC is not attached to any pods in this namespace`. Be careful to restore from the backup that is taken after the upgrade, and not from a backup taken before upgrade.

The `cloud-final.service` fails during upgrade

Upgrading to v10.0.6.0 only:

Sometimes during upgrade, there is an issue with the **cloud-final.service** and a node, and the appliance-manager enters a bad state.

To determine whether your upgrade encountered this problem, complete the following steps:

1. Check the output of **apic health-check** command for a result similar to the following example:

```
# apic health-check
INFO[0000] Log level: info
FATA[0000] Unable to cluster status: rpc error: code = Unavailable desc = connection error: desc = "transport: Error while dialing dial tcp 9.20.153.38:9178: connect: connection refuse
```

2. Check the response to the **journalctl -u appliance-manager | grep cloud-final** command and see if it looks like the following example:

```
# journalctl -u appliance-manager | grep cloud-final
Nov 21 19:41:58 apimdev1040 apic[2569]: Job for cloud-final.service failed because the control process exited with error code.
Nov 21 19:41:58 apimdev1040 apic[2569]: See "systemctl status cloud-final.service" and "journalctl -xe" for details.
```

If you determined that this was the problem, you can correct it by running each of the following commands on every node:

1. **systemctl restart cloud-final.service**
2. **apic lock**
3. **apic unlock**

Postgres replica fails to start due to permissions issue

Upgrading to v10.0.6.0 only:

Symptom:

```
2023-04-11 11:31:40,535 INFO: Lock owner: v10-0-5-up-ce0f24dc-site1-postgres-iszz-c5d9c4f5c-9d9fj; I am v10-0-5-up-ce0f24dc-site1-postgres-75845474bd-kzcjl
2023-04-11 11:31:40,537 INFO: starting as a secondary
2023-04-11 11:31:41.032 UTC [151610][]FATAL:  data directory "/pgdata/v10-0-5-up-ce0f24dc-site1-postgres" has invalid permissions
2023-04-11 11:31:41.032 UTC [151610][]DETAIL:  Permissions should be u=rwx (0700) or u=rwx,g=rx (0750).
2023-04-11 11:31:41,055 INFO: postmaster pid=151610
/tmp:5432 - no response
2023-04-11 11:31:41,091 INFO: Lock owner: v10-0-5-up-ce0f24dc-site1-postgres-iszz-c5d9c4f5c-9d9fj; I am v10-0-5-up-ce0f24dc-site1-postgres-75845474bd-kzcjl
2023-04-11 11:31:41,092 INFO: failed to start postgres
```

Resolve the issue by completing the following steps to correct the permissions and restart the replica pod:

1. Run the following command to exec into the pod:

```
k exec -it <pg-primary-pod> -- bash
```

2. Run the following command to reset the permissions:

```
chmod 0700 /pgdata/<pg-cluster-name>
```

3. Restart the failed pod.

Upgrade stuck with "Unable to upgrade appliance-base: exit status 100" message

Upgrading to v10.0.6.0 only:

This error can occur when the deployment is using an incorrect version of **containerd**. There is a known issue where upgrades from 10.0.1.7-eus or 10.0.1.8-eus to 10.0.5.1 incorrectly upgraded the **containerd** version and subsequent upgrades from 10.0.5.1 might encounter this error.

On each node, complete the following steps to determine the version of **containerd** and if necessary, downgrade it to the correct version:

1. Run the following set of commands on the healthy node to downgrade the version of **containerd**:

```
    systemctl stop appliance-manager
    systemctl stop kubelet
    systemctl stop containerd
    apt-get --allow-downgrades upgrade -y containerd.io
```

```
sed -i 's/KillMode=process/KillMode=mixed/g' /lib/systemd/system/containerd.service
systemctl daemon-reload
systemctl restart containerd
apic lock
apic unlock
```

2. Run the following command to verify that `containerd` now displays `containerd://1.5.11` for the CONTAINER-RUNTIME:

```
kubectl get nodes -o wide
```

Remember to complete these steps on every node.

Pod stuck in `Pending` status during upgrade

Upgrading to v10.0.6.0 only:

When upgrading, the scheduler might deploy a subset of the same microservice pods on the same node. This can prevent other pods with **requiredDuringSchedulingIgnoredDuringExecution** affinity rules from being deployed due to a lack of resources on a subset of nodes. To allow the pending containers to be deployed successfully, identify any pods of the same type that are scheduled on the same node and delete one of them. This will free up space and cause the deleted pod to get rescheduled. To identify pods that are eligible to be deleted, and then delete the pods, complete the following steps:

1. Run the following command and check for any pods of the same type that are on the same node:

```
kubectl get po -o=custom-columns='name:.metadata.name, node:.spec.nodeName,
antiaffinity:.spec.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution' | grep -v '<none>' | awk
'{print $1" "$2'}
```

   In the following example snippet, one of the two **apim** pods on the node test0186 should be deleted:

```
stv3-management-analytics-proxy-56848c8c69-phpdh test0186
stv3-management-analytics-proxy-56848c8c69-sc45f test0187
stv3-management-analytics-proxy-56848c8c69-scf6g test0188
stv3-management-apim-5574796948-6lnwj test0186
stv3-management-apim-5574796948-h9dgx test0186
stv3-management-apim-5574796948-tsb4g test0188
```

2. Run the following command to delete a pod:

```
kubectl delete po <pod_name>
```

Database replica pods stuck in Unknown or Pending state

Upgrading to v10.0.6.0 only:

In certain scenarios, a postgres replica pod may not recover to a healthy state when a restore completes, a node outage occurs, or after a fresh install or upgrade. In these cases, a postgres pod remains in a **Unknown** or a **Pending** state after a number of minutes. The pod fail to get into a **Running** state.

This situation occurs when the replicas do not initialize properly. You can use the **patronictl reinit** command to reinitialize the replica. Note that this command syncs the replica's volume data from the current Primary pod.

Use the following steps to get the pod back into a working state:

1. SSH into the VM as root.
2. Exec onto the failing pod:

```
kubectl exec -it <postgres_replica_pod_name> -n <namespace> -- bash
```

3. List the cluster members:

```
patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+--------------+----+-----------+
|                          Member                          |      Host      |  Role  |    State     | TL | Lag in MB |
+----------------------------------------------------------+----------------+--------+--------------+----+-----------+
|    fxpk-management-01191b80-postgres-586f899fdf-6s25b    | 172.16.172.244 |        | start failed |    |   unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s  | 172.16.148.51  | Leader |   running    |  3 |           |
|  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m  |  172.16.53.68  |        |   running    |  3 |         0 |
+----------------------------------------------------------+----------------+--------+--------------+----+-----------+
```

   In the example shown above **fxpk-management-01191b80-postgres-586f899fdf-6s25b** is not in running state.

   Note the **clusterName** and **replicaName** which are not up:

   - **clusterName** - **fxpk-management-01191b80-postgres**
   - **replicaName** - **fxpk-management-01191b80-postgres-586f899fdf-6s25b**

4. Run:

```
patronictl reinit <clusterName> <replicaName-which-is-not-running>
```

   Example:

```
patronictl reinit fxpk-management-01191b80-postgres fxpk-management-01191b80-postgres-586f899fdf-6s25b
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+--------------+----+-----------+
|                          Member                          |      Host      |  Role  |    State     | TL | Lag in MB |
+----------------------------------------------------------+----------------+--------+--------------+----+-----------+
|    fxpk-management-01191b80-postgres-586f899fdf-6s25b    | 172.16.172.244 |        | start failed |    |   unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s  | 172.16.148.51  | Leader |   running    |  3 |           |
|  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m  |  172.16.53.68  |        |   running    |  3 |         0 |
+----------------------------------------------------------+----------------+--------+--------------+----+-----------+
Are you sure you want to reinitialize members fxpk-management-01191b80-postgres-586f899fdf-6s25b? [y/N]: y
Success: reinitialize for member fxpk-management-01191b80-postgres-586f899fdf-6s25b
```

5. Run `patronictl list` again.
   You may also observe that the replica is on a different Timeline (TL) and possibly have a Lag in MB. It may take a few minutes for the pod to switch onto the same TL as the others and the Lag should slowly go to 0.

   For example:

```
bash-4.2$ patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+---------+---------+----+-----------+
|                         Member                         |      Host      |  Role   |  State  | TL | Lag in MB |
+--------------------------------------------------------+----------------+---------+---------+----+-----------+
|    fxpk-management-01191b80-postgres-586f899fdf-6s25b  | 172.16.172.244 |         | running |  1 |     23360 |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader | running |  3 |           |
|  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |         | running |  3 |         0 |
+--------------------------------------------------------+----------------+---------+---------+----+-----------+
```

6. The pod that previously was in an `Unknown` or `Pending state` or `(0/1) Running` state is now in `(1/1) Running` state.

The `etcd` pod is stuck in `Terminating` state

Upgrading to v10.0.6.0 only:

During an upgrade, you might see a health-check reporting the upgrade is stuck in `ETCD` stage and that an `etcd` pod is stuck in the `Terminating` state.

Verify the issue by completing the following steps:

1. SSH into the VM as root.
2. Run the following command and verify that the upgrade stage is `ETCD`:

   ```
   apic status
   ```

3. Run the following command to determine whether an `etcd` pod is stuck in the `Terminating` state:

   ```
   kubectl get pods -n namespace | grep etcd
   ```

Resolve the issue by completing the following steps:

1. Run the following command to retrieve the names of the `etcd` pods:

   ```
   kubectl get pods -n namespace -o wide | grep etcd
   ```

2. On the pod that is stuck, SSH into the VM as root.
3. Run the following command to restart the pod:

   ```
   systemctl restart kubelet
   ```

Maintaining API Connect

You can use utilities to complete maintenance tasks such as backup, restore, and certificate management in a VMware environment.

Note: When maintaining API Connect, do not use `kubectl exec` commands to access API Connect pods unless advised by IBM.
Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

- **Advanced installation on VMware**
  Optionally install additional software.
- **Advanced configuration on VMware**
  Perform configuration tasks on your API Connect deployment on VMware.
- **Advanced configuration for management subsystem**
  Specify advanced configuration for the management subsystem.
- **Configuring rate limits on the gateway nodes on VMware**
  Create an env.yaml file on each Gateway node to configure the default rate limit.
- **Backing up and restoring on VMware**
  Backup and restore API Connect on VMware.
- **Disaster recovery**
  Prepare for disaster events and recover API Connect on VMware if a disaster event occurs.
- **Disabling and re-enabling the analytics subsystem on VMware**
  Disable the analytics subsystem by shutting down the VM that hosts it.
- **Maintaining a two data center deployment**
  How to maintain a two data center disaster recovery (DR) deployment on VMware, including information about normal operation, failure handling, and recovery.
- **Monitoring and health checks**
  Monitor your deployment and complete health checks on subsystems.
- **Logging**
  Configure logging for your deployment on VMware.
- **Troubleshooting**
  Troubleshoot your deployment on VMware.

Advanced installation on VMware

Optionally install additional software.

See:

- **Installing the IBM License Metric Tool on VMware**
  The IBM® License Metric Tool (ILMT) helps you determine whether your IBM API Connect deployment is compliant with licensing requirements.
- **Installing the toolkit**
- **Installing the Automated API behavior testing application**
  Install the Automated API behavior testing application in your IBM API Connect deployment on VMware.

Installing the IBM License Metric Tool on VMware

The IBM® License Metric Tool (ILMT) helps you determine whether your IBM API Connect deployment is compliant with licensing requirements.

About this task

ILMT provides useful features for managing virtualized environments and measuring license utilization. ILMT discovers the software that is installed in your infrastructure, helps you to analyze the consumption data, and allows you to generate audit reports. Each report provides you with different information about your infrastructure; for example the computer groups, software installations, and the content of your software catalog.

By default, every ILMT audit report presents data from the previous 90 days. You can customize the type and amount of information displayed in a report by using filters, and save your personal settings for future use. You can also export the reports to .csv or .pdf format, and schedule report emails so that specified recipients are notified when important events occur.

To deploy the ILMT with API Connect, complete the following steps for the Management, Developer Portal, and Analytics OVAs. The instructions refer to topics in the ILMT documentation:

Procedure

1. Add a disconnected data source to your ILMT deployment as explained in Adding a data source.
2. Download the scanner installer as explained in Downloading the disconnected scanner package (disconnected scenario).
3. Install the scanner and run scans as explained in Installing the disconnected scanner and gathering scan results (disconnected scenario).
4. Set up daily transfer of scan results to ILMT as explained in Setting up daily transfer of scan results to the License Metric Tool server (disconnected scenario).

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just to need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
   - To download the toolkit from IBM Fix Central, complete the following steps:
     - Open the IBM Fix Central site in your browser.
     - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
     - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
     - In the Text field, enter `toolkit`, then click Continue.
     - Select the toolkit file that you want to download.
     - Click Continue, then follow the instructions to complete the download operation.
   - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
     - Open the Cloud Manager or API Manager user interface.
     - On the welcome page, click the Download Toolkit tile. The two toolkit options are listed.
     - Click your platform alongside either the CLI option or the CLI + LoopBack + Designer option as required, then save the associated compressed file to your local file system.
     - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the designer_credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 6.

- To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 5.
- Close the Install API Connect Toolkit window.

2. Extract the contents of the toolkit compressed file to a folder of your choice.
   The contents of the file depend on the your chosen toolkit option and platform, as follows:

   - The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.
   - The apic or apic.exe file is the CLI for IBM API Connect including LoopBack support.
     Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.
   - The api_designer-*platform* file is the API Designer user interface application for the specified platform.

3. Optional: Delete the **`$HOME/.apiconnect/node_clis`** directory.
   You need to do this only if you replaced a version of **`apic`** or apic.exe and are using the **`apic lb4`** command. You need to delete the directory get **`apic`** to unpack the new loopback.

   On Windows, $HOME is defined by environment USERPROFILE.

4. Run the CLI.
   - For the Mac OSX or Linux® platforms, complete the following steps:
     - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Make the CLI file an executable file by entering the following command:

       `chmod +x download_name`

       Where *download_name* is the name of the toolkit file that you downloaded, either apic or apic-slim.
     - Run CLI commands as follows:

       `./apic command_name_and_parameters`

       or

       `./apic-slim command_name_and_parameters`

       For details of the CLI commands, see apic.
   - For the Windows platform, complete the following steps:
     - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Run CLI commands as follows:

       `apic command_name_and_parameters`

       or

       `apic-slim command_name_and_parameters`

       For details of the CLI commands, see apic.

   Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.

5. Install the toolkit credentials.
   If you do not install the toolkit credentials that are provided for download, as detailed previously in the toolkit credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

   `apic client-creds:set toolkit_credentials_file_path/credentials.json`

   where *credentials_file_path* is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.
   Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
   To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

   `apic client-creds:clear`

   For increased security, an administrator can remove the default credentials from the management server by completing the following steps:
   a. Log in to the management server as an administrator; see Logging in to a management server.
   b. Delete the default credentials by running the following commands:

   ```
   apic registrations:delete toolkit --server mgmt_endpoint_url
   apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
   ```

6. Install the API Designer credentials.
   If you do not install the API Designer credentials that are provided for download, as detailed previously in the API Designer credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the **`APIC_DESIGNER_CREDENTIALS`** environment variable to the credentials download location, using the mechanism appropriate for your operating system.

   After you have set the **`APIC_DESIGNER_CREDENTIALS`** environment variable, your API Designer uses the new credentials to authenticate with the management server.

   - Windows:
     If you are using Windows, create an environment variable using one of the following methods:

     - Create a permanent environment variable so that you can start API Designer from any location on your computer:
       - Open the Environment Variables page: Click Start > Settings > System and in the "Related Settings" section of the page, click Advanced System Settings.
       - On the Advanced tab of the System Properties dialog box, click Environment Variables.
       - In the "User variables" section, click New and create an environment variables with the following settings:
         - Variable: **`APIC_DESIGNER_CREDENTIALS`**

- Value: *<designer_credentials_file_path>*\designer_credentials.json where **`<designer_credentials_file_path>`** is the location where you stored the designer_credentials.json file.
- Click OK to save the new environment variable, and then exit the dialog box.

- If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
  - Open the Windows command prompt.
  - Run the following command to set the temporary environment variable:

    ```
    set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
    ```

    where **`<designer_credentials_file_path>`** is the location where you stored the designer_credentials.json file.

    Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.
  - Now run the following command to start API Designer:

    ```
    C:\"Program Files\API Designer\API Designer.exe"
    ```

    By default, API Designer is installed in the C:\"Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

- Mac:
  If you are using Mac OS X, create an environment variable using one of the following methods:

  - Run the following command to set the global environment variable:

    ```
    launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
    ```

    where **`<designer_credentials_file_path>`** is the location where you stored the API Designer credentials JSON file.
  - Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

    ```
    APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open
    <designer_application_file_path>/'API Designer.app'
    ```

    where:
    - **`<designer_credentials_file_path>`** is the location to which you downloaded the API Designer credentials JSON file.
    - **`<designer_application_file_path>`** is the location to which you downloaded and uncompressed the API Designer application.

7. Start the API Designer application from the location to where you stored the extracted file.
   Note:
   - To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
     - In Windows File Explorer, navigate to the USER_HOME\AppData\Local\Programs\api-designer folder.
     - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
   - To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see Developing your APIs and applications.

For information on using the toolkit CLI, see Using the developer toolkit command-line tool.

Installing the Automated API behavior testing application

Install the Automated API behavior testing application in your IBM® API Connect deployment on VMware.

About this task

Use the following steps to install the Automated API behavior testing application as part of your initial deployment, or to add it in later.
Note: It is not possible to use the Automated API behavior testing application with a two data center disaster recovery configuration (Two data center warm-standby deployment strategy on VMware).

Procedure

1. Run the following **`apicup`** commands to install or update your deployment with the the Automated API behavior testing application:

   ```
   apicup subsys set mgmt test-and-monitor-enabled true
   apicup certs set mgmt hub --clear
   apicup certs set mgmt turnstile --clear
   apicup subsys set mgmt hub hub-endpoint
   apicup subsys set mgmt turnstile turnstile-endpoint
   apicup subsys install mgmt
   ```

   where:
   - **`mgmt`** is the name of your Management server (which you are either installing or updating).
   - **`hub-endpoint`** is an endpoint on the ingress subdomain for the API Connect stack; for example: hub.testsrv0231.subnet1.example.com.
   - **`turnstile-endpoint`** is an endpoint on the ingress subdomain for the API Connect stack; for example: turnstile.testsrv0231.subnet1.example.com.

   Attention: The hub and turnstile endpoints should be distinct and must not overlap with any of the 4 management endpoints.

2. Verify that the application deployed properly by completing the following steps:
    a. Log in to API Manager.
    b. On the Home page, click the Test APIs tile.
    c. Verify that the Automated API behavior testing opens.

Advanced configuration on VMware

Perform configuration tasks on your API Connect deployment on VMware.

See:

- **Adding a static route on a virtual machine**
  You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.
- **Adding disk space to a VMware appliance**
  Increase disk space on the VMware appliance.
- **Appliance boot mode configuration**
  Configure the boot mode for the appliance VMs.
- **Running commands at boot with iso-ignored boot mode**
  When `iso-ignored` boot mode is configured, complete the following steps on each appliance that should run commands at boot.
- **Changing deployment profiles on VMware**
  You can change an API Connect installation to use a different deployment profile.
- **Changing the DNS server configuration on appliances**
  Complete this task only if you must change the DNS addresses after the initial boot of the VM.
- **Configuring API Connect subsystems in a cluster**
  This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.
- **Configuring SSHD to limit access to your deployment**
  How to configure SSHD in order to limit host access to your VMware deployment, or to change the SSHD cipher level.
- **Enabling Developer Portal feature flags on VMware**
  Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.
- **Managing an appliance data disk**
  You can use `apic` commands to manage appliance data disks in your VMware deployment.
- **Replica override for microservices on VMware**
  Modify the replica count for microservices by using template overrides for Custom Resources.
- **Testing a new configuration against a current cluster**
  You can use the `apicup` utility to test the validity of a new configuration before you install it.
- **TLS certificate concepts and operations**
  Information about internal API Connect certificates, renewing expired certificates, exporting certificates, and other certificate maintenance operations.
- **Use JWT security instead of mTLS between subsystems**
  If your network requires TLS termination on load-balancers located between your API Connect subsystems, then disable mTLS and enable JWT to provide application layer security.
- **Credentials and encryption secrets reference**
  API Connect user credentials and database encryption secrets that are managed with the **apicup certs** command.

Adding a static route on a virtual machine

You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.

About this task

Add commands to your additional `cloud-init` file. You can do this for the Management, Analytics, and Portal subsystems.

Procedure

1. Specify an additional cloud-init file:

   ```
   apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
   ```

2. Add lines to your cloud-init file.
   Syntax:

   ```
   bootcmd:
    - ip route add <destination>/<mask> via <gateway> dev eth<n>
   ```

   Example:

   ```
   bootcmd:
    - ip route add 172.27.218.0/24 via 172.27.218.1 dev eth1
    - ip route add 172.26.203.0/24 via 172.27.218.1 dev eth1
   ```

3. Regenerate the ISO file.

   ```
   apicup subsys install <subsys> --out <plan-directory>
   ```

4. Restart the ISO, and ensure that the node(s) have this updated ISO attached at startup.

Adding disk space to a VMware appliance

Increase disk space on the VMware appliance.

About this task

For multi-node deployment of the appliance, only one VM at a time should have its disk space augmented. The subsystem should be in good health before proceeding to the next node. Health of the subsystem can be checked with **`apicup subsys health-check <subsystem-name>`**.

Restriction:
The increased disk capacity of a VMware appliance won't be reflected in the storage size of the PVCs that are hosted on the appliance, as those PVCs are immutable. This restriction doesn't impact the Portal and Analytics subsystems, as the PVC storage size isn't used to enforce any disk usage limit, so the subsystems can use all of the additional disk space. However, for the Management subsystem the PVC storage size is used in the database storage utilization computation, and that might trigger disk usage warnings.

The most common reason for the Management subsystem database to run out of disk space, is due to Write Ahead Log (WAL) file accumulation in relation to an incorrectly configured backup, or an unavailable backup server. If this type of condition arises, adding disk space might help with the health of the appliance control plane, but it won't increase the disk space that's available to the database, so you must resolve the WAL file accumulation condition. If the disk space that's available to the Management database must be increased, you should carry out a disaster recovery operation of the Management subsystem, using a larger data disk size for the new installation, so that adding disk space after the install won't be needed.

Procedure

1. Shutdown the virtual machine, either by issuing a shutdown command as root from the VM, or by using the VMware console or command line interface.
   For example, use the VMware console user interface and click the red rectangle.

2. Use either the VMware console or command line interface to add a new device to the VM, of type Hard Disk and of the desired size to be added to the appliance.
   For example, on the VMware console:
   a. Click Edit settings.
   b. Click Add new device. From the drop-down menu, select Hard Disk.
   c. Enter size in GB and click OK.
3. Use either the VMware console or the command line interface to power on the VM.
   As the VM starts it should detect the newly added disk and use it to augment the available capacity for the /data/secure mount point.
4. Optionally you may verify that a new disk **`sdc`** was added (or **`sdd`** if you already added one disk, and so on). Log in to the server and observe the new disk. For example:

```
root@apimdev1139:~# lsblk
NAME                MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
sda                   8:0    0  100G  0 disk
├─sda1                8:1    0 99.9G  0 part  /
├─sda14               8:14   0    4M  0 part
└─sda15               8:15   0  106M  0 part  /boot/efi
sdb                   8:16   0  250G  0 disk
└─apiconnect-data   252:0    0  260G  0 lvm
  └─apicSecureDisk  252:1    0  260G  0 crypt /data/secure
sdc                   8:32   0   10G  0 disk
└─apiconnect-data   252:0    0  260G  0 lvm
  └─apicSecureDisk  252:1    0  260G  0 crypt /data/secure
sr0                  11:0    1   44K  0 rom
```

Appliance boot mode configuration

Configure the boot mode for the appliance VMs.

By default every appliance node requires the presence of an ISO file attached at boot.

Version 10.0.4.0 or later: You can configure individual VMs so that they can be booted and rebooted without an ISO being attached. Each appliance VM (node) is configured individually.

You can:

- Check the current boot mode of an appliance
- Configure an appliance for iso-ignored boot mode
- Configure an appliance for iso-required boot mode
- Revert back to iso-required boot mode by booting the appliance in rescue mode

Check the current boot mode of an appliance

The default boot mode for all appliances is **`iso-required`**. To check the current boot mode:

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Use **`apic boot-mode`** to check the current boot mode of the appliance. For example:

```
root@ip-192-168-122-241:~# apic boot-mode
INFO[0000] Log level: info
```

```
INFO[0000] current boot mode is: iso-required
```

Configure an appliance for `iso-ignored` boot mode

An appliance can be configured to use the **iso-ignored** boot mode instead of the default **iso-required**. Prerequisite: The appliance must have first booted with its configuration ISO attached and in **iso-required** boot mode (default) before the boot mode can be changed to **iso-ignored**.

You can configure an appliance to use he **iso-ignored** boot mode instead of the default **iso-required**.

Prerequisite: The appliance must have first booted with its configuration ISO attached and in **iso-required** boot mode (default), before you can change the boot mode to **iso-ignored**.

Note: If you added a static route to the routing table, as documented in Adding a static route on a virtual machine, and if you are relying on a **bootcmd** from the ISO, then using the **iso-ignored** boot mode causes the **bootcmd** section being ignored or ineffective.

1. Connect to the target appliance via SSH then switch to the root user:

   ```
   ssh apicadm@{ova appliance hostname}
   sudo -i
   ```

2. Edit the file **/etc/default/grub.d/50-cloudimg-settings.cfg** to ensure that the **GRUB_TIMEOUT** and **GRUB_RECORDFAIL_TIMEOUT** are set to the value **5**. Then run the command **update-grub**. For example:

   ```
   root@ip-192-168-122-241:~# update-grub
   Sourcing file `/etc/default/grub'
   Sourcing file `/etc/default/grub.d/50-cloudimg-settings.cfg'
   Sourcing file `/etc/default/grub.d/init-select.cfg'
   Generating grub configuration file ...
   Found linux image: /boot/vmlinuz-5.4.0-84-generic
   Found initrd image: /boot/initrd.img-5.4.0-84-generic
   done
   ```

3. Set the appliance boot mode to **iso-ignored** with the command **apic boot-mode iso-ignored**. For example:

   ```
   root@ip-192-168-122-241:~# apic boot-mode iso-ignored
   INFO[0000] Log level: info
   INFO[0000] current boot mode is: iso-ignored
   ```

4. Shutdown the VM, and remove the CD/DVD device from the VM configuration through VSphere.
   For any subsequent boot of the appliance while it remains in **iso-ignored** boot mode, any ISO file attached will be ignored, and the boot will proceed as normal, whether an ISO file is attached or not.

   Warning: If the appliance was booted in **iso-ignored** boot mode, it is possible to change its boot mode to **iso-required**. However, as stated in the prerequisites, it is not possible to immediately switch back to **iso-ignored**, and the next boot of the appliance must happen with the configuration ISO attached and boot mode **iso-required**.

Configure an appliance for `iso-required` boot mode

The mode **iso-required** is the default boot mode for all appliances. If the appliance boot mode was changed to **iso-ignored** you can revert back to **iso-required** boot mode.

Warning:
If the appliance was booted in **iso-ignored** boot mode, it is possible to change its boot mode to **iso-required**. However, you cannot immediately switch back to **iso-ignored**, and the next boot of the appliance must happen with the configuration ISO attached and boot mode **iso-required**. After the appliance is booted with ISO attached in **iso-required** boot mode, the boot mode can then be switched to **iso-ignored** if needed.

1. Connect to the target appliance via SSH then switch to the root user:

   ```
   ssh apicadm@{ova appliance hostname}
   sudo -i
   ```

2. Set the appliance boot mode to **iso-required** with the command **apic boot-mode iso-required**. For example:

   ```
   root@ip-192-168-122-241:~# apic boot-mode iso-required
   INFO[0000] Log level: info
   INFO[0000] current boot mode is: iso-required
   ```

   Important: For any subsequent boot of the appliance while it remains in **iso-required** boot mode, the configuration ISO file must be connected at boot and for every boot.

Revert back to `iso-required` boot mode by booting the appliance in rescue mode

When an appliance is configured with the **iso-ignored** boot mode, the boot sequence ignores any attached ISO. This means that it is not possible to influence the appliance configuration during its boot. In case the appliance is not booting properly and the boot mode needs to be reverted back to **iso-required**, proceed as follows:

1. Access to the VMware console for the Appliance, and after causing it to reboot, bring up a console to the appliance. You can give focus to the window by clicking the mouse into it. Press the **Esc** key to access the Linux grub boot menu. For example:

   ```
   GNU GRUB version 2.04

   *Ubuntu
   Advanced options for Ubuntu
   ```

2. Press **e** and navigate using arrow keys to the line starting with **linux** to append **systemd.unit=rescue.target**

```
GNU GRUB version 2.04
.
.
.
insmod part_gpt
insmod ext2
if [ x$feature_platform_search_hint = xy ];  then
   search --no-floppy --fs-uuid --set=root e46da1b8-55ao-4df9-842e-\
     8d80c3a22ffc
else
   search --no-floppy --fs-uuid --set=root e46da1b8-55ao-4df9-842e-8\
     d80c3a22ffc
fi
linux      /boot/vmlinuz-5.4.0-84-generic root=LABEL=cloudimg-roo\
   tfs ro console=tty1 console=ttyS0 net.ifnames=0 bioosdevname=0 systemd.unit\
   =rescue.target
initrd     /boot/initrd.img-5.4.0-84-generic
```

3. Press **Ctrl+x** to boot.
4. Press **Enter** to enter maintenance mode. Run the commands:

   ```
   rm -f /etc/cloud/cloud-init.disabled
   ```

   and

   ```
   echo -n "iso-required" > /usr/local/lib/appliance-config/boot-mode
   ```

   ```
   [   3.442687] systemd[1]: Mounted Kernel Debug Filesystem
   [   3.444253] systemd[1]: Mounted Kernel Trace Filesystem
   [   3.445680] systemd[1]: Finished Create list of static device nodes for the current kernel
   [   3.446777] systemd[1]: Finished Set console scheme.

   [   3.471847] systemd[1]: Mounted FUSE Control File System
   [   3.472964] systemd[1]: Started Journal Service
   Press Enter for maintenance:
   (or press Ctrl-D to continue):
   root#ip-192-168-122-241:~# rm -f /etc/cloud/cloud-init.disabled
   root#ip-192-168-122-241:~# echo -n "iso-required" > /usr/local/lib/appliance-config/boot-mode
   root#ip-192-168-122-241:~#
   ```

5. Reboot the appliance with correct configuration ISO attached.

Running commands at boot with `iso-ignored` boot mode

When **iso-ignored** boot mode is configured, complete the following steps on each appliance that should run commands at boot.

About this task

If you configured the appliance to boot in **iso-ignored** mode as documented in Appliance boot mode configuration, the **bootcmd** lines will be ignored. For each appliance node that should run commands at boot, complete the following steps.

Procedure

1. SSH into the appliance as root.
2. Create the /usr/local/bin/appliance-boot-commands.sh script to be executed at boot; for example:

   ```
   cat << EOF > /usr/local/bin/appliance-boot-commands.sh
   #!/bin/bash

   ip route add 172.27.218.0/24 via 192.168.122.1 dev eth0
   ip route add 172.26.203.0/24 via 192.168.122.1 dev eth0
   EOF
   ```

   This step takes the same example, and essentially achieves the same result, as the procedure in Adding a static route on a virtual machine.

3. Make the script executable by running the following command:

   ```
   chmod +x /usr/local/bin/appliance-boot-commands.sh
   ```

4. Create the following systemd service file /lib/systemd/system/appliance-boot-commands.service:

   ```
   cat << EOF > /lib/systemd/system/appliance-boot-commands.service
   [Unit]
   After=network-online.target

   [Service]
   Type=oneshot
   ExecStart=/usr/local/bin/appliance-boot-commands.sh
   ```

```
RemainAfterExit=false
StandardOutput=journal

[Install]
WantedBy=multi-user.target
EOF
```

5. Enable the systemd service by running the following command:

   ```
   systemctl enable appliance-boot-commands
   ```

   Upon subsequent boots, the **/usr/local/bin/appliance-boot-command.sh** script will be executed.

Changing deployment profiles on VMware

You can change an API Connect installation to use a different deployment profile.

For information on the available deployment profiles, see Planning your deployment topology and profiles. The steps for changing deployment profile after installation depend on whether you want to change to a profile that has a different number of VMs and whether additional CPU and memory resources are required for the profile you move to.
Note: The procedures to change deployment profile that are described in this topic do not permit the endpoints to be changed. The API Connect endpoints are listed here: Deployment overview for endpoints. If you want to change a one replica deployment to a three replica deployment, and you used your VM hostnames in your endpoints, then you must configure load-balancers and logical DNS records so that your original VM hostnames route to your new VMs. Alternatively, you can change endpoints by following the form factor migration procedure: Migrating from v10 to v10 on a different form factor.

Moving to a profile that has the same number of VMs

If you are moving to a profile that requires greater CPU and memory resources, follow these steps:

1. Complete the disaster recovery preparation steps for your subsystems: Preparing for a disaster.
2. Shutdown your API Connect VMs.
3. Update the CPU and memory resources for your API Connect VMs in your VMware console, as required for your new profile.
4. Restart your VMs.
5. In your project directory, update your deployment profile:

   ```
   apicup subsys set <subsystem_name> deployment-profile=<new profile>
   ```

6. Apply the new profile:

   ```
   apicup subsys install <subsystem_name>
   ```

If you are moving to a profile that requires lower CPU and memory resources, follow these steps:

1. Complete the disaster recovery preparation steps for your subsystems: Preparing for a disaster.
2. In your project directory, update your deployment profile:

   ```
   apicup subsys set <subsystem_name> deployment-profile=<new profile>
   ```

3. Apply the new profile:

   ```
   apicup subsys install <subsystem_name>
   ```

4. Shutdown your API Connect VMs.
5. Update the CPU and memory resources for your API Connect VMs in your VMware console, as required for your new profile.
6. Restart your VMs.

If for any reason you are not able to change the CPU or memory on your VMs, redeploy them following the disaster recovery process: Recovering from a disaster.

Moving from a one replica to a three replica deployment profile

1. Complete the disaster recovery preparation steps for your subsystems: Preparing for a disaster.
   Note: You do not need to take VMware snapshots, since your existing VMs are deleted and replaced when you change deployment profile.
2. In your project directory, update your deployment profile:

   ```
   apicup subsys set <subsystem_name> deployment-profile=<three replica profile>
   ```

3. Define the hostname and network interfaces for the two new VMs in each of your subsystems. Use the `apicup hosts create` and `apicup iface create` commands. For more information, see the hosts and interface create steps in the installation instructions for each subsystem:
   - Configuring the Management subsystem.
   - Configuring the Analytics subsystem.
   - Configuring the Developer Portal subsystem.
4. Shutdown your existing API Connect VMs.
   Note: To minimize downtime, you can delay shutting down your existing deployment until you are about to deploy their replacement VMs in the next step.
5. Follow the disaster recovery steps for each subsystem: Recovering from a disaster, but note that you must create new ISO files. Do not attempt to reuse the previous ISO file for one of the VMs in your new three replica deployment.

Moving from a three replica to a one replica deployment profile

1. Complete the disaster recovery preparation steps for your subsystems: Preparing for a disaster.
   Note: You do not need to take VMware snapshots, since your existing VMs are deleted and replaced when you change deployment profile.
2. In your project directory, update your deployment profile:

```
apicup subsys set <subsystem_name> deployment-profile=<one replica profile>
```

3. Delete two of your three VMs from your configuration with the `apicup hosts delete` command.
4. Shutdown your existing API Connect VMs.
   Note: To minimize downtime, you can delay shutting down your existing deployment until you are about to deploy their replacement VMs in the next step.
5. Follow the disaster recovery steps for each subsystem: Recovering from a disaster, but note that you must create new ISO files. Do not attempt to reuse any previous ISO files for your new one replica deployment.

Changing the DNS server configuration on appliances

Complete this task only if you must change the DNS addresses after the initial boot of the VM.

Before you begin

Verify that you have VMware console access to the VM, as well as the correct password. If you cannot **ssh** into the appliance, you can use the VMware console interactive login instead (use the **apicadm** login and the password configured as **default-password** in the **apicup** project).

About this task

This task is only valid for making changes to DNS resolution. The IP address of the VM cannot be changed at any time after the initial boot.

Procedure

1. Edit the /etc/netplan/50-cloud-init.yaml file and update the list of nameserver addresses.
   Attention: Typically, you do not edit this file manually. You should only make direct changes to the /etc/netplan/50-cloud-init.yaml file when you need to update the nameserver addresses.
   The following example shows what the list of nameserver addresses looks like in the file:

```
network:
    ethernets:
        eth0:
            addresses:
            - 192.168.122.242/24
            nameservers:
                addresses:
                - 1.1.1.1
                - 1.0.0.1
                - 8.8.8.8
                search:
                - nip.io
            routes:
            -   metric: 10
                to: 0.0.0.0/0
                via: 192.168.122.1
    version: 2
```

2. Run the following command to apply the changes:

```
sudo netplan apply
```

3. Run the following command to verify the changes:

```
cat /run/systemd/resolve/resolv.conf
```

4. Attach an updated ISO to the VM to ensure all artifacts are up-to-date in case a disaster recovery is needed.
   a. Update the **apicup** project configuration with the correct DNS values.
   b. Generate a new ISO based on the updated project.
   c. Attach the new ISO to the VM.

Configuring API Connect subsystems in a cluster

This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.

Before you begin

To create a cluster of hosts for each API Connect subsystem, use **apicup** to create a subsystem with all the required parameters, and to add as many hosts as needed to the configuration file. The configuration file is a .yml file in the project directory.

For each host of a subsystem added in the .yml file, a separate ISO file is created for the cluster member VM. Note that the ISO files for each VM must stay attached during the whole lifetime of the VM.

In an API Connect cluster in a VMware environment, the first three nodes are master nodes. Additional nodes are worker nodes.

Note: To add a new host to an existing cluster, you can create the host, regenerate the ISO and attach it to the new virtual machine, and it will automatically join the cluster.
To use these instructions, you should first review:

- Requirements for initial deployment on VMware
- Load balancer configuration in a VMware deployment
- Deployment overview for endpoints
- Firewall requirements on VMware
- Firewall enabled ports for clustered OVA deployments
- Important: For best performance it is recommended that the network latency between any 2 nodes be as low as possible. Do not configure nodes from the same subsystem cluster across multiple data centers with a high latency network. A high latency network is one that experiences more than 30ms latency between nodes.

About this task

This page presents a concise step-by-step flow, with sample commands, for the configuration of each subsystem. As you step through the flow, you might want to refer back to the detailed configuration steps for each subsystem. The detailed instructions provide additional considerations for each step, and include optional configuration tasks for backups, logging, message queues (analytics), and password hashing. Each of the subsystem pages describe how to use the VMware console to deploy the ISOs that you create here.

Detailed configuration steps:

- Deploying the Management virtual appliance
- Deploying the Analytics virtual appliance
- Deploying the Developer Portal virtual appliance

The example commands uses the following values for DNS server, internet gateway, host names and IP addresses:

Component	Host names and IP addresses
DNS Name Server	`IP: 192.168.1.1`
Internet gateway	`IP: 192.168.1.2`
Manager on VM1	`Hostname: manager1.sample.example.com` `IP: 192.168.1.101`
Manager on VM2	`Hostname: manager2.sample.example.com` `IP: 192.168.1.102`
Manager on VM3	`Hostname: manager3.sample.example.com` `IP: 192.168.1.103`
Analytics on VM4	`Hostname: analytics1.sample.example.com` `IP: 192.168.1.104`
Analytics on VM5	`Hostname: analytics2.sample.example.com` `IP: 192.168.1.105`
Analytics on VM6	`Hostname: analytics3.sample.example.com` `IP: 192.168.1.106`
Developer Portal on VM7	`Hostname: portal1.sample.example.com` `IP: 192.168.1.107`
Developer Portal on VM8	`Hostname: portal2.sample.example.com` `IP: 192.168.1.108`
Developer Portal on VM9	`Hostname: portal3.sample.example.com` `IP: 192.168.1.109`

Procedure

1. Create the Management subsystems
   a. Create the Management subsystem.

      ```
      apicup subsys create mgmt management
      ```

   b. Set deployment-profile to `n3xc4.m16`.

      ```
      apicup subsys set mgmt deployment-profile=n3xc4.m16
      ```

      If you omit this step, the deployment-profile defaults to `n1xc4.16`, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

   c. Specify the license version you purchased.
      `apicup subsys set` ***`mgmt`***
      `license-use=<`*`license_type`*`>`

      The *license_type* must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

   d. Set management endpoints
      Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
Management REST API URL	`apicup subsys set mgmt platform-api platform-api.sample.example.com`
Consumer (Portal) REST API URL	`apicup subsys set mgmt consumer-api consumer-api.sample.example.com`
Cloud Manager UI	`apicup subsys set mgmt cloud-admin-ui cloud-admin-ui.sample.example.com`
API Manager UI	`apicup subsys set mgmt api-manager-ui api-manager-ui.sample.example.com`

   e. Set the search domain for the VM.

      ```
      apicup subsys set mgmt search-domain sample.example.com
      ```

   f. Set the DNS Name Server for the VM to look up endpoints.

      ```
      apicup subsys set mgmt dns-servers 192.168.1.1
      ```

   g. Set a Public Keyfile.

This is the public key of the user account that you want to use to **ssh** from, to the appliance.

```
apicup subsys set mgmt ssh-keyfiles "id_rsa.pub"
```

h. Create the hosts for the subsystem.
You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the previous example with a strong password that meets your security requirements.

```
apicup hosts create mgmt manager1.sample.example.com password123
apicup hosts create mgmt manager2.sample.example.com password123
apicup hosts create mgmt manager3.sample.example.com password123
```

i. Set the network interface. Note that the last parameter is the Internet Gateway.

```
apicup iface create mgmt manager1.sample.example.com eth0 192.168.1.101/255.255.255.0 192.168.1.2
apicup iface create mgmt manager2.sample.example.com eth0 192.168.1.102/255.255.255.0 192.168.1.2
apicup iface create mgmt manager3.sample.example.com eth0 192.168.1.103/255.255.255.0 192.168.1.2
```

j. Set the network traffic interfaces.

```
apicup subsys set mgmt traffic-iface eth0
apicup subsys set mgmt public-iface eth0
```

k. Verify the host configuration.

```
apicup hosts list mgmt
```

Note: This command might return the following messages, which you can ignore:

```
* host is missing traffic interface
* host is missing public interface
```

l. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

```
apicup subsys set mgmt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.

m. Validate the installation.

```
apicup subsys get mgmt --validate
```

n. Create an ISO file in a plan folder. For example, **mgmtplan-out**.

```
apicup subsys install mgmt --out mgmtplan-out
```

If you have multiple nodes listed for the hosts, when you run the **--out** command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

o. To deploy the management ISOs on VMware, see Deploying the Management subsystem OVA file.

2. Create the analytics subsystems
   a. Create the subsystem:

```
apicup subsys create analyt analytics
```

   b. Set deployment-profile to **n3xc4.m16**.

```
apicup subsys set analyt deployment-profile=n3xc4.m16
```

   If you omit this step, the deployment-profile defaults to **n1xc2.16**, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

   c. Specify the license version you purchased.

```
apicup subsys set analyt
license-use=<license_type>
```

   The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

   d. Set analytics ingestion endpoint
   Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following value points to a sample load balancer URL.

Component	Command
analytics-ingestion	`apicup subsys set analyt analytics-ingestion=analytics-ingestion.sample.example.com`

   e. Set the search domain for the VM.

```
apicup subsys set analyt search-domain sample.example.com
```

   f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set analyt dns-servers 192.168.1.1
```

   g. Set a Public Keyfile.
   This is the public key of the user account that you want to use to **ssh** from, to the appliance

```
apicup subsys set analyt ssh-keyfiles "id_rsa.pub"
```

   h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

```
apicup subsys set analyt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.

i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the following password with a strong password that meets your security requirements.

```
apicup hosts create analyt analytics1.sample.example.com password123
apicup hosts create analyt analytics2.sample.example.com password123
apicup hosts create analyt analytics3.sample.example.com password123
```

j. Set the network interface.
Note that the last parameter is the Internet Gateway.

```
apicup iface create analyt analytics1.sample.example.com eth0 192.168.1.104/255.255.255.0 192.168.1.2
apicup iface create analyt analytics2.sample.example.com eth0 192.168.1.105/255.255.255.0 192.168.1.2
apicup iface create analyt analytics3.sample.example.com eth0 192.168.1.106/255.255.255.0 192.168.1.2
```

k. Check the host configuration for problems.

```
apicup hosts list analyt
```

l. Validate the installation.

```
apicup subsys get analyt --validate
```

m. Create an ISO file in a plan folder. For example, `analytplan-out`.

```
apicup subsys install analyt --out analytplan-out
```

If you have multiple nodes listed for the hosts, when you run the `--out` command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

n. To deploy the ISOs, see Deploying the Analytics subsystem OVA file.

3. Create the portal subsystems

a. Create the portal.

```
apicup subsys create port portal
```

b. For three replica environments, set deployment-profile to `n3xc4.m8`.

```
apicup subsys set port deployment-profile=n3xc4.m8
```

If you omit this step, the deployment-profile defaults to `n1xc4.m8`, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

c. Specify the license version you purchased.

```
apicup subsys set port
license-use=<license_type>
```

The *license_type* must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

d. Set the portal endpoints.
Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
portal-admin	`apicup subsys set port portal-admin=portal-admin.sample.example.com`
portal-www	`apicup subsys set port portal-www=portal-www.sample.example.com`

e. Set the search domain for the VM.

```
apicup subsys set port search-domain sample.example.com
```

f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set port dns-servers 192.168.1.1
```

g. Set a Public Keyfile.
This is the public key of the user account that you want to use to **ssh** from, to the appliance

```
apicup subsys set port ssh-keyfiles "id_rsa.pub"
```

h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use `apicup` to set the hashed password for your subsystem:

```
apicup subsys set port default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.

i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses.

```
apicup hosts create port portal1.sample.example.com password123
apicup hosts create port portal2.sample.example.com password123
apicup hosts create port portal3.sample.example.com password123
```

Replace the example password in the previous example with a strong password that meets your security requirements.

j. Set the network interface.
Note that the last parameter is the Internet Gateway.

```
apicup iface create port portal1.sample.example.com eth0 192.168.1.107/255.255.255.0 192.168.1.2
apicup iface create port portal2.sample.example.com eth0 192.168.1.108/255.255.255.0 192.168.1.2
apicup iface create port portal3.sample.example.com eth0 192.168.1.109/255.255.255.0 192.168.1.2
```

k. Check the host configuration for problems.

```
apicup hosts list port
```

l. Validate the installation.

```
apicup subsys get port --validate
```

m. Create an ISO file in a plan folder. For example, `portplan-out`.

```
apicup subsys install port --out portplan-out
```

If you have multiple nodes listed for the hosts, when you run the `--out` command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

n. To deploy the ISOs, see Deploying the Developer Portal subsystem OVA file.

Configuring SSHD to limit access to your deployment

How to configure SSHD in order to limit host access to your VMware deployment, or to change the SSHD cipher level.

About this task

The following instructions show how to configure SSHD in order to limit VMware access to a certain set of IP addresses, and how to change the SSHD cipher level.

Attention:

- SSHD configuration settings are not included in the IBM® API Connect backups. However, the settings are kept when you upgrade to a new fix pack.
- If you change the SSHD cipher level, and encounter issues with the new configuration, you must revert your cipher changes and retest. If after the retest with the original cipher level that came with IBM API Connect you still have issues, contact IBM Support.

Procedure

- The following instructions show you how to configure SSHD in order to limit VMware access to a certain set of IP addresses.
  1. Log in to the target virtual machine by using an SSH tool, and switch to the root user. For example, to log in to the Management subsystem, run the following commands:

     ```
     ssh ip_address -l apicadm
     sudo -i
     ```

  2. Move to the following folder:

     ```
     /etc/ssh/sshd_config.d
     ```

  3. Create a new configuration file with the extension .conf that contains the IP address of the host that you want to allow to access your deployment. For example, to create the file run the following command:

     ```
     vi filename.conf
     ```

     Then, edit the file by using the following format, which in this example is allowing users from IP address `123.135.1.2`:

     ```
     AllowUsers *@123.135.1.2
     ```

     Additional hosts can be added by separating the IP address patterns with a space. For example:

     ```
     AllowUsers *@123.135.1.2 *@135.168.1.2
     ```

  4. Restart the SSHD service by running the following command:

     ```
     systemctl restart sshd.service
     ```

- The following instructions show you how to configure SSHD to change the cipher level.
  1. Log in to the target virtual machine by using an SSH tool, and switch to the root user. For example, to log in to the Management subsystem, run the following commands:

     ```
     ssh ip_address -l apicadm
     sudo -i
     ```

  2. Move to the following folder:

     ```
     /etc/ssh/sshd_config.d
     ```

  3. Create a new configuration file with the extension .conf that contains the list of ciphers that you want to support. For example, if you want to remove the 128 bit UMAC cipher from the following list of currently supported ciphers:

     ```
     MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
     ```

     Create the .conf file by running the following command:

     ```
     vi filename.conf
     ```

     Then, remove that cipher from the list by adding the following line to the file:

     ```
     MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,hmac-sha2-512,hmac-sha2-256
     ```

  4. Restart the SSHD service by running the following command:

     ```
     systemctl restart sshd.service
     ```

Results

Your SSHD configuration is updated to limit access to your VMware to a certain set of IP addresses, or to change the cipher level.

Enabling Developer Portal feature flags on VMware

Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.

About this task

You can add a template override to the Developer Portal subsystem CR to change the default behavior of the Portal subsystem, or to turn specific features on and off. Table 1 describes the available feature flags.

Table 1. List of available feature flags for the Developer Portal

Feature flag name	Default Value	Pod	Container	Description

`PORTAL_SKIP_WEB_ENDPOINT_VALIDATION`	`true`	`www`	`admin`	Controls whether the Portal subsystem checks whether the Portal web endpoint is accessible.
				
				Sometimes, the endpoint cannot be reached, for example due to the complexity of the networks. In which case the following type of error can be seen in the `portal-www` pod, and `admin` container logs:
				
				`An error occurred contacting the provided portal web endpoint: example.com`
				`The provided Portal web endpoint example.com returned HTTP status code 504`
				
				You can disable the check by setting this flag to `false`.

`ENABLE_TRUSTED_REVERSE_PROXY`	`false`	`www`	`admin`	Controls whether the Drupal `trusted_reverse_proxy` module can manage the reverse proxies list.
				
				If you have multiple load balancers and reverse proxies in your upstream network, and the perimeter module is triggered, the incorrect IP address might be banned rather than the intended client IP address. However, you can manage which IP addresses are banned by using the Drupal `trusted_reverse_proxy` module, and setting this feature flag to `true`.
				
				The Drupal module inspects the `x-forwarded-for` headers to identify the reverse proxies, and trusts that the first IP address found in the list is the client IP. For example, in `X-Forwarded-For: <client>, <proxy1>, <proxy2>`, the client IP `<client>` will be banned. For more information about this module, see https://www.drupal.org/project/trusted_reverse_proxy.
				
				To use this module, you must ensure that all of the proxies in your upstream network, including the ingress controller, are configured correctly so that the `x-forwarded-for` header is passed through to the `portal-www` pod. For example, the default behavior of the `nginx-ingress-controller` is to ignore the inbound `x-forwarded-for` header, and create a new one. To change this behavior, update the `nginx-ingress-controller` `configmap` with the following information:
				
				`data:`
				`  compute-full-forwarded-for: "true"`
				`  use-forwarded-headers: "true"`
				
				Warning: Enable this feature flag only if you trust your upstream reverse proxies, as it is possible to trick the `x-forwarded-for` header.

Procedure

1. Create an `extra-values.yaml` file, or open an existing `extra-values.yaml` file.
2. In the file, append the feature flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the `trusted_reverse_proxy` feature on all possible UI pages.

   ```
   spec:
     template:
     - containers:
       - env:
          - name: ENABLE_TRUSTED_REVERSE_PROXY
            value: "true"
          name: container
       name: pod
   ```

   Where:
   - *container* is the name of the portal container.
   - *pod* is the name of the portal pod.

   Note: You can add multiple feature flags to the file.
3. Save the file.
4. Run the following command to set the `extra-values.yaml` file:

   ```
   apicup subsys set <portal_subsystem> extra-values-file <path_to_portal_extra-values.yaml_file>
   ```

5. Apply the overrides to the portal subsystem by running the following command:

   ```
   apicup subsys install <SUBSYSTEM_NAME>
   ```

   The Developer Portal subsystem is updated to enable or disable features as specified.

Managing an appliance data disk

You can use **apic** commands to manage appliance data disks in your VMware deployment.

The API Connect deployment on VMware uses 2 partitions. The first contains the base operating system, while the second is encrypted so that any customer data that is stored on disk uses the encrypted volume. Encryption is done with Linux Unified Key Setup (LUKS) disk encryption.

During installation of each API Connect subsystem, you specify a password **HD-PASSWD** when configuring the host:

```
apicup hosts create <SUBSYS> <HOSTNAME> <HD-PASSWD>
```

If you want to force a restart of processes, without requiring a full restart of the virtual machine, you can use the command **apic lock** to stop the Kubernetes node on the virtual machine and lock the secured storage. When you are ready to restart processes, you can use **apic unlock** to restart the Kubernetes node. The command **apic unlock** uses the password to unlock the partition so that files can be read from it and written to it. The unlock command also starts the **apic** daemon, also known as the **appliance-manager** service.

You can check that status of this service with:

```
sudo systemctl status appliance-manager
```

One **appliance-manager** daemon runs on each node, where it manages the Kubernetes cluster, processes update and upgrade requests, and gathers logs.

apic command	Description
lock	Shut down appliance services and lock the secured storage
logs	Retrieve logs from all nodes in the cluster
status	Report on cluster status
unlock	Unlock the secure storage and start the appliance
version	Get the API Connect appliance base version

Replica override for microservices on VMware

Modify the replica count for microservices by using template overrides for Custom Resources.

When API Connect is deployed, the deployment profile you select drives the number of replicas to be used for most deployment. For one replica profiles, specified by **n1x...**, the replica count is 1. For three replica profiles, specified by **n3x...**, the replica count is 3.

You can override the replica count for individual deployments by using template overrides.

- Template overrides are a piece of yaml that should be added to the Kubernetes custom resource. The examples provided in this topic show only that the **template:** element should be under the main **spec:** element of a CR. The rest of the CR is not shown.
- When applying overrides for Appliance deployments (virtual machines), the yaml sample provided as example must be added in an extra-values-file for the subsystem. To view an example of documenting a template override for an Appliance, see Setting rate limits for public APIs on the management service

Management subsystem

For a Management CR in Kubernetes or OpenShift, the following override specifies 5 replicas for the **apim** deployment:

```
spec:
  template:
  - name: apim
    replicaCount: 5
```

You can also configure replicate count through a similar template override for:

- **juhu**
- **ldap**
- **lur**

Analytics subsystem

The Analytics microservices that can be scaled using template override are:

- **ingestion**
- **mtls-gw**
- **storage-shared**
  Note that this microservice cannot be scaled below 2 replicas when using a three replica deployment profile.

Testing a new configuration against a current cluster

You can use the **apicup** utility to test the validity of a new configuration before you install it.

The **apicup** utility is used to set configuration properties for subsystems on API Connect on VMware appliances. The utility can be used for installation, upgrade, and maintenance activities such as backup and restore.

The usage pattern is to set values for each parameter you need for a subsystem, and then deploy the new values with the **apicup subsys install** command.

You can use the **--dry-run** option to test the validity of your values prior to deploying them to an existing cluster:

```
apicup subsys install <subsystem_name> --dry-run
```

Important: You cannot use **apicup subsys install <SUBSYS> --dry-run** for a fresh install or an upgrade. The **--dry-run** feature is for testing proposed configuration changes on an existing cluster.
For example, if you want to configure S3 backups for you management subsystem, the command flow is:

1. Follow the instructions for configuring S3 backupsReconfiguring backup settings for the management subsystem V10.0.6.0 by issuing the required **apicup subsys set** commands:

   ```
   apicup subsys set mgmt <setting>=<value>
   apicup subsys set mgmt <second_setting>=<value>
   apicup subsys set mgmt <third_setting>=<value>
   .
   .
   .
   ```

2. Do a dry run of the install command:

   ```
   apicup subsys install mgmt --dry-run
   ```

   Example message on success:

   ```
   managementcluster.management.apiconnect.ibm.com/management configured (server dry run)
   ```

   Example message on failure:

   ```
   Error: Failed to execute dry-run:....
   ```

   The error message also contains details about the error.

3. When dry run returns success, deploy:

   ```
   apicup subsys install mgmt
   ```

TLS certificate concepts and operations

Information about internal API Connect certificates, renewing expired certificates, exporting certificates, and other certificate maintenance operations.

This topic covers advanced certificate configuration procedures that are not required in day-to-day API Connect operations. For best practices relating to API Connect certificates, see API Connect TLS certificate best practices.

API Connect certificate types

All TLS certificates that are generated and used by API Connect fall into one of the following categories:

- CA certificates - API Connect creates self-signed CA certificates to sign all the API Connect end-entity certificates. The CA certificates are:
  - **ingress-ca** - used by the ingress-issuer. The ingress-ca signs all user-facing and inter-subsystem certificates.
  - **root-ca** - a self-signed root certificate that signs the **ingress-ca** certificate.
  - **management-ca** - signs all the management intra-subsystem certificates.
  - **portal-ca** - signs all the portal intra-subsystem certificates.
  - **analytics-ca** - signs all the analytics intra-subsystem certificates.

  CA certificates have a default duration of 10 years.
  Do not customize CA certificates. The only scenarios when CA certificates require updating are:
  - Expiry, after 10 years.
  - Synchronizing the **ingress-ca** certificate between data centers in multiple data center deployments.
- Ingress certificates - Ingress certificates are end-entity certificates that are signed by the **ingress-ca** certificate and secure the API Connect endpoints. Ingress certificates are divided into two types:
  - Inter-subsystem certificates - certificates that are used to secure the communication between API Connect subsystems, for example between the management subsystem and gateway. By default, communication between most subsystems uses mTLS. It is possible to use JWT instead of mTLS: Using JWT instead of mTLS on OVA.
    Do not customize inter-subsystem certificates.
  - User-facing certificates - certificates that API Connect users see when they interact with the API Connect UIs and REST API.
    You can customize your user-facing certificates: Customizing your user-facing certificates

  All the ingress certificates have a duration of 2 years.
- Intra-subsystem certificates - certificates that are used between software components in the same subsystem. Intra-subsystem certificates are signed by a subsystem specific CA certificate: **management-ca**, **portal-ca**, **analytics-ca**. The gateway subsystem is a single pod, and has no intra-subsystem certificates.
  Do not customize intra-subsystem certificates.

Note: The inter and intra-subsystem certificates use of a self-signed root CA presents no security risk. For internal communications with a limited number of predefined endpoints, use of locally generated self-signed CA certificates can be more secure than external CA certificates, as certificates are only ever issued for the known components and the domain of trust is kept as small as possible.

  Certificates validation errors reference table.

Certificate reference VMware

Details of all API Connect TLS certificates on VMware.

The **apicup certs list** command returns all the API Connect TLS certificates that can be configured with the **apicup** command.
Note: The **apicup certs list** command also returns credentials and encryption secrets that are used by API Connect. For information about these secrets and credentials, see Credentials and encryption secrets reference.

Common certificates

Common certificates exist in all subsystems of an API Connect deployment, and must be identical in each subsystem to enable them to communicate with each other.

Because you deploy your API Connect subsystems from a single project directory, these certificates are automatically set to be the same on all subsystems.

Do not customize any of the common certificates.

Table 1. Common certificates

Certificate name	Description
`root-ca`	CA certificate that is the root of the certificate chain for all other API Connect certificates. Do not update this certificate.
`ingress-ca`	Intermediate CA certificate used to generate all API Connect ingress certificates. Do not customize this certificate. If the certificate expires (duration is 20 years), see: Renewing ingress-ca. If you have multiple data centers that are managed from different project directories, you can synchronize this certificate, see: Synchronizing the ingress-ca certificate.
`appliance-client`	A client certificate that is used by the **apicup** command to communicate with the API Connect subsystem appliances. Requires EKU `clientAuth`. Do not update this certificate.
`k8s-ca`	CA certificate that forms the root of the certificate chain for the Kubernetes cluster components that run in the API Connect subsystem appliance. Do not update this certificate.

Management certificates

The following table lists the certificates that exist on the management subsystem, in addition to the common certificates.

Table 2. Management subsystem certificates

Certificate name	Description
`portal-client`	The `portal-client` certificate is an inter-subsystem ingress certificate that is presented to the developer portal subsystem during portal service registration. For successful portal registration the `portal-client` certificate must meet these requirements: • Specify EKU `clientAuth`. • Signed by the same CA (`ingress-ca`) as the `portal-admin-ingress` certificate that secures the admin endpoint on the developer portal. • The subject name must match the `adminClientSubjectDN` in the portal subsystem. If you have a multiple data center deployment, both data centers must use an identical subject name. Do not update this certificate.
`analytics-client-client`	A legacy certificate, it is not used from v10.0.5 onwards.

Certificate name	Description
`analytics-ingestion-client`	The `analytics-ingestion-client` certificate is an inter-subsystem ingress certificate that is presented to the analytics subsystem during analytics service registration. For successful analytics registration the `analytics-ingestion-client` certificate must meet these requirements: • Specify EKU `clientAuth`. • Signed by the same CA (`ingress-ca`) as the `analytics-ingestion-ingress` certificate that secures the ingestion endpoint on the analytics subsystem. • The subject name must match the `clientSubjectDN` in the analytics subsystem. `analytics-ingestion-client` is also used by the gateway subsystem to authenticate with the analytics ingestion endpoint, for the transmission of API event data. For multiple data center deployments, both data centers must have an identical subject name. Do not update this certificate.
`platform-api`	The `platform-api` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope. The endpoint in the management subsystem configuration uses the same name: `platform-api` The hostnames for which the certificate is valid must include the `platform-api` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.
`consumer-api`	The `consumer-api` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope. The endpoint in the management subsystem configuration uses the same name: `consumer-api` The hostnames for which the certificate is valid must include the `consumer-api` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.
`api-manager-ui`	The `api-manager-ui` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI. The endpoint in the management subsystem configuration uses the same name: `api-manager-ui`. The hostnames for which the certificate is valid must include the `api-manager-ui` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.
`cloud-admin-ui`	The `cloud-admin-ui` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI. The endpoint in the management subsystem configuration uses the same name: `cloud-admin-ui`. The hostnames for which the certificate is valid must include the `cloud-admin-ui` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.
`hub`	Used by the Automated API behavior testing application. User-facing ingress certificate for the `hub-endpoint`.
`turnstile`	Used by the Automated API behavior testing application. User-facing ingress certificate for the `turnstile-endpoint`.
`management-replication-client`	Used in 2DCDR deployments only. The `management-replication-client` certificate is an inter-subsystem ingress client certificate that is used when connecting to the `management-replication` endpoint in the other data center. Requires EKU `clientAuth`.
`management-replication-ingress`	Used in 2DCDR deployments only. The `management-replication-ingress` certificate is an inter-subsystem ingress server certificate that is used to secure the `management-replication` endpoint. `management-replication-ingress` must be valid for the endpoint defined by `apicup subsys set <subsystem> management-replication=<endpoint>` Requires EKU `serverAuth`.

Portal subsystem certificates

The following table lists the certificates that exist on the management subsystem, in addition to the common certificates.

Table 3. Portal subsystem certificates

Certificate name	Description

Certificate name	Description
`mgmt-consumer-api`	The `mgmt-consumer-api` certificate is an inter-subsystem ingress certificate that secures the consumer API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem. This certificate must be identical to the `consumer-api` certificate in the management subsystem. Do not update this certificate.
`mgmt-platform-api`	The `mgmt-platform-api` certificate is an inter-subsystem ingress certificate that secures the platform API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem. This certificate must be identical to the `platform-api` certificate in the management subsystem. Do not update this certificate.
`portal-admin-ingress`	The `portal-admin-ingress` certificate is an inter-subsystem ingress certificate that is used to secure the portal administration endpoint. The management subsystem communicates with this endpoint to register the portal and to send portal configuration updates. Do not update this certificate.
`portal-replication-client`	Used in 2DCDR deployments only. The `portal-replication-client` certificate is an inter-subsystem ingress client certificate that is used when connecting to the `portal-replication` endpoint in the other data center. Requires EKU `clientAuth`.
`portal-replication-ingress`	Used in 2DCDR deployments only. The `portal-replication-ingress` certificate is an inter-subsystem ingress server certificate that is used to secure the `portal-replication` endpoint. `portal-replication-ingress` must be valid for the endpoint defined by `apicup subsys set <subsystem> portal-replication=<endpoint>` Requires EKU `serverAuth`.
`portal-www-ingress`	The `portal-www-ingress` certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites. The endpoint is called `portal-www` in the portal subsystem configuration.

Analytics subsystem certificates

The following table lists the certificates that exist on the management subsystem, in addition to the common certificates.

Table 4. Analytics subsystem certificates

Certificate name	Description
`analytics-ca`	Internal certificate used for communication between analytics subsystem components. Do not update this certificate.
`analytics-ingestion-ingress`	The `analytics-ingestion-ingress` certificate is an inter-subsystem ingress certificate that is used to secure the analytics ingestion endpoint, which is used for the following: • Receiving API event data from associated gateways. • Configuration and analytics queries from the management subsystem. Do not update this certificate.
`service-client`	Internal certificate used for communication between analytics subsystem components. Do not update this certificate.
`service-server`	Internal certificate used for communication between analytics subsystem components. Do not update this certificate.

Ingress certificates

The following table lists all the certificates across all subsystems that are signed by the `ingress-ca`. If you renew your `ingress-ca` certificate, then you must also renew all the ingress end-entity certificates that are listed in this table. For steps on renewing the `ingress-ca`, see Renewing ingress-ca.

Table 5. Certificates signed by `ingress-ca`

Certificate name	Description
`portal-client`	The `portal-client` certificate is an inter-subsystem ingress certificate that is presented to the developer portal subsystem during portal service registration. For successful portal registration the `portal-client` certificate must meet these requirements: • Specify EKU `clientAuth`. • Signed by the same CA (`ingress-ca`) as the `portal-admin-ingress` certificate that secures the admin endpoint on the developer portal. • The subject name must match the `adminClientSubjectDN` in the portal subsystem. If you have a multiple data center deployment, both data centers must use an identical subject name. Do not update this certificate.
`analytics-client-client`	A legacy certificate, it is not used from v10.0.5 onwards.

Certificate name	Description
`analytics-ingestion-client`	The `analytics-ingestion-client` certificate is an inter-subsystem ingress certificate that is presented to the analytics subsystem during analytics service registration. For successful analytics registration the `analytics-ingestion-client` certificate must meet these requirements: • Specify EKU `clientAuth`. • Signed by the same CA (`ingress-ca`) as the `analytics-ingestion-ingress` certificate that secures the ingestion endpoint on the analytics subsystem. • The subject name must match the `clientSubjectDN` in the analytics subsystem. `analytics-ingestion-client` is also used by the gateway subsystem to authenticate with the analytics ingestion endpoint, for the transmission of API event data. For multiple data center deployments, both data centers must have an identical subject name. Do not update this certificate.
`platform-api`	The `platform-api` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope. The endpoint in the management subsystem configuration uses the same name: `platform-api` The hostnames for which the certificate is valid must include the `platform-api` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.
`consumer-api`	The `consumer-api` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope. The endpoint in the management subsystem configuration uses the same name: `consumer-api` The hostnames for which the certificate is valid must include the `consumer-api` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.
`api-manager-ui`	The `api-manager-ui` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI. The endpoint in the management subsystem configuration uses the same name: `api-manager-ui`. The hostnames for which the certificate is valid must include the `api-manager-ui` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.
`cloud-admin-ui`	The `cloud-admin-ui` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI. The endpoint in the management subsystem configuration uses the same name: `cloud-admin-ui`. The hostnames for which the certificate is valid must include the `cloud-admin-ui` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.
`hub`	Used by the Automated API behavior testing application. User-facing ingress certificate for the `hub-endpoint`.
`turnstile`	Used by the Automated API behavior testing application. User-facing ingress certificate for the `turnstile-endpoint`.
`portal-admin-ingress`	The `portal-admin-ingress` certificate is an inter-subsystem ingress certificate that is used to secure the portal administration endpoint. The management subsystem communicates with this endpoint to register the portal and to send portal configuration updates. Do not update this certificate.
`portal-www-ingress`	The `portal-www-ingress` certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites. The endpoint is called `portal-www` in the portal subsystem configuration.
`analytics-ingestion-ingress`	The `analytics-ingestion-ingress` certificate is an inter-subsystem ingress certificate that is used to secure the analytics ingestion endpoint, which is used for the following: • Receiving API event data from associated gateways. • Configuration and analytics queries from the management subsystem. Do not update this certificate.
`management-replication-client`	Used in 2DCDR deployments only. The `management-replication-client` certificate is an inter-subsystem ingress client certificate that is used when connecting to the `management-replication` endpoint in the other data center. Requires EKU `clientAuth`.

Certificate name	Description
`management-replication-ingress`	Used in 2DCDR deployments only. The **`management-replication-ingress`** certificate is an inter-subsystem ingress server certificate that is used to secure the **`management-replication`** endpoint. **`management-replication-ingress`** must be valid for the endpoint defined by **`apicup subsys set <subsystem> management-replication=<endpoint>`** Requires EKU **`serverAuth`**.
`mgmt-consumer-api`	The **`mgmt-consumer-api`** certificate is an inter-subsystem ingress certificate that secures the consumer API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem. This certificate must be identical to the **`consumer-api`** certificate in the management subsystem. Do not update this certificate.
`mgmt-platform-api`	The **`mgmt-platform-api`** certificate is an inter-subsystem ingress certificate that secures the platform API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem. This certificate must be identical to the **`platform-api`** certificate in the management subsystem. Do not update this certificate.
`portal-replication-client`	Used in 2DCDR deployments only. The **`portal-replication-client`** certificate is an inter-subsystem ingress client certificate that is used when connecting to the **`portal-replication`** endpoint in the other data center. Requires EKU **`clientAuth`**.
`portal-replication-ingress`	Used in 2DCDR deployments only. The **`portal-replication-ingress`** certificate is an inter-subsystem ingress server certificate that is used to secure the **`portal-replication`** endpoint. **`portal-replication-ingress`** must be valid for the endpoint defined by **`apicup subsys set <subsystem> portal-replication=<endpoint>`** Requires EKU **`serverAuth`**.

User-facing certificates

The following table lists all the certificates that are used for user-facing endpoints.

Table 6. User-facing endpoint certificates.

Certificate name	Description
`portal-www-ingress`	The **`portal-www-ingress`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites. The endpoint is called **`portal-www`** in the portal subsystem configuration.
`api-manager-ui`	The **`api-manager-ui`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI. The endpoint in the management subsystem configuration uses the same name: **`api-manager-ui`**. The hostnames for which the certificate is valid must include the **`api-manager-ui`** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **`serverAuth`**.
`cloud-admin-ui`	The **`cloud-admin-ui`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI. The endpoint in the management subsystem configuration uses the same name: **`cloud-admin-ui`**. The hostnames for which the certificate is valid must include the **`cloud-admin-ui`** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **`serverAuth`**.
`consumer-api`	The **`consumer-api`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope. The endpoint in the management subsystem configuration uses the same name: **`consumer-api`** The hostnames for which the certificate is valid must include the **`consumer-api`** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **`serverAuth`**.
`platform-api`	The **`platform-api`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope. The endpoint in the management subsystem configuration uses the same name: **`platform-api`** The hostnames for which the certificate is valid must include the **`platform-api`** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **`serverAuth`**.
`hub`	Used by the Automated API behavior testing application. User-facing ingress certificate for the **`hub-endpoint`**.

Certificate name	Description
`turnstile`	Used by the Automated API behavior testing application. User-facing ingress certificate for the `turnstile-endpoint`.

Customizing user-facing certificates

How to set the user-facing endpoints of API Connect to use your own TLS server certificates.

Before you begin

Identify the user-facing certificates that you want to customize: Table 6.

Ensure that you have certificate, key, and CA PEM files for each certificate you want to customize. The PEM files must not be password-protected.

For example, to customize the certificate that secures the Cloud Manager UI, you must have the following PEM files: cloud-admin-ui-cert.pem, cloud-admin-ui-key.pem, cloud-admin-ui-ca.pem

User-facing certificates must meet the following requirements:

- Specify Extended Key Usage (EKU) of `serverAuth`.
- Include the Subject Alternative Name (SAN) of the endpoint that they secure.
- If the certificate is signed by an intermediate CA, then the ca.pem file must contain the full chain to root CA.

About this task

You update the user-facing certificates with the **apicup** command.

You can set custom user-facing certificates during installation, or you can update them after installation, replacing the default certificates that are generated.

Note: API Connect verifies certificates when you set them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your custom certificates before they expire.

Procedure

1. If you are updating a user-facing certificate after installation, you must first clear the default certificate that was created:

   ```
   apicup certs set <subsystem name> <certificate name> --clear
   ```

   For example, to clear the certificate that secures the Cloud Manager UI:

   ```
   apicup certs set mgmt cloud-admin-ui --clear
   ```

2. Set the user-facing certificate with the **apicup certs set** command, supplying the PEM files for your new certificate:

   ```
   apicup certs set <subsystem name> <certificate name> <cert file> <key_file> <ca file>
   ```

   For example:

   ```
   apicup certs set mgmt cloud-admin-ui cert.pem key.pem ca.pem
   ```

3. If you are updating the certificate after installation, then apply the update with `apicup subsys install`

   ```
   apicup subsys install <subsystem name>
   ```

4. You can verify that the certificate is updated with **apicup certs list**:

   ```
   apicup certs list <subsystem name>
   ```

   Example output:

   ```
   Common certificates
   ===================

   Name                        Summary                                                                 Validation errors
   ----                        -------                                                                 -----------------
   ...

   Subsystem def-management certificates
   =====================================

   Name                              Summary                                                           Validation errors
   ----                              -------                                                           -----------------
   ...
   cloud-admin-ui                    CN: cloud-admin-ui
                                     SubjectKeyId: 9E:8B:FA:7E:92:70:EC:86:2F:C3:3A:20:E8:13:EA:F4
                                     AuthorityKeyId: E4:AB:09:FF:A9:7D:D3:70:DD:AD:69:C4:A4:34:8D:96
   ...
   ```

   Note: Along with the user-facing certificates, the **apicup certs list** command outputs details of other internal API Connect certificates and secrets that you should not update.

Certificate expiry and renewal

How to renew and replace TLS certificates in your VMware deployment.

The instructions in this topic apply only to the management, portal, and analytics subsystems. For gateway appliance-specific instructions, see *Configuring the API Connect Gateway Service* in the appropriate version of the DataPower documentation.
Note: The API invocation certificate (the certificate that is presented to callers of your APIs) is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.
All ingress certificates in API Connect have a duration of 2 years. To avoid an outage when they expire, they must be manually renewed before expiration.

The **ingress-ca** CA certificate has a duration of 10 years and also requires manual steps to renew it before expiry.

Intra-subsystem certificates are renewed automatically.

Identifying expired certificates

The **apicup** tool does not check certificate expiry, to check for expired certificates you must login to your VMs and use the **apicops** tool:

1. Login to each subsystem VM:

   ```
   ssh apicadm@<subsystem hostname>
   ```

   Note: If you have a three replica deployment, login to only one of the VMs of each subsystem.
2. Switch to the root user:

   ```
   sudo -i
   ```

3. Install the **apicops** tool: The API Connect operations tool: apicops:
   a. Download the latest **apicops-v10-linux** executable file:

      ```
      wget <URL of latest apicops-v10-linux>
      ```

      For example:

      ```
      wget https://github.com/ibm-apiconnect/apicops/releases/download/<latest version>/apicops-v10-linux
      ```

   b. Add execute permissions to **apicops-v10-linux**:

      ```
      chmod a+x apicops-v10-linux
      ```

4. Run the **apicops certs:validate** command:

   ```
   ./apicops-v10-linux certs:validate -s <subsystem>
   ```

   where *<subsystem>* is the subsystem you are running the command on, either: Management, portal, or analytics.
   The **apicops** command reports any certificates that are expired or within 60 days of expiry.

   You can ignore the message:

   ```
   Cannot check who signed the certificate returned by ... as no ingress issuer was provided
   ```

   this is expected on VMware deployments.
5. Renew any certificates that are expired or approaching expiry, except for the certificates that are listed under the heading **Validating subsystem certificates for <subsystem name>**, these are intra-subsystem certificates that are renewed automatically.

   ```
   Validating subsystem certificates for abc-management
   Good certificate: <subsystem name>-ca
   Good certificate: <subsystem name>-client
   Good certificate: <subsystem name>-server
   ```

   Follow the step in Renewing certificates to renew expired or nearly expired certificates.

Renewing certificates

Use the **apicup** command to renew certificates.
Warning: Use these steps to renew only end-entity ingress certificates as defined here: ingress certificates. If you want to renew the **ingress-ca** certificate, then see Renewing ingress-ca.

1. Clear the existing certificate with the **apicup certs clear** command:

   ```
   apicup certs set --clear <subsystem> <certificate name>
   ```

   Repeat for all ingress certificates that you want to renew.
2. Generate new certificates for all the certificates that you cleared in step 1:

   ```
   apicup certs generate <subsystem>
   ```

   You do not need to specify the certificates with the **apicup certs generate**, the command identifies all empty (cleared) certificates in the subsystem and generates new ones.
3. Apply the updated certificates to the subsystem:

   ```
   apicup subsys install <subsystem>
   ```

Renewing `ingress-ca`

Use the **apicup** command to renew **ingress-ca**, and then renew all the end-entity certificates the are signed by **ingress-ca**.

1. Clear the **ingress-ca** certificate:

```
apicup certs set --clear <management subsystem> ingress-ca
```

Although this command specifies *<management subsystem>*, because **ingress-ca** is a common certificate, it is cleared for all subsystems. You do not need to repeat this command for every portal or analytics subsystem that is managed from the same project directory.

2. Generate a new **ingress-ca**:

```
apicup certs generate <subsystem>
```

The **generate** command creates certificates for all previously cleared certificates, you do not need to specify **ingress-ca** in this command.

3. Clear all the ingress end-entity certificates that are signed by **ingress-ca**:

```
apicup certs set --clear <subsystem> <certificate name>
```

For a list of the ingress certificates, see Ingress certificates.

4. Generate new ingress end-entity certificates for each subsystem:

```
apicup certs generate <subsystem>
```

5. Apply the updated certificates to all subsystems:

```
apicup subsystem install <subsystem>
```

Extracting and copying certificates

How to extract certificate contents and apply them to API Connect subsystems in other environments.

If you have a two data center disaster recovery deployment, or have API Connect subsystems in different data centers that are managed by different project directories, then it is necessary to manually synchronize the TLS certificates between the environments.

Synchronizing the `ingress-ca` certificate

To export the **ingress-ca** certificate from your target environment, follow these steps:

1. Extract the **ingress-ca** public certificate to a file called ingress-ca-cert.pem

```
apicup certs get <subsystem> ingress-ca > ingress-ca-cert.pem
```

2. Extract the **ingress-ca** private key to a file called ingress-ca-key.pem

```
apicup certs get <subsystem> ingress-ca -t key > ingress-ca-key.pem
```

3. Extract the **ingress-ca** CA to a file called ingress-ca-CA.pem

```
apicup certs get <subsystem> ingress-ca -t ca > ingress-ca-CA.pem
```

Note: The **ingress-ca** certificate is the same for all subsystems that are managed from the same project directory, so you can specify any subsystem in the **apicup certs get** command.
To apply the exported **ingress-ca** certificate to another environment, follow these steps:

1. Apply the exported certificate files to the **ingress-ca**:

```
apicup certs set <subsystem> ingress-ca ingress-ca-cert.pem ingress-ca-key.pem ingress-ca-CA.pem
```

Note: The **ingress-ca** certificate is the same for all subsystems that are managed from the same project directory, so you can specify any subsystem in the **apicup certs set** command.

2. Clear all the ingress end-entity certificates that are signed by **ingress-ca**:

```
apicup certs set --clear <subsystem> <certificate name>
```

For a list of the ingress certificates, see Ingress certificates.

3. Generate new ingress end-entity certificates for each subsystem:

```
apicup certs generate <subsystem>
```

4. Apply the updated certificates to all subsystems:

```
apicup subsystem install <subsystem>
```

Rotating the portal intra-subsystem certificates on VMware

Use the **apicup** command to rotate the portal intra-subsystem certificates.

The portal's intra-subsystem certificates: **portal-ca**, **portal-client**, and **portal-server**, are not shown in the **apicup certs list** output, and cannot be updated with **apicup certs set**. If you want to renew these certificates, you can use the **apicup subsys rotate-secrets** command.
Warning: The portal intra-subsystem certificates are internal certificates that are created and renewed automatically. Renewing these certificates with **apicup subsys rotate-secrets** is only necessary in specific failure scenarios and should be done only if advised by IBM support.
To rotate the Developer Portal subsystem secrets, certificates, or both, run the following command:

```
apicup subsys rotate-secrets portal
```

```
Rotate portal subsystem secrets

Usage:
  apicup subsys rotate-secrets SUBSYS [flags]

Flags:
      --certs strings              List of certificates you want to rotate (Listing an issuer will rotate any certs issued by
the issuer e.g listing just portal-ca will rotate portal-ca, portal-client and portal-server)
      --encryption-secret string   Optional value to set the encryption secret to, if supplied secret exists in the env. If not
supplied the rotated secret will be random.
  -h, --help                       help for rotate-secrets
      --rotate-encryption-secret   Set to true if you want to rotate the encryption secret.
      --wait                       Wait for the operation to complete or fail.
      --wait-timeout duration      Command timeout in seconds. (default 40s)

Global Flags:
      --accept-license   Deprecated. Use apicup licenses commands to work with licenses
      --debug            Enable debug logging
```

For example, to rotate the encryption secret to a random value run the following command:

```
apicup subsys rotate-secrets portal --rotate-encryption-secret true
```

The following example rotates the encryption secret to a named secret (note that first you must exec into the Developer Portal OVA to create the secret):

```
apicup subsys rotate-secrets portal --rotate-encryption-secret --encryption-secret my-new-secret
```

The following example rotates all of the Developer Portal certificates:

```
apicup subsys rotate-secrets portal --certs portal-ca
```

The following example rotates just the server and client certificates:

```
apicup subsys rotate-secrets portal --certs portal-server,portal-client
```

To list any Developer Portal secret rotations that were created by using the `rotate-secrets` command:

```
apicup subsys list-rotate-secrets portal --timeout 30
```

Where:

- *portal* is the name of your Developer Portal subsystem.
- `--timeout` (optional) is the duration in seconds of the command timeout. Default is 40 seconds.

To delete any Developer Portal secret rotations that were created by using the `rotate-secrets` command:

```
apicup subsys delete-rotate-secret portal --rotate-secret-name secret_name --wait true --wait-timeout 80

Delete a secret rotation of the subsystem

Usage:
  apicup subsys delete-rotate-secret SUBSYS [flags]

Flags:
  -h, --help                         help for delete-rotate-secret
      --rotate-secret-name string    Value of a Portal Secret Rotation CR name to delete.
      --wait                         Wait for the operation to complete or fail.
      --wait-timeout duration        Command timeout in seconds. (default 1m0s)

Global Flags:
      --accept-license   Deprecated. Use apicup licenses commands to work with licenses
      --debug            Enable debug logging
```

Apicup certs command reference

Documentation of the **apicup certs** command you use to manage API Connect TLS certificates and secrets.

The **apicup certs** command is used to set, clear, and generate the TLS certificates that are used by API Connect. The **apicup certs** command is also used to manage some of the secrets used by API Connect, such as remote backup server credentials and database encryption secrets.

After you modify certificates with the **apicup certs** command, you must apply the changes to your subsystems with:

```
apicup subsys install <subsystem name>
```

Setting and clearing certificates

Run the `apicup certs set` command:

Table 1. apicup certs set

Command	Values	Result

Command	Values	Result
`apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [flags]`	Parameters are: • SUBSYS - name of the subsystem to which the certificate applies • CERT_NAME - name of the certificate; see Certificate reference VMware for a list of certificates that can be set for each subsystem. • CERT_FILE - Path to the certificate file in PEM format. • KEY_FILE - Path to the private key file in PEM format. • CA_FILE - Path to the certificate authority (CA) file. The contents of the file might be the concatenation of an intermediate CA and the root CA (in that order). **Note:** When you set the `root-ca` certificate, omit the CA_FILE parameter.	Sets the specified certificate to be applied when **apicup subsys install** is run.
`apicup certs set SUBSYS CERT_NAME [KEY_FILE] [flags]`	KEY_FILE - The file that contains the encryption-secret for field level encryption in the management database. Applies only to the management subsystem . The certificate name is `encryption-secret`. The type is secure random bytes with a length of 128 bytes. For example, `apicup certs set mgmt1 encryption-secret /path/to/encryption-secret.bin`. **Note:** Do not specify any of the [CERT_FILE KEY_FILE CA_FILE] parameters when you set the encryption-secret.	Applies the `encryption-secret` when the management subsystem is installed.
`flags` • `--clear` • `--help`	Flags are: • --clear - Clears the specified certificate. For example, `apicup certs set mgmt1 encryption-secret --clear` • --help - Displays help for the command.	The specified certificate is cleared. When you make configuration changes such as changing endpoints, the corresponding certificate must be cleared so that a new certificate can be set.

Viewing details of a certificate

Run the `apicup certs get` command:

Table 2. apicup certs get

Command	Values	Result
`apicup certs get SUBSYS CERT_NAME [flags]`	Parameters are: • SUBSYS - name of the subsystem to which the certificate applies • CERT_NAME - name of the certificate to retrieve; see Certificate reference VMware for a list of certificates	Returns the specified certificate for the specified subsystem.
`flags` • `--output string` • `--type string` • `--help`	Flags are: • --output string- Specify a file for the retrieved values, or specify "-" to send to stdout. The default is "-" to send to stdout. For example, `apicup certs get mgmt1 --output myCertsFile` • --type string - Returns only the specified type. If not specified, the type is cert. For example, `apicup certs get mgmt1 --type ca` • --help - Displays help for the command.	• For --output: The specified certificate is retrieved and sent to stdout or saved to the specified file • For --type: Certificates are retrieved that match the type specified. .

List the certificates for a subsystem

Run the command **apicup certs list**:

Table 3. apicup certs list

Command	Values	Result
`apicup certs list SUBSYS [flags]`	Parameters are: • SUBSYS - name of the subsystem for which you want to list certificates	Returns a list of certificates that are configured for the subsystem.
`flags` • `--help`	Flags are: • --help - Displays help for the command.	Help text is displayed.

Generate certificates

The `apicup certs generate` command generates and sets default certificates. The `generate` command generates and sets a certificate only if it is not already set.

Note: The **apicup subsys install** operation also generates and sets any unset certificates, but use the `apicup certs generate` command so that you can set them and review them before you install.

Table 4. apicup certs generate

Command	Values	Result
`apicup certs generate SUBSYS [flags]`	Parameters are: • SUBSYS - name of the subsystem for which you want to generate certificates	Generates certificates that are currently not set for the subsystem. Generates self-signed certificates.
`flags` • `--help`	Flags are: • --help - Displays help for the command.	Help text is displayed.

Certificate validation reference

Certificates validation errors reference table.

The following table lists the certificate validation errors that the **apicup certs** command might report.

Validation	Messages	Error	Action to take
Verify that the certificate is set properly.	`certificate <cert> not set`	The certificate is not set.	
	`unable to load cert <cert>`	The certificate is set but cannot be read.	
Verify certificate key usage (Extended Key Usage).	`unable to verify cert <cert>: missing key usage <n>`	The certificate is missing the required key usage.	Check Certificate reference VMware to confirm the EKU required for the certificate.
Verify the certificate signing CA. If available, the CA file is loaded. Then the certificate is verified against the provided CA file, including enforcement of Extended Key Usage.	`unable to parse CA to verify cert <cert>`	The CA file could not be parsed and loaded.	
	`unable to verify cert <cert>`	The certificate failed verification against the provided CA file.	One possible reason for receiving this error is that the correct EKU is missing.
Verify certificate hosts.	`unable to verify cert <cert>: missing <host>`	The certificate is not valid for the required host.	See Certificate reference VMware for the required hosts.
Verify that a certificate that is being used as a CA is a CA certificate.	`unable to verify cert <cert>: certificate is not a CA`	The certificate is not a valid CA.	
Verify client certificate match. The `portal-client`, and `analytics-ingestion-client` certificates are verified against the CA of `portal-admin-ingress`, and `analytics-ingestion-ingress`.	`a CA certificate must be provided for this certificate`	The CA certificate is missing for one of the `portal-admin-ingress`, and `analytics-ingestion-ingress`.	The common certificates `portal-client`, and `analytics-ingestion-client` must be set before you set any custom certificates.
	`client cert cannot be verified against provided CA certificate`	The verification failed.	

Use JWT security instead of mTLS between subsystems

If your network requires TLS termination on load-balancers located between your API Connect subsystems, then disable mTLS and enable JWT to provide application layer security.

JWT security provides application layer security and can be used instead of mTLS when there are load-balancers located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.

1. To enable JWT and disable mTLS, first identify the JWKS URL from the management subsystem:

   ```
   apicup subsys get <management subsystem>

   ...
   jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
   validate JWT -- this is unsettable and is generated based on the platform-api endpoint
   ...
   ```

2. Disable mTLS and enable JWT on portal and analytics by setting the `mtls-validate-client` and `jwks-url` values with **apicup**:

   ```
   apicup subsys set <portal> mtls-validate-client=false
   apicup subsys set <portal> jwks-url=appliance1.apic.acme.com/api/cloud/oauth2/certs

   apicup subsys set <analytics> mtls-validate-client=false
   apicup subsys set <analytics> jwks-url=appliance1.apic.acme.com/api/cloud/oauth2/certs
   ```

3. Apply the change to portal and analytics with `apicup subsys install`:

   ```
   apicup subsys install <subsystem_name>
   ```

4. To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the DataPower documentation.

Note: Do not disable mTLS without enabling JWT.

Credentials and encryption secrets reference

API Connect user credentials and database encryption secrets that are managed with the **apicup certs** command.

The **apicup certs** command is used to manage various credentials and encryption secrets that are used by API Connect management and portal subsystems.
Note: For details of the TLS certificates that you can manage with the **apicup certs** command, see Certificate reference VMware.

Management subsystem credentials and secrets

The following table lists all the secrets and credentials that are returned from the **apicup certs list <management subsystem>** command:

Table 1. Management subsystem credentials and secrets

Secret or credential name	Description
`atm-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`consumer-toolkit-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`consumer-ui-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`database-backup-auth-ssh-key`	SSH key for authentication with a remote SFTP backup server.
`designer-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`encryption-secret`	A 128-bytes long encryption secret that is used to do field level encryption in the management subsystem database. If you want to modify this credential, open a support case.
`juhu-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`toolkit-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`ui-credential`	Credential used in internal API Connect communication. Do not modify this credential.

Portal subsystem credentials and secrets

The following table lists all the secrets and credentials that are returned from the **apicup certs list <portal subsystem>** command:

Table 2. Portal subsystem credentials and secrets

Secret or credential name	Description
`encryption-secret`	A 128-bytes long encryption secret that is used to do field level encryption in the portal subsystem database.
`original-encryption-secret`	A copy of the encryption-secret that was first used to generate the Kubernetes secret name. Do not modify this secret.
`site-backup-auth-ssh-key`	Authentication key for your remote portal backup SFTP server.

Advanced configuration for management subsystem

Specify advanced configuration for the management subsystem.

Note: VMware deployments include subsystem settings that cannot be reconfigured without a complete deployment. For example, for the Management Service these settings include hosts, endpoints, interfaces (`public-iface`, `traffic-iface`), IP ranges of the Kubernetes pod and the service networks (`k8s-pod-network`, `k8s-service-network`). Before reconfiguring, review the installation instructions for your subsystem to determine which settings are optional during initial installation and thus able to be updated later.
See:

- **Setting rate limits for public APIs on the management service**
  Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.
- **Configuring maximum size of client requests to the Management subsystem on VMware**
  You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.
- **Enabling API governance on VMware**
  You can optionally configure API governance in API Connect on VMware by enabling the governance microservice.
- **Configuring monetization on VMware**
  You can optionally configure monetization in API Connect on a VMware virtual machine by enabling the billing microservice.
- **Configuring use of an external NTP server**
  You can optionally configure an external NTP server for use by API Connect when deploying on a VMware virtual machine.
- **Overriding resources for Postgres components on VMware V10.0.6.0**
  You can optionally override the CPU and Memory resources used by postgres database components.
- **Enabling UI feature flags on VMware**
  Use a template override to update the installation CR with settings that control UI features.

Setting rate limits for public APIs on the management service

Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.

Before you begin

These instructions assume you have the kubectl command-line tool installed. For more information, see https://kubernetes.io.

About this task

Rate limits can be set for public APIs on the management service. Rate limits on APIs help provide protection from DDoS (distributed denial of service) attacks. Without a rate limit, API calls from public APIs are unlimited.

The rate limit configuration requires that the header contains the actual client IP address. Any load balancer or proxy (for example, HAProxy) that is installed in front of the management service must be configured to pass the actual client IP address.

This procedure must be performed on a running API Connect deployment.

Rate limits are calculated as requests per seconds per client.

Note: If the rate limit has been reached on the management subsystem, the client will get an HTTP error: **`429 Too Many Requests`**.

Procedure

- Set a rate limit:
  1. Add the following entries to the extra-values-file:

     ```
     spec:
       template:
       - name: juhu
         containers:
         - name: juhu
           env:
           - name: RATE_LIMIT_PER_CLIENT
             value: "10"
           - name: LIMIT_REQUEST_OPTION
             value: "burst=10 nodelay"
     ```

     In this example, the first option sets the rate to 10 requests per second (10r/s). The second option allows 10 requests boosted without delay within < 1 second. You can customize as needed.

     The **`rateLimitPerClient`** property sets **`rate`**, and **`limitRequestOption`** sets **`[burst=number] [nodelay | delay=number]`** in the following nginx configuration:

     ```
     limit_req_zone key zone=name:size rate=rate;
     limit_req zone=name [burst=number] [nodelay | delay=number];
     ```

     Note that **`zone`** has been pre-defined and can't be configured. For more details, see the nginx doc http://nginx.org/en/docs/http/ngx_http_limit_req_module.html.

  2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
  3. Use **`apicup`** to update the VMware **`extra-values-file`** attribute to point to the new or updated management subsystem extra-values file:

     ```
     apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
     ```

     Where:
     - *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.
     - *<extra_values_file_path_and_name>* is the fully qualified path and name of your extra-values file.

     For example:

     ```
     apicup subsys set ds10-management extra-values-file /workspace/v10012/my_extra_values.yaml
     ```

  4. Verify that the configuration settings are valid in the apiconect-up-v10.yaml by running the following command:

     ```
     apicup subsys get <mgmt_subsystem_name> --validate
     ```

     The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
  5. Run **`apicup`** to update the settings in the deployed Management subsystem.

     ```
     apicup subsys install <management-subsystem>
     ```

  6. Enter the following command to connect to the management subsystem using SSH:

     ```
     ssh ip_address -l apicadm
     ```

     You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

  7. Select Yes to continue connecting, and once connected:

     ```
     sudo -i
     ```

  8. Validate that the juhu pod has restarted by listing the pods:

     ```
     kubectl get pods  grep juhu
     ```

  9. Check the AGE column to ensure a new juhu pod has started.
  10. If the older juhu pod is still running, delete it with the following command:

      ```
      kubectl delete pods <old-juhu-pod>
      ```

- Disable a rate limit:
  1. Remove the values from the extra-values-file.
  2. Run **`apicup`** to update the settings in the deployed Management subsystem.

     ```
     apicup subsys install <management-subsystem>
     ```

3. Enter the following command to connect to the management subsystem using SSH:

   ```
   ssh ip_address -l apicadm
   ```

   You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

4. Select Yes to continue connecting, and once connected:

   ```
   sudo -i
   ```

5. Validate that the juhu pod has restarted by listing the pods:

   ```
   kubectl get pods  grep juhu
   ```

6. Check the AGE column to ensure a new juhu pod has started.
7. If the older juhu pod is still running, delete it with the following command:

   ```
   kubectl delete pods <old-juhu-pod>
   ```

Configuring maximum size of client requests to the Management subsystem on VMware

You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.

About this task

The default maximum size is 8 megabytes. You can increase this value.

Increasing the setting can be useful if you get errors when using the CLI to import a large API. Example error:

```
HTTP/1.1 413 Request Entity Too Large
```

Note:

- These instructions apply only to VMware installations. For Kubernetes installations, see Configuring maximum size of client requests to the Management subsystem.
- These instructions use an extra-values file. This file can be used to define CR overrides. Note that extra-values files for a CR can contain more than one override. If you already use an extra-values file, you can add the new override to it.
- All of the commands must be run in the `apicup` management project directory.

Procedure

1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

   ```
   spec:
     template:
     - name: juhu
       containers:
       - name: juhu
         env:
         - name: CLIENT_MAX_BODY_SIZE
           value: "12m"
   ```

2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
3. Use `apicup` to update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file:

   ```
   apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
   ```

   Where:
   - *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.
   - *<extra_values_file_path_and_name>* is the fully qualified path and name of your extra-values file.

   For example:

   ```
   apicup subsys set ds10-management extra-values-file /workspace/v10011/my_extra_values.yaml
   ```

4. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

   ```
   apicup subsys get <mgmt_subsystem_name> --validate
   ```

   The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
5. Update the management VMware with the updated setting.

   ```
   apicup subsys install <mgmt_subsystem_name>
   ```

6. Monitor the health-check output until the management subsystem is healthy by running the following command:

   ```
   apicup subsys health-check <mgmt_subsystem_name>
   ```

   If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

```
Error: Cluster not in good health:
 ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
 ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.

Enabling API governance on VMware

You can optionally configure API governance in API Connect on VMware by enabling the governance microservice.

About this task

API governance is an optional add-on to IBM® API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process.

Note:

- These instructions apply only to VMware installations. For Kubernetes, OpenShift, and IBM Cloud Pak for Integration installations, see Enabling API governance on Kubernetes.
- API governance rulesets cannot be added to your deployment until the governance microservice is enabled.
- All of the commands must be run in the `apicup` management project directory.

To enable or disable the governance microservice, see the following instructions:

- **Enabling the governance microservice**
- **Disabling the governance microservice**

After the governance microservice is enabled, API governance resources can be created. For more information, see Configuring API governance in the Cloud Manager, and Configuring API governance in the API Manager.

Procedure

- **Enabling the governance microservice**
  1. Open your API Connect installation project directory.
  2. Run the following `apicup` command to enable the governance microservice:

     ```
     apicup subsys set <mgmt_subsystem_name> governance-enabled=true
     ```

     Where *`<mgmt_subsystem_name>`* is the name of the management subsystem that you are configuring.

  3. Install the new setting for the governance microservice by running the following command:

     ```
     apicup subsys install <mgmt_subsystem_name> --debug
     ```

     Including the `--debug` option enables the debug output for the command.

  4. Monitor the health-check output until the management subsystem is healthy by running the following command:

     ```
     apicup subsys health-check <mgmt_subsystem_name>
     ```

     If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

     ```
     Error: Cluster not in good health:
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
     ```

     When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.
- **Disabling the governance microservice**
  1. Open your API Connect installation project directory.
  2. Run the following `apicup` command to disable the governance microservice:

     ```
     apicup subsys set <mgmt_subsystem_name> governance-enabled=false
     ```

     Where *`<mgmt_subsystem_name>`* is the name of the management subsystem that you are configuring.

  3. Install the new setting for the governance microservice by running the following command:

     ```
     apicup subsys install <mgmt_subsystem_name> --debug
     ```

     Including the `--debug` option enables the debug output for the command.

Results

Note that when the governance microservice is enabled, there are a number of new deployments, jobs, and pods in the `ManagementCluster` namespace. These Kubernetes governance resources have names containing either `compliance-service` or `compliance-ui`. For example:

```
kubectl get pods -n apic | grep compliance
management-compliance-service-f6cdf95fc-t4qkx                     1/1     Running     0          127m
management-compliance-ui-59897fcc4-zm25v                          1/1     Running     0          126m
management-up-compliance-service-data-populate-0-to-1-t2f4d       0/1     Completed   1          132m
management-up-compliance-service-schema-0-to-1-2lkqq              0/1     Completed   0
```

Configuring monetization on VMware

You can optionally configure monetization in API Connect on a VMware virtual machine by enabling the billing microservice.

Before you begin

Important: If the optional billing microservice is enabled, you must increase the memory for the API Manager for VMware component by 0.5 GB.

About this task

API Connect includes a subscription billing microservice that allows API providers to define pricing plans in their API Products, and monetize their API offerings. If a Product contains a pricing plan, API Consumers must enter their payment information into the Developer Portal before they can subscribe to that plan. API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

Note:

- These instructions apply only to VMware installations. For Kubernetes installations, see Configuring monetization on Kubernetes.
- To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements on Kubernetes and Firewall requirements on VMware for more information about this requirement.
- Provider organizations cannot add any billing integrations until the billing microservice is enabled.
- After provider organizations have added billing integrations, the billing microservice must not be disabled.
- All of the commands must be run in the `apicup` management project directory.

To enable or disable the billing microservice, you must configure a management subsystem extra-values file. See the following instructions:

- **Enabling the billing microservice**
- **Disabling the billing microservice**

Procedure

- **Enabling the billing microservice**
  1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

     ```
     spec:
       billing:
         enabled: true
     ```

  2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
  3. Update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file.
     Run the following `apicup` command to insert the location of the extra-values file:

     ```
     apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
     ```

     Where:
     - *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.
     - *<extra_values_file_path_and_name>* is the fully qualified path and name of your extra-values file.

     For example:

     ```
     apicup subsys set ds10-management extra-values-file /workspace/v10011/monetization.yaml
     ```

  4. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

     ```
     apicup subsys get <mgmt_subsystem_name> --validate
     ```

     The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
  5. Update the management VMware with the updated billing value.
     Install the new setting for the billing microservice by running the following command:

     ```
     apicup subsys install <mgmt_subsystem_name> --debug
     ```

     Including the `--debug` option enables the debug output for the command.
  6. Monitor the health-check output until the management subsystem is healthy by running the following command:

     ```
     apicup subsys health-check <mgmt_subsystem_name>
     ```

     If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

     ```
     Error: Cluster not in good health:
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
     ```

     When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.
     The billing microservice is now enabled, and provider organization owners can create billing integration resources for API providers in the API Manager UI.
     For more information, see Monetizing your Products.

- **Disabling the billing microservice**

Important: After provider organizations have added billing integrations, the billing microservice must not be disabled.

1. Edit the management subsystem extra-values file in the `apicup` management project directory, and change the `enabled` configuration option to `false`:

   ```
   spec:
     billing:
       enabled: false
   ```

2. Save the changed extra-values file.
3. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

   ```
   apicup subsys get <mgmt_subsystem_name> --validate
   ```

   The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
4. Update the management VMware with the altered billing value.
   Install the updated setting for the billing microservice by running the following command:

   ```
   apicup subsys install <mgmt_subsystem_name> --debug
   ```

   Including the `--debug` option enables the debug output for the command.
5. Monitor the health-check output until the management subsystem is healthy by running the following command:

   ```
   apicup subsys health-check <mgmt_subsystem_name>
   ```

   If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

   ```
   Error: Cluster not in good health:
    ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
    ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
   ```

   When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.
   The billing microservice is now disabled.

Configuring use of an external NTP server

You can optionally configure an external NTP server for use by API Connect when deploying on a VMware virtual machine.

About this task

Secure communication between API Connect subsystems relies on the system time being in sync on all hosts. For example, time stamps are checked to ensure that certificates are valid. When API Connect is deployed behind a firewall that blocks access to the internet, the API Connect subsystems cannot by default access a Network Time Protocol (NTP) server.

You can use an additional cloud-init file to manually specify an NTP server for use by the subsystems. Complete the following steps.

Procedure

1. Create the cloud-init file extra values file, and enter the configuration details that you want to overwrite. For example:

   ```
   ntp:
     enabled: true
     ntp_client: systemd-timesyncd
     servers:
       - time.google.com
   ```

2. Use `apicup` to specify the cloud-init file.
   Syntax:

   ```
   apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
   ```

   Example:

   ```
   apicup subsys set mgmt additional-cloud-init-file myCloudInitFile.yaml
   ```

3. Install the subsystem. Note that the output directory must be empty:

   ```
   apicup subsys install mgmt --out mgmtplan-out
   ```

4. Deploy the VMware image (.ova) with the ISO file that is generated.
   To review the deployment steps, see Deploying the Management virtual appliance.

5. Verify that the correct NTP server is being used:

   ```
   journalctl -u systemd-timesyncd
   ```

   Example output for the NTP server that was set in Step 1:

```
Nov 05 21:09:24 h-apicdev-4 systemd[1]: Starting Network Time Synchronization...
Nov 05 21:09:24 h-apicdev-4 systemd[1]: Started Network Time Synchronization.
Nov 05 21:09:24 h-apicdev-4 systemd-timesyncd[1697]: Synchronized to time server 216.239.35.8:123 (time.google.com).
```

Overriding resources for Postgres components on VMware V10.0.6.0

You can optionally override the CPU and Memory resources used by postgres database components.

About this task

Note: The information in this topic applies to V10.0.6.0 only.
There are three postgres components:

- `postgres`
- `pgBouncer`
- `pgBackRest`

The default resources used in `postgrespgBouncer` and `pgBackRest` components are:

Table 1. Postgres component default resources

Resource	Postgres DB	pgBouncer	pgBackRest
Memory Request	512Mi	24Mi	48Mi
Memory Limit	8Gi	128Mi	128Mi
CPU Request	600m	80m	80m
CPU Limit	1500m	200m	200m

Procedure

To override resources, complete the following procedure

1. Create an extra-values yaml file, or add values to an existing extra-values file.
   - Ensure that you specify the name of the container for the resource you want to override. Names:
     - `postgres`
     - `pgBouncer`
     - `pgBackRest`
   - You can override multiple postgres components in parallel. Adding one container section under `mgmt-pgcluster` template.
   - You can override just a single value, such as CPU limit.

   Examples:
   - Example yaml, to replace all `postgres` resources:

     ```
     spec:
       template:
       - name: mgmt-pgcluster
         containers:
         - name: postgres
           resources:
             requests:
               cpu: 1500m
               memory: 8Gi
             limits:
               cpu: 600m
               memory: 512Mi
     ```

   - Example yaml, to replace all `pgBouncer` resources:

     ```
     spec:
       template:
       - name: mgmt-pgcluster
         containers:
         - name: pgBouncer
           resources:
             requests:
               cpu: 200m
               memory: 128Mi
             limits:
               cpu: 300m
               memory: 256Mi
     ```

   - Example yaml,to replace CPU limit of `postgres` database:

     ```
     spec:
       template:
       - name: mgmt-pgcluster
         containers:
         - name: postgres
           resources:
             limits:
               cpu: 1000m
     ```

   - Example yaml, to replace CPU limits of `postgres` database and `pgBouncer`:

     ```
     spec:
       template:
     ```

```
  - name: mgmt-pgcluster
    containers:
    - name: postgres
      resources:
        limits:
          cpu: 1000m
    - name: pgBouncer
      resources:
        limits:
          cpu: 1000m
```

2. Set the extra values file:

```
apicup subsys set <SUBSYSTEM_NAME> extra-values-file=<PATH_TO_EXTRA_VALUES_FILE>
```

3. Apply the overrides:

```
apicup subsys install <SUBSYSTEM_NAME>
```

4. Check health of cluster:

```
apicup subsys health-check <SUBSYSTEM_NAME>
```

Results

The postgres components will restart with updated values.

Enabling UI feature flags on VMware

Use a template override to update the installation CR with settings that control UI features.

About this task

You can add a template override to the Management subsystem CR and use it to control whether specific features are available in the UI. Some features can be optionally disabled by users (by disabling them in the browser) provided you have enabled the feature for the cluster as a whole. Table 1 describes the available feature flags.

Table 1. Flags and settings for controlling UI features

Feature ID	Default Value	Partial Override For	Description
`ffAdvancedPublish`	`true`		Enable advanced publish option (deprecated)
`allOmniSearch`	`true`		Enables OmniSearch for all lists. This flag is used in conjunction with other flags.
`draftsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for drafts list
`catalogProductsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for catalog
`orgsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for org lists
`appsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apps
`subscriptionsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for subscriptions, if disabled, subscription lists will be removed from catalog list
`requestedApprovalsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for requested approvals
`approvalTasksOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for approvals
`productApisOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apis within products
`membersOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for member lists

Procedure

1. Add the template override to the `management-extra-values.yaml` file.
2. In the file, append the feature-flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the OmniSearch feature on all possible UI pages.

```
spec:
  template:
    - name: ui
      containers:
      - name: ui
        env:
          - name: APIC_UI_FEATURES
            value: allOmniSearch=always
```

   `APIC_UI_FEATURES` is a URL-encoded string. Each parameter is formed as `featureId=$featureValue`, and you can list multiple parameters with the `&` delimiter (`featureId=$featureValue&featureId=$featureValue`).

   Use the `featureId` values from Table 1. For each feature, specify one of the following `featureValue` settings:

   - `true` - On by default, but can be overridden by the user, for their browser alone
   - `false` - Off by default, but can be overridden by the user, for their browser alone
   - `never` - Off regardless of browser setting, disabled in feature flag page
   - `always` - On regardless of browser setting, disabled in feature flag page
3. Save the file.
4. Run the following command to update the deployment:

```
apicup subsys set <management_subsystem> extra-values-file <path_to_management-extra-values.yaml_file>
```

The cluster is updated to enable or disable features as specified.

Configuring rate limits on the gateway nodes on VMware

Create an env.yaml file on each Gateway node to configure the default rate limit.

The Gateway uses scale limits (instead of strict limits) by default to enforce rate limits. This improves the gateway's performance by providing the ability to handle large amounts of rate-limited traffic.

1. To configure the rate limit, create a file called env.yaml with the settings provided in Table 1:

Table 1. Rate limit settings

Setting	Type	Default	Optoins	Comments
`USE_RATE_LIMIT_DEFINITION`	boolean	`true`	• `true` Use scale limits • `false` Use strict limits	Determines the type of rate limiting to use on the Gateway node.
`RATE_LIMIT_UPDATE_MODE`	enumerated	`prior`	• `none`No limits in a plan are incremented after a limit is reached. • `all` All limits in a plan are incremented after a limit is reached. • `prior` Retains the behavior from pre-V10 releases: When the plan rate limit is reached, all limits in the plan that are sorted before that plan limit will be incremented.	Determines how the counts within a plan are incremented when a rate limit is hit. Applies only to scale limits.
`RATE_LIMIT_SORT_BY_DURATION`	boolean	`true`	• `true` Sort the rate limits by duration. • `false` Revert to the previous sort order.	Determines the sort order for rate limits in a plan, which in turn determines the sequence in which they are applied.
`RATE_LIMIT_USE_OFFSET`	boolean	`false`	• `true` Prevent all rate limit counts for an interval from being reset at the same time. • `false` Allow all rate limit counts for an interval to be reset at the same time.	Allow or prevent all of the rate limit counts for an interval from being reset at the same time. Preventing the simultaneous reset protects backends from being saturated with requests by resetting the counts for different subscribers of a plan at different points with in the interval. Applies only to scale limits.
`RATE_LIMIT_DEFINITION_RESPONSE_HEADERS`	boolean	`true`	• `true` Show the `x-rate-limit` headers. • `false` Hide the `x-rate-limit` headers.	Show or hide the `x-rate-limit` headers in an API response. Applies only to scale limits.

2. Save the file in the local:/ directory on the Gateway node so that the file persists on reboots of both physical and virtual machines. The settings apply only to the node where the file is stored, so each node in the Gateway cluster requires its own copy of the file.

Backing up and restoring on VMware

Backup and restore API Connect on VMware.

Backups are for recovery of the API Connect subsystems in the same environment that the backups were taken. If you want to move your API Connect deployment to a different environment and change the form factor or modify your API Connect endpoints, then see Migrating from v10 to v10 on a different form factor.

Note: For information about how to maintain a two data center deployment, including backup and restore considerations, see Maintaining a two data center deployment.

- **Backing up and restoring the Management subsystem**
  Backup your management project directory and configure scheduled database backups.

- **Backing up and restoring the Management subsystem V10.0.6.0**
  You can back up and restore your Management subsystem in your VMware environment.
- **Backing up and restoring the Developer Portal**
  You can backup and restore a Developer Portal in a VMware environment.
- **Backing up and restoring the Analytics database on VMware**
  The IBM® API Connect Analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

Backing up and restoring the Management subsystem

Backup your management project directory and configure scheduled database backups.

Management subsystem backups are intended for restoration in the same environment where they were taken, or a different environment that has the same network configuration, endpoints, and deployment profile.

A management subsystem backup consists of:

Project directory backup
: The original project directory that was created with the **apicup** command during the initial product installation is essential for disaster recovery, see: First steps for deploying in a VMware environment. The project directory contains the YAML files that describe your deployment, encryption keys, and deployment ISO files. It is not possible to restore the management database on a deployment that uses a new or different project directory.

  Take a new backup of your project directory every time you make any configuration changes with the **apicup** command. Store your project directory backups at a remote location.

  Ensure that you keep all files related to your management subsystem in the project directory, so they are included in your project directory backup. For example:

  - Any TLS certificate **.pem** files that were used to customize management subsystem certificates.
  - Your management extra-values.yaml file, if you created one, for example: Configuring maximum size of client requests to the Management subsystem on VMware.

Management database backup
: Your management database backup contains everything that you create and configure in the Cloud Manager and API Manager UI (APIs, products, TLS profiles, user registries, and so on), or with the toolkit CLI or REST API. You configure your management subsystem to run scheduled backups. You can also take backups on-demand. The configuration of your database backups, such as S3 object store credentials, are defined by the management configuration YAML file in your project directory. Therefore, to restore the management database backup after a disaster, you must first restore your project directory.

Configuring management subsystem backups

1. Take a backup of your project directory manually, and store the backup at a remote location. Whenever you update your management subsystem with the **apicup** command, you should take a new backup of this directory.
2. Configure management database backups: Configuring management database backups.

Snapshots

Take a Virtual Machine (VM) snapshot of all your management VMs; see Using VM snapshots for infrastructure backup and disaster recovery. Taking snapshots does require a brief outage while all the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can provide faster recovery when compared to redeploying OVAs and restoring from a database backup.

Important: VM snapshots are not an alternative to the standard API Connect backups that are described in this section. Do not rely solely on VM snapshots for your backups.

- **Configuring management database backups**
  Use **apicup** to configure the database backup settings, before or after management subsystem installation.
- **Running an on-demand backup of the management database**
  Create a management database backup at any time, with **apicup**.
- **Restoring the management database backup**
  Use **apicup** to list backups and restore a selected backup of the management subsystem
- **Recovering from a disaster**
  Recover the management subsystem in a VMware environment.

Configuring management database backups

Use **apicup** to configure the database backup settings, before or after management subsystem installation.

About this task

- You use the **apicup** utility to configure backup settings for the management subsystem.
- Backups can be scheduled or generated manually (on-demand).
- You must backup both the management and portal subsystems at the same time, to ensure synchronicity across the services.
- You must have a remote S3 object-store available to store your management database backups.
  Types of S3 backups supported:
  - IBM Cloud Object Storage
  - AWS S3
  - Any custom S3, such as minIO

- The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: **`x509: certificate signed by unknown authority`**
- Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For information on the registration credentials, see Changing the registration client_id and client_secret for applications.
- You can modify any of the backup settings at any time, but if you change the **`database-backup-auth-user`** or **`database-backup-auth-pass`** settings, you must also run:

  `apicup subsys db-reload <subsystem_name>`

  after applying the new settings with:

  `apicup subsys install <subsystem_name>`

Procedure

1. Use **`apicup`** to specify backup settings:

   `apicup subsys set <subsystem_name> <setting>=<value>`

Table 1. Configuration settings for backup of management subsystem database

Parameter	Description
`database-backup-auth-pass`	The password for the server specified in **`database-backup-host`**. This is the S3 Secret Access Key parameter. The password is converted and stored in Base64 encoded format. For example: **`apicup subsys set <subsystem_name> database-backup-auth-pass '<password>'`** Note that you cannot use the `=` sign to assign the password to **`database-backup-auth-pass`**. If you change this value later, to apply the change you must run **`apicup subsys db-reload <subsystem_name>`** after **`apicup subsys install <subsystem_name>`**
`database-backup-auth-user`	The username for the server specified in **`database-backup-host`**. This is the S3 Secret Key ID. **`apicup subsys set <subsystem_name> database-backup-auth-user <username>`** If you change this value later, to apply the change you must run **`apicup subsys db-reload <subsystem_name>`** after **`apicup subsys install <subsystem_name>`**
`database-backup-host`	The backups host. Specify S3 endpoint with the corresponding S3 region in the format **`<S3endpoint>/<S3region>`**: • **`apicup subsys set <subsystem_name> database-backup-host=s3.ibm.com/eu-west-2`** • **`apicup subsys set <subsystem_name> database-backup-host=s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard`**
`database-backup-path`	The path to the location of the backup. Specify the name of your S3 bucket to store backup data, in the format **`bucket-name/folder`**. The use of subdirectories in the bucket name is not supported. When your deployment includes a management subsystem in two different clusters (with active databases), the two management subsystems cannot use the same S3 bucket name in the database backup configurations. Each management subsystem must use a unique S3 bucket name. Ensure that **`bucket-name/folder`** is empty. **`apicup subsys set <subsystem_name> database-backup-path=bucket-name/apic-backup`**
`database-backup-schedule`	Cron schedule for performing automatic backups. The format for the schedule is: • `******` • `------` • |||||| • ||||| +----- day of week (0 - 6) (Sunday=0) • |||| +------- month (1 - 12) • ||| +--------- day of month (1 - 31) • || +----------- hour (0 - 23) • | +------------- min (0 - 59) • +--------------- sec (0 - 59) The default is an empty string, which means no backups are taken. The timezone for backups is UTC. This example will schedule a back up daily at 1am. **`apicup subsys set <subsystem_name> database-backup-schedule="0 0 1 * * *"`**
`backup-certs`	**Optional**. Backup certificates to use for TLS communication between API Connect and the backup server. For example: **`apicup subsys set <subsystem_name> backup-certs=<certificate_name>`**

Parameter	Description
`database-backup-s3-uri-style`	**Optional**: Specifies whether the URI is in the form of `host` or `path`. `apicup subsys set <subsystem_name> database-backup-s3-uri-style='<host|path>'` Supported values: • `host` • `path`
`database-backup-repo-retention-full`	The number of days of backups to retain. For example, if `database-backup-repo-retention-full` is set to 30, then backups for the last 30 days are retained. Older backups are deleted. After a restore, the count of the number of days is reset to zero. Minimum value: 1 Maximum value: 9999999 Default: none

2. Confirm that the backup settings pass validation:

   ```
   apicup subsys get <subsystem_name> --validate
   ```

   If you are configuring the backup settings before install, then skip the remaining steps and continue with the installation process. Verify that your backups are working after installation.
3. Apply the settings:

   ```
   apicup subsys install <subsystem_name>
   ```

4. Ensure that the changes were applied successfully:

   ```
   apicup subsys health-check <subsystem_name>
   ```

5. Take a new backup of your project directory.
   Your backup configuration settings are stored in your project directory. Take a new backup of your project directory every time you update your backup settings or make any other configuration updates with the **apicup** command.

6. Verify that your backup settings are correct by running an on-demand backup: Running an on-demand backup of the management database.

Running an on-demand backup of the management database

Create a management database backup at any time, with **apicup**.

Before you begin

- Database backup settings for the management subsystem must be configured. See Configuring management database backups.
- Take a backup of the portal database at the same time as you take a backup of the management database. The portal database and management database must remain consistent with each other.
- Do not attempt to run more than one management database backup at a time. Check that no backups are running:

  ```
  apicup subsys list-backups <management subsystem name>
  ```

  Check that the scheduled backup is not configured to run before you expect your on-demand backup to finish:

  ```
  apicup subsys get <management subsystem name> database-backup-schedule
  ```

Procedure

1. Check that your management subsystem is healthy:

   ```
   apicup subsys health-check <management subsystem name>
   ```

   When successful, the command returns silently with an exit code of `0`.

2. Use the **apicup** command to start the backup process:

   ```
   apicup subsys backup <management subsystem name>
   ```

   To view available flags, use `-h`:

   ```
   apicup subsys backup management -h
   Backup management subsystem
   Usage:
     backup SUBSYS [flags]Flags:
         --debug                  Enable debug logging
     -h, --help                   help for backup
         --wait                   Wait for the operation to complete or fail.
         --wait-timeout duration  Command timeout in seconds. (default 40s)
   ```

3. Monitor the backup process with:

   ```
   apicup subsys list-backups <management subsystem name>
   ```

   Example output:

   ```
   NAME                AGE   CLUSTER                         PHASE       ERROR
   mgmt-backup-qdbfn   65m   boaz-auto1-87f65bf8-site1-db    completed
   ```

For more information about the backup, use the `detailed-output` flag:

```
apicup subsys list-backups <management subsystem name> --detailed-output=true
```

Restoring the management database backup

Use `apicup` to list backups and restore a selected backup of the management subsystem

Before you begin

- When you restore the management subsystem database, you must then restore the portal subsystem database from a backup that was taken at the same time. The database backups of the management and portal must be taken at the same time to ensure that the portal sites are consistent with management database.
- Restoring the management database requires downtime and is a destructive process that deletes current data and copies backup data. During the restoration process, external traffic must be stopped.
- To restore the management database, you must use the original project directory that was created with `apicup` during the initial product installation. You cannot restore the database without the initial project directory. If necessary, restore the project directory from your Project directory backup.

About this task

Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For more information about the registration credentials, see Changing the registration client_id and client_secret for applications.

Procedure

1. List the available backups:

   ```
   apicup subsys list-backups <management subsystem name>
   ```

   Example output:

   ```
   # apicup subsys list-backups mgmt
   NAME                AGE   CLUSTER                          PHASE       ERROR
   mgmt-backup-qdbfn   65m   boaz-auto1-87f65bf8-site1-db   completed
   mgmt-backup-qdfdd   24h   boaz-auto1-87f65bf8-site1-db   completed
   ```

   Take note of the name of the backup that you want to restore.
   If the backup you want to restore is not listed, but you know where it is on the S3 object-store, then you can restore by using the backup ID instead of the backup name, see step 3.

2. Restore the backup, by using the backup name identified in step 1.

   ```
   apicup subsys restore <management subsystem name> --name <backupname> <flags>
   ```

   Available flags:

   ```
   apicup subsys restore mgmt --help
   Restore management subsystem

   Usage:
     restore SUBSYS [flags]

   Flags:
         --debug                                Enable debug logging
     -h, --help                                 help for restore
         --host <host>/<myregion>               FQDN for DB backups server in format <host>/<myregion>
         --id string                            ID of the backup to restore
         --name string                          Name of the backup to restore
         --password string                      Password for DB backups server
         --path string                          Path for DB backups server
         --username string                      Username for DB backups server
         --wait                                 Wait for the operation to complete or fail.
         --wait-timeout duration                Command timeout in seconds. (default 40s)
   ```

   Example:

   ```
   apicup subsys restore boaz-ova2-management --name mgmt-backup-qdbfn

   Starting restore...
   please check later for completion status of restore
   ManagementRestore is RestoreInProgress
   ```

3. Restore the backup, by using a backup ID.
   If you do not have a backup name for the backup you want to restore, you can use a backup ID. Look on your S3 object-store to identify the ID of the management database backup that you want to restore.
   In your S3 store, management database backups appear as folders that use a datestamp for their name, and are located inside the backup path. Example of management subsystem and its full path on an S3 store:

   ```
   apic-mgmt-backups/impr-restore/m1-65288d1d-db-2023-09-14T01:30:40Z/base/20230914T013040
   ```

   - `apic-mgmt-backups/impr-restore/m1-65288d1d-db-2023-09-14T01:30:40Z` is the backup path. The datestamp `2023-09-14T01:30:40Z` indicates when the management database was created (not when the backup was created). The management database is created on initial installation, and recreated when a backup restore is run. The path with the most recent datestamp should contain the most recent backups.
   - `20230914T013040` is the backup ID. The format indicates the date and time that the backup was taken.

- `base` is an autogenerated path segment and is ignored.

When you restore with a backup ID, you must include the S3 host, path, username, and password as flags in the restore command:

```
apicup subsys restore <management subsystem name> --id <backup ID> --host <S3 hostname> --username <S3 username> --
password <S3 password> --path <S3 backup path>
```

For example:

```
apicup subsys restore boaz-ova2-management --id 20230725T162548 --host s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-gb
--username 'a05e7aace2ab43b5941326429c8c071c' --password '3e510a1d9b06189b57334d064badf6abc39ab5a51d9bdcf7' --path
upgrade-test/boaz-ova1-management-22/management-site1-db-2023-11-16T12:30:02Z

Starting restore...
INFO[0000] Creating generic secret mgmt-restore-auth-secret.
please check later for completion status of restore
ManagementRestore is RestoreInProgress
root@apicdev3067:/home/apicadm/boaz-ova2# k get mgmtr
NAME                  STATUS              MESSAGE
BACKUP               CLUSTER                PITR                  AGE
NAME                  STATUS     MESSAGE                                                  BACKUP              CLUSTER
PITR                   AGE
mgmt-restore-t6ss5    Complete   Restore process completed (DB Restore + DRR job)    mgmt-backup-cdkv6   boaz-ova2-
management   2023-07-25T16:25:58   127m
mgmt-restore-tgxl2    Complete   Restore process completed (DB Restore + DRR job)                        boaz-ova2-
management
```

4. Monitor the restore:

   ```
   apicup subsys list-restores <management subsystem name>
   ```

5. When the management database restore shows the status `RestoreSuccessful`, restore your portal database backup: Restoring the Developer Portal subsystem.

Recovering from a disaster

Recover the management subsystem in a VMware environment.

About this task

Recovering the management subsystem involves re-creating your management ISO files, redeploying your management VMs with the new ISO files, and then restoring the management database from your backup.

Important points:

- In a clustered deployment, if any one VM is corrupted then all the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.
- When you restore the management subsystem database, you must then restore the portal subsystem database from a backup that was taken at the same time. The database backups of the management and portal must be taken at the same time to ensure that the portal sites are consistent with management database.
- The disaster recovery process is intended for restoration of API Connect in the same network environment with the same endpoints. If you want to change API Connect endpoints or migrate to a different form-factor, see Migrating from v10 to v10 on a different form factor.

Procedure

1. Use the same project directory that you used for your original deployment, or a restore of your Project directory backup.
2. Create your ISO files:

   ```
   apicup subsys install <subsystem name> --out <output directory>
   ```

   where *<output directory>* is the directory where the ISO files are to be created.
   Note: If your original ISO files are still available and you haven't upgraded from the original installation, you can reuse them. However, if you have upgraded your original deployment, you must create new ISO files using the version of **apicup** that corresponds to the version your API Connect installation was on at the time of the disaster. For example, do not attempt to deploy v10.0.7.x OVAs with ISO files that were created with **apicup** v10.0.6.0.
3. Deploy your new management VMs: Deploying the Management subsystem OVA file.
4. Verify your new management deployment, but do not log in to the Cloud Manager UI or attempt to configure or change any other settings: Verify installation of the Management subsystem.
5. Restore your management database backup, using backup ID. See step 3 on Restoring the management database backup.

Backing up and restoring the Management subsystem V10.0.6.0

You can back up and restore your Management subsystem in your VMware environment.

About this task

Note: This page is for v10.0.6 only. For v10.0.7 the management backup documentation is Backing up and restoring the Management subsystem

- You use the `apicup` utility to configure backup settings for the management subsystem.
- Database backups can be used to restore the database for disaster recovery.
- Backups can be scheduled or generated manually (on-demand). You can then list what backups are available and then use one to restore your Management subsystem if required.
- Postgres replica pods depend on a successful completed backup. If backup configuration is not correct, replica pods won't come up.

- Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For information on the registration credentials, see Changing the registration client_id and client_secret for applications.

Note: You must backup both the management and portal subsystems at the same time, to ensure synchronicity across the services.

Types of backups supported:

- Cloud-based S3 storage
  - IBM Cloud Object Storage
  - AWS S3
  - **v10.0.2.0 or later:** Any custom S3, such as minIO
- SFTP
- Local Backups

- **Configuring backup settings during initial installation of the management subsystem V10.0.6.0**
  You can use the `apicup` utility to configure backup settings during initial installation of the management subsystem
- **Verify configuration for s3 backup V10.0.6.0**
  Verify that the configuration for s3 backups succeeded.
- **Reconfiguring backup settings for the management subsystem V10.0.6.0**
  You can use the `apicup` utility to add or reconfigure backup settings for the management subsystem, after completion of initial installation.
- **Backing up the management subsystem V10.0.6.0**
  Use apicup to create a manual backup of the management subsystem
- **Restoring the management subsystem V10.0.6.0**
  Use `apicup` to list backups and restore a selected backup of the management subsystem
- **Troubleshooting management subsystem backups on VMware V10.0.6.0**
  You can troubleshoot failures of the management subsystem backups.

Configuring backup settings during initial installation of the management subsystem V10.0.6.0

You can use the `apicup` utility to configure backup settings during initial installation of the management subsystem

Before you begin

Note: This page is for v10.0.6 only. For v10.0.7 the management backup documentation is Backing up and restoring the Management subsystem
Review Backing up and restoring the Management subsystem V10.0.6.0.
Note: You must backup both the management and portal subsystems at the same time, to ensure synchronicity across the services.

About this task

- During an initial installation, use these steps to configure the backup settings prior to creating the initial management ISO.
- You can configure scheduled backups, or generate manual (on-demand) backups.
- Changing backup settings results in database downtime, unless `database-backup-protocol=sftp`.
- Backup to S3 providers of type `custom` is supported in v10.0.2.0 or greater. For `custom` S3, provide values for `database-backup-certs` and `database-backup-s3-uri-style`.
- OpenSSH key authentication for SFTP is supported.
- When you specify a filepath in a backup setting, be sure to escape any blank spaces in the path.

Important: For S3 backups of the management subsystem, do not use retention features provided by Cloud-based S3 storage providers. Use of such features can result in periodic deletion of archived backups, which can cause backup corruptions that can cause database restores to fail.

Procedure

1. Use `apicup` to specify backup settings:
   - For most settings, use `apicup subsys`:

     ```
     apicup subsys set <subsystem_name> <setting>=<value>
     ```

   - When configuring ssh-key authentication for SFTP, use `apicup certs`

     ```
     apicup certs set <subsystem_name> database-backup-auth-ssh-key <ssh-key-file-path>
     ```

Table 1. Configuration settings for backup of management subsystem

Parameter	Description

Parameter	Description
database-backup-protocol	The type of the backup. Supported types: • **objstore** **apicup subsys set mgmt database-backup-protocol=objstore** • **sftp** **apicup subsys set mgmt database-backup-protocol=sftp** The default value is **sftp**. • **local** - Local storage backups **apicup subsys set mgmt database-backup-protocol=local** Note: • The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: **x509: certificate signed by unknown authority**.
database-backup-auth-pass	The password for the server specified in **database-backup-host**. If using object store, this would be the S3 Secret Access Key parameter. The password will be stored in Base64 encoded format. For example: **apicup subsys set mgmt database-backup-auth-pass '<*password*>'** Note that you cannot use the `=` sign to assign the password to **database-backup-auth-pass**.
database-backup-auth-user	The username for the server specified in **database-backup-host**. If using object store, this would be the S3 Secret Key ID. **apicup subsys set mgmt database-backup-auth-user <*user_name*>**
database-backup-auth-ssh-key	Optional: OpenSSH private key for DB backups using SFTP only. Changing this value will restart the DB. Important: • Use **apicup certs** to set this value. Do not use **apicup subsys**. • Only OpenSSH keys are supported.[1] **apicup certs set mgmt database-backup-auth-ssh-key <*ssh private key filepath*>**
database-backup-s3provider	When using **objstore** type backup, specify the name of the S3 provider to use. Specify one of the supported values: • **ibm** • **aws** • **custom** - **v10.0.2.0 or later** Not required for local backups or SFTP backups. **apicup subsys set mgmt database-backup-s3provider=ibm**
database-backup-host	The backups host: • For **objstore** type backup, specify S3 endpoint with the corresponding S3 region in the format **<S3endpoint>/<S3region>** **apicup subsys set mgmt database-backup-host=s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard** • For **sftp** type, the SFTP server hostname **apicup subsys set mgmt database-backup-host=my.sftp.backup.domain.example.com** • Not required for local storage backups
database-backup-path	The path to the location of the backup: • For **objstore** backups, the name of your S3 bucket to store backup data. For example, **bucket-name/folder**. The use of subdirectories in the bucket name is not supported. **apicup subsys set mgmt database-backup-path=apic-backup** Note: When your deployment includes a management subsystem in two different clusters (with active databases), the two management subsystems cannot use the same s3 bucket name in the database backup configurations. Each management subsystem must use a unique s3 bucket name. Ensure that **bucket-name/folder** is empty. If the folder was previously used for backups, the folder will not be empty, and stanza create might encounter an error. ◦ **Explanation:** Once a folder is used, archive.info and backup.info files are created. During stanza creation, the process compares the database version and database system id between the two info files and the current Postgres database cluster. Stanza creation fails if there is a mismatch. To prevent this possibility, remove all files from the folder before configuring. • For **sftp** type, the full absolute path of the folder on the SFTP server, beginning with /. **apicup subsys set mgmt database-backup-path=<*folder_name*>** • Not required for local storage backups
database-backup-port	The port for the protocol to connect to the **database-backup-host**. The backup port is not required for object storage. Default: 22 **apicup subsys set mgmt database-backup-port=<*port_number*>**
database-backup-retries	For **sftp** type backups, the number of times the **ibm-apiconnect** Operator attempts backups in the event of a failed SFTP backup. **apicup subsys set mgmt database-backup-retries=3** Default value: **0**. Not used for **objstore** or local storage backup.

Parameter	Description
`database-backup-schedule`	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * • - - - - - • | | | | | • | | | | +----- day of week (0 - 6) (Sunday=0) • | | | +------- month (1 - 12) • | | +--------- day of month (1 - 31) • | +----------- hour (0 - 23) • +------------- min (0 - 59) The backup schedule defaults to `0 0 * * *`. This means a backup is run every day at midnight and minute zero. The timezone for backups is UTC. For local backups, the default is 01:00 UTC. When you configure a host, if you do not specify a value for **`database-backup-schedule`**, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed. `apicup subsys set mgmt database-backup-schedule="0 0 * * *"`

`database-backup-certs`	Custom certificate. Used only when **`s3Provider`** is set to **`custom`**. Most of the custom S3 providers are created based on custom CA certificate.
	
	This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be **`ca.crt`** and value should be base64 encoded value of CA certificate.
	
	The API Connect management subsystem validates the custom S3 certificate against the customer-provided CA certificate.
	
	Sample bash script to create the Kubernetes secret:
	
	`cat >customs3ca.yaml <<EOF`
	`apiVersion: v1`
	`data:`
	`  ca.crt: $(base64 <path-to-ca-certificate> | tr -d '\n' )`
	`kind: Secret`
	`metadata:`
	`  name: custom-server-ca`
	`type: generic`
	`EOF`
	
	`kubectl apply -f customs3ca.yaml -n <namespace>`
	
	For example:
	
	`apicup subsys set mgmt database-backup-certs=my-custom-s3-ca-cert`

`database-backup-s3-uri-style`	Valid values: **`host`** and **`path`**. Default value: **`host`** Only allowed if **`s3Provider`** is set to **`custom`**. Some custom S3 providers require URI style to be set to **`path`**. For example, minIO supports both **`host`** and **`path`** style setup. You can create a minIO S3 server to only accept **`path`** style client communications. **Important**: Contact your custom S3 administrator before configuring this field. If not properly configured, upstream custom S3 can reject connections from the client, such as API Connect management subsystem. `apicup subsys set mgmt database-backup-s3-uri-style='<host|path>'`
`database-backup-repo-retention-full`	The number of full S3 or local backups to retain. Not supported for SFTP. When the next full backup successfully completes, and the specified number of retained backups is reached, the oldest full backup is deleted. All incremental backups and archives associated with the oldest full backup also expire. Incremental backups are not counted for this setting. Applies to both manual backups and scheduled backups. Minimum value: **`1`** Maximum value: **`9999999`** Default: none (S3 backups), 14 (local backups).

2. Verify that your settings are valid:
   - To view all subsystem settings except **`database-backup-auth-ssh-key`**:

     `apicup subsys get <subsystem_name> --validate`

   - To view **`database-backup-auth-ssh-key`**:

     `apicup certs get <subsystem_name> database-backup-auth-ssh-key --type key`

3. Return to the instructions for installing the management subsystem: Deploying the Management virtual appliance.
   Note that the configuration settings for backups will be installed when you run **`apicup subsys install <subsystem_name>`** after all configuration settings are complete.

4. **S3 backups only**: After you complete the deployment of the Management subsystem in the previous step, continue to Verify configuration for s3 backup V10.0.6.0.

[1] PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see https://www.puttygen.com/.

Verify configuration for s3 backup V10.0.6.0

Verify that the configuration for s3 backups succeeded.

About this task

Note: This page is for v10.0.6 only. For v10.0.7 the management backup documentation is Backing up and restoring the Management subsystem
When you configure Management subsystem backups, the operator runs a **stanza-create** job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

Procedure

1. SSH into the management appliance.
2. Check the status of the **stanza-create** job:

```
kubectl get jobs -n <namespace> | grep stanza
```

- On success:
  - The **stanza-create** job status is **1/1**:

```
kubectl get jobs | grep stanza
m1-b722e361-postgres-stanza-create          1/1           5s         127m
```

  - The **stanza-create** job shows **status: "True"** and **type: Complete**:

```
kubectl get job m1-b722e361-postgres-stanza-create -o yaml

status:
  completionTime: "2021-04-13T18:38:50Z"
  conditions:
    - lastProbeTime: "2021-04-13T18:38:50Z"
      lastTransitionTime: "2021-04-13T18:38:50Z"
      status: "True"
      type: Complete
 startTime: "2021-04-13T18:38:45Z"
 succeeded: 1
```

  - The **stanza-create** pod is in **Completed** state:

```
kubectl get pods | grep stanza
m1-b722e361-postgres-stanza-create-q4fvp                        0/1     Completed   0          127m
```

  - Exec into the pod:

```
kubectl exec -it <backrest-shared-repo-pod> -- bash
```

  - The **pgbackrest** command returns the S3 contents in valid JSON:

```
pgbackrest info --output json --repo1-type s3

"backup":{"held":false}},"message":"ok"}}][pgbackrest@m1-b722e361-postgres-backrest-shared-repo-69cdfdfdd5-rs882
/
```

- On failure:
  - **stanza-create** pods fail, and job status is **0/1**:

```
kubectl get jobs | grep stanza
 m1-3bfe12ac-postgres-stanza-create          0/1           32m        32m
```

  - Listing all pods brought up by **stanza-create** job shows multiple pods because a job tries **backoffLimit** times to complete the job. By default, there will be **7** pods in error state:

```
kubectl get pods | grep stanza
 m1-3bfe12ac-postgres-stanza-create-726z4                       0/1     Error       0          11m
 m1-3bfe12ac-postgres-stanza-create-9vq4n                       0/1     Error       0          22m
 m1-3bfe12ac-postgres-stanza-create-gbtgb                       0/1     Error       0          30m
 m1-3bfe12ac-postgres-stanza-create-gl5g5                       0/1     Error       0          17m
 m1-3bfe12ac-postgres-stanza-create-q8qhw                       0/1     Error       0          26m
 m1-3bfe12ac-postgres-stanza-create-t84zs                       0/1     Error       0          8m54s
 m1-3bfe12ac-postgres-stanza-create-z8tfs                       0/1     Error       0          12m
```

    Note: In some cases, the pods are cleaned by Kubernetes and the logs of these pods can be lost.

  - Pod log errors show a reason for the failure. For example, when a hostname is not valid:

```
kubectl logs m1-3bfe12ac-postgres-stanza-create-gbtgb

time="2021-04-13T20:01:19Z" level=info msg="pgo-backrest starts"
time="2021-04-13T20:01:19Z" level=info msg="debug flag set to false"
time="2021-04-13T20:01:19Z" level=info msg="backrest stanza-create command
requested"
time="2021-04-13T20:01:19Z" level=info msg="s3 flag enabled for backrest command"
time="2021-04-13T20:01:19Z" level=info msg="command to execute is [pgbackrest
stanza-create  --db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --
repo1-type=s3]"
time="2021-04-13T20:01:19Z" level=info msg="command is pgbackrest stanza-create  --
db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --repo1-type=s3 "
time="2021-04-13T20:05:21Z" level=error msg="command terminated with exit code 49"
time="2021-04-13T20:05:21Z" level=info msg="output=[]"
```

  - Job status is set to **type: Failed** and **status: "True"**, with **reason: BackoffLimitExceeded**:

```
kubectl get job m1-3bfe12ac-postgres-stanza-create -o yaml

status:
  conditions:
    - lastProbeTime: "2021-04-13T20:28:03Z"
      lastTransitionTime: "2021-04-13T20:28:03Z"
      message: Job has reached the specified backoff limit
      reason: BackoffLimitExceeded
      status: "True"
      type: Failed
      failed: 7
startTime: "2021-04-13T20:01:18Z"
```

- If pod logs are lost, you can execute a command inside the **backrest-shared-repo** pod:
  - Obtain the **backrest-shared-repo** pod name:

    ```
    kubectl get pods -n <namespace> | grep backrest-shared-repo
    ```

    For example:

    ```
    kubectl get pods | grep backrest-shared-repo
    m1-eb8edc18-postgres-backrest-shared-repo-98dd46cc6-twl95   1/1     Running
    ```

  - Exec into the pod:

    ```
    kubectl exec -it <backrest-shared-repo-pod> -- bash
    ```

  - Run:

    ```
    pgbackrest info --output json --repo1-type s3
    ```

    For example, for invalid hostname:

    ```
    ERROR: [049]: unable to get address for 'test1-v10-backup.s3.exampleaws.com': [-2] Name or service not knownCopy
    ```

    The exact **ERROR:** will vary depending on the misconfiguration. Common errors:

    Invalid access key
    Invalid access key secret
    Invalid bucket region
    Invalid bucket or folder path
- To fix the incorrect settings, see Reconfiguring backup settings for the management subsystem V10.0.6.0.

Reconfiguring backup settings for the management subsystem V10.0.6.0

You can use the **apicup** utility to add or reconfigure backup settings for the management subsystem, after completion of initial installation.

Before you begin

Note: This page is for v10.0.6 only. For v10.0.7 the management backup documentation is Backing up and restoring the Management subsystem
If you have a two data center disaster recovery deployment, before you configure S3 backup settings you must first disable 2DCDR on both sites, and then re-enable 2DCDR after reconfiguring your backup settings. Follow these steps:

1. Disable 2DCDR for the management subsystems on both sites:

   ```
   apicup subsys set <management subsystem> multi-site-ha-enabled=false
   apicup subsys install <management subsystem>
   ```

2. Configure your S3 backup settings. You must specify different backup locations for each data center, see Backup and restore considerations for a two data center deployment.
3. Enable 2DCDR for the management subsystems on both sites:

   ```
   apicup subsys set <management subsystem> multi-site-ha-enabled=true
   apicup subsys install <management subsystem>
   ```

About this task

Warning: If you use the S3 backup protocol, changes to the backup settings result in a short period of database downtime.

- After initial installation, use these steps to add or reconfigure the backup settings.
- When you add or reconfigure backups after completion of the initial installation, the steps are the same as configuring during the initial installation, with the addition of using **apicup** to install (activate) the new settings immediately after adjusting the settings. During initial configuration, you typically wait to use **apicup** to activate settings until all other subsystem settings (unrelated to backup) are complete.
- You can add or reconfigure scheduled backups, or generate manual (on-demand) backups.
- When you specify a filepath in a backup setting, be sure to escape any blank spaces in the path.

Note: You must backup both the management and portal subsystems at the same time, to ensure synchronicity across the services.

Procedure

1. Use **apicup** to specify backup settings:

   ```
   apicup subsys set <subsystem_name> <setting>=<value>
   ```

Table 1. Configuration settings for backup of management subsystem

Parameter	Description

`database-backup-protocol`	The type of the backup. Supported types:
	• `objstore`
	`apicup subsys set mgmt database-backup-protocol=objstore`
	• `sftp`
	`apicup subsys set mgmt database-backup-protocol=sftp`
	The default value is `sftp`.
	• `local` - Local storage backups
	`apicup subsys set mgmt database-backup-protocol=local`
	Note:
	• The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: `x509: certificate signed by unknown authority`.

`database-backup-auth-pass`	The password for the server specified in `database-backup-host`. If using object store, this would be the S3 Secret Access Key parameter. The password will be stored in Base64 encoded format. For example: `apicup subsys set mgmt database-backup-auth-pass '<password>'` Note that you cannot use the `=` sign to assign the password to `database-backup-auth-pass`.
`database-backup-auth-user`	The username for the server specified in `database-backup-host`. If using object store, this would be the S3 Secret Key ID. `apicup subsys set mgmt database-backup-auth-user <user_name>`
`database-backup-auth-ssh-key`	**Version 10.0.3.0 or later**: Optional: OpenSSH private key for DB backups using SFTP only. Changing this value will restart the DB. Important: • Use `apicup certs` to set this value. Do not use `apicup subsys`. • Only OpenSSH keys are supported.[1] `apicup certs set mgmt database-backup-auth-ssh-key <ssh private key filepath>`
`database-backup-s3provider`	When using `objstore` type backup, specify the name of the S3 provider to use. Specify one of the supported values: • `ibm` • `aws` • `custom` Not required for local backups or SFTP backups. `apicup subsys set mgmt database-backup-s3provider=ibm`

`database-backup-host`	The backups host:
	• For `objstore` type backup, specify S3 endpoint with the corresponding S3 region in the format `<S3endpoint>/<S3region>`
	`apicup subsys set mgmt database-backup-host=s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard`
	• For `sftp` type, the SFTP server hostname
	`apicup subsys set mgmt database-backup-host=my.sftp.backup.domain.example.com`
	• Not required for local storage backups

`database-backup-path`	The path to the location of the backup:
	• For `objstore` backups, the name of your S3 bucket to store backup data. For example, `bucket-name/folder`. The use of subdirectories in the bucket name is not supported.
	`apicup subsys set mgmt database-backup-path=apic-backup`
	Note: When your deployment includes a management subsystem in two different clusters (with active databases), the two management subsystems cannot use the same s3 bucket name in the database backup configurations. Each management subsystem must use a unique s3 bucket name.
	Ensure that `bucket-name/folder` is empty. If the folder was previously used for backups, the folder will not be empty, and stanza create might encounter an error.
	◦ **Explanation:** Once a folder is used, archive.info and backup.info files are created. During stanza creation, the process compares the database version and database system id between the two info files and the current Postgres database cluster. Stanza creation fails if there is a mismatch. To prevent this possibility, remove all files from the folder before configuring.
	• For `sftp` type, the folder name on the SFTP server
	`apicup subsys set mgmt database-backup-path=<folder_name>`
	• Not required for local storage backups

`database-backup-port`	The port for the protocol to connect to the `database-backup-host`. The backup port is not required for object storage. Default: 22 `apicup subsys set mgmt database-backup-port=<port_number>`
`database-backup-retries`	For `sftp` type backups, the number of times the `ibm-apiconnect` Operator attempts backups in the event of a failed SFTP backup. `apicup subsys set mgmt database-backup-retries=3` Default value: `0`. Not used for `objstore` or local storage backup.

Parameter	Description
`database-backup-schedule`	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * • - - - - - • | | | | | • | | | | +----- day of week (0 - 6) (Sunday=0) • | | | +------- month (1 - 12) • | | +--------- day of month (1 - 31) • | +----------- hour (0 - 23) • +------------- min (0 - 59) The backup schedule defaults to `0 0 * * *`. This means a backup is run every day at midnight and minute zero. The timezone for backups is UTC. When you configure a host, if you do not specify a value for **database-backup-schedule**, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed. `apicup subsys set mgmt database-backup-schedule="0 0 * * *"`
`backup-certs`	**Optional**. Backup certificates to use for TLS communication between API Connect and the backup server. Supported for custom s3 backups only. Use this setting when you have set **database-backup-s3provider=custom** For example: `apicup subsys set mgmt backup-certs=<certificate_name>`
`database-backup-s3-uri-style`	**Optional**: Specifies whether the URI is in the form of **host** or **path**. Used only with custom s3providers. Use this setting when you have set **database-backup-s3provider=custom**. `apicup subsys set mgmt database-backup-s3-uri-style='<host|path>'` Supported values: • **host** • **path**
`database-backup-repo-retention-full`	The number of full S3 or local backups to retain. Not supported for SFTP. When the next full backup successfully completes, and the specified number of retained backups is reached, the oldest full backup is deleted. All incremental backups and archives associated with the oldest full backup also expire. Incremental backups are not counted for this setting. Applies to both manual backups and scheduled backups. Minimum value: **1** Maximum value: **9999999** Default: none (S3 backups), 14 (local backups).

Note: To view all subsystem settings for the management subsystem:

```
apicup subsys get <subsystem_name> --validate
```

2. Apply the settings:

   ```
   apicup subsys install <subsystem_name>
   ```

3. Ensure that the changes were applied successfully:

   ```
   apicup subsys health-check <subsystem_name>
   ```

[1] PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see https://www.puttygen.com/.

Backing up the management subsystem V10.0.6.0

Use apicup to create a manual backup of the management subsystem

Before you begin

Note: This page is for v10.0.6 only. For v10.0.7 the management backup documentation is Backing up and restoring the Management subsystem
You must have configured backups for the subsystem. See Configuring backup settings during initial installation of the management subsystem V10.0.6.0

About this task

Use this task to create an on-demand, or manual, backup of the management system.

To set up scheduled backups, see the **schedule** option in Configuring backup settings during initial installation of the management subsystem V10.0.6.0.

Procedure

1. Ensure that there are no Management subsystem backups in Running state before creating a new Management backup.
2. Ensure your system is healthy:

   ```
   apicup subsys health-check [subsystem_name]
   ```

When successful, the command returns silently with an exit code of `0`.

3. Make sure that the management cluster status is Running and the READY condition displays the same value before and after the "/".
SSH into the appliance and run `kubectl`:

```
kubectl get mgmt
NAME    READY   STATUS    VERSION      RECONCILED VERSION   AGE
mgmt    16/16   Running   10.0.2.0   10.0.2.0         19h
```

Note: Be sure `READY` status is `16/16`. If you have just configured or reconfigured the backup settings, there is a period of time when the postgres pods are taken offline and brought back up with the new configuration. During this time, the `kubectl get mgmt` command will show `11/11` instead of `16/16`. If you start a backup before the Management cluster is on `16/16`, the backup attempt might stall indefinitely.

4. Create a backup:

```
apicup subsys backup [subsystem_name] [flags]
```

Decide which of the two types of manual backups you want to do:

- `full`: backs up the entire Management subsystem database.

  ```
  apicup subsys backup management --type full
  ```

- `incr`: backs up any data that has not been backed up since the last `full` or `incr` backup.

  ```
  apicup subsys backup management  --type incr
  ```

To view additional flags, use `-h`:

```
./apicup subsys backup management -h
Backup management subsystem
Usage:
  backup SUBSYS [flags]Flags:
      --debug                   Enable debug logging
  -h, --help                    help for backup
      --type string             Type of backup to take ['incr' (backup data starting from last backup), 'full' (complete
backup)] (default "full")
      --wait                    Wait for the operation to complete or fail.
      --wait-timeout duration   Command timeout in seconds. (default 40s)
```

Restoring the management subsystem V10.0.6.0

Use `apicup` to list backups and restore a selected backup of the management subsystem

Before you begin

Note: This page is for v10.0.6 only. For v10.0.7 the management backup documentation is Backing up and restoring the Management subsystem

- If you have to perform a restore, you must complete the restoration of the management service first, and then immediately restore the developer portal. The backups of the management and portal must be taken at the same time to ensure that the portal sites are consistent with management database.
- When restoring, the management, analytics, and developer portal subsystems must be at the same version and fix pack level.
- Restoring the Management Service requires database downtime and is a destructive process that deletes current data and copies backup data. During the restoration process, external traffic must be stopped.
- In a Disaster Recovery scenario, do not log in to the administration UI or attempt to configure or change any settings prior to restoring the backup. Restore the backup immediately after installing the subsystem.
- To restore the management database, you must use the original project directory that was created with `apicup` during the initial product installation. You cannot restore the database without the initial project directory because it contains pertinent information about the cluster. The endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored system. Successful restoration depends on use of a *single* `apicup` project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.
- Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.
- Map the DNS entries from the source cluster to the corresponding IP addresses on the target cluster. Record the DNS entries for each endpoint before starting the restore.
- When restoring the management database, the endpoints (on the new cluster which is the target for the restoration) have to be the same as those on the old cluster (the source of the backup).

About this task

Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For information on the registration credentials, see Changing the registration client_id and client_secret for applications.

Note: There is a known issue where sometimes a restore from the Management subsystem's SFTP backup succeeds but the data is not restored. If this happens, run the restore again.

Procedure

1. To list the available backups:

```
apicup subsys list-backups [subsystem_name] [flags]
```

Example:

```
# apicup subsys list-backups mgmt
NAME                  STATUS   ID                  CLUSTER      TYPE   CR TYPE   AGE
```

```
management-3aa3bebf   Ready    20200929-152150F   management   full   record    10h
management-3c4ca8df   Ready    20200929-115520F   management   full   record    20h
management-5tbxj      Ready    20200929-224349F   management   full   create    17h
management-f10af337   Ready    20200925-133703F   management   full   record    5d2h
management-jtlcd      Ready    20200929-224349F   management   full   create    25h
management-zxjtz      Ready    20200929-224349F   management   full   create    28h
```

Optional flags:

```
./apicup subsys list-backups -h
List backups of the subsystem
Usage:
  apicup subsys list-backups SUBSYS [flags]
Flags:
  -h, --help               help for list-backups
      --timeout duration   Command timeout in seconds. (default 40s)
Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Attention: You can restore the Management subsystem from any backup where the STATUS is Ready; however, you should avoid restoring to the initial system backup. During installation, the Management database is used for an initial system backup before certain database schema jobs are complete. Restoring to this backup will result in an unstable system.

2. To restore a selected backup:

```
apicup subsys restore [subsystem_name] --name <backup_name> [flags]
```

Example, where **management-zxjtz** is the value of **<backup_name>**, chosen from the backup **NAMES** listed by **apicup subsys list-backups** in Step 1:

```
apicup subsys restore mgmt --name management-zxjtz
```

Optional flags:

```
apicup subsys restore management -h
Restore management subsystem

Usage:
  restore SUBSYS_NAME [flags]

Flags:
      --debug                                Enable debug logging
  -h, --help                                 help for restore
      --name string                          Name of the backup to restore
      --wait                                 Wait for the operation to complete or fail.
      --wait-timeout duration                Command timeout in seconds. (default 40s)
```

3. You can list your restores and their statuses.

```
apicup subsys list-restores [subsystem_name] [flags]
```

To view the optional flags, use **-h**:

```
apicup subsys list-restores -h
List restores of the subsystem

Usage:
  apicup subsys list-restores SUBSYS [flags]

Flags:
  -h, --help               help for list-restores
      --timeout duration   Command timeout in seconds. (default 40s)

Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Troubleshooting management subsystem backups on VMware V10.0.6.0

You can troubleshoot failures of the management subsystem backups.

Note: This page is for v10.0.6 only. For v10.0.7 the management backup documentation is Backing up and restoring the Management subsystem

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
See:

- **Troubleshooting resiliency issues V10.0.6.0**
  Resolve resiliency issues with API Connect management system backups.
- **Troubleshooting stanza-create job for S3 backup configuration V10.0.6.0**
  Troubleshoot configuration of s3 backups when the stanza-create job fails.
- **Restore failure with compliance pod error on VMware V10.0.6.0**
  Compliance pod reports an error, and restore does not progress.

Troubleshooting resiliency issues V10.0.6.0

Resolve resiliency issues with API Connect management system backups.

Note: This page is for v10.0.6 only. For v10.0.7 the management backup documentation is Backing up and restoring the Management subsystem

pgbackrest-shared-repo resiliency problems

If the Kubernetes node hosting pgbackrest-shared-repo pod is down and the PVC attached to the pod has strict zone requirements (for example, in AWS or other clouds) or if the storage class is set to **local-storage**, then pgbackrest-shared-repo pod will not get rescheduled to another Kubernetes node.

As a result, there is a single point of failure and the following conditions might occur:

- Backups of the management database fails
- Disk space fills with accumulated Postgres wal (Write-Ahead Logging) files

To avoid this problem, monitor the disk usage: Monitoring Postgres disk usage on VMware.

When the Kubernetes node comes back up, the pod is scheduled and all the processes should resume properly.

Troubleshooting stanza-create job for S3 backup configuration V10.0.6.0

Troubleshoot configuration of s3 backups when the stanza-create job fails.

Note: This page is for v10.0.6 only. For v10.0.7 the management backup documentation is Backing up and restoring the Management subsystem
When you configure Management subsystem backups for s3 providers, the operator runs a **stanza-create** job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

SSH into the appliance VM, and check the status of the **stanza-create** job:

```
kubectl get jobs -n <namespace> | grep stanza
```

On failure:

- **stanza-create** pods fail, and job status is **0/1**:

  ```
  kubectl get jobs | grep stanza
   m1-3bfe12ac-postgres-stanza-create          0/1           32m        32m
  ```

- Listing all pods brought up by **stanza-create** job shows multiple pods because a job tries **backoffLimit** times to complete the job. By default, there will be **7** pods in error state:

  ```
  kubectl get pods | grep stanza
   m1-3bfe12ac-postgres-stanza-create-726z4                      0/1     Error       0          11m
   m1-3bfe12ac-postgres-stanza-create-9vq4n                      0/1     Error       0          22m
   m1-3bfe12ac-postgres-stanza-create-gbtgb                      0/1     Error       0          30m
   m1-3bfe12ac-postgres-stanza-create-gl5g5                      0/1     Error       0          17m
   m1-3bfe12ac-postgres-stanza-create-q8qhw                      0/1     Error       0          26m
   m1-3bfe12ac-postgres-stanza-create-t84zs                      0/1     Error       0          8m54s
   m1-3bfe12ac-postgres-stanza-create-z8tfs                      0/1     Error       0          12m
  ```

  Note: In some cases, the pods are cleaned by Kubernetes and the logs of these pods can be lost.

- Pod log errors show a reason for the failure. For example, when a hostname is not valid:

  ```
  kubectl logs m1-3bfe12ac-postgres-stanza-create-gbtgb

  time="2021-04-13T20:01:19Z" level=info msg="pgo-backrest starts"
  time="2021-04-13T20:01:19Z" level=info msg="debug flag set to false"
  time="2021-04-13T20:01:19Z" level=info msg="backrest stanza-create command
  requested"
  time="2021-04-13T20:01:19Z" level=info msg="s3 flag enabled for backrest command"
  time="2021-04-13T20:01:19Z" level=info msg="command to execute is [pgbackrest
  stanza-create  --db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --
  repo1-type=s3]"
  time="2021-04-13T20:01:19Z" level=info msg="command is pgbackrest stanza-create  --
  db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --repo1-type=s3 "
  time="2021-04-13T20:05:21Z" level=error msg="command terminated with exit code 49"
  time="2021-04-13T20:05:21Z" level=info msg="output=[]"
  ```

- Job status is set to **type: Failed** and **status: "True"**, with **reason: BackoffLimitExceeded**:

  ```
   kubectl get job m1-3bfe12ac-postgres-stanza-create -o yaml

  status:
    conditions:
      - lastProbeTime: "2021-04-13T20:28:03Z"
        lastTransitionTime: "2021-04-13T20:28:03Z"
        message: Job has reached the specified backoff limit
        reason: BackoffLimitExceeded
        status: "True"
        type: Failed
        failed: 7
  startTime: "2021-04-13T20:01:18Z"
  ```

- If pod logs are lost, you can execute a command inside the **backrest-shared-repo** pod:
  1. Obtain the **backrest-shared-repo** pod name:

     ```
     kubectl get pods -n <namespace> | grep backrest-shared-repo
     ```

For example:

```
kubectl get pods | grep backrest-shared-repo
m1-eb8edc18-postgres-backrest-shared-repo-98dd46cc6-twl95   1/1     Running
```

2. Exec into the pod:

   ```
   kubectl exec -it <backrest-shared-repo-pod> -- bash
   ```

3. Run:

   ```
   pgbackrest info --output json --repo1-type s3
   ```

   For example, for invalid hostname:

   ```
   ERROR: [049]: unable to get address for 'test1-v10-backup.s3.exampleaws.com': [-2] Name or service not knownCopy
   ```

   The exact `ERROR:` will vary depending on the misconfiguration. Common errors:

   Invalid access key
   Invalid access key secret
   Invalid bucket region
   Invalid bucket or folder path

- To fix the incorrect settings, see Reconfiguring backup settings for the management subsystem V10.0.6.0.

Restore failure with compliance pod error on VMware V10.0.6.0

Compliance pod reports an error, and restore does not progress.

Note: This page is for v10.0.6 only. For v10.0.7 the management backup documentation is Backing up and restoring the Management subsystem
This failure can happen in a situation where a backup is taken on a system where API governance has never been enabled, and the restore of that backup is done onto a system which has API governance enabled. In this situation the API governance database is missing, and consequently the compliance pods report an error.

Symptoms

The compliance service pods are continually restarting, and the restore does not progress. You can SSH into the appliance VM, and check the log of the compliance pod. For example:

```
kubectl logs management-up-compliance-data-populate-0-to-<nnn>-<xx>-<yy>
```

The log of the compliance pod shows an error like the following example:

```
2023-05-19T03:34:31.771Z bhendi:error Database availability check to management-0bfd2507-postgres:5432 failed, try again in
2000 ms,
error: : database "compliance" does not exist, stack: error: database "compliance" does not exist
```

Resolution

Delete all of the compliance jobs, and then start the restore again. For example:

```
kubectl -n <namespace> delete job management-up-compliance-service-data-populate-0-to-1 management-up-compliance-service-
schema-0-to-1
```

Backing up and restoring the Developer Portal

You can backup and restore a Developer Portal in a VMware environment.

About this task

It is strongly recommended that you configure the backup parameters for your portal service during installation. If you did not do so when you installed API Connect in your runtime environment, you must configure the backups for the Developer Portal before performing an upgrade. These backups can then be used to restore the Developer Portal if required. When your Developer Portal subsystem is running, you can also make on-demand backups by using the command line.

Note:

- You must backup both the management and portal subsystems at the same time, to ensure synchronicity across the services.
- When restoring, the management, analytics, and developer portal subsystems must be at the same version and fix pack level.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

- To complete a backup and restore of your Portal Subsystem, you must use apicup to configure the backup settings.
- Backups can be scheduled or generated manually (on-demand).

- You can then list the available backups are available and select one to restore your Portal Subsystem when necessary.
- Supported backup types:
  - Cloud-based S3 storage
    - IBM Cloud Object Storage
    - AWS S3
  - SFTP

- **Configuring backup settings for the Developer Portal subsystem**
  You can use the **apicup** utility to configure backup settings for the Developer Portal subsystem
- **Backing up the Developer Portal subsystem**
  After you have configured backup settings, you can use **apicup** to create a manual backup of the Developer Portal.
- **Restoring the Developer Portal subsystem**
  You can use **apicup** to restore the Developer Portal subsystem.

Configuring backup settings for the Developer Portal subsystem

You can use the **apicup** utility to configure backup settings for the Developer Portal subsystem

Before you begin

Review Backing up and restoring the Developer Portal.

About this task

- During an initial installation, use these steps to configure the backup settings prior to creating the initial management ISO.
- You can configure scheduled backups, or generate manual (on-demand) backups.
- OpenSSH key authentication for SFTP is supported.
- When you specify a filepath in a backup setting, be sure to escape any blank spaces in the path.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

Tip: If you are using remote backups, and there are a large number of rows in your **portalbackup** list that have a **CR TYPE** of **record**, there might be a slow down in system performance, including during Developer Portal upgrades. Although there is no upper limit to how many portal backups you can have, it is recommended that you prune your remote backups so that the number of rows does not become excessively large. One **portalbackup** row of type **record**, corresponds to one backup file on the configured remote backup server. For more information, see Overview of the Developer Portal backup resources v10.0.6.0.

Procedure

1. Open your API Connect installation project directory.
2. Run the following commands to set the location and timing of your backups:

```
apicup subsys set <subsystem_name> <setting>=<value>

apicup subsys set ptl site-backup-host=mybackuphost.com
apicup subsys set ptl site-backup-port=22
apicup subsys set ptl site-backup-auth-user=mybackupauthusername
apicup subsys set ptl site-backup-auth-pass=mybackupauthpassword
apicup subsys set ptl site-backup-path=/site-backups
apicup subsys set ptl site-backup-protocol=sftp
apicup subsys set ptl site-backup-certs=<custom-s3-server-CA-cert>
apicup subsys set ptl site-backup-s3-uri-style=<host-or-path>
apicup subsys set ptl site-backup-schedule="0 2 * * *"
apicup subsys set ptl site-priority-list=portal.a1.example.com/test-1/spacecatalog,portal.a1.example.com/test-
4/cat3,portal.a1.example.com/test-3/cat1
```

Use **apicup certs** instead of **apicup subsys** to configure ssh-key authentication for SFTP:

```
apicup certs set ptl site-backup-auth-ssh-key <ssh-key-file-path>
```

The backup parameters are detailed in the following table.

Table 1. Portal backup parameters

Parameter	Description
site-backup-host	The fully qualified domain name of the backup server, in lowercase only. • For **objstore** type backup, specify the S3 endpoint with the corresponding S3 region in the format **<S3endpoint>**, or with an optional S3 region in the format **<S3endpoint>/<S3region>**. **apicup subsys set ptl site-backup-host=s3.eu-gb.cloud-object-storage.appdomain.cloud** • For **sftp** type, the SFTP server hostname **apicup subsys set ptl site-backup-host=my.sftp.backup.domain.example.com**

Parameter	Description
site-backup-port	The port for the protocol to connect to the **site-backup-host**. Defaults to **22** if not explicitly set. The backup port is not required for object storage but if specified, is typically port 443. **apicup subsys set ptl site-backup-port=22**
site-backup-auth-user	The user name for the server specified in **site-backup-host**. If using object storage, the user name is the S3 Secret Key ID. **apicup subsys set ptl site-backup-auth-user=<*user_name*>**
site-backup-auth-pass	The password for the server specified in **site-backup-host**. If using object storage, the password is the S3 Secret Access Key parameter. The password is stored in Base64 encoded format, and must not be edited directly in the apiconnect-up.yml file. **apicup subsys set ptl site-backup-auth-pass=*password***
site-backup-auth-ssh-key	**Version 10.0.3.0 or later:** OpenSSH key for database backups by using SFTP. Important: • Use **apicup certs** to set this value. Do not use **apicup subsys**. • Only OpenSSH keys are supported.[1] **apicup certs set ptl site-backup-auth-ssh-key=<*ssh-key-file-path*>**
site-backup-path	The location of where the backups are stored: • S3 - the name of your S3 bucket to store backup data, optionally followed by a **/** and then any subdirectories inside the bucket. Valid examples: **bucket** **bucket/path** **bucket/lots/of/paths** Example: **apicup subsys set ptl site-backup-path=apic-backup** • SFTP - the full absolute path of the folder on the SFTP server, beginning with **/**. **apicup subsys set ptl site-backup-path=<*/folder*>**
site-backup-protocol	The protocol that is used to communicate with your remote backup endpoint. Specify one of the following values: • **sftp** - for secure file transfer protocol • **local** - for local storage • **objstore** - for S3 compatible object storage Starting with v10.0.3.0, the default protocol is **local** (earlier releases used **sftp** as the default). For example: **apicup subsys set ptl site-backup-protocol=local**
site-backup-certs	The name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.2. This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be **ca.crt** and the value is the base64-encoded value of the CA certificate. If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Portal subsystem already trusts the server certificate. You can test this by configuring the Portal backup to your S3/object-store server without providing the CA certificate. If you do need to provide the CA certificate then you must provide the entire chain in the **ca.crt** member of the secret, as follows: **intermediate-certificate-1** **intermediate-certificate-2** **. . .** **intermediate-certificate-*n*** **root-certificate** Where the first certificate in the **ca.crt** member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the **ca.crt** member is the issuer of the preceding certificate. The root certificate in the **ca.crt** member must be self-signed. If there are no intermediate certificates involved, then the **ca.crt** member contains only the root certificate. The following sample bash script creates a Kubernetes secret: **cat >customs3ca.yaml <<EOF** **apiVersion: v1** **data:** **ca.crt: $(base64 <*path-to-ca-certificate*> | tr -d '\n')** **kind: Secret** **metadata:** **name: custom-server-ca** **type: generic** **EOF** **kubectl apply -f customs3ca.yaml -n <*namespace*>**
site-backup-s3-uri-style	Optional. Indicates whether URIs to your S3 backup should use specify a host or a path value. When not specified, defaults to **host**. Supported beginning with 10.0.2. Valid values: **host** and **path**. Some custom S3 providers require URI style to be set to **path**. For example, MinIO supports both **host** and **path** style setup. You can create a MinIO S3 server to only accept **path** style client communications. **Important**: Contact your custom S3 administrator before configuring this field. If not properly configured, an upstream custom S3 can reject connections from the client, such as the API Connect Management subsystem.

Parameter	Description

`site-backup-schedule`	The schedule for how often automatic Portal backups are run. The format for the schedule is any valid cron string, as follows:
	
	`* * * * *`
	`- - - - -`
	`| | | | |`
	`| | | | +----- day of week (0 - 6) (Sunday=0)`
	`| | | +------- month (1 - 12)`
	`| | +--------- day of month (1 - 31)`
	`| +----------- hour (0 - 23)`
	`+------------- min (0 - 59)`
	
	For example: `30 22 * * 1` performs backups at 10:30 pm on Mondays.
	The default backup schedule is `0 2 * * *` (runs every day at 2 am).
	
	The timezone for backups is UTC.
	
	`apicup subsys set ptl site-backup-schedule="0 2 * * *"`

`site-priority-list`	Optional list of prioritized sites to restore. Default: empty.
	
	`apicup subsys set <portal-subsystem-name> site-priority-list <comma-separated-list-of-sites>`
	
	For example:
	
	`apicup subsys set ptl site-priority-list portal.a1.example.com/e2etest-1/spacecatalog,portal.a1.example.com/e2etest-4/cat3,portal.a1.example.com/e2etest-3/cat1`

3. At any time you can view the current Portal subsystem values:
   - For most values:

     `apicup subsys get ptl`

     where ***ptl*** is the name that you assigned to your Portal service. The output from this command lists all of the subsystem settings, including backup, and indicates whether there are any errors. You must fix any errors before continuing.

   - For ssh-key authentication for SFTP:

     `apicup certs get ptl site-backup-auth-ssh-key`

4. Activate the backup settings by running the following command:

   `apicup subsys install ptl`

   where ***ptl*** is the name that you assigned to your Portal service.
5. Validate the installation with the new backup parameters by running the following command:

   `apicup subsys get ptl --validate`

   where ***ptl*** is the name that you assigned to your Portal service. The output from this command lists all of the subsystem settings, including backup, and indicates whether the values are valid or invalid. You must correct any invalid values before continuing.
6. Ensure that the changes were applied successfully:

   `apicup subsys health-check <subsystem_name>`

- **Overview of the Developer Portal backup resources v10.0.6.0**
  How to manage your Developer Portal remote backup resources.

[1] PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see https://www.puttygen.com/.

Overview of the Developer Portal backup resources v10.0.6.0

How to manage your Developer Portal remote backup resources.

Note: This page is for V10.0.6.0 only. For V10.0.7.0 the backup, restore, and disaster recovery processes are documented in Backing up, restoring, and disaster recovery.
Note: This information is relevant only if you're taking remote Developer Portal backups.
The Developer Portal uses two types of portal backup resources. When you run the command **`kubectl get portalbackup`**, you see a list of backups, for example:

```
NAME                  ID                TASK ID      STATUS   TYPE     CR TYPE   CLUSTER   AGE     COMMENT
my-backup-f91ms       n/a               20b47fe090f5 Ready    system   create    portal    78m
portal-record-222cg   20220108.010033                Ready    system   record    portal    94m
portal-record-22xdc   20220702.010339                Ready    site     record    portal    9m49s
portal-record-245j7   20221002.010340                Ready    site     record    portal    5m
portal-record-246hm   20221218.010103                Ready    site     record    portal    32m
portal-record-24h44   20220509.010037                Ready    site     record    portal    68m
portal-record-24wb4   20221003.010029                Ready    site     record    portal    60m
portal-record-264mh   20221119.010453                Ready    system   record    portal    78m
```

There are two types of resources listed, and these are denoted by the **`CR TYPE`** column; **`create`** or **`record`** types.

1. **`create`**: This resource is a representation of a **`portalbackup`** task that was created manually. See Backing up and restoring the Developer Portal in a Kubernetes environment v10.0.6.0, Backing up Developer Portal on OpenShift and Cloud Pak for Integration v10.0.6.0, or Backing up the Developer Portal subsystem on VMware, for information about how to create a manual portal backup.
2. **`record`**: This resource is generated by the operator, and it's a representation of a backup file that's stored on the remote backup server. A record listing can be modified only to add a comment to it. You can describe each record to understand which file it is referring to by running the following command:

   `kubectl describe portalbackup portal-record-name`

For example:

```
kubectl describe portalbackup portal-record-zmmfw
.
.
Name:         portal-record-zmmfw
Namespace:    apic
Labels:       createdBy
.
.
Full Backup Name:        my-portal-s3-hostname@my-porg@catal-20220604.010302.tar.gz
```

Record rows are generated and updated on a schedule, according to the backups that exist on your remote backup server. If you have 10 backup files stored on your remote server, then there will be 10 record rows; one row for each file.

The Developer Portal doesn't have a retention policy for remote backups. Therefore, it's your responsibility to ensure that you're keeping the number of backups that are stored remotely under control. An excessive number of portal backups results in delays administrating and upgrading the Developer Portal. This is due to the operator needing to maintain the excessive number of record rows that correspond to each remote portal backup.

Backing up the Developer Portal subsystem

After you have configured backup settings, you can use **apicup** to create a manual backup of the Developer Portal.

About this task

You can make on-demand backups of your Developer Portal system, sites, and complete service, by running the following **apicup** commands in your API Connect installation project directory.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

Tip: If you are using remote backups, and there are a large number of rows in your **portalbackup** list that have a **CR TYPE** of **record**, there might be a slow down in system performance, including during Developer Portal upgrades. Although there is no upper limit to how many portal backups you can have, it is recommended that you prune your remote backups so that the number of rows does not become excessively large. One **portalbackup** row of type **record**, corresponds to one backup file on the configured remote backup server. For more information, see Managing your remote portal database backups.

Procedure

1. Ensure your system is healthy:

   ```
   apicup subsys health-check [subsystem_name]
   ```

   When successful, the command returns silently with an exit code of **0**.

2. Create a backup:

   ```
   apicup subsys backup [subsystem_name] [flags]
   ```

   - To backup the Portal system configuration (and not the sites), run the following command:

     ```
     apicup subsys backup ptl --type system
     ```

   - To backup a specific Portal site or all sites, run the following command:

     ```
     apicup subsys backup ptl --type site --site-name arg
     ```

     where *arg* is a specific site UUID or URL, or to backup all sites use the argument **installed**.
   - To backup the entire Portal service (the system and all installed sites), run the following command:

     ```
     apicup subsys backup ptl
     ```

     Where *ptl* is the name that you assigned to your Portal service.
     Note: To restore a Developer Portal service, you need backups of both the Portal system and the installed sites.

   To view additional flags, use **-h**:

```
apicup subsys backup portal -h
Backup portal subsystem

Usage:
  backup SUBSYS [flags]

Flags:
      --comment string          Comment to add to the backup CR before creation
      --debug                   Enable debug logging
  -h, --help                    help for backup
      --site-name string        Site to restore to the remote server if TYPE=site. Accepts site uuid/url or 'installed' to
backup all installed sites.
      --type string             Type of backup to take ['system' (backup Portal System), 'site' (backup Portal Site),
'all' (complete backup)] (default "all")
```

```
      --wait                    Wait for the operation to complete or fail.
      --wait-timeout duration   Command timeout in seconds. (default 40s)
```

3. To view the available backups and their status:

   ```
   apicup subsys list-backups [subsystem_name] [flags]
   ```

   Optional flags:

   ```
   ./apicup subsys list-backups -h
   List backups of the subsystem
   Usage:
     apicup subsys list-backups SUBSYS [flags]
   Flags:
     -h, --help               help for list-backups
         --timeout duration   Command timeout in seconds. (default 40s)
   Global Flags:
         --accept-license   Accept the license for API Connect
         --debug            Enable debug logging
   ```

Restoring the Developer Portal subsystem

You can use **apicup** to restore the Developer Portal subsystem.

About this task

You can restore your Developer Portal service by using the backups that exist on your remote server, by running the following **apicup** commands in your API Connect installation project directory. Note that before you can run these commands, you must have configured your remote backup server details, and have valid backups of both the Portal system and the installed sites. See Configuring backup settings for the Developer Portal subsystem and Backing up the Developer Portal subsystem.
Note:

- If you have to perform a restore, you must complete the restoration of the management service first, and then immediately restore the developer portal. The backups of the management and portal must be taken at the same time to ensure that the portal sites are consistent with management database.
- Restoration requires a functioning Developer Portal. In a disaster recovery scenario, you might need to reinstall the Developer Portal subsystem before you can restore the backed-up data. For disaster recovery, see Recovering the Developer Portal subsystem on VMware.

Procedure

1. To view the available backups and their status:

   ```
   apicup subsys list-backups subsystem_name [flags]
   ```

   Optional flags:

   ```
   ./apicup subsys list-backups -h
   List backups of the subsystem
   Usage:
     apicup subsys list-backups SUBSYS [flags]
   Flags:
     -h, --help               help for list-backups
         --timeout duration   Command timeout in seconds. (default 40s)
   Global Flags:
         --accept-license   Accept the license for API Connect
         --debug            Enable debug logging
   ```

2. Review which restore actions will be performed
   To see what restore actions are performed when the **apicup subsys restore** *ptl* command is run, you can use the following command:

   ```
   apicup subsys restore ptl --dry-run --timestamp [now|YYYYMMDD.HHMMSS]
   ```

   where **--timestamp** can be **now**, so the latest backup file that is available is used. Or you can specify a timestamp in the format of ***YYYYMMDD.HHMMSS*** to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given.
   Note:
   - From IBM® API Connect Version 10.0.3.0, the timestamp format changed to ***YYYYMMDD.HHMMSS***. For Version 10.0.2.0 and earlier, the timestamp format is ***YYYY-MM-DD HH:MM:SS***.
   - With the **--dry-run** option, the utility runs through the restore steps without executing them. You can use this option to see if the restore from the selected backup will succeed.
     The **--dry-run** option starts with the following output message:

     ```
     Starting restore...please check later for completion status of restore
     PortalRestore is Running
     ```

     To view the results of the dry-run, you can either look in the portal restore CR for a message of completion (or failure) or you can get a high-level status by entering:

     ```
     apicup subsys list-restores <subsys_name>
     ```

     Status values can be: **Ready**, **Completed**, **Failed** or **Running**.
3. Run the following command, and attach any flags as appropriate.

   ```
   apicup subsys restore [SUBSYS_NAME] [flags]
   ```

   - To restore your Portal service, run the following command:

```
apicup subsys restore ptl --timestamp [now|YYYYMMDD.HHMMSS]
```

where `--timestamp` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given. This command executes the portal restore process, which downloads the system backup and all of the site backups from the remote server, and installs them within the Portal stack. This process will then restore the system configuration from the found backup, and restore all of the sites. Note that if a backed up site is already installed on the current stack, then the site is reinstalled by using the backup (the site is overwritten by the backup). If there are multiple sites to restore, then these sites are queued for restoring. You can track the restoration process within the Portal `www admin` logs.

- By default the restore is a complete restore. You can optionally include `--type all` on the command line to specify a complete restore, but the flag is not required, as a complete restore is performed by default. Note that a complete restore supports only remote restores.
  Note that the complete restore uses the `priorityList` configuration setting that you specified in Configuring backup settings for the Developer Portal subsystem.

- To restore just the Portal system configuration, run the following command:

  ```
  apicup subsys restore ptl --type system --system-name arg
  ```

  where `arg` can be a `.tgz` name or also accepts `backup ID` if `TYPE=system` and `CR TYPE=record` from the `list-backups` command.

  Note that if Portal system configuration information exists on the current stack, running this command will overwrite that configuration.

- To restore just the Portal sites, run the following command:

  ```
  apicup subsys restore ptl --type site --site-name arg
  ```

  where `arg` can be the site backup tgz file name or URL, to restore a particular site by using the specified backup ID (or the latest backup file found if using a URL). Or you can use the argument `all` to restore all of the Portal sites that have backup files on the remote server. Note that if any of the backed up sites are already installed on the current stack, then they are reinstalled by using the backup (the sites are overwritten by the backup).

```
❯ ./apicup subsys restore <portal> -h
Restore portal subsystem

Usage:
  restore SUBSYS [flags]

Flags:
      --custom-platform-api-hostname string   The custom platform API hostname to override for the portal system when
restoring it. Used only when performing a portal restore system or portal restore all.
      --custom-url string                     The custom URL to override for the portal site when restoring it. Used only
when performing a portal site restore.
      --debug                                 Enable debug logging
      --dry-run                               Runs a dry run of the command, returning the actions that will be taken.
  -h, --help                                  help for restore
      --site-name string                      File to restore site from which should exist on the pod's local filesystem
or the remote server. Also accepts backup ID if TYPE=site and CR TYPE=record.
      --system-name string                    File to restore system from which should exist on the pod's local filesystem
or the remote server. Also accepts backup ID if TYPE=system and CR TYPE=record.
      --timestamp string                      In YYYYMMDD.HHMMSS format, specify a timestamp to retrieve the backup from.
The nearest backup, searching backwards from this timestamp, is used.
      --type string                           Type of restore to take ['system' (restore Portal System), 'site' (restore
Portal Site), 'all' (complete restore)] (default "all")
      --wait                                  Wait for the operation to complete or fail.
      --wait-timeout duration                 Command timeout in seconds. (default 40s
```

4. To view your restores and their statuses, run:

   ```
   apicup subsys list-restores <subsys_name> <flags>
   ```

   Help output:

   ```
   apicup subsys list-restores -h
   List restores of the subsystem

   Usage:
     apicup subsys list-restores SUBSYS [flags]

   Flags:
     -h, --help               help for list-restores
         --timeout duration   Command timeout in seconds. (default 40s)

   Global Flags:
         --accept-license   Accept the license for API Connect
         --debug            Enable debug logging
   ```

5. To list the Portal backup sites, use the Portal CLI command. See Using the **sites** commands.
6. To list the Portal system sites, use the Portal CLI command. See Using the **platforms** commands.

Backing up and restoring the Analytics database on VMware

The IBM® API Connect Analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

About this task

Begin by configuring your backup configuration, which optionally includes a schedule if you want to automate your backups. You can run backups manually as needed. To restore a backup, review the set of available backups, and then restore the selected backup.

- **Configuring backup settings for Analytics**
  Use the `apicup` utility to configure backup settings for the Analytics database in your VMware environment.
- **Running a backup of the Analytics database**
  Initiate a backup of the API Connect Analytics database on VMware.
- **Restoring the Analytics database**
  Restore a selected backup of the IBM API Connect Analytics database on VMware.

Configuring backup settings for Analytics

Use the `apicup` utility to configure backup settings for the Analytics database in your VMware environment.

About this task

The Analytics database can be backed up and restored from an S3 repository. S3-compatible object storage is required; for example, IBM Cloud Object Storage.
Note:

- Only host-style S3 backups are supported. Path-style S3 backups are not supported.
- If you are using a self-managed S3 backup server, check that you have a DNS hostname entry and matching TLS certificate for your S3 backup endpoint.
- When you specify a filepath in a backup setting, be sure to escape any blank spaces in the path.

Procedure

1. Use the `apicup` utility to configure the backup settings.
   Configure each setting by running the following command with the key and value from Table 1 that you want to apply:

   ```
   apicup subsys set <analytics_subsystem> <key> <value>
   ```

   Table 1 shows the supported backup settings with the default value (if any) and a description of each setting.

   Table 1. Analytics backup settings

Key	Default value	Description
`analytics-backup-auth-pass`		Server password for Analytics backups.
`analytics-backup-auth-user`		Server user name for Analytics backups.

`analytics-backup-host`		The S3 endpoint with the corresponding S3 region in the format:
		`s3.s3region.s3domain`
		For example:
		`s3.eu-gb.cloud-object-storage.appdomain.cloud`
		Attention: A path style host value (formatted as `S3endpoint/S3region`) is not supported for AWS.

Key	Default value	Description

`analytics-backup-certs`		The name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.2. This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be `ca.crt` and the value is the base64-encoded value of the CA certificate.
		
		If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Portal subsystem already trusts the server certificate. You can test this by configuring the Portal backup to your S3/object-store server without providing the CA certificate.
		
		If you do need to provide the CA certificate then you must provide the entire chain in the `ca.crt` member of the secret, as follows:
		
		`intermediate-certificate-1`
		`intermediate-certificate-2`
		`. . .`
		`intermediate-certificate-n`
		`root-certificate`
		
		Where the first certificate in the `ca.crt` member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the `ca.crt` member is the issuer of the preceding certificate. The root certificate in the `ca.crt` member must be self-signed.
		
		If there are no intermediate certificates involved, then the `ca.crt` member contains only the root certificate.
		
		The following sample bash script creates a Kubernetes secret:
		
		`cat >customs3ca.yaml <<EOF`
		`apiVersion: v1`
		`data:`
		`  ca.crt: $(base64 <path-to-ca-certificate> | tr -d '\n' )`
		`kind: Secret`
		`metadata:`
		`  name: custom-server-ca`
		`type: generic`
		`EOF`
		
		`kubectl apply -f customs3ca.yaml -n <namespace>`

`analytics-backup-path`		A combination of the S3 bucket and the base path within the bucket, using the format: `bucket_name/path`
`analytics-backup-chunk-size`	1GB	(Optional) Specifies how large files are stored. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB.
`analytics-backup-schedule`	0 2 * * *	(Optional) Determines how often backups will be invoked automatically. The format for the schedule is any valid `cron` string. The timezone for backups is UTC. Backing up once a day is probably sufficient; remember that the more frequently you run backups, the more storage space you need.
`analytics-enable-compression`	true	(Optional) Determines whether metadata files are stored in compressed format.
`analytics-enable-server-side-encryption`	false	(Optional) Determines whether files are encrypted. When set to true, files are encrypted on the server side using AES256.

2. Validate the backup settings by running the following command:

   `apicup subsys get <analytics_subsystem> --validate`

3. Apply the backup settings to the Analytics subsystem by reinstalling with the following command:

   `apicup subsys install <analytics_subsystem>`

4. Verify that the backup settings were successfully applied by running the following command:

   `apicup subsys health-check <analytics_subsystem>`

Running a backup of the Analytics database

Initiate a backup of the API Connect Analytics database on VMware.

About this task

Procedure

1. Perform a health check of your Analytics system by running the following command:

   `apicup subsys health-check <analytics_subsystem>`

   If successful, the command returns silently with exit code 0.

2. Start the backup by running the following command and including the appropriate flags:

   `apicup subsys backup <analytics_subsystem>`

   View the list of supported flags by running the `backup` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys backup analytics -h
Backup analytics subsystem

Usage:
  backup SUBSYS [flags]

Flags:
      --comment string          Comment to add to the backup CR before creation
      --debug                   Enable debug logging
  -h, --help                    help for backup
      --ignore-unavailable      If false, the backup will fail if an index is missing. If true, missing indices will be
skipped and the backup will continue.
      --indices strings         Indice(s) you'd like to backup (all/apievents/ui/summary). It can be set to any
combination of indices (e.g. ui or ui,apievents).
      --wait                    Wait for the operation to complete or fail.
      --wait-timeout duration   Command timeout in seconds. (default 40s)
```

Note: The `--indices` flag can be set to `all|apievents|ui|summary`, or the names of individual indexes. `all` includes `apievents`, `ui`, and `summary` indices. Multiple values can be supplied with a comma-separated list. For example, to backup all UI data and all data from August of 2022:

```
--indices ui, "apic-api-2022.08*"
```

3. Optionally view a list of available backups, and the status of each, by running the following command:

   ```
   apicup subsys list-backups <analytics_subsystem>
   ```

   View the list of supported flags by running the `list-backups` command with the `-h` (help) flag, as shown in the following example:

   ```
   apicup subsys list-backups -h
   List backups of the subsystem

   Usage:
     apicup subsys list-backups SUBSYS [flags]

   Flags:
     -h, --help               help for list-backups
         --timeout duration   Command timeout in seconds. (default 40s)

   Global Flags:
         --accept-license   Accept the license for API Connect
         --debug            Enable debug logging
   ```

Restoring the Analytics database

Restore a selected backup of the IBM® API Connect Analytics database on VMware.

About this task

Use the `apicup` utility to view the list of available backups for the Analytics database, and then restore a selected backup.

Procedure

1. Retrieve a list of available backups, and the status of each, by running the following command:

   ```
   apicup subsys list-backups <analytics_subsystem>
   ```

   View the list of supported flags by running the `list-backups` command with the `-h` (help) flag, as shown in the following example:

   ```
   apicup subsys list-backups -h
   List backups of the subsystem

   Usage:
     apicup subsys list-backups SUBSYS [flags]

   Flags:
     -h, --help               help for list-backups
         --timeout duration   Command timeout in seconds. (default 40s)

   Global Flags:
         --accept-license   Accept the license for API Connect
         --debug            Enable debug logging
   ```

   The response includes the unique ID of each backup. Note the ID of the backup that you want to restore, so you can use in it in the next step.

2. Restore a backup by running the following command with the appropriate flags:

   ```
   apicup subsys restore <analytics_subsystem>
   ```

   View the complete list of supported flags by running the `restore` command with the `-h` (help) flag, as shown in the following example:

   ```
   apicup subsys restore analytics -h
   Restore analytics subsystem

   Usage:
      restore SUBSYS [flags]

   Flags:
         --debug                   Enable debug logging
   ```

```
  -h, --help                    help for restore
      --id string               ID of the backup to restore
      --ignore-unavailable      If false, the restore will fail if an index is missing. If true, missing indices will be
skipped and the restore will continue.
      --indices strings         Indice(s) you'd like to restore (all/apievents/ui). It can be set to any combination of
indice(s) (eg. ui or ui,apievents) (default [all])
      --override                If set to true, then the restore operation will override existing indices.
      --wait                    Wait for the operation to complete or fail.
      --wait-timeout duration   Command timeout in seconds. (default 40s)
```

- `--id` the backup ID provided must be enclosed in double quotes.
- `--indices` can be set to `all|apievents|ui|summary`, or the names of individual indices. `all` includes `apievents`, `ui`, and `summary` indices. Multiple values can be supplied with a comma-separated list. For example, to restore all UI data and all data from August of 2022:

  ```
  --indices "ui,apic-api-2022.08*"
  ```

- `--override` by default is set to `false` to prevent you from accidentally replacing existing indices. If `--override` is set to `false` and you specify indices that already exist in the database that you are restoring, then the restore fails. The failure prevents you from accidentally replacing or losing data that exists in the current database.

3. Optionally view a list of available restores, and the status of each, by running the following command:

   ```
   apicup subsys list-restores <analytics_subsystem>
   ```

   View the list of supported flags by running the `list-restores` command with the `-h` (help) flag, as shown in the following example:

   ```
   apicup subsys list-restores -h
   List restores of the subsystem

   Usage:
     apicup subsys list-restores SUBSYS [flags]

   Flags:
     -h, --help               help for list-restores
         --timeout duration   Command timeout in seconds. (default 40s)

   Global Flags:
         --accept-license   Accept the license for API Connect
         --debug            Enable debug logging
   ```

   Important:
   For deployment profiles with fewer than 3 storage nodes, the restore process is never marked as `Complete`. The storage cluster status is expected to be yellow and to have more than 0 unassigned shards. In this situation, the restore process is likely to be complete when there are 0 initializing shards.

Disaster recovery

Prepare for disaster events and recover API Connect on VMware if a disaster event occurs.

You must complete preparation steps prior to a disaster in order to recover API Connect on VMware.

The backups that you create for disaster recovery are for recovery of the API Connect subsystems in the same environment that the backups were taken, or in a different environment that has the same network configuration and API Connect form factor. If you want to move your API Connect deployment to a different environment and change the form factor or modify your API Connect endpoints, then see Migrating from v10 to v10 on a different form factor.
Note: For information about how to maintain a two data center deployment, including failover and recovery procedures, see Maintaining a two data center deployment.

- **Preparing for a disaster**
  Prepare your API Connect deployment for disaster recovery in a VMware environment.
- **Recovering from a disaster**
  Recover the API Connect subsystems on VMware.
- **Using VM snapshots for infrastructure backup and disaster recovery**
  You can use VM snapshots to backup and restore the infrastructure used by API Connect on VMware, and also for infrastructure disaster recovery.

Preparing for a disaster

Prepare your API Connect deployment for disaster recovery in a VMware environment.

Important: Successful disaster recovery of API Connect depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery.

- **Preparing the management subsystem for disaster recovery on VMware V10.0.6.0**
  Prepare a Management subsystem for disaster recovery by taking specific steps before and after the installation of the subsystem.
- **Preparing the Developer Portal subsystem for disaster recovery on VMware**
  Prepare a Developer Portal subsystem for disaster recovery by taking specific steps immediately after the installation of the subsystem.
- **Preparing the Analytics subsystem for disaster recovery on VMware**
  Prepare the API Connect Analytics subsystem for disaster recovery in a VMware environment.

Preparing the management subsystem for disaster recovery on VMware V10.0.6.0

Prepare a Management subsystem for disaster recovery by taking specific steps before and after the installation of the subsystem.

About this task

Note: This topic covers disaster recovery preparation for V10.0.6.0. For v10.0.7.0 see Backing up and restoring the Management subsystem.

- This task must be performed before any disaster event occurs, and also prior to the installation of a replacement Management subsystem during the recovery process. Best practice is to complete these steps immediately after initial configuration of a management subsystem during your original v10 deployment.
- Any `local` backups are presumed to have been lost in the disaster scenario and are non-recoverable in this procedure.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

Procedure

1. Make sure that you have a backup that can be used in case of a disaster event:
   - For backup configuration, see Configuring backup settings during initial installation of the management subsystem V10.0.6.0.
   - If scheduled backups were configured during backup configuration, you should have access to a backup on the specified cloud storage.
   - You can perform a manual backup at any time. See Backing up the management subsystem V10.0.6.0.
2. Ensure that you have a backup of your project directory.
   The original project directory that was created with the `apicup` command during the initial product installation is required for disaster recovery, see: First steps for deploying in a VMware environment. The project directory contains the yaml files that describe your deployment, encryption keys, and deployment ISO files. It is not possible to restore the subsystem databases on a deployment that uses a new or different project directory.
3. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see Using VM snapshots for infrastructure backup and disaster recovery for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.
   Important: VM snapshots are not an alternative to the standard API Connect backups that are described in the previous step. Do not rely solely on VM snapshots for your backups.

What to do next

You should now complete the preparation steps for the Developer Portal subsystem; see Preparing the Developer Portal subsystem for disaster recovery on VMware.

Preparing the Developer Portal subsystem for disaster recovery on VMware

Prepare a Developer Portal subsystem for disaster recovery by taking specific steps immediately after the installation of the subsystem.

About this task

- Perform this task before any disaster event occurs, and also prior to the installation of a replacement Developer Portal subsystem for the recovery process.
- Best practice is to complete these steps immediately after initial configuration of a Developer Portal subsystem during your original v10 deployment.
- Any `local` backups are presumed to have been lost in the disaster scenario and are non-recoverable in this procedure.
- Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. For information about preparing the Management subsystem, see Preparing the management subsystem for disaster recovery on VMware V10.0.6.0.
  If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

Procedure

1. Before the initial installation, configure the Developer Portal subsystem for database backups. See Configuring backup settings for the Developer Portal subsystem.
2. Ensure you create a backup:
   - You can perform a manual backup at any time. See Backing up the Developer Portal subsystem.
   - If you configure scheduled backups as part of Configuring backup settings for the Developer Portal subsystem, backups to the specified cloud storage take place at the configured time.
3. Ensure that you have a backup of your project directory.
   The original project directory that was created with the `apicup` command during the initial product installation is required for disaster recovery, see: First steps for deploying in a VMware environment. The project directory contains the yaml files that describe your deployment, encryption keys, and deployment ISO files. It is not possible to restore the subsystem databases on a deployment that uses a new or different project directory.
4. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see Using VM snapshots for infrastructure backup and disaster recovery for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.
   Important: VM snapshots are not an alternative to the standard API Connect backups that are described in the previous step. Do not rely solely on VM snapshots for your backups.

What to do next

To restore the Developer Portal on VMware after a disaster, see Recovering the Developer Portal subsystem on VMware.

Preparing the Analytics subsystem for disaster recovery on VMware

Prepare the API Connect Analytics subsystem for disaster recovery in a VMware environment.

About this task

Preparing for disaster recovery involves backing up analytics data and your project directory.

Procedure

1. Perform a backup of the Analytics database.
   Scheduling automatic backups ensures that a recovery includes recent updates. For more information on configuring backups, see Configuring backup settings for Analytics.

2. Ensure that you have a backup of your project directory.
   The original project directory that was created with the `apicup` command during the initial product installation is required for disaster recovery, see: First steps for deploying in a VMware environment. The project directory contains the yaml files that describe your deployment, encryption keys, and deployment ISO files. It is not possible to restore the subsystem databases on a deployment that uses a new or different project directory.
3. Ensure that you have a backup of the `analytics-extra-values.yaml` file if you created one: Analytics extra-values file. This file might be included in the project directory backup if you kept it there.
4. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see Using VM snapshots for infrastructure backup and disaster recovery for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.
   Important: VM snapshots are not an alternative to the standard API Connect backups that are described in the previous step. Do not rely solely on VM snapshots for your backups.

Recovering from a disaster

Recover the API Connect subsystems on VMware.

- **Recovering the Management subsystem on VMware V10.0.6.0**
  Recover the management subsystem from backups after a disaster event.
- **Recovering the Developer Portal subsystem on VMware**
  Recover the Developer Portal on VMware.
- **Recovering the Analytics subsystem on VMware**
  Recover the API Connect Analytics subsystem in a VMware environment.

Recovering the Management subsystem on VMware V10.0.6.0

Recover the management subsystem from backups after a disaster event.

Before you begin

Note: This topic covers disaster recovery for V10.0.6.0. For v10.0.7.0 see Recovering from a disaster.
To successfully recover the management subsystem, you must have previously completed the steps in Preparing the management subsystem for disaster recovery on VMware V10.0.6.0.
You must use the same project directory that you used for your original deployment, or a restore of your project directory backup, to ensure that configuration and secret information is transferred to the replacement deployment.

In a clustered deployment, if any one VM is corrupted then all of the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

Procedure

1. Determine which backup to restore from.
   a. Obtain a list of the available backups for your backup type:
   - s3 backups
     - For IBM®'s Cloud Object Storage, you can check currently stored backups in the COS console. Select Buckets > Objects. See the Object Names displayed on the <*cos_name*>/backup/db panel. For example:

       ```
       20200605-105429F
       20200605-100008F
       20200605-11040F
       ```

     - For Amazon's AWS, you can check currently stored backups in the S3 console For example, under Amazon S3 > *cluster_name* > old cluster > backup > db:

       ```
       20200606-144315F
       20200606-145011F
       ```

   - SFTP backups
     View the SFTP backups available on your remote storage site:

```
-rw-r--r--    1 root     root     13092333 Aug 26 08:56 20200826-154646F.tgz
-rw-r--r--    1 root     root     18703758 Aug 26 09:10 20200826-160010F.tgz
-rw-r--r--    1 root     root     24318561 Aug 26 09:21 20200826-161301F.tgz
```

b. Select the backup ID of the backup you want to restore. For example, in the sample SFTP backup list, for the Aug 26 09:21 backup, the backup ID is **20200826-161301F**.
Each filename contains the date, time, and type of the backup stored. The format of the backup ID is **YYYYMMDD-HHMMSS<F|I>**. Full backups are denoted with a suffix **F** on the ID. Incremental backups are denoted with a suffix **I** on the ID. For incremental backups, ensure each incremental backup has its prior full backup also present in storage. You can check this by examining the ID **<prior-backup-id>_<backup-id>**.

Note:
During the disaster recovery process, the S3 configuration detail of the older management system is used, but the older management system must be in offline mode. The old subsystem must be offline because you cannot have two management systems simultaneously using the same s3 bucket name in the database backup configurations.

2. Make sure you know the management database cluster name. Use the following steps applicable to your backup type:

Backup type	How to obtain database cluster name
s3	a. Open your IBM Cloud® Object Storage or AWS S3 console and proceed to the bucket location where the old Management subsystem backups are located. b. Download **backup/db/<backup-id>/pg_data/postgresql.conf.gz**. Open **postgresql.conf** to view the database cluster name: • IBM Cloud Object Storage **cluster_name = 'm1-a6287572-postgres'** • **m1** - Management subsystem name • **a6287572** - site name • AWS S3 **cluster_name = 'm1-c91dc0b9-postgres'** • **m1** - Management subsystem name • **c91dc0b9** - site name
SFTP	a. Recover the Management database cluster name and siteName by examining the SFTP backup tar. Download or move the SFTP backup tar file and decompress (untar) it. b. Open **<management-subsystem-name>-<siteName>-postgres-backrest-shared-repo/backup/db/<backup-id>/pg_data/postgresql.conf.gz** which contains the management subsystem name and siteName. For example: **# Do not edit this file manually!** **# It will be overwritten by Patroni!** **include 'postgresql.base.conf'** **archive_command = 'source /opt/cpm/bin/pgbackrest/pgbackrest-set-env.sh && pgbackrest archive-push "%p"'** **archive_mode = 'True'** **archive_timeout = '60'** **autovacuum_vacuum_cost_limit = '1000'** **autovacuum_vacuum_scale_factor = '0.01'** **cluster_name = 'm1-f785a3e3-postgres'** In this example: • **cluster_name** has both the management subsystem name and siteName • **m1** - Management subsystem name • **f785a3e3** - site name

3. Use your prior existing project directory, or a restore of your project directory backup, to install the Management subsystem:
   a. Create your ISO files

   apicup subsys install *mgmt* --out *mgmt*plan-out

   The **--out** parameter and value are required.

   In this example, the ISO files are created in the myProject/*mgmt*plan-out directory.
   Note: If your original ISO files are still available and you did not upgrade from the original installation, you can reuse them. However, if you upgraded your original deployment, you must create new ISO files by using the version of **apicup** that corresponds to the version your API Connect installation was on at the time of the disaster. For example, do not attempt to deploy v10.0.6.x OVAs with ISO files that were created with **apicup** v10.0.5.3.
   b. Deploy the files into the replacement VMs. See Deploying the Management subsystem OVA file.
   c. Verify the deployment. See Verify installation of the Management subsystem.
   Important:
   For S3, the recovery remains in an intermediate state until the restore is complete, and Postgres wal files might cause serious disk issues. To avoid this possibility, continue immediately with the next step.

   Note that if you delay completion of the restore:

   - Health check might fail. In this case, you can still proceed to the next step and perform a restore.
   - Postgres wal files might cause problems by consuming all disk space. In this case, you must either:
     - Re-install the system, prepare again for disaster recovery, and perform the restore.
     - Or increase disk space so that the system returns to a stable state, and then proceed with the restore.
4. Once your Management subsystem is ready, confirm the backup ID noted in Step 1 is present on the sftp or s3 server.
5. After a few moments, confirm there is a **ManagementBackup** of type **record** and its backup ID matches with the backup ID noted in Step 1.
   You can list the management backups using:

   apicup subsys list-backups <subsystem_name>

   For example:

```
NAME                STATUS   ID                CLUSTER                          SUBSYSTEM    TYPE   CR TYPE   AGE
mgmt-backup-8hqqg   Ready    20200826-161301F  management-82b290a2-postgres     management   full   record    40s
```

6. Perform a Management Restore using the name of the backup that has the ID you want to restore.
   For example, for ID **20200826-161301F** the backup name is **mgmt-backup-8hqqg**.

   For instructions on how to restore, see Restoring the management subsystem V10.0.6.0.

   Once the Management Restore has completed and the database is running again, the data of the old Management subsystem will be successfully restored onto the new Management subsystem. Manual and scheduled backups should perform as normal once again.

What to do next

You should now complete the recovery steps for the Developer Portal subsystem on VMware, see Recovering the Developer Portal subsystem on VMware.

Recovering the Developer Portal subsystem on VMware

Recover the Developer Portal on VMware.

Before you begin

Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. If you must recover a deployment due to a disaster, you must first complete Recovering the Management subsystem on VMware V10.0.6.0, and then immediately recover the Developer Portal.

Recovery of the Portal subsystem is also dependent on prior completion of the preparation steps: Preparing the Developer Portal subsystem for disaster recovery on VMware

About this task

- In a disaster recovery scenario, an installation of a new Developer Portal subsystem is required.
- In a clustered deployment, if any one VM is corrupted then all of the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.
- You must use the same project directory that you used for your original Portal deployment, or a restore of your project directory backup, to ensure that configuration and secret information is transferred to the replacement deployment. The **apiconnect-up-v10.yaml** file contains Portal configuration.

Use the following steps to recover the data from your previous Developer Portal subsystem.

Procedure

1. Use your prior existing project directory, or a restore of your project directory backup, to install the replacement Portal subsystem:
   a. Create your ISO files.

      ```
      apicup subsys install portal-subsystem-name --out portal-subsystem-nameplan-out
      ```

      The **--out** parameter and value are required.

      In this example, the ISO files are created in the myProject/*portal-subsystem-name*plan-out directory.
      Note: If your original ISO files are still available and you did not upgrade from the original installation, you can reuse them. However, if you upgraded your original deployment, you must create new ISO files by using the version of **apicup** that corresponds to the version your API Connect installation was on at the time of the disaster. For example, do not attempt to deploy v10.0.6.x OVAs with ISO files that were created with **apicup** v10.0.5.3.
   b. Deploy the files into the replacement VMs. See Deploying the Developer Portal subsystem OVA file.
   c. Verify the deployment. See Verifying deployment of the Developer Portal subsystem.
2. View the available backups and their status:

   ```
   apicup subsys list-backups [subsystem_name] [flags]
   ```

   Optional flags:

   ```
   ./apicup subsys list-backups -h
   List backups of the subsystem
   Usage:
     apicup subsys list-backups SUBSYS [flags]
   Flags:
     -h, --help               help for list-backups
         --timeout duration   Command timeout in seconds. (default 40s)
   Global Flags:
         --accept-license   Accept the license for API Connect
         --debug            Enable debug logging
   ```

3. Perform a Developer Portal restore.
   Run the following command, and attach any flags as appropriate.

   ```
   apicup subsys restore [SUBSYS_NAME] [flags]
   ```

   - To restore your Portal service, run the following command:

     ```
     apicup subsys restore ptl --timestamp [now|YYYYMMDD.HHMMSS]
     ```

     where **--timestamp** can be **now**, so the latest backup file that is available is used. Or you can specify a timestamp in the format of ***YYYYMMDD.HHMMSS*** to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given. This command executes the portal restore process, which downloads the system backup and all of the site backups from the remote server, and installs them within the Portal stack. This process will then

restore the system configuration from the found backup, and restore all of the sites. Note that if a backed up site is already installed on the current stack, then the site is reinstalled by using the backup (the site is overwritten by the backup). If there are multiple sites to restore, then these sites are queued for restoring. You can track the restoration process within the Portal `www admin` logs.
Note: From IBM® API Connect Version 10.0.3.0, the timestamp format changed to ***`YYYYMMDD.HHMMSS`***. For Version 10.0.2.0 and earlier, the timestamp format is ***`YYYY-MM-DD HH:MM:SS`***.

- For a disaster recovery scenario, it is advised that you restore all sites and systems. By default the restore is a complete restore. You can optionally include `--type all` on the command line to specify a complete restore, but the flag is not required, as a complete restore is performed by default.
  Note that the complete restore uses the `priorityList` configuration setting that you specified in Configuring backup settings for the Developer Portal subsystem.
- For more information, see Restoring the Developer Portal subsystem

Recovering the Analytics subsystem on VMware

Recover the API Connect Analytics subsystem in a VMware environment.

About this task

Recovering the Analytics subsystem involves deploying a new installation of the Analytics subsystem and then restoring the Analytics database from a back-up copy.

You must use the same project directory that you used for your original deployment, or a restore of your project directory backup, to ensure that configuration and secret information is transferred to the replacement deployment.

In a clustered deployment, if any one VM is corrupted then all of the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.

Procedure

1. Use your prior existing project directory, or a restore of your project directory backup, to install the replacement Analytics subsystem:
   a. Create your ISO files:

      `apicup subsys install` ***`install-subsystem-name`*** `--out` ***`analyt`***`plan-out`

      The `--out` parameter and value are required.

      In this example, the ISO files are created in the myProject/*analyt*plan-out directory.
      Note: If your original ISO files are still available and you did not upgrade from the original installation, you can reuse them. However, if you upgraded your original deployment, you must create new ISO files by using the version of `apicup` that corresponds to the version your API Connect installation was on at the time of the disaster. For example, do not attempt to deploy v10.0.6.x OVAs with ISO files that were created with `apicup` v10.0.5.3.
   b. Deploy the files into the replacement VMs. See Deploying the Analytics subsystem OVA file.
   c. Verify the deployment. See Verifying deployment of the Analytics subsystem.
2. Restore the Analytics data from backup, as explained in Restoring the Analytics database.

Using VM snapshots for infrastructure backup and disaster recovery

You can use VM snapshots to backup and restore the infrastructure used by API Connect on VMware, and also for infrastructure disaster recovery.

Backup and restore procedures for the databases used by IBM API Connect on VMware are described in Backing up and restoring on VMware. The procedures back up all of the state required by API Connect but do not include the underlying infrastructure software or other internal state.

In some scenarios, you may want to perform backups and disaster recovery at an infrastructure layer. You can do this by taking snapshots of the virtual machines or underlying storage volumes, providing that you follow the constraints described here.

Note that performing backups at the infrastructure layer differs from the standard approach in that not only is the database state backed up, but also the precise state of the software. This approach can be useful, for example, when testing upgrades of production systems.

VM snapshots should not be used as an alternative to taking normal backups. Ideal times to take VM snapshots are after initial install and configuration, and before and after upgrades. In the event of a disaster, reverting to the last snapshot taken and then restoring the standard daily backup can be faster than redeploying OVAs and restoring the backup.

- Requirements for taking a consistent backup of an API connect system at the infrastructure level
  - An API Connect system can be approximated by the following diagram:

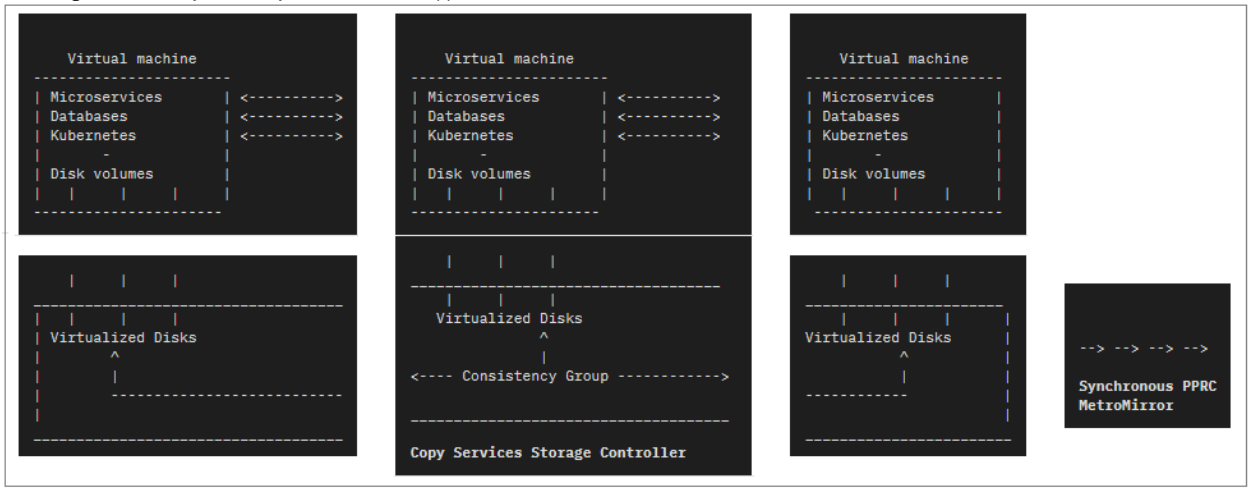
  - The system comprises multiple Virtual Machine images which are running Kubernetes, multiple databases, with the API Connect micro services running on top. There is transactional communication between the virtual machines which is occurring at all levels of this stack. This communication occurs all the time, even if the system is seemingly idle.

- Within the system there are multiple stateful or database layers on the software that maintain a consistency protocol. For example `etcd` upon which Kubernetes is based uses the Raft consensus algorithm. These algorithms depend for consistency on the basic assertion that time flows forwards on all systems together. If one or more of the virtual machine's state where to move backwards relative to the others by even the smallest quantum of time then consistency would be lost and the system might behave badly.

  Clearly, if Virtual Machine snapshots are taken across multiple virtual machines it is certain that these snapshots will not be taken at precisely the same time. The result will be a backup that contains a system state that contains data from snapshots taken at slightly different times. It is possible that such a backup system may be restored and may appear to work correctly but hidden deep within it there may be undetected inconsistencies that will cause strange unpredictable errors and inconsistencies later. These issues can be extremely difficult to diagnose.

  It is also possible that you can test this procedure successfully multiple times and see no apparent problem occurring. Irrespective of the apparent success of tests, corruption can be occurring in the system state. For this reason, taking VM snapshots or clones of a running API Connect system is not supported.

- How to take a consistent backup of an API connect system at the infrastructure level
  - The only way to take a consistent backup of an API connect system using VM snapshots and clones is to shut down ALL of the virtual machines comprising the system before taking the snapshot or clone.
  - Once the virtual machines are stopped at the VM level, time is effectively frozen. Then a snapshot can be taken on all the VMs. A clone can be made from the snapshot taken on each VM. This set of clones represent a valid, consistent state that the API Connect system was in when it was shut down.
  - Once all of the snapshots and clones have been taken the original API Connect system can be restarted.
- Restoring an API Connect System from VM clones
  - The Cloned VMs represent a valid state of the original API Connect system. They will restart in exactly the same way as the original system restarted.
  - If the objective is to stand up another instance of the cloned API connect system for testing or DR purposes, the following must be true:
    - The original system and the cloned system must be isolated from one another. The clone will be using the same hostnames and IP addresses as the original and so must be stood up in a separate virtual machine hosting environment with Network Address Translation between itself and any network to which the original system is stood up.
    - The cloned system must be stood up in an identical environment in terms of its hardware, software and network.
- Disaster Recovery approaches using Disk Replication:
  - A common DR approach used by enterprises is to use disk based replication. In this case, a storage controller such as IBM's San Volume Controller provides Copy Services. You can use Copy Services to create a completely consistent copy of a set of disks. IBM calls this feature *Synchronous Remote Copy* or *MetroMirror*. Other storage vendors have similar features.
  - If you use Remote Copy to synchronize disk images to a DR site then IBM will support API connect used with these systems so long as the copy at the DR site is completely consistent. Ensuring this consistency is the responsibility of the storage controller and its configuration. It is **critically important** to ensure that ALL of the disk volumes for all of the VMs or nodes in the entire API Connect system are in the same remote copy consistency group as shown in the following image. This ensures that DR scenarios do not create inconsistent volumes. If the disks are not in the same consistency group then the copy will not be managed consistently and the system will not be supported.



- Infrastructure based backup of API Connect using vSphere
  - The following procedure outlines steps to clone a VMware instance of API Connect v10, using the following topology:

    - 3 Management Nodes
    - 3 Portal Nodes
    - 3 Analytics Nodes
    - 3 Gateways
  - Each of these components has a load balancer with its own IP address. The load balancers all sit on a single VM. The cluster is installed and configured on 13 VMs in VMware. In this example, the system was populated with data and APIs. These should first be tested to ensure that all published APIs respond as expected. Once this is done, use vSphere UI to complete the following steps:

  1. Power off VMs
     To power off the VMs in sync, schedule a "shutdown guest OS" such that all the VMs shutdown at the same time. Although the shutdown does not occur at exactly the same instant, this does allow the shutdown for every machine to be as close in time as possible.

  2. Take snapshots
     Take snapshots of each VM after shutdown. Using the scheduling feature in the UI, schedule a snapshot of all the VMs at the same instant. If cloning should adversely affect the system in any way then the original VMs can be reverted back to these snapshots.

  3. Clone VMs
     Use the clone feature of the UI to create a clone of each VM. This VM should sit in the same resource pool as the original cluster. This is simply an exact copy of the disks of the original machine. The clones and originals are in no way coupled.

  4. Power on clones
     Schedule the power-on for each clone VM such that all the clone VMs power on simultaneously. Once this is done, test the cluster to ensure that the APIs respond as expected. For the example cluster topology shown earlier on this page, it can take a couple of hours after power-on for all the APIs to respond as expected.

Disabling and re-enabling the analytics subsystem on VMware

Disable the analytics subsystem by shutting down the VM that hosts it.

Before you begin

This operation requires the use of the Analytics CLI.

About this task

Disabling the analytics subsystem stops the collection and storage of data as well as making the subsystem unavailable.

When you disable analytics, there will be no data in either the API Manager Dashboards or third-party offloads.

Procedure

1. Back up your analytics data as explained in Backing up and restoring the Analytics database on VMware.
2. Shut down the analytics VMs.
   You can shut down the VMs using one of the following methods:
   - Use the VMware console
   - **`ssh`** into the images and run the **`shutdown`** command

Re-enabling analytics

3. Start your analytics VMs.

Maintaining a two data center deployment

How to maintain a two data center disaster recovery (DR) deployment on VMware, including information about normal operation, failure handling, and recovery.

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see Two data center warm-standby deployment strategy on VMware.

See the following topics for information about failure handling, backup, upgrade, and removing a 2DCDR deployment.

- **Backup and restore considerations for a two data center deployment**
  Points to consider when you configure backups and restoring a two data center disaster recovery (2DCDR) deployment on VMware.
- **How to failover a two data center deployment**
  If a failure occurs in your active data center, then failover to your warm-standby data center.
- **How to failover a two data center deployment V10.0.6.0**
  How to detect failures, and perform service failover, in a two data center disaster recovery deployment on VMware.
- **Removing a two data center deployment**
  You can remove your two data center disaster recovery deployment on VMware.

Backup and restore considerations for a two data center deployment

Points to consider when you configure backups and restoring a two data center disaster recovery (2DCDR) deployment on VMware.

The 2DCDR backup requirements are different for the portal and management subsystems.

Management 2DCDR backup requirements

- Different remote backup locations must be specified for each data center.
- Both active and warm-standby management subsystems run the scheduled backup job.
- V10.0.7.0 and later: To restore a backup, 2DCDR must be disabled first.
- V10.0.6.0 only: Before you configure S3 backup settings you must first disable 2DCDR on both sites, and then re-enable 2DCDR after reconfiguring your backup settings.
  1. Disable 2DCDR for the management subsystems on both sites:

     ```
     apicup subsys set <management subsystem> multi-site-ha-enabled=false
     apicup subsys install <management subsystem>
     ```

  2. Configure your S3 backup settings.

3. Enable 2DCDR for the management subsystems on both sites:

```
apicup subsys set <management subsystem> multi-site-ha-enabled=true
apicup subsys install <management subsystem>
```

You do not need to do this for SFTP or local backups.

- V10.0.6.0 only: Restores must be run on the active data center.

Portal 2DCDR backup requirements

- The backup settings for both the active and warm-standby portal must be identical.
- Only the active data center portal takes backups. On failover, the backup job of the new warm-standby is disabled, and the backup job of the new active is enabled.
- Portal restores are only done on the active data center.

Configuring backups for 2DCDR deployments

Keeping the different portal and management 2DCDR backup requirements in mind, the actual steps for configuring backups for both subsystems are the same as for a single API Connect deployment: Backing up and restoring on VMware.

Related concepts

- Two data center warm-standby deployment strategy on VMware

Related tasks

- Installing a two data center deployment

How to failover a two data center deployment

If a failure occurs in your active data center, then failover to your warm-standby data center.

Note: The steps in this topic apply to API Connect V10.0.7.0 and later. If you are on V10.0.6.0, then refer to How to failover a two data center deployment V10.0.6.0.
Before you begin the failover process, first confirm that failover is the correct action to take.

Failover to the warm-standby is the appropriate action to take in the following circumstances:

- The failure is with the active data center itself, for example:
  - All VMs in the active data center are down.
  - Network connectivity to the active data is down.
- The API Connect deployment in the active data center is in a failed state. For example, the **health-check** command returns errors, and you are not able to resolve these errors.

  ```
  apicup subsys <subsystem name> health-check
  ```

The failover steps that you must follow depend on the condition of your active data center:

- **Failover steps when active site is responsive**
  Demote your active data center to warm-standby, and then promote your warm-standby data center to active.
- **Failover steps when active site is inaccessible**
  Disable network access to your failed active data center, and promote your warm-standby data center to active.

Failover steps when active site is responsive

Demote your active data center to warm-standby, and then promote your warm-standby data center to active.

About this task

Note: The steps in this topic apply to API Connect V10.0.7.0 and later. If you are on V10.0.6.0, then refer to How to failover a two data center deployment V10.0.6.0.
The steps in this topic cover how to complete a failover in the following scenarios:

- When the active management and portal subsystems are in a healthy state.
- The problem that the active management or portal subsystem has (that requires the failover) does not prevent the running of the **apicup** commands that are necessary to convert the active to warm-standby.

If the active site is not accessible, or responsive to **apicup** commands, then refer to Failover steps when active site is inaccessible.
For both management portal subsystems, the order in which failover is done is critical to prevent an active-active scenario that can cause a split-brain. The first step in failover is to demote the active data center to warm-standby, confirm that this demotion was successful, and then promote the original warm-standby to active.

In the steps provided in this topic, the active data center is called DC1, and the warm-standby data center is called DC2.

Procedure

- **Management subsystem failover**
  1. Set DC1 to be warm-standby.

a. Set the `multi-site-ha-mode` property to `passive` in DC1:

```
apicup subsys set <DC1 management> multi-site-ha-mode=passive
```

b. Apply the update to DC1:

```
apicup subsys install <DC1 management> --accept-dr-data-deletion
```

Note: When an active management subsystem is converted to warm-standby, all contents of its management database are deleted (to be replaced by the contents from the other data center when it becomes the active). The `--accept-dr-data-deletion` flag is acknowledgment that you accept this temporary loss of data.

c. Monitor the progress of the conversion to warm-standby:

```
apicup subsys health-check <DC1 management> -v
```

Important: If the management subsystem does not successfully convert to warm-standby, then do not proceed any further. Treat DC1 as an inaccessible data center, and refer to Failover steps when active site is inaccessible.

2. Set DC2 to be the active data center.
   a. Confirm that DC2 is ready for promotion to active:

```
apicup subsys health-check <DC2 management> -v
```

Output should show:

```
...
ReadyForPromotion
...
```

   b. Set the `multi-site-ha-mode` property to `active` in DC2:

```
apicup subsys set <DC2 management> multi-site-ha-mode=active
```

   c. Apply the update to DC2:

```
apicup subsys install <DC2 management> --skip-health-check
```

3. Monitor the failover process:

```
apicup subsys health-check <subsystem name>
```

When failover is complete the health-check command returns no output in either data center. Use the `-v` flag to see more information:

```
apicup subsys health-check <subsystem name> -v
```

4. Update your dynamic router to redirect all management subsystem traffic to DC2 instead of DC1.

- **Developer Portal service failover**

The following instructions show how to failover DC1 to DC2 for the Developer Portal service. If you have multiple portal services, then you must repeat these steps for each Developer Portal service that you want to failover.

1. Set DC1 to be warm-standby.
   a. Set the `multi-site-ha-mode` property to `passive` in DC1:

```
apicup subsys set <DC1 portal> multi-site-ha-mode=passive
```

   b. Apply the update to DC1:

```
apicup subsys install <DC1 portal> --skip-health-check
```

   c. Monitor the progression to warm-standby
      i. Login to one of the portal VMs in DC1 using SSH:

```
ssh apicadm@<portal hostname>
```

      ii. Switch to root user:

```
sudo -i
```

      iii. Run `kubectl describe ptl`, and look for `HA Mode` in the `Status` section of the output:

```
kubectl describe ptl

...
Status:
  ...
  HA Mode: progressing to passive
```

When `Status.HA Mode` shows `progressing to passive`, set portal in DC2 to be active, as described in step 2.

Warning: The `Spec` section of the output also has an `HA mode` property, take care to ensure that you are checking the `HA mode` in the `Status` section.

2. Set DC2 to be active.
   a. Set the `multi-site-ha-mode` property to `active` in DC2:

```
apicup subsys set <DC2 portal> multi-site-ha-mode=active
```

   b. Apply the update in DC2:

```
apicup subsys install <DC2 portal> --skip-health-check
```

3. Monitor the failover process:

```
apicup subsys health-check <subsystem name>
```

When failover is complete the health-check command returns no output in either data center. Use the `-v` flag to see more information:

```
apicup subsys health-check <subsystem name> -v
```

4. Update your dynamic router to redirect all traffic to DC2 instead of DC1.

Results

How long it takes to complete the failover varies, and depends on hardware speed, network latency, and the size of the databases. However, here are some approximate timings:

For the management subsystem:

- `warm-standby` to `active` approximately 5 minutes
- `active` to `warm-standby` approximately 15 minutes

For the portal subsystem:

- `warm-standby` to `active` 15 - 40 minutes
- `active` to `warm-standby` approximately 10 minutes

Failover steps when active site is inaccessible

Disable network access to your failed active data center, and promote your warm-standby data center to active.

About this task

Note: The steps in this topic apply to API Connect V10.0.7.0 and later. If you are on V10.0.6.0, then refer to How to failover a two data center deployment V10.0.6.0.
Follow the steps in this procedure when your active site is inaccessible, or the API Connect subsystems in your active site are not responding to **apicup** operations.

Procedure

1. Update the network configuration in your failed data center to isolate the API Connect subsystems in this data center, so that they cannot communicate with each other, nor with the warm-standby data center. Network isolation is necessary to prevent a split-brain situation, which occurs if your active site recovers unexpectedly and starts communicating with your other subsystems.
2. Promote your warm-standby management subsystem to active:

   ```
   apicup subsys set <mgmt_subsystem> multi-site-ha-mode=active
   ```

   Apply the change with:

   ```
   apicup subsys install <mgmt_subsystem> --force-promotion --skip-health-check
   ```

   Monitor the progress of the promotion with:

   ```
   apicup subsys health-check <mgmt_subsystem>
   ```

   when the command returns no output, the promotion to active is complete.
   Use the `-v` flag to see more information:

   ```
   apicup subsys health-check <subsystem name> -v
   ```

3. Promote your warm-standby portal subsystem to active:

   ```
   apicup subsys set <portal_subsystem> multi-site-ha-mode=active
   ```

   Apply the change with:

   ```
   apicup subsys install <portal_subsystem>
   ```

   Monitor the progress of the promotion with:

   ```
   apicup subsys health-check <mgmt_subsystem>
   ```

   when the command returns no output, the promotion to active is complete.
   Use the `-v` flag to see more information:

   ```
   apicup subsys health-check <subsystem name> -v
   ```

4. Update your dynamic router to redirect all traffic to DC2 instead of DC1.

What to do next

If API Connect in your failed data center cannot be recovered, do not leave your remaining data center as a 2DCDR active with no functioning warm-standby. You have the following options:

- Convert your remaining data center to a stand-alone, and continue with one data center. See Removing a two data center deployment.
- Install a new warm-standby data center to replace the failed one. See Installing a two data center deployment.

If you are able to recover your failed data center, before you re-enable network access, set the management and portal subsystems to warm-standby:

1. Set the `multi-site-ha-mode` property to `passive` for the management subsystem in DC1:

```
apicup subsys set <DC1 management> multi-site-ha-mode=passive
```

2. Apply the update to DC1:

```
apicup subsys install <DC1 management> --accept-dr-data-deletion
```

Note: When an active management subsystem is converted to warm-standby, all contents of its management database are deleted (to be replaced by the contents from the other data center when it becomes the active). The `--accept-dr-data-deletion` flag is acknowledgment that you accept this temporary loss of data.

3. Monitor the progress of the conversion to warm-standby:

```
apicup subsys health-check <DC1 management> -v
```

4. Set the `multi-site-ha-mode` property to `passive` for the portal subsystem in DC1:

```
apicup subsys set <DC1 portal> multi-site-ha-mode=passive
```

5. Apply the update to DC1:

```
apicup subsys install <DC1 portal> --skip-health-check
```

6. Monitor the progress of the conversion to warm-standby:

```
apicup subsys health-check <DC1 portal> -v
```

7. When you have confirmed that both management and portal subsystems in DC1 are set to warm-standby, you can re-enable the network to the DC1 API Connect subsystems, and the two data centers should synchronize their API Connect data.
Monitor the health at both data centers with:

```
apicup subsys health-check <DC1 management> -v
```

How to failover a two data center deployment V10.0.6.0

How to detect failures, and perform service failover, in a two data center disaster recovery deployment on VMware.

Before you begin

Note: The steps in this task apply to API Connect V10.0.6.0. If you are on V10.0.7.0 or later, then refer to How to failover a two data center deployment.
Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see Two data center warm-standby deployment strategy on VMware.

About this task

Note:
The steps in this task apply to API Connect v10.0.6. If you are on v10.0.7 or later, then refer to How to failover a two data center deployment.

Failure handling comprises of two main concepts; failure detection, and failover of services.
Failure detection is about detecting that a failure has happened, and then alerting the relevant administrator for them to take action. Failure detection is different from system monitoring. Failure detection checks are run often and fast (for example, every 5 seconds). As such they are normally more limited in what they check. In API Connect, failure checks detect only whether the database and web server are online, and nothing more. Whereas monitoring checks typically are run less frequently, but are more likely to check for things like CPU, memory, and disk space usage. The results of these checks can then be recorded to perform historical trend analysis to spot memory leaks for example.

If a failure is detected, it's then important to make sure that the cluster or service is definitely offline. So, for example, if data center one (DC1) appears to have an outage, and the plan is to failover to data center two (DC2), then it's important to make sure that the pods in DC1 really are offline. If the DC1 pods are actually still running, then they might continue to send data to DC2, which would lead DC2 to think it wasn't the active deployment, and then that could lead to split-brain. A fast way to ensure that the cluster or service really is offline, is to drop the network link to those pods in your VMware infrastructure, and then delete them.

The failure detection endpoint must be location specific and must be exempt from any traffic routing, so that it's possible to explicitly check the health of each data center regardless of how traffic is being routed.

You can failover a specific service, for example `portal_service_1`, or all of the services that are running in a particular data center. The following sections describe how failover is achieved.

The operational states of an API Manager service:

Operational state	Description
`progressing to active`	Pods are progressing to the active state, but none are capable of serving traffic.
`active`	All of the pods are ready and in the correct disaster recovery state for the active data center.
`progressing to passive`	Pods are progressing to the warm-standby state, but none are capable of serving traffic.
`passive`	All of the pods are ready and in the correct disaster recovery state for the warm-standby data center.

The operational states of a Developer Portal service:

Operational state	Description
`progressing to active`	Pods are progressing to the active state, but none are capable of serving traffic.
`progressing to active (ready for traffic)`	At least one pod of each type is ready for traffic. The dynamic router can be linked to this service.
`active`	All of the pods are ready and in the correct disaster recovery state for the active data center.
`progressing to passive`	Pods are progressing to the warm-standby state, but none are capable of serving traffic.
`progressing to passive (ready for traffic)`	At least one pod of each type is ready for traffic.
`passive`	All of the pods are ready and in the correct disaster recovery state for the warm-standby data center.
`progressing to down`	Pods are moving from warm-standby state to down.
`down`	The multi-site HA mode is deleted from the warm-standby data center.

You can run the following command to check the operational state of a service:

```
kubectl describe ServiceName
```

Where `ServiceName` is the name of the API Manager or Developer Portal service.
Important:

- If the active data center is offline, do not change the `multi-site-ha-enabled` setting to `false` on the warm-standby data center, as this action deletes all the data from the databases.
  If you want to revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center, and then redeploy the warm-standby data center.

  If the active data center is offline, you must first change the warm-standby data center to be active, and then change the `multi-site-ha-enabled` setting to `false` on the now active data center.
- If the warm-standby data center is offline for more than 24 hours, there can be issues with the disk space on the active data center so you must revert your deployment to a single data center topology. To revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center. When the warm-standby site has been redeployed, the `multi-site-ha-enabled` setting can be reapplied to the active site.

Procedure

- **API Manager service failover**
  To initiate a failover from DC1 to DC2 you first must set DC1 to warm-standby, before making the warm-standby data center active. This action is needed to prevent split-brain, as there cannot be two active services or clusters at the same time. If the failover is being done because the current active data center has had a complete outage, then you should ensure that the network links to that data center are dropped in your VMware infrastructure, in order to avoid the potential for split-brain occurring. The offline data center must be set to warm-standby before the network links are restored. The following instructions show how to failover DC1 to DC2 for the API Manager service.

  1. Set DC1 (in this example, located in Dallas) to be warm-standby.
     Run `apicup` to change the `multi-site-ha-mode` property to `passive` on the Dallas data center, for example:

     ```
     apicup subsys set mgmt_dallas multi-site-ha-mode=passive
     ```

     where
     - `mgmt_dallas` is the name of the management service on DC1.

     Note: If DC1 is completely down, and you cannot set it to be warm-standby at this point, you must ensure that the network links to DC1 are removed before continuing to set DC2 to be active. You must then not restore the network links to DC1 until you can set DC1 to be warm-standby.
  2. Run `apicup` to update the settings on DC1, for example:

     ```
     apicup subsys install mgmt_dallas
     ```

  3. Log in to the virtual machine management subsystem on DC1 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

     ```
     kubectl describe ServiceName
     ```

     The service is ready for traffic when the `Ha mode` part of the `Status` object is set to `passive`. For example:

     ```
     Status:
       ...
       Ha mode:                              passive
       ...
     ```

  4. Set DC2 (in this example, located in Raleigh) to be active.
     Run `apicup` to change the `multi-site-ha-mode` property to `active` on the Raleigh data center, for example:

     ```
     apicup subsys set mgmt_raleigh multi-site-ha-mode=active
     ```

     where
     - `mgmt_raleigh` is the name of the management service on DC2.
  5. Run `apicup` to update the settings on the services on DC2.
     For example:

     ```
     apicup subsys install mgmt_raleigh
     ```

  6. Update your dynamic router to redirect all traffic to DC2 instead of DC1. Note that until the DC2 site becomes `active`, the UIs might not be operational.
  7. Log in to the virtual machine management subsystem on DC2 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

     ```
     kubectl describe ServiceName
     ```

     The service is ready for traffic when the `Ha mode` part of the `Status` object is set to `active`. For example:

     ```
     Status:
       ...
       Ha mode:                              active
       ...
     ```

- **Developer Portal service failover**
  To initiate a failover for the Developer Portal from DC1 to DC2 you first must ensure that the existing DC1 is warm-standby, before making the warm-standby data center active, in order to prevent split-brain. The following instructions show how to failover DC1 to DC2 for the Developer Portal service. You must repeat these steps for each Developer Portal service that you want to failover.

  Note:
  - Switching a Developer Portal service to warm-standby mode instantly restarts all of its `portal-db` and `portal-www` pods at the same time. Therefore, if you don't have an active Developer Portal service that is online, there will be an outage of the Developer Portal web sites until the warm-standby data center is ready to accept traffic.

- If you want to monitor the failover process, you can run the following command to check the status of the Portal pods in the ***PortalService*** CR file:

  ```
  kubectl describe ServiceName
  ```

  For more details about the status information in a **PortalCluster** CR file, see the Example section.
- Do not edit the ***PortalService*** CR file during the failover process.

1. Set DC1 (in this example, located in Dallas) to be warm-standby.
   Run **apicup** to change the **multi-site-ha-mode** property to **passive** on the Dallas data center, for example:

   ```
   apicup subsys set port_dallas multi-site-ha-mode=passive
   ```

   where
   - ***port_dallas*** is the name of the Portal service on DC1.

   Note: If DC1 is completely down, and you cannot set it to be warm-standby at this point, you must ensure that the network links to DC1 are removed before continuing to set DC2 to be active. You must then not restore the network links to DC1 until you can set DC1 to be warm-standby.
2. Run **apicup** to update the settings on DC1, for example:

   ```
   apicup subsys install port_dallas --skip-health-check
   ```

   Important: You must not wait for the active DC **Status** to become **warm-standby**, before failing over the warm-standby DC to become **active**. You should change the DC1 **multi-site-ha-mode** to **passive**, and then run the **kubectl describe *ServiceName*** command, and as soon as the **haMode** is set to **progressing to passive**, you must change DC2 to be **active**.
3. Set DC2 (in this example, located in Raleigh) to be active.
   Run **apicup** to change the **multi-site-ha-mode** property to **active** on the Raleigh data center, for example:

   ```
   apicup subsys set port_raleigh multi-site-ha-mode=active
   ```

   where
   - ***port_raleigh*** is the name of the Portal service on DC2.
4. Run **apicup** to update the settings on the services on DC2.
   For example:

   ```
   apicup subsys install port_raleigh --skip-health-check
   ```

5. Update your dynamic router to redirect all traffic to DC2 instead of DC1.
6. Log in to the virtual machine management subsystem on DC2 by using an SSH tool, and run the following command to check that the Developer Portal service is ready for traffic:

   ```
   kubectl describe ServiceName
   ```

   The service is ready for traffic when the **haMode** part of the **Status** object is set to **active**. For example:

   ```
   Status:
     ...
     haMode:                              active
     ...
   ```

- **Entire data center failover**
  To failover an entire datacenter, follow the previous steps to failover the API Manager service, followed by the steps to failover each Developer Portal service in that data center.

  How long it takes to complete the failover varies, and depends on hardware speed, network latency, and the size of the databases. However, here are some approximate timings:

  For API Manager:
  - **warm-standby** to **active** approximately 5 minutes
  - **active** to **warm-standby** approximately 15 minutes

  For Developer Portal:
  - **warm-standby** to **active** 15 - 40 minutes
  - **active** to **warm-standby** approximately 10 minutes

Example

Example of the status section of a **PortalCluster** CR file for an active data center that you can view by running the **kubectl describe *PortalService*** command:

```
status:
  conditions:
  - lastTransitionTime: "2020-04-27T08:00:25Z"
    message: 4/6
    status: "False"
    type: Ready

      - name: "10.0"
      - name: 10.0.0
      - name: 10.0.0.0
      versions:
      - name: 10.0.0.0-1038
    reconciled: 10.0.0.0-1038
```

Meaning of the **haMode** for the active data center:

- **active** - this is the active data center, or the only data center, and all pods are ready and accepting traffic.
- **progressing to active** - this is the active data center, or the only data center, and there are no pods ready yet.
- **progressing to active (ready for traffic)** - this is the active data center, or the only data center, and there is at least one pod of each type, www, db, and nginx, ready, so the data center is accepting traffic.

Example of the status section of a **PortalCluster** CR file for a warm-standby data center that you can view by running the **kubectl describe *PortalService*** command:

```
status:
  conditions:
  - lastTransitionTime: "2020-04-21T10:54:54Z"
    message: 6/6
    status: "True"
    type: Ready

```

Meaning of the **haMode** for the warm-standby data center:

- **passive** - this is the warm-standby data center, and all pods are ready and accepting traffic.
- **progressing to passive** - this is the warm-standby data center, and there are no pods ready yet.
- **progressing to passive (ready for traffic)** - this is the warm-standby data center, and there is at least one pod of each type, www, db, and nginx, ready, so the data center is accepting traffic.

What to do next

As soon as a failure on a data center has been resolved, the failed data center should be brought back online and re-linked to the currently active data center in order to maintain the highest availability; see Recovering from a failover of a two data center deployment V10.0.6.0 for more information.

Recovering from a failover of a two data center deployment V10.0.6.0

How to recover a two data center disaster recovery deployment on VMware.

Before you begin

Note: The steps in this task apply to API Connect V10.0.6.0. If you are on V10.0.7.0 or later, then refer to How to failover a two data center deployment.
Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see Two data center warm-standby deployment strategy on VMware.

About this task

After a failure has been resolved, the failed data center can be brought back online and re-linked to the currently active data center. It's important to do this as soon as possible, in order to reinstate disaster recovery. Otherwise, if another failure occurred before the failed data center is brought back online, there could be a complete outage.

The failed data center can be brought back online as the new active primary data center, or it can be brought back as a warm-standby secondary data center and the currently active data center kept as the primary one. This decision will be based on your own company policies about recovering from a failure.

The amount of data that is sent when recovering from a failover, will depend on how long the outage lasted, and how much activity there was during that period.

Important:

- If the active data center is offline, do not change the `multi-site-ha-enabled` setting to `false` on the warm-standby data center, as this action deletes all the data from the databases.
  If you want to revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center, and then redeploy the warm-standby data center.

  If the active data center is offline, you must first change the warm-standby data center to be active, and then change the `multi-site-ha-enabled` setting to `false` on the now active data center.
- If the warm-standby data center is offline for more than 24 hours, there can be issues with the disk space on the active data center so you must revert your deployment to a single data center topology. To revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center. When the warm-standby site has been redeployed, the `multi-site-ha-enabled` setting can be reapplied to the active site.

Procedure

- **Recovering from an API Manager failover**
  The following instructions show how to bring data center one (DC1) back as the primary (`active`) data center, and assume that DC1 is now online and in the warm-standby state. If you prefer, you can keep DC1 as the secondary data center, and leave data center two (DC2) as the primary (`active`) data center.

  1. Set DC2 (in this example, located in Raleigh) to be warm-standby.
     Run `apicup` to change the `multi-site-ha-mode` property to `passive` on the Raleigh data center, for example:

     ```
     apicup subsys set mgmt_raleigh multi-site-ha-mode=passive
     ```

     where
     - *`mgmt_raleigh`* is the name of the management service on DC2.
  2. Run `apicup` to update the settings on DC2, for example:

     ```
     apicup subsys install mgmt_raleigh
     ```

  3. Log in to the virtual machine management subsystem on DC2 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

     ```
     kubectl describe ServiceName
     ```

     The service is ready for traffic when the `Ha mode` part of the `Status` object is set to `passive`. For example:

     ```
     Status:
       ...
       Ha mode:                          passive
       ...
     ```

     You must also ensure that the database in DC2 has replicated over completely before proceeding.
  4. Set DC1 (in this example, located in Dallas) to be active.
     Run `apicup` to change the `multi-site-ha-mode` property to `active` on the Dallas data center, for example:

```
apicup subsys set mgmt_dallas multi-site-ha-mode=active
```

where
- *mgmt_dallas* is the name of the management service on DC1.

5. Run **apicup** to update the settings on DC1.
   For example:

```
apicup subsys install mgmt_dallas
```

6. Update the dynamic router to redirect all traffic to DC1 instead of DC2. Note that until the DC1 site becomes **active**, the UIs might not be operational.
7. Log in to the virtual machine management subsystem on DC1 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

```
kubectl describe ServiceName
```

   The service is ready for traffic when the **Ha mode** part of the **Status** object is set to **active**. For example:

```
Status:
  ...
  Ha mode:                          active
  ...
```

- **Recovering from a Developer Portal failover**
  When recovering from a Developer Portal failover, how much data is sent from the now warm-standby data center (in this example, DC2) back to the newly recovered active data center (in this example, DC1) varies depending on how much time has passed and how many changes have been made in the meantime.

  If possible, the Portal sends an Incremental State Transfer (IST), which is a replay of the transactions that have happened since the failed data center, DC1, became unreachable. The IST can grow to be up to 3 GB in size. If the IST grows larger than 3 GB, then the Portal sends a State Snapshot Transfer (SST) instead, which is basically a full copy of the whole database. How long this process takes depends on how many Portal sites there are, how much content in each of those sites, how active they are (as in number of transactions), and how fast the network speed is between the data centers. However, it is likely to take in the range 5 - 60 minutes.

  You can check whether the Developer Portal servers are in sync by running the **status** command in the **portal-www** pod admin container. If all servers show as **primary**, then they are in sync and traffic can be directed wherever needed. For information about running the status command, see Verifying deployment of the Developer Portal subsystem.

  Note:
  - If you want to monitor the recovery process, you can log in to the virtual machine Portal subsystem by using an SSH tool, and run the following command to check the status of the Portal pods in the ***PortalService*** CR file:

```
kubectl describe ServiceName
```

    For more details about the status information in a **PortalCluster** CR file, see the Example section.
  - Do not edit the ***PortalService*** CR file during the recovery process.

  The following instructions show how to bring DC1 back as the active primary data center, and switch DC2 to be the warm-standby secondary data center. Again, you can keep DC2 as the active primary data center if you prefer, and leave DC1 to be warm-standby.

  1. Set DC2 (in this example, located in Raleigh) to be warm-standby.
     Run **apicup** to change the **multi-site-ha-mode** property to **passive** on the Raleigh data center, for example:

```
apicup subsys set port_raleigh multi-site-ha-mode=passive
```

     where
     - *port_raleigh* is the name of the Portal service on DC2.

  2. Run **apicup** to update the settings on the services on DC2.
     For example:

```
apicup subsys install port_raleigh --skip-health-check
```

     Important: You must not wait for the active DC **Status** to become **warm-standby**, before changing the warm-standby DC to become **active**. You should change the DC2 **multi-site-ha-mode** to **passive**, and then run the **kubectl describe** *ServiceName* command, and as soon as the **haMode** is set to **progressing to passive**, you must change DC1 to be **active**.
  3. Set DC1 (in this example, located in Dallas) to be active.
     Run **apicup** to change the **multi-site-ha-mode** property to **active** on the Dallas data center, for example:

```
apicup subsys set port_dallas multi-site-ha-mode=active
```

     where
     - *port_dallas* is the name of the Portal service on DC1.

  4. Run **apicup** to update the settings on the services on DC1.
     For example:

```
apicup subsys install port_dallas --skip-health-check
```

  5. Update the dynamic router to redirect all traffic to DC1 instead of DC2.
  6. Log in to the virtual machine Portal subsystem on DC1 by using an SSH tool, and run the following command to check that the Developer Portal service is ready for traffic:

```
kubectl describe ServiceName
```

     The service is ready for traffic when the **Ha mode** part of the **Status** object is set to **active**. For example:

```
Status:
  ...

Removing a two data center deployment

You can remove your two data center disaster recovery deployment on VMware.

Before you begin

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see Two data center warm-standby deployment strategy on VMware.

About this task

If you decide to remove your two data center disaster recovery (DR) deployment, you go from two data centers to one. The active data center remains as the only working system. The warm-standby data center has its data deleted.

Warning: If the active data center is offline, do not disable 2DCDR in the warm-standby data center, as this action deletes all the data from the management and portal databases.
As part of the installation, you configured the `multi-site-ha` settings on each data center, as described in the following table:

Table 1. The `multi-site-ha` settings

Setting	Description
`multi-site-ha-enabled`	Indicates whether two data center DR deployment is enabled. Set to `true` to enable two data center DR. Set to `false` to disable two data center DR. The default value is `false`.
`multi-site-ha-mode`	The state of the data center in the context of the two data center deployment. Valid values are: • `active` - indicates the primary data center • `passive` - indicates the warm-standby data center
`management-replication`	Required only for the management subsystem. The external ingress name for the management subsystem in the current data center in the two data center deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`portal-replication`	Required only for the portal subsystem. The external ingress name for the portal subsystem in the current data center in the two data center deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`replication-peer-fqdn`	The ingress hostname for the other data center in the two data center deployment. This information is required so that the two data centers can communicate with each other.

If you want to revert to a single data center topology, or temporarily remove the warm-standby data center from DR, you must disable the `multi-site-ha` configuration on the active data center, and then remove the warm-standby data center. If the active data center is offline, you must first change the warm-standby data center to be active, and then disable the `multi-site-ha` configuration on the now active data center.

Procedure

- Disable the `multi-site-ha` configuration on the active data center:
  1. Disable the `multi-site-ha` configuration on the management subsystem of the active data center:

     ```
     apicup subsys set mgmt multi-site-ha-enabled=false
     apicup subsys install mgmt
     ```

  2. Disable the `multi-site-ha` configuration on the portal subsystem of the active data center:

     ```
     apicup subsys set ptl multi-site-ha-enabled=false
     apicup subsys install ptl
     ```

- Disable the `multi-site-ha` configuration on the warm-standby data center:
  Note:
  Disabling 2DCDR on the warm-standby results in deletion of all data on the warm-standby.

  If you do not plan to keep the warm-standby installation, you can uninstall API Connect on the warm-standby, you do not need to convert it to a stand-alone before you uninstall.
  1. Disable the `multi-site-ha` configuration on the management subsystem of the warm-standby data center:

     ```
     apicup subsys set mgmt multi-site-ha-enabled=false
     apicup subsys install mgmt --accept-dr-data-deletion
     ```

  2. Disable the `multi-site-ha` configuration on the portal subsystem of the warm-standby data center:

     ```
     apicup subsys set ptl multi-site-ha-enabled=false
     apicup subsys install ptl
     ```

Monitoring and health checks

Monitor your deployment and complete health checks on subsystems.

See:

- **Checking cluster health on VMware**
  You can use `apicup` to check the health of the API Connect clusters in your VMware deployment.
- **Monitoring Postgres disk usage on VMware**
  Monitor disk usage by the Postgres database in the management subsystem, when deployed on VMware.
- **Obtaining simple health check data of Developer Portal sites by using a REST API call**
  Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.
- **Monitoring the network with SNMP**
  Presents a table of OID trees that you can poll using SNMP Get.

Checking cluster health on VMware

You can use **apicup** to check the health of the API Connect clusters in your VMware deployment.

The **health-check** command checks a number of criteria to determine the health of their cluster. When all criteria are successfully met, the command displays no output, and exits with a status of **0**. When one or more criteria are not met, the command stops processing and displays a message with the failure and exits with a status of **1**.

The command takes no arguments. The only option is the **--verbose** flag. If **--verbose** is set the command prints all checks that were performed.

The **health-check** is run against the namespace that is specified in apiconnect-up.yaml.

The health check is run on the specified subsystem.

The command verifies that for the specified subsystem:

- The **apicup** version matches the API Connect release version.
- All cluster members are running the same API Connect release version.
- All cluster members have a deployment status of **Done**.
- Docker is running.
- **kubelet** is running
- All Kubernetes-defined nodes are running.
- The Kubernetes Control Plane pods are running:
  - **etcd/kube-apiserver**
  - **kube-system.kube-controller**
  - **kube-scheduler**
  - **kube-apiserver-proxy**
- The add-on Kubernetes Deployments are fulfilled:
  - **coredns**
  - **metrics-server**
- The add-on Kubernetes DaemonSets are fulfilled:
  - **calico-node**
  - **ingress-nginx-ingress-controller**
  - **kube-proxy**

Syntax:

```
Usage:
  apicup subsys health-check <SUBSYS>  [flags]

Flags:
  -h, --help                help for health-check
      --kubeconfig string   (optional) absolute path to the kubeconfig file (default "/Users/<username>/.kube/config")
  -v, --verbose             Verbose output

Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Example usage, for a subsystem named **mgmt**:

```
../apicup subsys health-check mgmt
```

Note:

- The command flag **--kubeconfig string** does not apply to deployments on VMware.

- In a multi-node OVA cluster, the **apicup subsys health-check** command does not return status information if a majority of the nodes are down. To obtain status information, start more nodes. Status is returned only when a quorum is achieved.

Monitoring Postgres disk usage on VMware

Monitor disk usage by the Postgres database in the management subsystem, when deployed on VMware.

Postgres Database is the core database used in Management Subsystem. It is important to monitor the Postgres disk usage.

The APIConnect operator tracks the current disk usage of the Postgres components, and regularly updates **apic health-check** command.

APIConnect operator regularly updates the **ManagementCluster** instance status which is reflected in the **apic health-check** command.

apic health-check command reports WARNING state when disk utilization reaches 60%.

apic health-check command reports ERROR state when disk utilization reaches 70% and Postgres is brought down.

Management Cluster disk stats

The **ManagementCluster** instance has **.status.postgresDataStats** where the operator prints the current disk usage of Postgres components. Use **kubectl** to view the status.

To use **kubectl**, first ssh into the appliance as **root**.

```
kubectl get mgmt -o json | jq .status.postgresDataStats
[
  {
    "instanceName": "management-site1-db-1",
    "podName": "",
    "pvcCapacity": 51200,
    "pvcName": "",
    "pvcType": "WAL",
    "pvcUsed": 400,
    "pvcUsedPercentage": 8
  },
  {
    "instanceName": "management-site1-db-1",
    "podName": "",
    "pvcCapacity": 184320,
    "pvcName": "",
    "pvcType": "PostgreSQL",
    "pvcUsed": 95,
    "pvcUsedPercentage": 8
  }
]
```

Warning condition is populated at 60% usage

When one of the Postgres components occupy 60% usage, the operator marks the overall status of the **ManagementCluster** to **Warning** with an appropriate warning message, which is included in the output from **apic health-check** command.

The warning condition explains why the warning condition was set.

To use **apic**, first ssh into the appliance as **root**.

```
apic health-check
```

```
FATA[0007] Cluster not in good health:
ManagementCluster is not Ready or Complete | State: 17/17 Phase:
  Warning Message: Current WAL disk usage of nihar-stac-3955b42d-site1-postgres is 61 percent.
  DATABASE SHUTDOWN starts at 70 percent utilization. Please contact IBM Support immediately
```

If you encounter the warning, contact IBM support to fix the root cause.

Error condition is populated at 70% usage

An error condition is populated when the operator brings down Postgres because it is using 70% of available disk space. Postgres is brought down to avoid problems, such as disk corruption, that can occur if the disk becomes completely filled.

To use **apic**, first ssh into the appliance as **root**.

```
apic health-check
```

```
FATA[0011] Cluster not in good health:
ManagementCluster is not Ready or Complete | State: 17/17 Phase:
  Error Message: Current WAL disk usage of nihar-stac-3955b42d-site1-postgres is more than 70 percent,
  initiating DATABASE SHUTDOWN
```

If you encounter the error, contact IBM support to fix the root cause.

Important:
On VMware, because the entire disk is allocated to the worker node, in some cases before the operator reacts to 70% usage, , Kubernetes itself can face disk pressure and starts evicting pods. In these cases, increase the disk allocated to worker node in order to stabilize the worker node. See Adding disk space to a VMware appliance.

Obtaining simple health check data of Developer Portal sites by using a REST API call

Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

About this task

You can use the site health REST API to determine whether a particular Developer Portal site is running. The site health API returns the current system time of the site if both the database and web server are running. This API is fast and puts no load on the system, so it is ideal for use with load balancers to help them determine where to route traffic.

Procedure

To call the site health REST API, append **`/health`** to the end of your Developer Portal site URL in your web browser, as follows:

***`site_url`*`/health`**

Where ***`site_url`*** is the URL of the Developer Portal site that you want to check.
If both the database and web server of the site are running, the web browser returns the current system time. For example:

```
1511367695
```

If either the database or the web server of the site is not running, the web browser returns an error that the site can't be reached.
If you do get an error from the **`/health`** endpoint, refer to Gathering logs for a VMware environment and obtain the **`portal-www web`** logs, so that you can see more information on the error.

Monitoring the network with SNMP

Presents a table of OID trees that you can poll using SNMP Get.

Simple Network Management Protocol (SNMP) collects information from network devices, such as servers, printers, hubs, switches, and routers on an Internet Protocol (IP). SNMP employs addresses for network devices using a hierarchical numbering system called Object Identifiers (OID). The following table provides OID addresses for polling in SNMP to monitor API Connect servers.

Note:

- Only SNMP v2 and SNMP v3 are supported. However, it is not recommended to enable SNMP v2. Instead, configure SNMPv3 as shown in Configuring SNMPv3, and then enable it as shown in Enabling SNMP.
- If the server has two or more network interfaces, the SNMP request is sent only to the first network interface.
- SNMP is disabled by default for all hosts.
- This information applies to API Connect deployments in VMware environments. It does not apply to Kubernetes deployments.

Each entry in the table represents many individual items. Use snmpwalk or another SNMP polling utility to see the complete list. You can poll the following OID trees:

Table 1. Default SNMPv2 configuration

OID	SNMP Name	Notes
.1.3.6.1.2.1.1	SNMPv2-MIB::system	
.1.3.6.1.2.1.2	IF-MIB::interfaces	
.1.3.6.1.2.1.4	IP-MIB::ip	
.1.3.6.1.2.1.5	IP-MIB::icmp.	
.1.3.6.1.2.1.6	TCP-MIB::tcp	
.1.3.6.1.2.1.7	UDP-MIB::udp	
.1.3.6.1.2.1.11	SNMPv2-MIB::snmp	
.1.3.6.1.2.1.25.1	HOST-RESOURCES-MIB::hrSystem	Excluding .1.3.6.1.2.1.25.1.3 HOST-RESOURCES-MIB::hrSystemInitialLoadDevice Excluding .1.3.6.1.2.1.25.1.4 HOST-RESOURCES-MIB::hrSystemInitialLoadParameters
.1.3.6.1.2.1.25.2	HOST-RESOURCES-MIB::hrStorage	
.1.3.6.1.2.1.25.3	HOST-RESOURCES-MIB::hrDevice	
.1.3.6.1.4.1.2021.4	UCD-SNMP-MIB::memory	
.1.3.6.1.4.1.2021.10	UCD-SNMP-MIB::laTable	CPU Load Average
.1.3.6.1.4.1.2021.11	UCD-SNMP-MIB::systemStats	

Configuring SNMPv3

From an OVA shell prompt as root edit the file **`/etc/snmp/snmpd.conf`** so that its content is:

```
createUser readOnlyUser SHA authpassphrase AES privpassphrase
rouser readOnlyUser
agentAddress udp:161,udp6:[::1]:161
```

- Replace ***`authpassphrase`*** with the passphrase to be used for authentication,
- Replace ***`privpassphrase`*** with the passphrase to be used for privacy (encryption) of the communications.

Enabling SNMP

It is not recommended to start SNMP without first configuring it for SNMPv3. See Configuring SNMPv3.

Enable SNMP on each individual OVA node with the following commands from an OVA shell prompt as root:

```
systemctl start snmpd
systemctl enable snmpd
```

Sample output:

```
root@mgmt:~# systemctl start snmpd
root@mgmt:~# systemctl enable snmpd
snmpd.service is not a native service, redirecting to systemd-sysv-install
Executing /lib/systemd/systemd-sysv-install enable snmpd
insserv: warning: current start runlevel(s) (empty) of script `snmpd' overrides LSB defaults (2 3 4 5).
insserv: warning: current stop runlevel(s) (0 1 2 3 4 5 6) of script `snmpd' overrides LSB defaults (0 1 6).
```

Disabling SNMP

Disable SNMP on each individual OVA node with the following commands from an OVA shell prompt as root:

```
systemctl stop snmpd
systemctl disable snmpd
```

Sample output:

```
root@mgmt:~# systemctl stop snmpd
root@mgmt:~# systemctl disable snmpd
snmpd.service is not a native service, redirecting to systemd-sysv-install
Executing /lib/systemd/systemd-sysv-install disable snmpd
insserv: warning: current start runlevel(s) (empty) of script `snmpd' overrides LSB defaults (2 3 4 5).
insserv: warning: current stop runlevel(s) (0 1 2 3 4 5 6) of script `snmpd' overrides LSB defaults (0 1 6).
```

Checking SNMP status

Check whether SNMP is enabled on each individual OVA node with the following commands from an OVA shell prompt:

```
systemctl status snmpd
```

Sample output when SNMP is enabled and running:

```
apicadm@mgmt:~$ systemctl status snmpd
  snmpd.service - LSB: SNMP agents
   Loaded: loaded (/etc/init.d/snmpd; bad; vendor preset: enabled)
   Active: active (running) since Wed 2019-02-06 03:53:02 UTC; 2 days ago
     Docs: man:systemd-sysv-generator(8)
    Tasks: 1
   Memory: 6.0M
      CPU: 3min 1.641s
   CGroup: /system.slice/snmpd.service
           └─1366 /usr/sbin/snmpd -Lsd -Lf /dev/null -u snmp -g snmp -I -smux mteTrigger mteTriggerConf -p /run/snmpd.pid
...
```

Sample output when SNMP is stopped and disabled:

```
root@mgmt:~# systemctl status snmpd
   snmpd.service - LSB: SNMP agents
   Loaded: loaded (/etc/init.d/snmpd; bad; vendor preset: enabled)
   Active: inactive (dead)
     Docs: man:systemd-sysv-generator(8)
...
```

Logging

Configure logging for your deployment on VMware.

See:

- **Configuring remote logging for a VMware deployment**
  Logging collection is required for IBM Support to assist with troubleshooting. You can configure fluent-bit to collect and forward logs to a remote Syslog server.
- **Gathering logs for a VMware environment**
  The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.
- **Changing logging levels**
  You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

Configuring remote logging for a VMware deployment

Logging collection is required for IBM Support to assist with troubleshooting. You can configure fluent-bit to collect and forward logs to a remote Syslog server.

Before you begin

The fluent-bit service is already installed on the appliances and is configured to forward container logs to /var/log/syslog on the local machine.

Important: This article refers to third-party software that IBM does not control. As such, the software may change and this information might become outdated. In addition, the fluent-bit service was tested only for simple container log routing to local and remote Syslog servers as configured in the instructions that follow. Any customization of other fluent-bit settings (for example, to set up parsers or filters) is at your own risk and should be performed with caution by referring to the fluent-bit documentation.

About this task

Remote logs created with fluent-bit use the following format:

```
Mar 1 00:38:44 apicdev1147 calico-node-gqbv_42428a8ade169ad3 2023-03-01 00:38:44.684 [INFO][208] felix/int_dataplane.go 1245: Applying dataplane updates
```

Where:

- `Mar 1 00:38:44` is the time the log arrived on the remote server.
- `apicdev1147` is the hostname of the log source.
- `calico-node-gqbv_42428a8ade169ad3` is a portion of the pod name/container_id where the log is coming from.
- `2023-03-01 00:38:44.684` is the timestamp at which the logged event actually took place within the container.
- The rest of the log is the log message itself.

Logs posted to your local server look different, as in this example:

```
Feb 28 23:47:03 apicdev1147 fluent-bit[2332273]: [2] kube.var.log.containers.kqn2-management-portal-proxy-647b96b89f-pkz5w_default_portal-proxy-74a1723512574fdc23fb9c014b80c7e83aff225b9d44d995736251edd18c49b4.log: [1677628023.503190040, {"_p"=>"F", "log"=>"Tue, 28 Feb 2023 23:47:03 GMT express:router expressInit  : /healthz", "tag"=>"kqn2-management-_74a1723512574fdc", "time"=>"2023-02-28T23:47:03.503190005Z", "stream"=>"stderr"}]
```

On the local log, the whole fluent-bit JSON object is logged, which provides slightly more information (for example, the full file name of the log file) than in the remote log.

To configure remote logging, use the appropriate instructions for your deployed version of API Connect:

- Configuring remote logging
- Updating the remote logging configuration

Configuring remote logging

About this task

The fluent-bit service is already installed on the appliance and is configured to forward container logs to `/var/log/syslog` on the local machine. If you want to change the output destination to a remote Syslog server, complete the following steps:

Procedure

1. Create the /etc/fluent-bit/append-tag.lua file.
   a. Paste the following code into the new file:

```
function append_tag(tag, timestamp, record)
    new_record = record
    local pod_name = string.sub(string.match(tag, "^kube%.var%.log%.containers%.(.+)$"), 1, 16)
    local container_id = string.sub(string.match(tag, "-([^-]+)%.log$"), 1, 16)

    new_record["tag"] = pod_name .. "_" .. container_id
    return 1, timestamp, new_record
end
```

   b. Save and close the file.
2. Create the /etc/fluent-bit/fluent-bit-override.conf file.
   a. Add the following statements to the new file::
   Replace the variables in the `[OUTPUT]` section with values for your deployment:

```
[SERVICE]
        Daemon Off
        Flush 1
        Log_Level info
        Parsers_File parsers.conf
        HTTP_Server On
        HTTP_Listen 0.0.0.0
        HTTP_Port 2021
        Health_Check On

[INPUT]
        Name tail
        Path /var/log/containers/*.log
        multiline.parser docker, cri
        Tag kube.*
        Mem_Buf_Limit 5MB
        Skip_Long_Lines On

[INPUT]
        Name systemd
        Tag host.*
        Systemd_Filter _SYSTEMD_UNIT=kubelet.service
        Read_From_Tail On

[FILTER]
        Name kubernetes
        Match kube.*
        Merge_Log On
        Keep_Log Off
```

```
        K8S-Logging.Parser On
        K8S-Logging.Exclude On

[FILTER]
        Name lua
        Match kube.*
        Script /etc/fluent-bit/append-tag.lua
        call append_tag

[OUTPUT]
        Name syslog
        Match *
        Host <host>
        port 514
        mode udp
        syslog_format rfc5424
        syslog_maxsize 2048
        syslog_hostname_key hostname
        syslog_hostname_preset <hostname of local machine/log source>
        syslog_appname_key tag
        syslog_message_key log
```

Note: The default values shown in the `[OUTPUT]` section can be modified as explained in the fluent-bit documentation.

b. Save and close the file.

3. Run the following command to restart the fluent-bit service so it picks up the configuration changes:

```
systemctl restart appliance-manager && systemctl restart fluent-bit
```

Updating the remote logging configuration

To update the fluent-bit configuration, complete the following steps:

Procedure

1. Run the following command to edit the configuration file:

```
vim /etc/fluent-bit/fluent-bit-override.conf
```

2. Complete your configuration changes, then save and close the file.
3. Run the following command to restart the appliance-manager:

```
systemctl restart appliance-manager
```

Gathering logs for a VMware environment

The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.

About this task

When you contact IBM Support, logs and VMware environment data are normally required to help diagnosis. Run the `generate_postmortem.sh` script on each API Connect VM to gather all the required logs and data. The data that is gathered by the script includes OS-level information from each VM, so if you have a three replica deployment, it is recommended to run the `generate_postmortem.sh` script on each VM in the cluster.

The logs that are gathered by the `generate_postmortem.sh` script include the logs of the currently running API Connect processes. The logs have a maximum size, and older log messages are not retained when the maximum size is reached. To ensure that the logs gathered cover the time when the problem occurred, it is recommended to reproduce the problem and then immediately gather the logs. Offboarding the logs to an external server is the recommended best practice for long-term storage of log data. See Configuring remote logging for a VMware deployment.

Procedure

1. Connect to the target appliance with SSH:

```
ssh apicadm@<ova appliance hostname>
```

2. Switch to the *root user*:

```
sudo -i
```

3. Download the `generate_postmortem.sh` script. Enter the following command:

```
curl -s -o generate_postmortem.sh https://raw.githubusercontent.com/ibm-apiconnect/v10-postmortem/master/generate_postmortem.sh
```

Note: If your API Connect VMs do not have external internet access, download the `generate_postmortem.sh` script to another computer that has internet access, and copy it to your API Connect VMs.

4. Add execute permissions to the `generate_postmortem.sh` script. Enter the following command:

```
chmod +x generate_postmortem.sh
```

5. Run the postmortem tool by using the following command:

```
./generate_postmortem.sh --ova --pull-appliance-logs
```

6. Optional: Specify either management, portal, or analytics for more detailed logs from that subsystem. Specify `--diagnostic-all` for detailed logs of every subsystem:
   - Portal:

     ```
     ./generate_postmortem.sh --ova --diagnostic-portal --pull-appliance-logs
     ```

   - Management:
     - Download an additional file that gathers management database information: `edb_mustgather.py`:

       ```
       wget https://github.com/ibm-apiconnect/v10-postmortem/blob/master/edb_mustgather.sh
       ```

     - Run `generate_postmortem.sh` with `--diagnostic-manager`:

       ```
       ./generate_postmortem.sh --ova --diagnostic-manager --pull-appliance-logs
       ```

   - Analytics:

     ```
     ./generate_postmortem.sh --ova --diagnostic-analytics --pull-appliance-logs
     ```

   Note: The diagnostic level logs generated with the `--diagnostic-<subsystem name>` argument produce a much larger output file.
7. If you see errors when you run the `generate_postmortem.sh` script, run again with `--debug`:

   ```
   ./generate_postmortem.sh --ova --debug &>debug.log
   ```

   For more documentation on the script, see https://github.com/ibm-apiconnect/v10-postmortem.

Changing logging levels

You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

About this task

For apim-v2 pods, the default logging settings do not include entry and exit trace and logging of large payloads.

Logging of large payloads is typically needed if you are logging `apim:webhookPayload` or other processes that log large variables.

You can also set the debug level without needing to restart the pods.

You can enable the settings through either the APIM deployment YAML file, the toolkit, or the REST APIs. Note, you must use the toolkit or REST API to set the debug level without restarting the pods.

Procedure

- Updating the settings in the APIM deployment YAML file
  Note: This action causes a pod restart.
  - The DEBUG variable works the same as prior releases.

    ```
    - env:
        - name: DEBUG
          value:
    audit,bhendi:error,bhendi:probe,bhendi:flags,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:
    *
    ```

    To enable entry and exit trace, add `trace:*` to the start of the debug string:

    ```
    - env:
        - name: DEBUG
          value: trace:*,audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:webhookAudit,bhendi:cassandra-
    transactions,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*,apim:taskmanager:info
    ```

  - To enable large object logging:

    ```
    - env:
        - name: VELOX_LOG_FULL_PAYLOAD
          value: "true"
    ```

- Updating the settings by using the toolkit
  Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

  ```
  apic log-spec:get
  apic log-spec:update  LOG_SPEC_FILE
  ```

  Where the spec file contains:

  ```
  {"specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}
  ```

- Updating the settings by using the REST API
  Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

  ```
  GET /cloud/api/log-spec
  PUT /cloud/api/log-spec
  ```

  For example, to set debug level and large objects logging:

```
curl -k https://172.16.140.212:3003/api/cloud/log-spec -X PUT -H "Authorization: Bearer $BEARER"
    -H "Accept: application/json" -d '{"specification":
"apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error","large_objects": true}'
    -H "Content-Type: application/json"
```

The command responds with:

```
{
    "specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error",
    "large_objects": true,
    "message": "Successfully changed the log specification on all apim-v2 pods. Success on IP(s): 172.16.140.212,
172.16.140.213"
}
```

Note: The response might include the following warning, which can be ignored:

```
WARNING: Could not change the log specification on all apim-v2 pods. Success on IP(s): 4.5.6.7  Failed on IP(s): 1.2.3.4
```

To view the REST APIs for logging, go to API Connect REST APIs, and select IBM API Connect Platform - Cloud Management API 2.0.0 reference > Resource: Log Spec.

Troubleshooting

Troubleshoot your deployment on VMware.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
See:

- **Recreating a calico pod that is in the CrashLoopBackOff state**
  If you complete an upgrade and find that one or more of the calico pods are in the `CrashLoopBackOff` state, you can delete the pod to recreate it.
- **Running a filesystem check on a VMware root partition**
  You can run a filesystem check on the appliance root filesystem at boot time.
- **Troubleshooting the management database V10.0.6.0**
  You can troubleshoot the API Connect management database
- **Increasing the PostgreSQL archive_timeout on VMware**
  Increase the `archive_timeout` to `3600` (seconds) so that accumulated wal files do not cause a disk-space issue during a network outage.
- **Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment**
  In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.
- **Troubleshooting analytics on VMware**
  If your API Connect analytics subsystem encounters problems, see the analytics troubleshooting topics.

Recreating a calico pod that is in the `CrashLoopBackOff` state

If you complete an upgrade and find that one or more of the calico pods are in the `CrashLoopBackOff` state, you can delete the pod to recreate it.

Complete the following steps:

1. Get the names of the calico pods:

   ```
   kubectl -n kube-system get pods | grep calico
   ```

2. Recreate each pod by deleting it with the following command:

   ```
   kubectl -n kube-system delete pod <calico_pod_name>
   ```

Running a filesystem check on a VMware root partition

You can run a filesystem check on the appliance root filesystem at boot time.

About this task

If the appliance root filesystem is mounted read-only because it is corrupt, use the following steps to run **fsck** on root partition:

Procedure

1. Access to the VMware console for the Appliance, and after causing it to reboot, make sure to bring up a console to the appliance (as needed to give focus to the window by clicking the mouse into it), and press the `Esc` key repeatedly.
   You will see a boot screen similar to the following:

   ```
   GNU GRUB v2.02
   .
   ```

```
.
- Ubuntu
- Advanced options for Ubuntu
.
.
.
Press Enter to boot the selected OS, 'e' to edit the commands
before booting or 'c' for a command-line
```

2. Press **e** to edit the commands before booting, and add the lines `fsck.mode=force` and `fsck.repair=yes`.
   For example, the boot screen contents resemble:

```
GNU GRUB v2.02
.
.
set params 'Ubuntu'
    fsck.mode=force
    fsck.repair=yes
.
.
.
Press Ctrl-x or F10 to boot
.
```

3. Press F10 to boot.
4. The following command should show that **fsck** was run recently:

```
root@ip-230:~# sudo tune2fs -l /dev/sda1 | grep "Last checked"
Last checked:             Wed Jul  1 19:32:25 2020
```

Troubleshooting the management database V10.0.6.0

You can troubleshoot the API Connect management database

Database Replica Pods stuck in Unknown or Pending state

In certain scenarios, a postgres replica pod may not recover to a healthy state when a restore completes, a node outage occurs, or after a fresh install or upgrade. In these cases, a postgres pod remains in a **`Unknown`** or a **`Pending`** state after a number of minutes. The pod fail to get into a **`Running`** state.

This situation occurs when the replicas do not initialize properly. You can use the **`patronictl reinit`** command to reinitialize the replica. Note that this command syncs the replica's volume data from the current Primary pod.

Use the following steps to get the pod back into a working state:

1. SSH into the appliance as **`root`**.
2. Exec onto the failing pod:

```
kubectl exec -it <postgres_replica_pod_name> -n <namespace> -- bash
```

3. List the cluster members:

```
patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+--------------+----+-----------+
|                         Member                          |      Host      |  Role  |    State     | TL | Lag in MB |
+---------------------------------------------------------+----------------+--------+--------------+----+-----------+
|    fxpk-management-01191b80-postgres-586f899fdf-6s25b   | 172.16.172.244 |        | start failed |    |   unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader |   running    |  3 |           |
|  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        |   running    |  3 |         0 |
+---------------------------------------------------------+----------------+--------+--------------+----+-----------+
```

   In the example shown above **`fxpk-management-01191b80-postgres-586f899fdf-6s25b`** is not in running state.

   Note the **`clusterName`** and **`replicaName`** which are not up:

   - **`clusterName`** - **`fxpk-management-01191b80-postgres`**
   - **`replicaName`** - **`fxpk-management-01191b80-postgres-586f899fdf-6s25b`**

4. Run:

```
patronictl reinit <clusterName> <replicaName-which-is-not-running>
```

   Example:

```
patronictl reinit fxpk-management-01191b80-postgres fxpk-management-01191b80-postgres-586f899fdf-6s25b
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+--------------+----+-----------+
|                         Member                          |      Host      |  Role  |    State     | TL | Lag in MB |
+---------------------------------------------------------+----------------+--------+--------------+----+-----------+
|    fxpk-management-01191b80-postgres-586f899fdf-6s25b   | 172.16.172.244 |        | start failed |    |   unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader |   running    |  3 |           |
|  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        |   running    |  3 |         0 |
+---------------------------------------------------------+----------------+--------+--------------+----+-----------+
Are you sure you want to reinitialize members fxpk-management-01191b80-postgres-586f899fdf-6s25b? [y/N]: y
Success: reinitialize for member fxpk-management-01191b80-postgres-586f899fdf-6s25b
```

5. Run `patronictl list` again.
   You may also observe that the replica is on a different Timeline (TL) and possibly have a Lag in MB. It may take a few minutes for the pod to switch onto the same TL as the others and the Lag should slowly go to 0.

   For example:

```
bash-4.2$ patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) --------+--------+---------+----+-----------+
|                          Member                          |      Host      |  Role  |  State  | TL | Lag in MB |
+----------------------------------------------------------+----------------+--------+---------+----+-----------+
|    fxpk-management-01191b80-postgres-586f899fdf-6s25b    | 172.16.172.244 |        | running |  1 |     23360 |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51  | Leader | running |  3 |           |
|  fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m |  172.16.53.68  |        | running |  3 |         0 |
+----------------------------------------------------------+----------------+--------+---------+----+-----------+
```

6. The pod that previously was in an `Unknown` or `Pending state` or `(0/1) Running` state is now in `(1/1) Running` state.

Increasing the PostgreSQL `archive_timeout` on VMware

Increase the **archive_timeout** to **3600** (seconds) so that accumulated wal files do not cause a disk-space issue during a network outage.

About this task

PostgreSQL sends its wal archives to the backup location (S3 or local PVC) whenever the configured **archive_timeout** period elapses. By default, the **archive_timeout** is set to 60 seconds. During a network outage, the files cannot be transferred and instead accumulate on the current server, and could cause a disk-space issue. Increasing the **archive_timeout** value helps to mitigate this issue by creating archive files less frequently.

For information on tracking the Postgres disk space, see Monitoring Postgres disk usage on VMware.

Complete the following steps to increase the PostgreSQL **archive_timeout** value.

Procedure

1. SSH into the server by completing the following steps:
   a. Run the following command to connect as the API Connect administrator, replacing **ip_address** with the appropriate IP address:
      `ssh ip_address -l apicadm`
   b. When prompted, select Yes to continue connecting.
   c. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:
      `sudo -i`
2. Get the name of the **pgha** config map by running the following command:

   ```
   kubectl -n <namespace> get cm -l pgha-config='true'
   ```

   The response looks like the following example:

   ```
   NAME                                                DATA   AGE
   apis-produ-d18f3f0-0d18f3f0-postgres-pgha-config    5      22d
   ```

3. Edit the config map by running the following command:

   ```
   kubectl -n <namespace> edit configmap <config-map-name>
   ```

   In the command, replace ***<config-map-name>*** with the **NAME** returned in step 1.

4. Change the **archive_timeout** value to **3600**.
   The value must be an integer, and represents the number of seconds that must elapse before the archive file is generated.

5. Save the file and exit the editor.
   The configuration is updated automatically; archives will be generated and pushed every **3600** seconds.

Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment

In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

If a Gateway service is not configured properly for resiliency and is restarted, the gateways in the Gateway service will lose the configuration from the Management server. Configuration data from the Management server is maintained on the gateway service according to the gateway peering configuration on the gateways.

Preventing the loss of configuration data

For high availability in production environments, use a minimum of three gateways in the Gateway service. In non-production environments, if a single gateway is used, then availability can be improved by ensuring the persistence setting on the gateway peering configuration is set to **local://** or **RAID**; these settings apply to virtual and physical appliances only.

Forcing re-population of the configuration data

To repopulate the configuration data, complete the steps in the following section to trigger an outage-less DRR.

Triggering an outage-less DRR

To force a Dynamic Reregistration and Reconfiguration across a peer group from within the gateway service without requiring a restart, complete the following steps using the CLI. This process flushes the primary peering object configured for the apic-gw-service. This task can only be performed with CLI, and requires the default admin ID for running the **diag** command.

1. Use **ssh** to connect to gateway service.
2. Switch to the API Connect application:

   ```
   switch <APIC_APP_DOMAIN>
   ```

3. Show the current gateway-peering-status:

   ```
   show gateway-peering-status
   ```

4. If the server to which the ssh connection was made is not primary for the apic-gw-service gateway-peering object, force this server to become primary:

   ```
   config; gateway-peering-switch-primary <gateway-peering-name-for-apic-gw-service>;
   ```

5. Flush the apic-gw-service gateway-peering object:

   ```
   diag; gateway-peering-flush <gateway-peering-name-for-apic-gw-service>; exit
   ```

6. Disable and then re-enable the apic-gw-service object for every member of the gateway service:

   ```
   config; apic-gw-service; admin-state disabled; exit
   apic-gw-service; admin-state enabled; exit; exit
   ```

7. Confirm that the apic-gw-service was flushed and is now waiting for gateway service registration:
   Look in the debug log target for the apic-gw-service, located in logtemp:/// and check for a message similar to the following example:

   ```
   20200618T232339.332Z [0x88e000d7][apic-gw-service][notice]
   apic-gw-service(default): tid(2653): Waiting for gateway service registration.
   ```

   The DRR will be triggered by the next arrival of a webhook event. The Management server sends a heartbeat to the gateway at five-minute intervals, prompting the gateway to check whether it has lost its configuration and if so, trigger a DRR. In addition, if the Management server has previously marked a Catalog or cloud as being unavailable for a particular gateway service, a successful heartbeat triggers synchronization for that Catalog or cloud on that gateway service.

8. (Optional) Force a BAU webhook event to be sent from API Manager to trigger the DRR:
   If you do not want to wait for the Management server to send a heartbeat, you can trigger the DRR manually by completing the following steps:

   a. Open the API Manager.
   b. Open the Catalog.
   c. Click Settings > Edit.
   d. Update the Summary field with some text so that it is modified.
   e. Click Save.

When the event is received, the DRR is initiated.

Troubleshooting analytics on VMware

If your API Connect analytics subsystem encounters problems, see the analytics troubleshooting topics.

For problems with the analytics subsystem, see Troubleshooting analytics.

Migrating from IBM API Connect v5 Public Cloud to v10.0.6x

You cannot migrate direct to IBM® API Connect 10.0.6.0 or later from API Connect v5 Public Cloud. You must migrate to version 10.0.5.x or later, and then upgrade to 10.0.6.0 or later.

Restriction: A direct migration from API Connect v5 Public Cloud to API Connect 10.0.6.0 or later is not supported. You must migrate to 10.0.5.x as an interim step, and then upgrade to 10.0.6.0 or later if required. For information about migrating to 10.0.5.x, see Migrating from API Connect v5 Public Cloud in the IBM documentation for IBM API Connect 10.0.5.x.

Migrating a version 5 deployment to version 10.0.x

See the following note for information about migrating from API Connect 5.0.x.

Restriction: A direct migration from API Connect 5.0.x to API Connect 10.0.6.0 or later is not supported. You must migrate to 10.0.5.x as an interim step, and then upgrade to 10.0.6.0 or later if required. For information about migrating to 10.0.5.x, see Migrating a version 5 deployment in the IBM documentation for IBM® API Connect 10.0.5.x.

Migrating v5-compatible APIs to API Gateway

Use the migration utility to automate the migration of v5-compatible APIs to DataPower API Gateway APIs.

About this task

If your deployment includes v5-compatible APIs, they can only be used with the DataPower v5-compatible Gateway (also known as the v5c gateway). To use the v5-compatible APIs with the DataPower API Gateway, you must migrate the APIs to the newer format.

The migration process involves the following tasks:

1. Install and configure the required version of API Connect and migration tools.
2. Plan and test your migration to ensure all tools work as intended.
3. Use the API Connect operations tool (`apicops`) to extract API data from your v10.0.7.0 deployment.
4. Use the API Connect migration utility (AMU) to unpack the data into YML files for porting to the newer format.
5. Review the unpacked data and port the v5-compatible APIs to the format required by the DataPower API Gateway.
6. Use the AMU to load the ported APIs back into your v10.0.7.0 deployment.

- **Preparing the environment**
  Install all of the required applications before attempting to migrate v5-compatible APIs to the DataPower API Gateway.
- **Planning your API migration**
  Plan how you will migrate your v5-compatible APIs and then test the process.
- **Downloading and extracting the data to migrate**
  Use `apicops` to download data from API Connect, and then use the AMU to extract the data from the downloaded archive.
- **Converting v5-compatible API definitions**
  To convert v5-compatible APIs to the format required by the DataPower API Gateway, you must map all v5-compatible gateway services to DataPower API Gateway services, optionally specify any configuration settings to be used in the conversion, and use the AMU to port the API definitions.
- **Pushing custom policies and gateway extensions to the DataPower API Gateway**
  Use the AMU to push the Cloud Manager admin organization's data to the Management server, which pushes custom policies and gateway extensions to your DataPower API Gateway Services.
- **Pushing provider organization data**
  Use the AMU to push the provider organization data to the Management server.

Preparing the environment

Install all of the required applications before attempting to migrate v5-compatible APIs to the DataPower API Gateway.

About this task

Migrating v5-compatible APIs to the DataPower API Gateway requires the following applications:

- API Connect v10.0.7.0
- API Connect operations (`apicops`) tool, latest v10 release
- API Connect migration utility (AMU), release v10.0.7.0-Rx
- Node version 18.19.1 or later

Complete the following steps to set up your environment with the required applications:

Procedure

1. Upgrade to API Connect v10.0.7.0.
   Your API Connect deployment must be at 10.0.7.0. Refer to the upgrade instructions in the Installing and maintaining IBM API Connect section.

2. Download and configure the latest release of the `apicops` tool.
   Download the `apicops` binary for your operating system from GitHub at latest release and rename the file to apicops.

   Review the associated README for requirements and instructions for using the tool.

3. Download the migration utility v10.0.7.0-Rx.
   The API Connect migration utility (AMU) is available from IBM Fix Central. On Fix Central, set the Installed version to 10.0.7.0, and search for the text "migration" to locate the AMU.

4. Install Node version 18.19.1 or later.

What to do next

After you have installed the required applications for your environment, complete the following tasks to migrate your v5c-compatible APIs.

Planning your API migration

Plan how you will migrate your v5-compatible APIs and then test the process.

About this task

Plan the migration process, migrate a small set of APIs, and then test the results. You can refine settings and repeat the process as needed.

Procedure

1. Review all of the migration topics to ensure you understand the requirements, the general process, and important considerations.
2. Plan how you will migrate your v5-compatible APIs to the DataPower Gateway.
   Make sure you know exactly which APIs you want to migrate, and in which provider organizations and catalogs they are stored.
3. Migrate a proof-of-concept deployment.
   Migrate 10 to 20 of your most commonly used v5-compatible APIs to ensure that your migration tools are configured correctly and the migration process works as intended. Plan to run several test iterations of migration.

   You can use the migration utility's **`--dry-run`** option to perform iterations of the migration push without actually uploading data to API Connect. The test runs offer an opportunity to test for errors and warnings that need to be resolved before you perform the actual data push.

   You can use the migration utility's **`--move-subscriptions`** parameter to move subscriptions during the push operation that uploads converted data back into API Connect.
4. Test the APIs that you migrated as proof-of-concept.
   Testing the migrated APIs helps you to determine which migration utility settings you need for successfully converting the v5-compatible APIs to DataPower API Gateway. If needed, you can move or delete the results, modify the configuration settings, and run the migration again. When you rerun the migration **`port`** command using the same target folder for output, the utility skips artifacts that have already been converted to DataPower API Gateway.

Downloading and extracting the data to migrate

Use **`apicops`** to download data from API Connect, and then use the AMU to extract the data from the downloaded archive.

Procedure

1. Use **`apicops`** to extract and download data from API Connect as a .pgdmp archive file.
   Run the following command:

   `apicops postgres:pg_dump -e <archive_name>.pgdmp`

   where **`<archive_name>.pgdmp`** is a name that you create for the archive file that will contain the downloaded data; for example, v10_backup.pgdmp.
2. Copy the .pgdmp archive file to the location where you installed the AMU, storing it in the same directory as the AMU.
3. Use the AMU to unpack the archive stored in the .pgdmp archive file.
   Run the following command in the same directory where you stored the downloaded .pgdmp archive file (see Table 1 for available the parameters):

   On Windows: open a command window with Administrator privileges, and omit the "./" from the command.

   `./apicm archive:unpack-v10 <archive_name>.pgdmp`

   The first time you use the AMU, you are prompted to accept the license. You must accept the license to continue.

   Table 1. AMU **`archive:unpack-v10`** parameters

Parameter	Description
<archive_name>.pgdmp	Required. The .pgdmp archive file created containing the data downloaded from API Connect.
`--provider-orgs`	Optional. A comma-separated list containing one or more provider organization names. Use this parameter to unpack only the data for the specified provider organizations instead of unpacking the entire archive. Example: **`./apicm archive:unpack-v10 <archive_name>.pgdmp --provider-orgs=<pOrg1_name>,<pOrg2_name>,<pOrg3_name>`**

   When the command completes, the data is unpacked to the /cloud-v10 directory, which is located in the same directory as the AMU, and is populated with YAML files representing the configuration objects in the .pgdmp file.

   Important: The unpack directory must be named /cloud-v10. Do not rename the directory.

Converting v5-compatible API definitions

To convert v5-compatible APIs to the format required by the DataPower API Gateway, you must map all v5-compatible gateway services to DataPower API Gateway services, optionally specify any configuration settings to be used in the conversion, and use the AMU to port the API definitions.

Procedure

1. Map your v5-compatible Gateway Services to DataPower API Gateway services.
   You must map your v5-compatible Gateway Services (the v5c gateway) to DataPower API Gateway services so that the AMU command has a target for migrating custom policies and gateway extensions, and can migrate the configured gateway services for each catalog and space.

   a. In the unpacked data, locate the gateway services.
      Each of the gateway services in stored in cloud-v10/admin-org/availability-zones/*<az_name>*/gateway-services/.

   b. For each v5-compatible gateway service, create a mapping.yml file that contains the name of the DataPower API Gateway Service you want to map to.
      Create the mapping.yml file directly in the directory containing the v5-compatible gateway service. The file must contain 3 statements:
      - The artifact type, which is always **`gateway-service:`**

- The name of the DataPower API Gateway service (not the Title or ID)
- The gateway type for that gateway service, which is always **datapower-api-gateway** for converting to DataPower API Gateway service

For example, the following mapping.yml file maps the v5-compatible gateway service to the DataPower API Gateway service named "gateway-10-1" and specifies a target gateway of type **datapower-api-gateway**:

```
gateway-service:
  name: gateway-10-1
  gateway-type: datapower-api-gateway
```

If you have several v5-compatible gateway services and you want to map each of them to the same DataPower API Gateway service, copy the mapping.yml file into the directory for each of those v5-compatible gateway services.

Make sure to map all of the v5-compatible gateway services to DataPower API Gateway services before attempting to port the APIs in the next step.

2. Optional: Create a configuration file that defines settings for migrating the v5-compatible APIs.
In the directory where the AMU is stored, create a file called **config.yml** and use it to specify configuration settings (see Table 1 for the configuration settings).

Example **config.yml** file:

```
custom-policies-scope: global
emulate-v4-plan-rate-limit: false
deploy-policies:
  - proxy_1.5.0
  - redact_1.5.0
  - invoke_1.5.0
  - xslt_2.0.0
  - gatewayscript_1.0.0
  - switch_2.0.0
rewrite-apis:
  enable-api-logging: false
  proxy-policy: proxy_1.5.0
  redact-policy: redact_1.5.0
  invoke-policy: invoke_1.5.0
  xslt-policy: xslt_2.0.0
  gatewayscript-policy: gatewayscript_1.0.0
  if-policy: switch_2.0.0
  switch-policy: switch_2.0.0
  optimize-gws: false
  no-retitle: true
```

If you omit the config.yml file, you can optionally specify configuration settings as parameters on the command line when you port the APIs in the next step.

Table 1. Migration configuration settings

Parameter	Valid values	DataPower version required	Description
activity-log-policy	**activity-log_1.5.0, set-variable_2.0.0**	DP 10.0.4.0+	Defines how to process the v5 activity-log policy when the migration utility rewrites the API assembly. The default value is **activity-log_1.5.0**, which changes the activity-log version to 1.5.0. When set to **set-variable_2.0.0**, the migration utility sets context variables based upon the value of the activity-log content and error-content configuration values.
chunked-uploads	**true / false** The default value is **false**.	For **invoke_1.5.0**: 10.0.1.1+, 10.0.2.0+ For **invoke_2.0.0**: 10.0.0.0+	If an **invoke_1.5.0** or **proxy_1.5.0** policy exists in an assembly in the API, then set **chunked-uploads** to **true** to enable chunked encoding for HTTP 1.1 requests to the target server. If an **invoke_2.0.0** policy exists in an assembly after the migration, then set **chunked-uploads** to **false** explicitly for the policy, as the default value for **chunked-uploads** in API Gateway is **true**.
client-id-header-override	String. The string cannot contain spaces. Follow the guidelines for **apiKey name:**. No default value.	10.0.0.0+	Override the existing **X-IBM-Client_Id** name value with the new value. In API Gateway, **x-key-type** makes it possible to define custom naming for **client_id** and **client_secret**. Example: **--client-id-header-override="acme-foo"** In this example, the **securityDefinitions** property is changed from: **foo:** **type: apiKey** **name: X-IBM-Client-Id** **in: header** to the following: **foo:** **type: apiKey** **name: acme-foo** **in: header** **x-key-type: client_id** Calls to this API must supply **acme-foo: <client-id>** in the request header instead of the original **X-IBM-Client-Id: <client-id>**.

Parameter	Valid values	DataPower version required	Description
client-id-query-override	String. The string cannot contain spaces. Follow the guidelines for **apiKey name:**. No default value.	10.0.0.0+	Override the existing **client_id** name value with the new value. In API Gateway, **x-key-type** makes it possible to define custom naming for **client_id** and **client_secret**. Example: **--client-id-query-override="acme-foo"** In this example, the **securityDefinitions** property is changed from: **foo:** **type: apiKey** **name: client_id** **in: query** to the following: **foo:** **type: apiKey** **name: acme-foo** **in: query** **x-key-type: client_id** Calls to this API must supply **?acme-foo=<client-id>** in the query parameter instead of the original **?client_id=<client-id>**.
client-secret-header-override	String. The string cannot contain spaces. Follow the guidelines for **apiKey name:**. No default value.	10.0.0.0+	Override the existing **X-IBM-Client-Secret** name value with the new value. In API Gateway, **x-key-type** makes it possible to define custom naming for **client_id** and **client_secret**. Example: **--client-secret-header-override="acme-foo"** In this example, the **securityDefinitions** property is changed from: **foo:** **type: apiKey** **name: X-IBM-Client-Secret** **in: header** to the following: **foo:** **type: apiKey** **name: acme-foo** **in: header** **x-key-type: client_secret** Calls to this API must supply **acme-foo: <client-secret>** in the request header instead of the original **X-IBM-Client-Secret: <client-secret>**.
client-secret-query-override	String. The string cannot contain spaces. Follow the guidelines for **apiKey name:**. No default value.	10.0.0.0+	Override the existing **client_secret** name value with the new value. In API Gateway, **x-key-type** makes it possible to define custom naming for **client_id** and **client_secret**. Example: **--client-secret-query-override="acme-foo"** In this example, the **securityDefinitions** property is changed from: **foo:** **type: apiKey** **name: client_secret** **in: query** to the following: **foo:** **type: apiKey** **name: acme-foo** **in: query** **x-key-type: client_secret** Calls to this API must supply **?acme-foo=<client-secret>** in the query parameter instead of the original **?client_secret=<client-secret>**.
copy-id-headers-to-message	**true / false** The default value is **false**.	10.0.1.1+, 10.0.2.0+	When set to **true**, the **client-id** header is copied from **request.headers** to **message.headers** to be passed to the backend server. Set this parameter to **true** if your invoke backend services expect the **client-id** to be passed through.

Parameter	Valid values	DataPower version required	Description
custom-policies-scope	**catalog / global** The default value is **catalog**.	10.0.0.0+	When set to **catalog**, the original v5 or v5-compatible catalog that contains the custom policy is staged for pushing to the target catalog and organization in API Gateway. When set to **global**, the custom policy is staged for pushing to API Gateway and is visible to all organizations and catalogs within that gateway. **archive:port-to-apigw-v10** sets up the custom policies for pushing to API Gateway, but does not do the pushing. If **global** scope is used, **archive:push-v10** of the admin organization will push all custom policies associated with the configured gateways. If **catalog** scope is used, then the **archive:push-v10** of the admin organization will initialize the custom policies on the gateway. A subsequent **archive:push-v10** of the provider organization is needed to advertise the custom policies in the catalogs contained within the provider organization. Note: Potential conflicts between custom policies of the same name and version are resolved according to the following rules: • When set to **global** and two policies under the same gateway service have the same name, version, and md5 hash value, then the duplicates are discarded and a message is generated. • When set to **global** and two policies under the same gateway service have the same name, version, and a differing md5 hash value, then global scope cannot be applied. Catalog scope is used and a warning is generated. • When set to **catalog**, **<orgname>_<catname>_** is appended to the zip filename to maintain uniqueness.
deploy-policies	Any combination of the following values: **gatewayscript_1.0.0**,**if_1.5.0**, **invoke_1.5.0**, **proxy_1.5.0**,**redact_1.5.0**, **switch_1.5.0**, **validate-usernametoken_1.0.0**, **xslt_1.0.0** The default values are: **if_1.5.0**, **invoke_1.5.0**, **proxy_1.5.0**, **redact_1.5.0**, **switch_1.5.0**, **validate-usernametoken_1.0.0**, **xslt_1.0.0**	For **invoke_1.5.0**, **proxy_1.5.0**, **gatewayscript_1.0.0**, and **xslt_1.0.0**: 10.0.0.0+ For **if_1.5.0** and **switch_1.5.0**: 10.0.1.1+, 10.0.2.0+ For **redact_1.5.0**: 10.0.3.0+ For **validate-usernametoken_1.0.0**: 10.0.1.3+, 10.0.2.0+	Defines which backwards-compatible policies should be advertised by DataPower to API Manager. Note: Any legacy policies that are specified in the **config.yml** file or by using the **apicm** command must also be specified by using **deploy-policies**. If these policies are not specified by using **deploy-policies**, an error is returned.
emulate-v4-plan-rate-limit	**true / false** The default value is **false**.	10.0.1.2+, 10.0.2.0+	Determines whether all APIs emulate the v4 plan rate limit. If set to **true**, then API operations do not share the rate limit. This setting matches the behavior of the **x-ibm-gateway-emulate-v4-plan-rate-limit** v5 option.
enable-api-logging	**true / false** The default value is **true**.	10.0.0.0+	Log all changes that the migration utility makes when rewriting APIs. These changes are logged as comments in the API YAML file.
enforce-required-params	**true / false** The default value is **false**.	10.0.1.1+, 10.0.2.0+	When set to **true**, required parameters are enforced, which is the default behavior in API Gateway. When set to **false**, required parameters are not enforced, even if the required parameter checkbox selected.
gatewayscript-policy	One of the following values: **gatewayscript_1.0.0**, **gatewayscript_2.0.0** The default value is **gatewayscript_2.0.0**.	10.0.0.0+	Defines which gatewayScript policy the migration utility uses when rewriting the API assembly. **gatewayscript_1.0.0**: A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use **gatewayscript_1.0.0** if the gatewayScript policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings. **gatewayscript_2.0.0**: The migration utility rewrites the existing API to gatewayScript 2.0.0. This policy supports the **header-metadata** module for compatibility with the v5-compatible gateway. Specifying **gatewayscript_2.0.0** can cause migration errors or run-time errors. Use **gatewayscript_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
if-policy	One of the following values: **if_1.5.0**, **switch_2.0.0** The default value is **if_1.5.0**.	For **if_1.5.0**: 10.0.1.1+, 10.0.2.0+ For **switch_2.0.0**: 10.0.0.0+	Defines which **if** policy the migration utility uses when rewriting the API assembly. **if_1.5.0**: The migration utility rewrites the existing API to if 1.5.0. **switch_2.0.0**: The migration utility rewrites the existing API to switch 2.0.0. Specifying **switch_2.0.0** can cause migration errors or run-time errors. Use **switch_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.

Parameter	Valid values	DataPower version required	Description
invoke-policy	One of the following values: **invoke_1.5.0**, **invoke_2.0.0** The default value is **invoke_1.5.0**.	10.0.0.0+	Defines which invoke policy the migration utility uses when rewriting the API assembly. **invoke_1.5.0**: The migration utility rewrites the existing API to invoke 1.5.0. **invoke_2.0.0**: The migration utility rewrites the existing API to invoke 2.0.0. Specifying **invoke_2.0.0** can cause migration errors or run-time errors. Use **invoke_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
no-retitle	**true / false** The default value is **false**.	10.0.0.0+	Defines whether to append the porting suffix to the **title** of the migrated API, product, or OAuth provider. Set this option to **true** if you want the **title** of the migrated API, product, or OAuth provider to match the original **title** in the v5-compatible YAML file.
optimize-gws	**true / false** The default value is **false**.	10.0.0.0+	When set to **true**, gatewayScript policies are modified to map v5 functions to API Gateway functions. Setting **optimize-gws** to **true** is valid only for the **gatewayscript_2.0.0** policy. If it is set to **true** for gatewayscript_1.0.0, an error is generated. Note: Setting **optimize-gws** to **true** can result in performance enhancements. However, the modifications to gatewayScript policies by the migration utility can cause problems. When using this setting, review all gatewayScript policy modifications after migration.
porting-suffix	A string containing alphanumeric, dash, underscore and dot characters. The default value is **-apigw**.	10.0.0.0+	Defines the suffix to be used when renaming APIs, Products, OAuth Providers, and other ported artifacts. The suffix is appended to the version on APIs, Products and other ported artifacts that have versions, and onto the name for OAuth Providers and other ported artifacts that do not have versions. If **porting-suffix** is not specified then a value of **-apigw** will be used. The porting suffix can contain alphanumeric, dash, underscore and dot characters. Prior to AMU 10.0.5.4 the porting suffix could not be overridden and **-apigw** was appended to the name for all ported artifacts.
proxy-policy	One of the following values: **proxy_1.5.0**, **invoke_2.0.0** The default value is **proxy_1.5.0**.	10.0.0.0+	Defines which proxy policy the migration utility uses when rewriting the API assembly. **proxy_1.5.0**: The migration utility rewrites the existing API to **proxy 1.5.0**. **invoke_2.0.0**: The migration utility converts the proxy policy to invoke 2.0.0. Specifying **invoke_2.0.0** can cause migration errors or run-time errors. Use **invoke_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
redact-policy	One of the following values: **redact_1.5.0**, **redact_2.0.0** The default value is **redact_1.5.0**.	10.0.3.0+	Defines which redact policy the migration utility uses when rewriting the API assembly. **redact_1.5.0**: The migration utility rewrites the existing API to **redact 1.5.0**. **redact_2.0.0**: The migration utility rewrites the existing API to **redact 2.0.0**. Specifying **redact_2.0.0** can cause migration errors or run-time errors, including changes to what is redacted, particularly with redactions meant for JSON payloads. Use **redact_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
repair-wsdl-apis	**true / false** The default value is **true**.	10.0.1.1+, 10.0.2.0+	If an API ported from V5 is created from WSDL, the WSDL is read and checked for accuracy. If **repair-wsdl-apis** is set to **true**, then the API and WSDL are automatically repaired. For example, if the WSDL ZIP file contains unnecessary files, they are automatically removed if **repair-wsdl-apis** is **true**.
return-v5-responses	**true / false** The default value is **false**.	10.0.1.1+, 10.0.2.0+	When set to **true**, OAuth-related messages are printed in the v5 response format. When set to **false**, OAuth-related response messages are printed in API Gateway response format.
switch-policy	**switch_1.5.0**, **switch_2.0.0** The default value is **switch_1.5.0**.	For **switch_1.5.0**: 10.0.1.1+, 10.0.2.0+ For **switch_2.0.0**: 10.0.0.0+	Defines which switch policy the migration utility uses when rewriting the API assembly. **switch_1.5.0**: The migration utility rewrites the existing API to switch 1.5.0. **switch_2.0.0**: The migration utility rewrites the existing API to switch 2.0.0. Specifying **switch_2.0.0** can cause migration errors or run-time errors. Use **switch_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
use-config-file	**true / false** The default value is **false**.	10.0.0.0+	Use the **config.yml** file that is in the same directory as the **apicm** binary file that is being executed. If this file is used, configuration options cannot be set using the command line. The purpose of the config file is to specify the command inputs given on this page, but in an easy-to-read file format (YAML).
v5-request-headers	**true / false** The default value is **true**.	10.0.1.2+, 10.0.2.0+	When set to **true**, the following v5-compatible request headers are set: **Via**, **X-Global-Transaction-ID**, **X-Client-IP**. When set to **false**, these request headers are not set.
validate-usernametoken-policy	**validate-usernametoken_1.0.0** The default value is empty.	10.0.1.3+, 10.0.2.0+	Defines whether or not to use the **validate-usernametoken** v5 emulation policy when the migration utility rewrites the API assembly. When empty, the migration utility takes no action on the policy.
xslt-policy	One of the following values: **xslt_1.0.0**, **xslt_2.0.0** The default value is **xslt_1.0.0**.	10.0.0.0+	Defines which gatewayscript policy the migration utility uses when rewriting the API assembly. **xslt_1.0.0**: A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use **xslt_1.0.0** if the xslt policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings. **xslt_2.0.0**: The migration utility rewrites the existing API to xslt 2.0.0. Specifying **xslt_2.0.0** can cause migration errors or run-time errors. Use **xslt_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.

3. Use the AMU **port** command to convert the v5-compatible APIs to the DataPower API Gateway format.

When you run the **port** command with the AMU, there are 3 options for specifying configuration settings for your APIs:

- Store the settings in the config.yml migration configuration file.
  You must name the configuration file config.yml. Specify the **--use-config-file=true** parameter on the command line when you port the APIs.
- Include the configuration settings on the command line (see Table 2 for the configuration settings).
  Specify the settings as parameters on the command line. If you also specify a configuration file, any configuration settings specified as parameters directly on the command line are ignored.
- Accept the default configuration settings.
  If you don't specify a configuration file and also don't specify any configuration parameters on the command line, the AMU uses the default configuration when porting the APIs.

To port the APIs, run the following command:

On Windows: open a command window with Administrator privileges, and omit the "./" from the command.

```
./apicm archive:port-to-apigw-v10 <path_to_APIs> --enable-api-logging=false --use-config-file=true
```

where **<path_to_APIs>** represents one of the following locations:

- The top-level /cloud-v10 directory containing all of the extracted archive:
  The AMU ports all artifacts within the directory, including APIs, Products, OAuth providers, and custom policies. Running a subsequent **archive:push-v10** command pushes all of the converted artifacts to the DataPower API Gateway. Custom policies and OAuth providers are not migrated if a directory other than /cloud-v10 is specified.
  Attention: Running the **port** command on any subdirectory within the unpacked /cloud-v10 directory could leave the directory in an inconsistent state, and cause the subsequent **archive:push-v10** command to fail.
- A single API file, or a directory that contains only APIs or Products:
  When you are testing your migration settings, you might want to convert just a few APIs or Products to verify the settings. When you use this approach, you cannot use the high-level **archive:push-v10** command to push the artifacts to the DataPower API Gateway. Instead, you must push the ported artifacts into API Manager using either the toolkit or the user interface.

  When testing is complete, you can delete the artifacts from testing and run the **port** command on the top-level /cloud-v10 directory to convert all of the artifacts in one operation, and then use the **archive:push-v10** command to push them all to the DataPower API Gateway in a second operation.

Table 2. Parameters for the **port** command

Parameter	Description
--enable-api-logging=false	Optional. Disable logging. By default, logging is enabled for the conversion and all changes that the migration utility makes when rewriting APIs are logged as comments within the API's YAML file.
--use-config-file=true	Optional. When converting APIs, apply the configuration settings specified in the config.yml file that is stored in the same directory as the AMU.
Parameters from Table 1, Migration configuration settings.	Optional. Follow the format shown in Table 1, and prefix each parameter with the -- symbol and leave a blank space before the next parameter as shown in the example command.

4. Review the ported artifacts.
   The API conversion process annotates the YAML file and logs with information regarding the artifacts that it attempts to convert. For cases where additional information is available or further action is required, the YAML input file and logs contain links to documentation.

   Review the entire draft output YAML file for conformance, performance, and errors. Review the log files for messages about any manual actions that might be needed. For more information, see Reviewing APIs converted to DataPower API Gateway. By default, all changes that the migration utility makes when rewriting APIs are logged as common.

   Because of differences between the programming models of v5-compatible APIs and DataPower API Gateway APIs, the command might not be able to convert all items; you might need to manually convert the failed items. In these cases, messages generated by the **apicm archive:port-to-apigw-v10** command provide links to documentation that provides more details about changes you must make for the items to be compatible with DataPower API Gateway.

Pushing custom policies and gateway extensions to the DataPower API Gateway

Use the AMU to push the Cloud Manager admin organization's data to the Management server, which pushes custom policies and gateway extensions to your DataPower API Gateway Services.

About this task

Custom policies and gateway extensions are stored with the Cloud Manager admin organization data. To push the converted artifacts to the DataPower API Gateway Services, you push the Cloud Manager admin organization to the Management server.

Procedure

1. Log in to the Cloud Manager on the destination v10 Management Server as an Owner of the admin organization.
   Important: You must be logged in as an Owner of the admin organization to be able to migrate Cloud Manager admin organization data.
   On Windows: open a command window with Administrator privileges, and omit the "./" from the command.

   See Table 1 for the login parameters.

   Syntax:

   ```
   ./apicm login --server <cloud_manager_endpoint> --realm admin/<identity_provider> --username admin --password
   admin_password
   ```

Example for standalone deployment:

```
./apicm login --server cloud-admin-ui.mgmt.dev.apic10-stack.example.test --realm admin/default-idp-1 --username admin --password 'myadminpassword'
```

Example for Cloud Pak for Integration:

```
./apicm login --server cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod --realm admin/default-idp-1 --username admin --password 'myadminpassword'
```

Table 1. `login` parameters for the Cloud Admin organization

Parameter	Description

`--server <cloud_manager_endpoint>`	Required. The endpoint on the Management server for communication with the Cloud Manager user interface.
	
	Standalone deployment
	Example:
	`cloud-admin-ui.mgmt.dev.apic10-stack.example.test`
	
	The endpoint was specified when the management subsystem was installed. View the `apiconnect_api` definition in the `apiconnect-up.yml` file in the API Connect v10 installation project directory that you created for initial deployment of v10. Examples:
	• VMware: see the `cloud-admin-ui` endpoint in Deployment overview for endpoints.
	• Kubernetes: see the `admin` endpoint in Deployment overview for endpoints and certificates.
	Cloud Pak for Integration
	Syntax:
	`cpd-<APIC_namespace>.<your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance>`
	
	Example:
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`
	
	where `e2e` is *<APIC_namespace>* and `prod` is *<APIC_instance>*.
	
	Note: How to obtain the server URL on Cloud Pak for Integration
	Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using `oc get routes` because Zen modifies the route internally.
	a. Locate the Platform UI panel with entries for the deployment. Identify the row that has a `Type` column entry with the description `API management administration`.
	b. To display the endpoint, hover over the corresponding **prod** entry in the `Name` column for that row. The URL displays at the bottom of the panel. .
	`Name Type`
	`prod API management administration`
	`prod API management`
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/admin`
	c. Remove the trailing `/admin` from the endpoint:
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`

`--realm admin/default-idp-1`	Required. The `apicm login` example shows the expected `--realm` parameter values for a default API Connection administration organization. The default user is `admin` and the identity provider is `default-idp-1`.
	You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):`apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm`For example:
	`apic identity-providers:list --scope admin --server myserver.com --fields title,realm`
	`total_results: 2`
	`results:`
	`- title: Cloud Manager User Registry`
	`realm: admin/default-idp-1`
	`- title: Corporate LDAP user registry`
	`realm: admin/corporate-ldap`
	
	The `title` value indicates which identity provider to use; copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.

`--username admin`	Required. Administrative user with permissions to modify API Connect admin-org. The default user is `admin`.
`--password myadminpassword`	Required. Administrative user's password. Cloud Pak for Integration: When you installed with the top-level CR for CP4I, the password was auto-generated. To obtain the password, see step 5 in Installing API Connect:

2. Push the ported custom policies and gateway extensions to your DataPower API Gateway services.
In the same directory where you ran the `archive:unpack-v10` command, run the following command to push the ported custom policies and gateway extensions to your DataPower API Gateway services in the Cloud Manager administrative org (admin-org).

See the parameters in Table 2 as well as the usage notes that follow the table:

```
./apicm archive:push-v10 <cloud_manager_endpoint> <path_to_admin_org> [optional flags]
```

Example for standalone deployment (optional flags omitted):

```
./apicm archive:push-v10 cloud-admin-ui.mgmt.dev.apic10-stack.example.test cloud-v10/admin-org
```

Example for Cloud Pak for Integration (optional flags omitted):

```
./apicm archive:push-v10 cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod cloud-v10/admin-org
```

Note: If you observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See Migration troubleshooting .

Table 2. Parameters for the `archive:push-v10` command

Parameter	Description
<cloud_manager_endpoint>	Required. The endpoint on the Management server for communication with the Cloud Manager user interface. Standalone deployment Example: **`cloud-admin-ui.mgmt.dev.apic10-stack.example.test`** The endpoint was specified when the management subsystem was installed. View the **`apiconnect_api`** definition in the **`apiconnect-up.yml`** file in the API Connect v10 installation project directory that you created for initial deployment of v10. Examples: • VMware: see the **`cloud-admin-ui`** endpoint in Deployment overview for endpoints. • Kubernetes: see the **`admin`** endpoint in Deployment overview for endpoints and certificates. Cloud Pak for Integration Syntax: ***<cpd-APIC_namespace.your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance>*** Example: **`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`** where **`e2e`** is *<APIC_namespace>* and **`prod`** is *<APIC_instance>*. Note: How to obtain the server parameter on Cloud Pak for Integration Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using **`oc get routes`** because Zen modifies the route internally. a. Locate the Platform UI panel with entries for the deployment. Identify the row that has a Type column entry with the description **`API management administration`** b. To display the endpoint, hover over the entry in the Name column for that row. For example, hover over the **prod** entry, as shown in bold font, and the URL displays at the bottom of the panel. **`Name Type`** **`prod API management administration`** **`prod API management`** **`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/admin`** c. Remove the trailing **`/admin`** from the endpoint: **`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`**
<path_to_admin_org>	Required, the only supported value is cloud-v10/admin-org.
`--dry-run`	Optional. Perform a dry run to test the Admin org migration output. This option creates a project directory similar to cloud-v10, but named .workdir-*<apim_admin_server>*, where you can view how the data will be loaded into your new system. This option also displays the objects that will fail due to pre-existing or missing dependencies. For more information, see the 10.0.5.x Migration Troubleshooting section on apicm command line help.

Usage notes:

- On Windows: open a command window with Administrator privileges, and omit the "./" from the command.
- Run the **`archive:push-v10`** command in the same directory where you ran the **`archive:unpack-v10`** command, and always push the ported data back to the same v10 deployment where you extracted the data.
- The **`login`** command obtains a token that expires after eight hours.
  If the token expires while the **`archive:push-v10`** command is running, the AMU generates errors. In this case, log in again and re-run the **`push`** command. The token is refreshed every time you log in. For more information, see Token expiration .
- An alternative method of viewing endpoints is to run the **`kubectl get ingress`** and get the values from the output. For example, see the values in **bold** in the following sample output:

```
r7c221d8a33-apic-portal-director api.portal.dev.apic10-stack.example.test 80, 443 21h

```

Pushing provider organization data

Use the AMU to push the provider organization data to the Management server.

About this task

Pushing the provider organization data uploads the ported OAuth Providers, draft APIs, draft products, configured gateway services, and published products to the Management server.

Procedure

1. Log in to the API Manager user interface as an Owner or Administrator of the provider organization that you want to migrate.
   If you want to login using an OIDC user registry, see Logging in to a management server with an OIDC registry.

   Important: You cannot migrate a provider organization while you are logged in with the Cloud Manager admin organization. You must be logged in as the Owner or Administrator of the provider organization whose data you will push.
   Syntax:

   ```
   ./apicm login --server <api-manager-ui-endpoint> --realm provider/<identity_provider> --username <org_username> --password <org_password>
   ```

   Example for a standalone deployment:

   ```
   ./apicm login --server api-manager-ui.dev.apic10-stack.example.test --realm provider/default-idp-2 --username org_username@example.com --password myorgpassword
   ```

   Example for Cloud Pak for Integration:

   ```
   ./apicm login --server cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod --realm provider/default-idp-2 --username org_username@ex
   ```

   Table 1. `login` parameters for Provider organizations

Parameters	Description

<api-manager-ui-endpoint>	Required. The API Manager URL endpoint on the Management server for communication with the API Manager user interface.
	
	Standalone deployment
	Example:
	`api-manager-ui.dev.apic10-stack.example.test`
	The endpoint was specified when the Management subsystem was installed. To verify your endpoint setting, do one of the following:
	• View the `apiconnect-apim-ui` definition in the `apiconnect-up.yml` file in the API Connect installation project directory.
	• In the Cloud Manager UI, select Settings > Endpoints and view API Manager URL.
	Cloud Pak for Integration
	Syntax:
	`cpd-<APIC_namespace>.<your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance>`
	Example:
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`
	where `e2e` is *<APIC_namespace>* and `prod` is *<APIC_instance>*.
	Note: How to obtain the server URL on Cloud Pak for Integration
	Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using `oc get routes` because Zen modifies the route internally.
	a. Locate the Platform UI panel with entries for the deployment. Identify the row that has a `Type` column entry with the description `API management`
	b. To display the endpoint, hover over the corresponding **prod** entry in the `Name` column for that row. The URL displays at the bottom of the panel.
	`Name Type`
	`prod API management administration`
	`prod API management`
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/manage`
	c. Remove the trailing `/manage` from the endpoint:
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`

Parameters	Description

`--realm provider/identity_provider`	Required.
	The default `identity_provider` is `default-idp-2`.You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):
	
	`apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm`
	
	For example,
	
	`apic identity-providers:list --scope provider --server myserver.com --fields title,realm`
	`total_results: 2`
	`results:`
	`- title: Cloud Manager User Registry`
	`realm: provider/default-idp-2`
	`- title: Corporate LDAP user registry`
	`realm: provider/corporate-ldap`
	
	The `title` value indicates which identity provider to use; copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`
	.

`--username <org_username>`	Required. A user with permissions to modify the provider organization; typically this is the owner or administrator of the organization.
`--password <org_password>`	Required. The organization owner or administrator password.

2. Push the data for the provider organization.
   In the same directory where you ran the `archive:unpack-v10` command, run the following command to push the ported data to your API Manager. See the parameters in Table 2 as well as the usage notes that follow the table.

   Syntax:

   `./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> [optional flags]`

   Example for standalone deployment (optional flags are omitted):

   ```
   ./apicm archive:push-v10 api-manager-ui.mgmt.dev.apic10-stack.example.test cloud-v10/provider-orgs/production_Org
   ```

   Example for Cloud Pak for Integration (optional flags are omitted):

   ```
   ./apicm archive:push-v10 cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod cloud-v10/provider-
   orgs/production_Org
   ```

Table 2. `archive:push-v10` parameters for provider organizations

Parameters	Description

Parameters	Description
<*api-manager-ui-endpoint*>	Required. The API Manager URL endpoint on the Management server for communication with the API Manager user interface. Standalone deployment Example: **api-manager-ui.dev.apic10-stack.example.test** The endpoint was specified when the Management subsystem was installed. To verify your endpoint setting, do one of the following: • View the **apiconnect-apim-ui** definition in the **apiconnect-up.yml** file in the API Connect installation project directory. • In the Cloud Manager UI, select Settings > Endpoints and view API Manager URL. Cloud Pak for Integration Syntax: **cpd-<*APIC_namespace*>.<*your-company.domain.com*>/integration/apis/<*APIC_namespace*>/<*APIC_instance*>** Example: **cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod** where **e2e** is **<*APIC_namespace*>** and **prod** is **<*APIC_instance*>**. Note: How to obtain the server URL on Cloud Pak for Integration Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using **oc get routes** because Zen modifies the route internally. a. Locate the Platform UI panel with entries for the deployment. Identify the row that has a **Type** column entry with the description **API management** b. To display the endpoint, hover over the corresponding **prod** entry in the **Name** column for that row. The URL displays at the bottom of the panel. **Name Type** **prod API management administration** **prod API management** **cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/manage** c. Remove the trailing **/manage** from the endpoint: **cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod**
cloud-v10/provider-orgs/<*pOrg_name*>	Required. The location of your provider org within the **/cloud-v10** file hierarchy you created when you ran unpacked the data archive; for example: **cloud-v10/provider-orgs/production_Org**
--catalogs=<*list_of_names*>	Optional. Push data for only the specified catalogs if you don't want to push the entire provider organization. Use this parameter to specify the names of the catalogs you want to push (to specify multiple catalogs, use a comma-separated list): **./apicm archive:push-v10 <*api-manager-ui-endpoint*> cloud-v10/provider-orgs/<*pOrg_name*> --catalogs=<*catalog_name1,catalog_name2,catalog_name3*>**
--spaces=<*list_of_names*>	Optional. Push data for only the specified spaces if you don't want to push the entire provider organization. The **--catalogs** parameter must also be specified, and exactly one catalog must be specified. Use this parameter to specify the names of the spaces you want to push (to specify multiple spaces, use a comma-separated list). For example: **./apicm archive:push-v10 <*api-manager-ui-endpoint*> cloud-v10/provider-orgs/<*pOrg_name*> --catalogs=<*catalog_name*> --spaces=<*space_name1*>,<*space_name2*>,<*space_name3*>**
--products=<*list_of_name:version_pairs*>	Optional. Push data for only the specified products if you don't want to push the entire provider organization. The **--catalogs** parameter must also be specified, and exactly one catalog must be specified. If spaces are enabled on the catalog, then the **--spaces** parameter must also be specified, and exactly one space must be specified. Use this parameter to specify the names and versions of the products that you want to push (to specify multiple products, use a comma-separated list of name:version pairs as shown in the following examples. Example: catalog with spaces **./apicm archive:push-v10 <*api-manager-ui-endpoint*> cloud-v10/provider-orgs/<*pOrg_name*> --catalogs=<*catalog_name*> --spaces=<*space_name*> --products=<*prod_name1*>:<*prod_version1*>,<*prod_name2*>:<*prod_version2*>,<*prod_name3*>:<*prod_version3*>** Example: catalog without spaces: **./apicm archive:push-v10 <*api-manager-ui-endpoint*> cloud-v10/provider-orgs/<*pOrg_name*> --catalogs=<*catalog_name*> --products=<*prod_name1*>:<*prod_version1*>,<*prod_name2*>:<*prod_version2*>,<*prod_name3*>:<*prod_version3*>**
--dry-run	Optional. Perform a dry run to test the Admin org migration output. This option creates a project directory similar to **cloud-v10**, but titled **.workdir-<*api-manager-ui-endpoint*>** where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See Migration troubleshooting. **./apicm archive:push-v10 <*api-manager-ui-endpoint*> cloud-v10/provider-orgs/<*pOrg_name*> --dry-run**

Parameters	Description
`--no-drafts`	Optional. Do not push any draft APIs or products (draft objects are objects that have not been published). `./apicm archive:push-v10 <api-manager-ui-endpoint> <path_to_provider_org> --no-drafts` This option can be used with or without the **--catalogs** parameter.
`--drafts-only`	Optional. Only push ported draft APIs and products, and do not push any published APIs or products (draft objects are objects that have not been published). `./apicm archive:push-v10 <api-manager-ui-endpoint> <path_to_provider_org> --drafts-only` This option cannot be used with the **--catalogs** or **--no-drafts** parameters.
`--overwrite`	Optional. Overwrite any existing draft products, draft APIs, published products and their APIs, and OAuth Providers that are already on the deployment. If you set this parameter to false, these artifacts will be left intact.
`--move-subscriptions`	Optional. When this option is used, the subscriptions associated with v5-compatible-API-based products that were ported to API DataPower Gateway-based products and successfully pushed to the API Connect deployment will have their subscriptions moved to the new products, and the original v5-compatible-API-based products will be retired. This option can also be used on subsequent **archive:push-v10** commands to move the subscriptions even after the migrated products are published. Using the **--catalogs**, **--spaces**, and **--products** parameters with the **--move-subscriptions** parameters lets you narrow the set of products to have their subscriptions moved.

Usage notes:

- On Windows: open a command window with Administrator privileges, and omit the "./" from the command.
- Run the **archive:push-v10** command in the same directory where you ran the **archive:unpack-v10** command, and always push the ported data back to the same deployment where you extracted the data.
- The **login** command obtains a token that expires after 8 hours.
  If the token expires while the **archive:push-v10** command is running, the AMU generates errors. In this case, log in again and re-run the **push** command. The token is refreshed every time you log in. For more information, see migration_troubleshooting.html#migration_troubleshooting__token_expire.
- The **archive:push-v10** command only pushes only the following ported objects: OAuth Providers, draft APIs, draft products, configured gateway services, and published products.
- An alternative method of viewing endpoints is to run the **kubectl get ingress** and get the values from the output. For example, see the values in **bold** in the following sample output:

  ```
  r7c221d8a33-apic-portal-director api.portal.dev.apic10-stack.example.test 80, 443 21h
  r7c221d8a33-apic-portal-web portal.dev.apic10-stack.example.test 80, 443 21h
  re314d70920-apiconnect-api platform.mgmt.dev.apic10-stack.example.test 80, 443 22h
  re314d70920-apiconnect-apim-ui apim.mgmt.dev.apic10-stack.example.test 80, 443 22h

  rfe867a858b-dynamic-gateway-service-gw api.gw.dev.apic10-stack.example.test 80, 443 21h
  rfff5043330-analytics-client ac.dev.apic10-stack.example.test 80, 443 21h
  rfff5043330-analytics-ingestion ai.dev.apic10-stack.example.test
  ```

3. Test your newly ported products and APIs to make sure they are working as expected.
   If necessary make changes and push the updates to your API Connect deployment.

Migrating from v10 to v10 on a different form factor

Migrate an API Connect v10 deployment from one form factor to a different form factor.

If you want to move your API Connect deployment to a different platform or network environment, use the form factor migration process.

For brevity, "form factor migration" is referred to as just "migration" in the rest of this topic.

The typical use cases for the migration process are:

- Moving your API Connect deployment from one platform to another, without changing anything else. For example, if you originally deployed on Kubernetes, but want to move to OpenShift.
- Changing the endpoints of your API Connect deployment. For example, the consumer API or portal web endpoint. It is not possible to update your API Connect endpoints after installation. Also, if you want to move your API Connect deployment to a different network, it is likely that the move requires changing the API Connect endpoints.
- Combination of moving to a different platform and changing endpoints.

You do not need to use the migration process for:

- Changing your API Connect deployment profile. See:
  - Changing deployment profiles on VMware.
  - Changing deployment profiles on Kubernetes and OpenShift.
  - Changing deployment profiles on OpenShift top-level CR.
  - Changing the deployment profile on Cloud Pak for Integration.
- Backup, restore, and disaster recovery. See:
  - Backing up, restoring, and disaster recovery.
  - Backing up and restoring on VMware.

  Note:
  You can use the migration save script **save_v10_source_configuration.py** as an extra backup mechanism, but do not use the migration save script as an alternative to the standard backup process.

Key points and limitations of form factor migration:

- The API Connect version on the target system must match the API Connect version on the source system.
- The migration process applies only to the management and portal subsystems. The analytics and gateway subsystems do not require migration steps. The gateway receives its data from the management subsystem, and analytics database backups can be restored directly on the new deployment.

The supported migration paths are shown in the following table:

Table 1. Supported migration paths for API Connect v10

Source deployment platform of API Connect v10	Target deployment platform
Kubernetes	Cloud Pak for Integration..
Kubernetes	OpenShift Container Platform.
Kubernetes	Kubernetes.
VMware	Cloud Pak for Integration.
VMware	OpenShift Container Platform.
VMware	VMware. From V10.0.7.0 and later.
OpenShift Container Platform	Cloud Pak for Integration, keeping the same endpoints.
OpenShift Container Platform	Cloud Pak for Integration, moving to a different cluster, resulting in endpoint changes.
OpenShift Container Platform	OpenShift Container Platform, moving to a different cluster, resulting in endpoint changes.
Cloud Pak for Integration	Cloud Pak for Integration, moving to a different cluster, resulting in endpoint changes.

  Troubleshoot problems with v10 migration.
- **Shutting down the Postgres database**
  V10.0.6 only. Shutdown the Postgres database to ensure no changes are made to the database during migration.

v10 migration overview

Use migration scripts to migrate API Connect to another form factor, or to a different deployment on the same form factor.

The migration process consists of the following steps:

1. Extract the data from the management and portal subsystems databases of your source system, by using the provided Python script **`save_v10_source_configuration.py`**.
2. Install your target management and portal subsystems, setting new endpoints if required.
3. Specify the mapping of any changed endpoints in a YAML file.
4. Restore the data from your source system, by using the provided Python restore scripts.

Location of v10 migration scripts

You can obtain the scripts from Fix Central, search for **`apiconnect-operator-release-files_<version_number>`**. The scripts are located in the helper_files/formFactorMigration directory:

```
apiconnect-operator-release-files_VERSION_NUMBER/helper_files/formFactorMigration
```

On Kubernetes, OpenShift, and Cloud Pak for Integration, the migration scripts are run from a client computer that has access to the Kubernetes or OpenShift cluster. Scripts are supported on Linux and macOS.

On VMware, the migration scripts are run directly on the API Connect VMs.

v10 migration planning

Consider the following information when you plan your v10 migration:

- **Data migration**
  There are two ways to migrate data:
  - Perform complete migration of data:

    Before starting migration steps on the target system, have the target system ready with the same or larger topology than what is present in the source system. This means the number of Gateways, Portals, and Analytics subsystems must be same or more than what is present in the source system. Start the migration process, map the endpoints between source and target systems, and complete the migration process. All data is migrated. The target system must be validated and tested.

    If you do not want to migrate data for some subsystems on the source system, skip those endpoints in the mapping. Then, after migration is complete, manually delete the data from Cloud Manager and the API Manager UI on the source system.

- Perform migration in more than one step
  In this scenario, at the time of migration the API Connect target system does not have all the subsystems ready when compared to the total number of subsystems in the source system. Migration is run only for the Gateway and Portal subsystems that are available on the target system. At this point, the target system will still have some stale data related to the subsystems that are not migrated. You can then create additional subsystems (Gateways, Portals, or Analytics) on the target system, and run the necessary migration steps to complete the remaining migration process.

  - If additional Gateways or Analytics are added to the source system after completing the initial migration, you must:
    1. Add the new Gateway and Analytics related endpoints in the mapping file.
    2. Register Gateways and Portals on the target system. Complete Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
    3. Update the gateways in the catalog to point to the new Gateway systems. Complete Step 6 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
  - If additional Portals are added to the source system after completing the initial migration, you must:

    1. Add the new Portal related endpoints in the mapping file.
    2. Register gateways and portals on the target system. Complete Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
    3. Update the portals in the catalog to point to the new portal systems. Complete Step 4 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
    4. Restore portal backups for each site on the namespace where the new portal is installed. Complete Step 5 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
  - The stale data for which migration is not complete will remain on the target system until you install the additional subsystems and complete migration, or until you use the Cloud Manager or API Manager UI to manually delete it.

- Reuse of Gateways from the source system:
  1. Export the **`ingress-ca`** secret from the source system using the **`-export_cert`** flag in Preparing the source system. The secret is saved to **`data/MANAGEMENT_SUBSYSTEM_NAME/ingress-ca_secret.yaml`**.
  2. Install the **`ingress-ca`** secret manually on the target cluster. This step must be completed before you begin Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
     - **If using top-level CR on OpenShift:** The top-level CR name you are going to use while installing API Connect must be used while creating the secret name and its contents.
     - The name of the ingress-ca secret must be ***`TOP_CR_NAME`*`-ingress-ca`** in case of OpenShift using top-level CR, or CP4I. For Kubernetes or OpenShift using individual subsystems, it must be **`ingress-ca`**.
     - An example of an **`ingress-ca`** secret is given in the following example. If top-level CR is used, replace **`TOP_CR_NAME`** with the top-level CR name you are going to use to install API Connect. For Kubernetes or OpenShift using individual subsystems, all the values will be just **`ingress-ca`**.
     - After modifying the contents of **`ingress-ca`** and saving the yaml, create the secret using **`oc create -f filename.yaml -n NAMESPACE`**.

     ```
     apiVersion: v1
     data:
       ca.crt: CA_CRT
       tls.crt: TLS_CRT
       tls.key: TLS_KEY
     kind: Secret
     metadata:
       annotations:
         cert-manager.io/alt-names: ''
         cert-manager.io/certificate-name: TOP_CR_NAME-ingress-ca
         cert-manager.io/common-name: ingress-ca
         cert-manager.io/ip-sans: ''
         cert-manager.io/issuer-group: ''
         cert-manager.io/issuer-kind: Issuer
         cert-manager.io/issuer-name: TOP_CR_NAME-self-signed
         cert-manager.io/uri-sans: ''
       name: <TOPCR>-ingress-ca
     type: kubernetes.io/tls
     ```

  3. Run the migration steps, starting with Step 1 in Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration. Install API Connect, using the same TOP_CR_NAME (if using top-level CR), by following the remainder of the steps in Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
  4. When you complete Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration, do not map the source system gateways that are to be reused. Just skip them.
  5. Once the migration is complete, restart the gateways pods on the source system, wait for few minutes, and run the health check script to check the status of webhooks.
  6. Validate the APIs running on the source system gateways.
- Delta changes
  Once the migration procedure is started, any delta changes in the source system databases are not handled by the migration scripts. These changes must be handled manually.

  - To avoid delta changes, shut down the Postgres database in the management subsystem. See Shutting down the Postgres database.
    If you shutdown Postgres, you won't be able to login to the any of the API Connect UIs, or Toolkit CLI.

  - If there are delta changes to the management database after saving the configuration for the source system, you can optionally take another backup of the Management subsystem, just prior to restoring the Management subsystem. See Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Sizing
  Before installing the API Connect target system, make sure proper capacity planning is done to handle the production workloads. Ensure you have sufficient memory, CPU, and disk size as needed, based on the deployment profile being installed.

- Expected migration time
  The time required to complete migration can depend on the following:

  - The size of the management database. Backup and restore are dependent on this size.
  - Migration of the Portal and Gateway data in all the provider orgs depends on:
    - Number of provider orgs
    - Number of catalogs in these provider orgs

        - Whether Portals are configured for these catalogs
        - Total number of APIs published
    - Creation of Portal sites and restore of Portal backup depends on:
        - Deployment profile (n1, n3 etc) being used
        - Disk performance
        - Total number of Portal sites being create or restored
        - The amount of customization in a Portal site. Customization plays a role in the time needed to restore.

v10 migration requirements

Ensure your deployment meets the migrations prerequisites and requirements.

Subsystem requirements

All subsystems must be in a healthy state.

You must manually create storage classes like block storage or file system storage. Applies to all subsystems and, when installing on CP4I, to Platform Navigator.

Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

- Management subsystem:
    - **v10.0.6 only:** You must configure Management subsystems with either S3 or SFTP backups.
    - **v10.0.6 only:** If s3 storage is being used, postgres in the Management subsystem must be stopped on the source system.
      Note:
      Shutting down postgres is necessary in this scenario because two APIC deployments cannot both use the same S3 backup location. The target API Connect deployment will not start if postgres on the source deployment is up and connecting to the same S3 backup location.

      When postgres is stopped, there is no impact on the published APIs in the gateways. However, the Cloud Manager and API Manager UI will not available because the underlying microservices are down. Users are able to browse the APIs in the Portal. But new consumer orgs or applications or users cannot be created.

    - If the Postgres cluster name on the target is different than the source system, restore will fail. For more information on configuring the target system, see Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Developer Portal subsystem:
    - Developer Portal subsystems must be configured with either S3 or SFTP backups.
    - For Developer Portal subsystem, you must have all the mappings between old and new endpoints and hostnames.
- Gateway subsystem:
    - If a custom gateway image is being used on the source system, the same image must be used on the target system
    - For a Gateway subsystem, you must have all the mappings between old and new endpoints and hostnames.

Scripting requirements

- Python 3 and PyYAML python module must be present on the system where the scripts are run.
  To install the PyYAML module:

  ```
  pip3 install pyyaml
  ```

- Do not have any spaces in the complete directory path where the scripts are executed.
- Ensure that the API Connect version of the `apic` toolkit is the same version as for the scripts, and that the toolkit is located in the path where the scripts are executed. Validate toolkit commands to make sure the Cloud Manager and API Manager hostnames are resolved and able to run few commands. Make sure apic toolkit commands are working before trying out the scripts.
- If you are using hostnames, you may need to update the /etc/hosts file for the apic toolkit to work.
- When the scripts are run on the target system, the configuration (data directory) saved from the source system must be available in the location where scripts are present.
- Save the output logs for every script being executed.

Credentials requirements

- In all the scripts where the credentials are passed on the command line, these credentials are the admin org (Cloud Manager) credentials.
- You must be able to use `kubectl` (for native Kubernetes) or `oc` (OpenShift) commands to access the source system cluster and the target system cluster.
- To administer the admin org, you must have credentials with administrative role to access Cloud Manager.
- For provider orgs, if you do not use the migration user, and plan to use provider org credentials, you must have the provider org credentials for the API Manager interface.
- You must manually create:
    - Secrets for entitlement keys to download images from Docker registry.
    - DataPower admin credentials and secret, if the target system is native Kubernetes.
- After migration, the users on the target system will be in the same user registry as in the source system. For example, in CP4I, users from a local user registry (LUR) are not moved to a Zen user registry.

How to obtain hostnames

The hostnames used in the scripts (`--server` or `-s` or `-api_manager_hostname`) and also in the files `gateway_portal_mapping.yaml` or `provider_org_credentials.yaml` can be obtained using the following commands.

The command must be run on the source cluster or target cluster, based on the step for which the hostname is needed.

- Kubernetes:

  ```
  kubectl get ingress -n <NAMESPACE>
  ```

- OpenShift and Cloud Pak for Integration:

  ```
  oc get routes -n <NAMESPACE>
  ```

Example output on Kubernetes:

```
kubectl get ingress -n ask1
NAME                       CLASS    HOSTS                                                ADDRESS
PORTS     AGE

```

How to obtain realm values

The value of realm (**--realm** or **-r**) used while running the scripts can be obtained as shown in the following examples. The realm values are for Cloud Manager (admin org) and provider org.

- Example for Cloud Manager (admin org):
  The value is passed as a command line option while running the script.

  ```
  apic identity-providers:list --scope admin --fields title,realm --server api.test1-master.fyre.example.com
  total_results: 3
  results:
    - title: Cloud Manager User Registry
      realm: admin/default-idp-1
    - title: googleoidc
      realm: admin/googleoidc
    - title: ldap1
      realm: admin/ldap1
  ```

- Example for provider org realm values:
  The value is used in **provider_org_credentials.yaml** while updating Portal and Gateway information in the provider orgs, when the default migration user is not used. See Step 4 and Step 6 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

  ```
  apic identity-providers:list --scope provider --fields title,realm --server api.testuser1-master.fyre.example.com
  total_results: 3
  results:
    - title: API Manager User Registry
      realm: provider/default-idp-2
    - title: googleoidc
      realm: provider/googleoidc
    - title: ldap1
      realm: provider/ldap1
  ```

Backing up subsystems

It is necessary to backup the management and portal subsystem databases on the source system:

- Backing up and restoring on VMware
- Backing up, restoring, and disaster recovery on Kubernetes and OpenShift

Limitations

1. Analytics service and data is not migrated.
2. If migrating from v10 non-CP4I environment (source apic cluster) to v10 CP4i environment (target apic cluster), make sure the Cloud Manager password for **admin** user is not **7iron-hide** on the source cluster. If default password **7iron-hide** is used, migration will fail after step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration, as configurator job assumes that the install is a fresh installation, and changes the password automatically.

v10 migration steps

Complete the steps that are required for your v10 migration path.

Before you begin, ensure you have reviewed v10 migration overview and v10 migration requirements.
If migrating from OpenShift top-level CR to Cloud Pak for Integration on the same cluster, do not follow the steps here. Instead, refer to Migrating from OpenShift to Cloud Pak for Integration on the same cluster.

- **Preparing the source system**
  Run the **save_v10_source_configuration.py** script to gather the source system configuration.
- **Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration**
  On the target system, configure a cluster, create the necessary secrets, and install API Connect.
- **Installing the target system on VMware**
  Create the project directory, configure you target deployment, create the ISO files, and deploy your VMs.
- **Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration**
  Restore the saved configuration and backups from the source system onto the target system.
- **Restoring the target system on VMware**
  Restore the saved configuration and backups from the source system onto the target system.
- **Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration**
  Verify that the target system is in a healthy state and fully configured.
- **Verifying the target system on VMware**
  Verify that the target system is in a healthy state and fully configured.

Preparing the source system

Run the **save_v10_source_configuration.py** script to gather the source system configuration.

Before you begin

Review v10 migration requirements.

About this task

The **save_v10_source_configuration.py** script:

- Creates a data directory with all configuration saved in it.
- Generates two YAML files in the same directory as the script:
  - **gateway_portal_mapping.yaml**
  - **provider_org_credentials.yaml**

  Important: The YAML files must be filled in:
  - gateway_portal_mapping.yaml must be filled in if, when restoring onto the target system, you choose to run **register_gateway_portals_in_target.py** in silent mode. See step 3.c in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
  - provider_org_credentials.yaml must be filled in if, when restoring onto the target system, you choose not to use the migration user credentials while updating Portal and Gateway information. See step 4 and step 6 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

To view script parameters:

```
python3 save_v10_source_configuration.py --help
```

Procedure

1. Create a directory called **FFM** and copy all python scripts to this directory.
2. Kubernetes, OpenShift, or Cloud Pak for Integration: Save configuration from the source system.
   To save the source system configuration, run **save_v10_source_configuration.py** with the appropriate parameters for your deployment:
   - If all subsystems are in the same namespace, and you are using username/password authentication.
     This command saves configuration of all the installed subsystems in the namespace:

     ```
     python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n NAMESPACE
     ```

   - If a subsystem needs to be skipped so that its configuration is not saved:
     - Skip Portal:

       ```
       python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n
       NAMESPACE -skip_ptl
       ```

     - Skip Analytics:

       ```
       python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n
       NAMESPACE -skip_a7s
       ```

   - If all subsystems are in the same namespace, and you are using SSO authentication:

     ```
     python3 save_v10_source_configuration.py --sso -s PLATFORM_API_HOSTNAME -n NAMESPACE
     ```

   - If all subsystems are in different namespace, and you are using username/password authentication:

     ```
     python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns
     <mgmt_namespace>  -ptl_ns <ptl_namespace> -gw_ns <gw_namespace> -a7s_ns  <a7s_namespace>
     ```

   - If the cluster has multiple Gateways, Portals, or Analytics subsystems distributed across namespaces in the cluster, you can save the configuration of the source system using one of the ways shown below. Multiple namespaces need to be separated by "|" symbol. The namespaces used in below example

command are `ns1`, `ns2`, `ns3`. Both commands work the same way.

- `python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n "ns1|ns2|ns3"`
- `python3 save_v10_source_configuration.py -u USERNAME -p  PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns "ns1" -ptl_ns  "ns1|ns2" -gw_ns "ns1|ns2|ns3" -a7s_ns "ns1|ns2"`

- If ingress-ca certificates must be saved or exported in the configuration, run the previous commands with `-export_cert` flag. Applicable only when you are saving management subsystem configuration.

3. VMware: Save configuration from the source system.
   On VMware appliance, save the source configuration by running the `save_v10_source_configuration.py` script on the Management and Portal nodes.

   If you have a three replica deployment, run the `save_v10_source_configuration.py` script on just one of the VMs in the cluster.

   a. Copy the `apic` toolkit and `apicup` installer to the management node.
   b. Copy the script `save_v10_source_configuration.py` to the management node:
      - If `ingress-ca` and `root-ca` certificates must be saved in the configuration, copy this script to the project directory for this appliance and upload the project directory to the appliance. The script must be run from inside the project directory.
      - If `ingress-ca` and `root-ca` certificates are not needed, just copy this script to the appliance.
   c. Change to root user (`sudo -i`) and set PATH variable to the directory where the **apic** toolkit is present. This directory must be at the beginning of the path.
   d. Change to the directory where script is located. Check the PATH to verify that the **apic** toolkit is present. To validate, use `apic login` and `apicup version`.
   e. Collect source system configuration. If certificates needed, add the flag `-export_cert` to the command.

   ```
   python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns default
   ```

   f. On the Management node, from the location where the script is run, download the data directory, gateway_portal_mapping.yaml, and provider_org_credentials.yaml files. Copy them to the location where the form factor migration scripts are present.
   g. Copy the `save_v10_source_configuration.py` script to the Portal node and run the script as root user, using the following command:

   ```
   python3 save_v10_source_configuration.py -ptl_ns default -skip_mgmt
   ```

   On the Portal node, from the location where the script is run, download the `data` directory and merge it with the `data` directory downloaded from the Management node.
   If multiple Portal services are configured with the Management subsystem, repeat the same operation for each Portal.

What to do next

Configure your target deployment:

- Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration
- Installing the target system on VMware

Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration

On the target system, configure a cluster, create the necessary secrets, and install API Connect.

Before you begin

- Complete Preparing the source system.
- Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

About this task

Run the `create_secrets_in_target.py` script to create the necessary secrets. If necessary, shutdown the Postgres database, and then install API Connect, either manually or by running the `install_apic_on_ocp.py` script.

Note: For data migration, you have the option of performing a complete migration at once, or performing migration in more than one step. To review these options, see v10 migration planning.

Procedure

1. Configure a target cluster either Kubernetes or OpenShift or Cloud Pak for Integration, where you intend to migrate the source system data.
   - Note that this configuration is for the cluster only. No API Connect software is installed yet.
   - Make sure `KUBECONFIG` is set to this target cluster, so you can access the cluster using `oc` or `kubectl`.
2. Create the namespaces in the target cluster where you want the API Connect subsystems to run.
   - The namespaces can be different than the source system values.
   - If you have additional subsystems to be installed in different namespaces, create these namespaces also.
3. Run `create_secrets_in_target.py` to create the following secrets:
   - Database backup secrets for Management and Portal subsystems
   - Application credentials
   - Encryption secrets from the source system

   Usage examples:
   - If both Management and Portal are in the same namespace, or if Portal is not installed.

```
python3 create_secrets_in_target.py -n NAMESPACE
```

- If both Management and Portal are in different namespaces:

  ```
  python3 create_secrets_in_target.py -mgmt_ns <MGMT_NAMESPACE> -ptl_ns <PTL_NAMESPACE>
  ```

- If you are creating multiple Portal subsystems in the target API Connect system, to match the configuration of the source system, you must run the script more than once for each Portal subsystem from the source system.
  The script detects that there are two Portal subsystems in the source system, and prompts you to select the subsystem name that matches the target Portal, as shown in the following commands:

  - For Management and first Portal on the target system:

    ```
    python3 create_secrets_in_target.py -mgmt_ns <MGMT_NAMESPACE> -ptl_ns <PTL_NAMESPACE1>
    ```

  - For the second Portal on the target system:

    ```
    python3 create_secrets_in_target.py -skip_mgmt -ptl_ns <PTL_NAMESPACE2>
    ```

4. If applicable to your deployment, shutdown the Postgres database on your source system.
   You can shutdown the Postgres database now, to ensure that there are no delta changes to your source system while the remainder of the migration process takes place.

   Important: V10.0.6.0 only: If s3 backup is being used for the Management subsystem in the source system, the postgres database MUST be shutdown before launching the target API Connect cluster. If it is not shutdown, the launch of the target apic cluster will fail.
   For steps to shutdown Postgres database on Kubernetes or OpenShift, see Shutting down the Postgres database.

5. Launch the target API Connect system.
   a. Review prerequisites:
      - Have a new OpenShift cluster ready with enough resources (CPU, memory, and disk) as required for the installation profile you will use.
      - As needed, create an entitlement key to download the images related to API Connect.
      - The target system must match the topology (number of Gateways, Portals and Analytics) of the source system to ensure that all the data in the Management database is migrated. If all the data in the Management database is not migrated, the not migrated (stale) data must be manually deleted. Alternatively, you can attempt the remaining migration later after installing the additional Portals and Gateways. See v10 migration planning.

   Important: V10.0.6.0 only: If s3 backup is being used for the Management subsystem in the **target** system, once the Management subsystem is ready, you will see that the backup job pods and stanza-create job pods are in `Error` state. This is expected behavior. Once management backup is restored, the error resolves and backups will work. Since the backup will **not** happen until the Management database is restored, it is very important to restore Management subsystem backup on the target system (see step 2 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration) immediately after installing the target system. Any delay can cause the disk to fill up with write-ahead log (WAL) files.
   To review how to monitor Postgres db disk usage, see:

   - Monitoring Postgres disk usage on OpenShift
   - Monitoring Postgres disk usage on VMware
   - Monitoring Postgres disk usage on Kubernetes.

   b. Launch the target API Connect system either manually or by using the `install_apic_on_ocp.py` script:

      - To manually launch from the OpenShift cluster UI:

        This method is the recommended way to launch the target API Connect system for production systems.

        This method is also used for advanced customization or when using custom certificates while launching the target API Connect system.

        - Install and launch the target API Connect cluster. See the instructions for your deployment type:
          - API Connect on OpenShift: Deploying on OpenShift and Cloud Pak for Integration
          - Cloud Pak for Integration: Installation procedures with IBM Cloud Pak for Integration
        - Before creating the top level CR, use the yaml view to add the properties which you saved from the source system configuration.
          For the Management subsystem, the saved configuration is in `data/config.yaml`. For the Portal subsystem, the saved configuration is in `data/config_portal.yaml`.

          Important: If you do not use the configuration from the source system, the migration fails.
          - Management subsystem properties:
            - encryptionSecret
            - Management subsystem name
            - site name
            - database backup credentials
            - custom application credentials
            - originalUID
          - Portal subsystem properties:
            - encryptionSecret
            - site name
            - database backup credentials
            - originalUID

          Note: If target system is Kubernetes, the properties must be in the Management and Portal subsystem CRs.
        - The top level CR must look like the following example. The values for this top CR are from the generated artifacts (data/config.yaml and data/config_portal.yaml) after running Preparing the source system. Note that the example shows a value for `spec.management.name`. You can obtain this value from config.yaml.

          ```
          apiVersion: apiconnect.ibm.com/v1beta1
          kind: APIConnectCluster
          metadata:
            labels:
              app.kubernetes.io/instance: apiconnect
              app.kubernetes.io/managed-by: ibm-apiconnect
              app.kubernetes.io/name: apiconnect-minimum
            name: c1
            namespace: test1
          ```

    originalUID: 1adc672a-0e77-4890-b476-c41fcedb0b64
    portalBackup:
      credentials: ftp-mgmt-backup-secret
      host: 1.2.3.4
      path: /root/backup/portal1
      port: 22
      protocol: sftp
    siteName: cb06099f
  profile: n1xc7.m48
  storageClassName: rook-ceph-block
  version: 10.0.6.0
```

    - You can also use the script **`install_apic_on_ocp.py`** with **`-no_install`** flag to generate the top level CR yaml, and use the yaml in the OpenShift UI and customize further.
- To launch using the **`install_apic_on_ocp.py`** script:
  The script is used to launch API Connect on OpenShift or API Connect with Cloud Pak for Integration using a top level CR that specifies one of each subsystem type:
    - Management
    - Developer Portal
    - Analytics
    - API Gateway

  Prerequisite:
    - The OpenShift cluster must be ready, and accessible using **`oc`**.
    - **Important:** The script is used to launch **ONLY** the specific version of API Connect based on the downloaded version of the artifacts.

  Usage:

    - Run the script with **`--help`** option to show additional flags available like **`-production and -profile`**.
    - License use is set to **`nonproduction`** by default unless the flag **`-production`** is used while running this script.
    - The profile defaults to the one replica profile **`n1xc7.m48`**, to specify a different profile use the **`-profile`** flag. For details of the available profiles, see API Connect deployment profiles for OpenShift and Cloud Pak for Integration. The one replica profile deploys 1 replica of each pod and is only for light, non-critical workloads such as basic development and testing.
    - Optionally, you can use the **`-no_install`** flag if you want to generate the yaml files (top level CR and other files needed in installation) without installing. In the following example commands, add the **`-no_install`** flag to the existing command parameters. You can use this top level CR from the OpenShift UI, and create an API Connect cluster.
    - Note : If CP4I environment, check if configurator job is completed and also check the output of:

      `oc get apiconnectcluster -n NAMESPACE`

Example command invocations:

Note: Each of the example commands includes parameters for a three replica profile deployment: **`-production -profile n3xc16.m48`**. If you have a one replica profile, omit these parameters.

- API Connect on OpenShift:
    - If the apiconnect and DataPower operators must be installed in all namespaces:

      ```
      python3 install_apic_on_ocp.py -license LICENSE_VALUE -n NAMESPACE -name topCRName -storageclass_apic
      STORAGE_CLASS_NAME -production -profile n3xc16.m48
      ```

    - If the apiconnect and DataPower operators must be installed in a specific namespace:

```
python3 install_apic_on_ocp.py -license LICENSE_VALUE -n NAMESPACE  -name topCRName -storageclass_apic
STORAGE_CLASS_NAME  -operator_in_specific_namespace -production -profile n3xc16.m48
```

- API Connect in Cloud Pak for Integration:
  - If operators are in all namespaces:
    - V10.0.7.0 and later:

      ```
      python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
      STORAGE_CLASS_NAME1 -cp4i -production -profile n3xc16.m48
      ```

    - V10.0.6.0:

      ```
      python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
      STORAGE_CLASS_NAME1 -cp4i -storageclass_pn STORAGE_CLASS_NAME2 -license_pn LICENSE_VALUE2 -production
      -profile n3xc16.m48
      ```

  - If operators are in a specific namespace:
    - V10.0.7.0:

      ```
      python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
      STORAGE_CLASS_NAME1 -cp4i -operator_in_specific_namespace -production -profile n3xc16.m48
      ```

    - V10.0.6.0:

      ```
      python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
      STORAGE_CLASS_NAME1 -cp4i -storageclass_pn STORAGE_CLASS_NAME2 -license_pn LICENSE_VALUE2 -
      operator_in_specific_namespace -production -profile n3xc16.m48
      ```

    - V10.0.7.0:

      ```
      python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
      STORAGE_CLASS_NAME1 -cp4i -operator_in_specific_namespace -production -profile n3xc16.m48
      ```

    - V10.0.6.0:

      ```
      python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
      STORAGE_CLASS_NAME1 -cp4i -storageclass_pn STORAGE_CLASS_NAME2 -license_pn LICENSE_VALUE2 -
      operator_in_specific_namespace -production -profile n3xc16.m48
      ```

  - If operators are in all namespaces, with additional flags **`-production`** (for license to be set to production) and **`-profile`** (using n3 profile in this example):
    - V10.0.7.0:

      ```
      python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
      STORAGE_CLASS_NAME1 -cp4i -production -profile n3xc16.m48
      ```

    - V10.0.6.0:

      ```
      python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
      STORAGE_CLASS_NAME1 -cp4i -storageclass_pn STORAGE_CLASS_NAME2 -license_pn LICENSE_VALUE2 -production
      -profile n3xc16.m48
      ```

6. Optional: Install any additional Gateways, Developer Portals, or Analytics subsystems that are needed.
   - Complete this step now if your target system will have additional Gateways, Developer Portals, or Analytics subsystems to match what is there in the source API Connect system, and you want to complete data migration for all subsystems in one pass through the procedures in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
   - Skip this step now, and proceed to step 7 if either of the following cases are true:
     - If your target system will not need any additional Gateways, Developer Portals, or Analytics subsystems.
     - Your target system will have additional Gateways, Developer Portals, or Analytics subsystems but you want to first complete data migration based on the top CR installation (1 Management, 1 Portal, 1 Gateway, 1 Analytics), before you install any additional subsystems.

   Note: To review the data migration choices, see v10 migration planning.
   If you choose complete this step now, see:

   - Deploying on OpenShift and Cloud Pak for Integration
   - Installation procedures with IBM Cloud Pak for Integration
7. Next, restore the configuration from the source system. Continue with Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

Installing the target system on VMware

Create the project directory, configure you target deployment, create the ISO files, and deploy your VMs.

Form factor migration to VMware is supported from v10.0.7 only, and is only supported from a VMware environment. You cannot migrate a Kubernetes or OpenShift API Connect deployment to VMware.

When you install the target system, before you create the ISO files that are used in the OVA deployment, you must set some of the subsystem properties of your target system to the same values as your source system. Refer to the data directory that you created in Preparing the source system to find these values.

Other subsystem properties can be set to different values from your source subsystem. For example, the API endpoints such as **`portal-www`** and **`platform-api`**. Changing API endpoints is the typical use-case of a VMware to VMware migration.

Management subsystem

Follow the usual steps for configuring your management subsystem deployment: Configuring the Management subsystem, but set the following properties to the same values as your source system.

1. Subsystem name.

```
apicup subsys create <management subsystem name> management
```

where *<management subsystem name>* is the same as your source system.

2. Encryption secret.

```
apicup certs set <management subsystem name> encryption-secret --encoded-string <v10 source mgmt encryption secret>
```

where *<v10 source mgmt encryption secret>* is found in data/*<management subsystem name>*/encryption-secret-*.yaml

3. Site name.

```
apicup certs set <management subsystem name> site-name <v10 source mgmt site name>
```

where *<v10 source mgmt site name>* is found in data/*<management subsystem name>*/config.yaml

4. Credential secrets.

```
apicup certs set <management subsystem name> atm-credential --encoded-string '<encoded string>'
apicup certs set <management subsystem name> consumer-toolkit-credential --encoded-string '<encoded string>'
apicup certs set <management subsystem name> designer-credential --encoded-string '<encoded string>'
apicup certs set <management subsystem name> toolkit-credential --encoded-string '<encoded string>'
apicup certs set <management subsystem name> juhu-credential --encoded-string '<encoded string>'
apicup certs set <management subsystem name> consumer-ui-credential --encoded-string '<encoded string>'
apicup certs set <management subsystem name> ui-credential --encoded-string '<encoded string>'
apicup certs set <management subsystem name> discovery-credential --encoded-string '<encoded string>'
apicup certs set <management subsystem name> governance-credential --encoded-string '<encoded string>'
```

where *<encoded string>* is found in the corresponding secret YAML file in data/*<management subsystem name>*. For example:

```
<management subsystem name>-atm-cred.yaml
<management subsystem name>-ccli-cred.yaml
<management subsystem name>-cli-cred.yaml
<management subsystem name>-cui-cred.yaml
<management subsystem name>-dsgr-cred.yaml
<management subsystem name>-juhu-cred.yaml
<management subsystem name>-ui-cred.yaml
```

The encoded string is stored in `credential.json` property of each file:

```
apiVersion: v1
data:
  credential.json:
eyAiaWQiOiAiMzhmMzRjOTktODFhNC00NWFkLWFkOTgtMGM1MGFjN2YzYmJjIiwgInNlY3JldCI6ICI3OTIxYzE5Yi1jNWUwLTRhYzQtYTkyZC1iZjNmYWJlZWEwNDIiIH0=
kind: Secret
...
```

5. You can use the same management database backup configuration as your source system, or you can specify a new configuration.

Portal subsystem

Follow the usual steps for configuring your portal subsystem deployment: Configuring the Developer Portal subsystem, but set the following properties to the same values as your source system.

1. Subsystem name.

```
apicup subsys create <portal subsystem name> portal
```

where *<portalsubsystem name>* is the same as your source system.

2. Encryption secret.

```
apicup certs set <portal subsystem name> encryption-secret --encoded-string <v10 source ptl encryption secret>
```

where *<v10 source ptl encryption secret>* is found in data/*<ptl subsystem name>*/portal-encryption-secret-*.yaml

3. Site name.

```
apicup certs set <portal subsystem name> site-name <v10 source ptl site name>
```

where *<v10 source ptl site name>* is found in data/*<ptl subsystem name>*/config.yaml

4. Backup configuration.
Use the same backup configuration as your source system to restore your portal sites.

Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration

Restore the saved configuration and backups from the source system onto the target system.

Before you begin

- Complete Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

About this task

Use scripts to:

- Restore the Management subsystem
- Register Gateways and Portals on the target system
- Update Portals in the Catalog to point to new Portal systems
- Restore Portal backups for each site
- Update Gateways in the Catalog to point to new Gateway systems

All scripts run on the target system must be run from a location where the data directory is present so that the source configuration can be used.

Note: You can optionally run scripts in `--silent` mode, particularly for the following scenarios:

- Register Gateways and Portals in the target system. (Step 3)
- Update Portals in the Catalog to point to new Portal systems. (Step 4)
- Update Gateways in the Catalog to point to new Gateway systems. (Step 6)

If there are multiple Portals and Management subsystems present in the data directory (as saved during Preparing the source system), the restore script prompts you to select the subystem name to use for migration while running the script. If running in silent mode, that value must be supplied as an additional flag.

Deployments with multiple Portals and Gateways are a common scenario. The saved data can have multiple Management subsystems only if you ran **`save_v10_source_configuration.py`** against multiple clusters with different Management subsystem names, without cleaning the data directory.

Procedure

1. Before restoring the Management subsystem backup, determine whether there have been any delta changes to your source system since you backed up the Management subsystem database and Portal database.
   - If you shutdown the Postgres database, as instructed in Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration, there are no delta changes. Continue to step 2.
   - If you did not shutdown the Postgres database, there could be some delta changes to the Management database, because the Management subsystem on the source system remains in READY state. In this case, to ensure you capture the latest configuration, repeat Preparing the source system. By doing so, the Management and Portal databases are backed up again. The latest backup will then be used to restore to the target system.
2. Restore a Management subsystem backup onto the target system.
   a. On the target API Connect system, ensure that the Management subsystem is up and running,
   b. Run **`restore_management_db.py`**. Examples:
      - OpenShift or Kubernetes target system:

        ```
        python3 restore_management_db.py -n <mgmt namespace>
        ```

        or:

        ```
        python3 restore_management_db.py -mgmt_ns <mgmt namespace>
        ```

      - Cloud Pak for Integration target system:

        ```
        python3 restore_management_db.py -n <namespace> -s <platform API hostname>
        ```

      - If for some reason the management subsystem is not healthy, restore using the command:

        ```
        python3 restore_management_db.py -n <mgmt namespace> -ignore_health_check
        ```

3. Register Gateways and Portals on the target system.
   a. Prerequisites:
      - The **`register_gateway_portals_in_target.py`** script must be run on the target system after the Management database from the source system has been restored.
      - The Gateway and Developer Portal subsystems that need to be registered must be in a healthy state.
   b. Usage notes:
      - The credentials provided from this step will be same as the credentials used on the source system, because the Management database from the source system is restored.
      - Keep the endpoints ready for the new Gateway and Portal services so that they can be registered by running **`register_gateway_portals_in_target.py`**. To view endpoints, use **`oc get routes`**.
      - If you run **`register_gateway_portals_in_target.py`** for a Cloud Pak for Integration target system, and you see the error **`The API Connect Gateway Service is already registered to another API Manager instance`**, restart all the gateway pods, wait for them to become healthy, and run **`register_gateway_portals_in_target.py`** again.
      - Make sure the mapping of old URLs with the new ones are correct. For example, when the source system is a VMware appliance, if wrongly mapped (wrong values provided) communication errors occur during Gateway registration. Example errors messages:

        - **`"Error: An error occurred communicating with the gateways subsystem "`**
        - **`"error: 'Client network socket disconnected before secure TLS connection was established'"`**

        On the appliance, the Gateway Manager URL uses port **`3000`**.

   c. Run **`register_gateway_portals_in_target.py`** in either interactive mode or silent mode:

      - Interactive mode
        The **`register_gateway_portals_in_target.py`** script displays the Portal and Gateway endpoints from the source system, and prompts the user to enter the corresponding values from the target system. Examples:

        - If Management, Portal and Gateway subsystems are in the same namespace:

```
python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r
<realm name> -n <namespace>
```

- If Management, Portal and Gateway subsystems are in different namespaces, use `-mgmt_ns`, `-ptl_ns`, and `-gw_ns` to specify each, for example:

  ```
  python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r
  <realm name> -mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -gw_ns <gway namespace>
  ```

- If you are using SSO authentication, replace:

  ```
  -u <username> -p <password>
  ```

  with:

  ```
  --sso
  ```

- Multiple namespaces can alternatively be specified with `"ns1|ns2|ns3"` notation. For example:

  ```
  python3 register_gateway_portals_in_target.py -n "ns1|ns2|ns3" -u admin -p <password> -s <platform API
  hostname> -r admin/default-idp-1 -silent
  ```

  ```
  python3 register_gateway_portals_in_target.py -s <platform API hostname> -u admin -p <password> -r
  admin/default-idp-1 -mgmt_ns ns1 -ptl_ns "ns1|ns2" -gw_ns "ns1|ns2|ns3" -silent
  ```

- Silent mode
  The gateway_portal_mapping.yaml file, with mapping between old and new endpoints for Gateway, Portal, and Analytics endpoints, must be located in the same directory as **register_gateway_portals_in_target.py**.

  This gateway_portal_mapping.yaml file is generated when saving the source API Connect system configuration with properties data filled in. For every Gateway, Portal, and Analytics subsystem registered with Management in the source system, the yaml has the endpoint mapping between source and target systems.

  Remaining data must be filled to use the yaml in silent mode. All values must begin with **https://**.

  - Example:

    ```
    python3 register_gateway_portals_in_target.py -n <namespace> -u <username> -p <password> -s <platform API
    hostname> -r <realm name> -silent
    ```

  - Example: If the subsystems are in multiple namespaces.
    For example, ns1, ns2, ns3 namespaces contain the subsystems. Both of the following commands work the same way:

    ```
    python3 register_gateway_portals_in_target.py -n "ns1|ns2|ns3" -u <username> -p <password> -s <platform API
    hostname> -r <realm name> -silent
    ```

    ```
    python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r
    <realm name> -mgmt_ns ns1 -ptl_ns "ns1|ns2" -gw_ns "ns1|ns2|ns3" -silent
    ```

  - Example gateway_portal_mapping.yaml file with:
    - Two Gateways
    - One Portal or Analytics subsystem
    - All data mapped to the target API Connect system:

    ```
    analytics_mapping:
      registered_analytics_name:
        https://ac.source-apic.example.com: https://a1-a7s-ac-endpoint-apic1.apps.vlxocp-
    3278.cp.fyre.example.com
    gateway_mapping:
      registered_apigw_name:
        https://rgw.source-apic.fyre.example.com: https://a1-gw-gateway-apic1.apps.vlxocp-
    3278.cp.fyre.example.com
        https://rgwd.source-apic.fyre.example.com: https://a1-gw-gateway-manager-apic1.apps.vlxocp-
    3278.cp.fyre.example.com
      registered_v5gw_name:
        https://gw.source-apic.fyre.example.com: https://v5gw.gw.apps.vlxocp-3278.cp.fyre.example.com
        https://gwd.source-apic.fyre.example.com: https://v5gw.gwd.apps.vlxocp-3278.cp.fyre.example.com
    portal_mapping:
      registered_portal_name:
        https://api.portal.source-apic.fyre.example.com: https://a1-ptl-portal-director-apic1.apps.vlxocp-
    3278.cp.fyre.example.com
        https://portal.source-apic.fyre.example.com: https://a1-ptl-portal-web-apic1.apps.vlxocp-
    3278.cp.fyre.example.com
    ```

  - Example gateway_portal_mapping.yaml file with:
    - Only two Gateways
    - One Portal or Analytics
    - One Gateway not mapped
      Note that "not mapped" means that the data in the Management subsystem related to this Gateway is not mapped, and the Gateway will not be migrated during this migration phase.

      The Gateway could be migrated later; for example, after the second Gateway is created on the target system. Until the data related to the not-migrated Gateway or Portal is migrated or deleted, there will be stale data in the database.

      The same behavior can be achieved by leaving the values empty, or removing the entire section (name and mapping).

    ```
    analytics_mapping:
      registered_analytics_name:
        https://ac.source-apic.example.com: https://a1-a7s-ac-endpoint-apic1.apps.vlxocp-
    3278.cp.fyre.example.com
    gateway_mapping:
      registered_apigw_name:
    ```

```
    https://rgw.source-apic.fyre.example.com: https://a1-gw-gateway-apic1.apps.vlxocp-
3278.cp.fyre.example.com
    https://rgwd.source-apic.fyre.example.com: https://a1-gw-gateway-manager-apic1.apps.vlxocp-
3278.cp.fyre.example.com
  registered_v5gw_name:
    https://gw.source-apic.fyre.example.com: NEW_GATEWAY_API_ENDPOINT_BASE_IN_TARGET_SYSTEM
    https://gwd.source-apic.fyre.example.com: NEW_GATEWAY_ENDPOINT_IN_TARGET_SYSTEM
portal_mapping:
  registered_portal_name:
    https://api.portal.source-apic.fyre.example.com: https://a1-ptl-portal-director-apic1.apps.vlxocp-
3278.cp.fyre.example.com
    https://portal.source-apic.fyre.example.com: https://a1-ptl-portal-web-apic1.apps.vlxocp-
3278.cp.fyre.example.com
```

4. Use `update_to_new_portals.py` to update Portals in the catalog to point to new Portal systems.
   Note: If there is no Portal subsystem on the source system, skip this step. Also, skip this step if no Portal sites are created in any of the provider orgs. Continue with 6.
   a. Review prerequisites:
      - The Management and Portal subsystems on the target API Connect system must be in a healthy state.
      - The `update_to_new_portals.py` script must be run on the target system after the following actions have been completed:
        - The Management database from the source system has been restored.
        - The new Gateway or Portal instance is registered in the Cloud Manager, using script or from the UI.
      - The credentials for accessing the admin org (Cloud Manager UI) and, if required, the provider org (API Manager UI) must be available for running the script.
   b. Run the `update_to_new_portals.py` script in one of two modes, based on how the Provide Org credentials are available. The modes are:
      - Using a common migration user created by the script
      - Using credentials provided by the user in a yaml file

      Important: The provider org credentials must have administrative access.

   Examples:

   - Using a common migration user created by the script :
     The `update_to_new_portals.py` script runs in this mode by default. This script creates a migration user `muser1` in `migrationur` local user registry, and uses it to migrate Portal information in all the provider orgs. Once the migration is done, the user and user registry are deleted. There is no change in data once the migration is complete.

     Examples:

     - If the Management and Portal subsystems are in the same namespace

       ```
       python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -n
       <namespace> -api_manager_hostname <platform API hostname>  -silent
       ```

     - If using SSO authentication:

       ```
       python3 update_to_new_portals.py -s <platform API hostname> --sso -n <namespace> -api_manager_hostname
       API_MANAGER_HOSTNAME -silent
       ```

     - If the Management and Portal subsystems are in different namespaces:

       ```
       python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns
       <mgmt namespace> -ptl_ns <portal namespace>E -api_manager_hostname <platform API hostname>E -silent
       ```

   - Using credentials provided by the user in a `provider_org_credentials.yaml` file:
     The `provider_org_credentials.yaml` file, with some data filled in, is generated by the `save_v10_source_configuration.py` script you ran in Preparing the source system. The yaml file is available in the same directory as the script. The script has to be edited and all details filled in before it can be used.

     Examples:

     - If Management and Portal subsystems are in the same namespace:

       ```
       python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -n
       <namespace> -no_migration_user -silent
       ```

     - If using SSO authentication:

       ```
       python3 update_to_new_portals.py -s <platform API hostname> --sso -n <namespace> -no_migration_user -silent
       ```

     - If Management and Portal subsystems are in different namespaces:

       ```
       python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -
       mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -no_migration_user -silent
       ```

     Example provider_org_credentials.yaml:

     - With credentials given for every provider org. In this example, only two orgs are present.

       ```
       provider_org_credentials:
         apiManagerHostName: <platform API hostname>
         PORG_NAME_1:
           password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
           realm: provider/default-idp-2
           username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
         PORG_NAME_2:
           password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
           realm: provider/default-idp-2
           username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
         useSameCredentialsForAllProviderOrgs: false
       ```

     - With credentials given for just one provider org. Also requires `useSameCredentialsForAllProviderOrgs` set to true. This method can be used only when the same credentials are used for all provider orgs.

Note: In some cases, there are multiple provider orgs in the Management database.

```
provider_org_credentials:
  apiManagerHostName: <platform API hostname>
  PORG_NAME_1:
    password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
    realm: provider/default-idp-2
    username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
  useSameCredentialsForAllProviderOrgs: true
```

- With SSO credentials and just one provider org:

```
provider_org_credentials:
  apiManagerHostName: <platform API hostname>
  useSameCredentialsForAllProviderOrgs: false
  porg_anme:
    #sso authentication
    #the key(that can expire in sometime) has to be generated separately using
https://<apiManagerHostname>/auth/manager/sign-in/?from=TOOLKIT
    apiKey: some_key
```

5. Restore Portal backups for each site.
   Note: If there is no Portal subsystem on the source system, skip this step. Continue with 6.
   To restore the Portal sites on the target system, you can either use the using script restore_portal_db.py or complete a manual restore.

   - Restoring through the script:

     ```
     python3 restore_portal_db.py -n PORTAL_SUBSYSTEM_NAMESPACE
     ```

   - Restoring through manual steps:
     - Log in to the Portal admin container:

       ```
       oc exec -it <www_pod> -c admin -- bash
       ```

     - List the site backups:

       ```
       remote_transfer_backup -l
       ```

       The list of backups that need to be restored is available in the output logs as a report of Step 4.

     - Download each site backup, and run it for all sites:

       ```
       remote_transfer_backup -d <SITE_BACKUP_FILENAME>
       ```

     - Restore each of the site backups:

       ```
       restore_site -f -u <SITE_URL> <SITE_BACKUP_FILENAME>
       ```

   Note: If there are more than one Portal subsystems on the target system, as needed to correspond to the Portal subsystems on the source system, run the script for each of the matching source and target Portal subsystems.
   For example, if there are two Portals on the target system, matching what is on the source system, and these Portals are installed in namespaces **target1** (for the top-level CR) and **ptl2** (for second portal), then the script will be run twice, as follows:

   ```
   python3 restore_portal_db.py -n target1

   python3 restore_portal_db.py -n ptl2
   ```

6. Run **update_to_new_gateways.py** to update Gateways in the Catalog to point to new Gateway systems.
   a. Review prerequisites:
      - The Gateway subsystem must be in a healthy state.
      - The **update_to_new_gateways.py** script must be run on the target system after the following actions have been completed:
        - The Management database from the source system has been restored.
        - The new Gateway instance is registered in the Cloud Manager, using script or from the UI.
      - The credentials for accessing the admin org (Cloud Manager UI) and, if required, the provider org (API Manager UI) must be available for running the script.

   b. Run the **update_to_new_gateways.py** script in one of two modes, based on how the Provider Org credentials are available. The modes are:
      - Using a common migration user created by the script
      - Using credentials provided by the user in a yaml file

      Important: The provider org credentials must have administrative access.
      - Using a common migration user created by the script:
        The **update_to_new_gateways.py** script runs in this mode by default. This script creates a migration user **muser1** in **migrationur** local user registry, and uses it to migrate Portal information in all the provider orgs. Once the migration is done, the user and user registry are deleted. There is no change in data once the migration is complete.

        Examples:

        - If the Management and Gateway subsystems are in the same namespace:

          ```
          python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -
          n <namespace> -api_manager_hostname <platform API hostname>  -silent
          ```

        - If using SSO authentication:

          ```
          python3 update_to_new_gateways.py -s <platform API hostname> --sso -n <namespace> -api_manager_hostname
          <platform API hostname> -silent
          ```

        - If the Management and Gateway subsystems are in different namespaces:

          ```
          python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -
          mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -api_manager_hostname <platform API hostname> -silent
          ```

- Using credentials provided by the user in a `provider_org_credentials.yaml` file:
  The `provider_org_credentials.yaml` file, with some data filled in, is generated by the `save_v10_source_configuration.py` script you ran in Preparing the source system. The yaml file is available in the same directory as the script. The script has to be edited and all details filled in before it can be used.

  - If the Management and Gateway subsystems are in the same namespace:

    ```
    python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -n <namespace> -no_migration_user -silent
    ```

  - If using SSO authentication:

    ```
    python3 update_to_new_gateways.py -s <platform API hostname> --sso -n <namespace> -no_migration_user -silent
    ```

  - If the Management and Gateway subsystems are in different namespaces:
    Note that if multiple gateway subsystems present across namespaces, you can give multiple namespaces separated by the "|" symbol for `-gw_ns`.

    ```
    python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns <mgmt namespace> -gw_ns GW_NAMESPACE -no_migration_user -silent
    ```

  - Example provider_org_credentials.yaml
    - With credentials given for every provider org, and only two orgs present:

      ```
      provider_org_credentials:
        apiManagerHostName: <platform API hostname>
        PORG_NAME_1:
          password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
          realm: provider/default-idp-2
          username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
        PORG_NAME_2:
          password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
          realm: provider/default-idp-2
          username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
        useSameCredentialsForAllProviderOrgs: false
      ```

    - With credentials given for just one provider org, and `useSameCredentialsForAllProviderOrgs` is set to `true`.
      This can be used only when same credentials are used for all provider orgs.

      Note: There can be multiple provider orgs in the Management database.

      ```
      provider_org_credentials:
        apiManagerHostName: <platform API hostname>
        PORG_NAME_1:
          password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
          realm: provider/default-idp-2
          username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
        useSameCredentialsForAllProviderOrgs: true
      ```

    - With SSO credentials and just one provider org:

      ```
      provider_org_credentials:
        apiManagerHostName: <platform API hostname>
        useSameCredentialsForAllProviderOrgs: false
        porg_anme:
          #sso authentication
          #the key(that can expire in sometime) has to be generated separately using
      https://<apiManagerHostname>/auth/manager/sign-in/?from=TOOLKIT
          apiKey: some_key
      ```

7. Continue to Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

Restoring the target system on VMware

Restore the saved configuration and backups from the source system onto the target system.

Restoring the management subsystem

1. Copy the toolkit CLI apic executable to your FFM directory. See Installing the toolkit. Ensure that your toolkit CLI version matches the API Connect version of your target management VM.
   You created the FFM directory in Preparing the source system. The FFM directory contains Python scripts, YAML files, and a data directory that contains your exported source system data.

2. Login to your target management VM with SSH, and switch to the root user:

   ```
   ssh apicadm@<management hostname>
   ```

   ```
   sudo -i
   ```

   If you deployed a three replica management profile, then login to just one of the VMs.

3. Copy the FFM directory to your target management VM.
4. Ensure that the FFM directory is set first in your `PATH` variable:

   ```
   export PATH=<FFM directory>:$PATH
   ```

Note: The API Connect VMs have an executable that is called apic in the **PATH** variable. The toolkit CLI apic must come before it in the **PATH** so that the restore scripts run correctly.

5. Run the management database restore script:

   ```
   python3 restore_management_db.py -n default
   ```

   Tip: To get help information with the restore scripts, run them with the flag **--help**.

   ```
   python3 <script name> --help
   ```

   The script output shows the progress and when the restore is complete.

6. Edit the gateway_portal_mapping.yaml file and set the endpoints on right side of the file to the endpoints defined for your target VM. The endpoint values can be obtained from the apiconnect-up-v10.yml file in your project directory.
7. Run the register gateway and portals script:

   ```
   python3 register_gateway_portals_in_target.py -s <platform API endpoint> -u admin -p <password> -r admin/default-idp-1 -n default -silent
   ```

   where
   - *<platform API endpoint>* is defined in the apiconnect-up-v10.yml file in your project directory.
   - *<password>* is the admin password that is used on your source system.

8. Run the update portals script:

   ```
   python3 update_to_new_portals.py -s <platform API endpoint> -u admin -p <password> -r admin/default-idp-1 -n default -api_manager_hostname <platform API endpoint> -silent
   ```

9. Run the update gateways script:

   ```
   python3 update_to_new_gateways.py -s <platform API endpoint> -u admin -p <password> -r admin/default-idp-1 -n default -api_manager_hostname <platform API endpoint> -silent
   ```

Restoring the portal subsystem

1. Login to your target portal VM with SSH, and switch to the root user:

   ```
   ssh apicadm@<portal hostname>
   ```

   ```
   sudo -i
   ```

   If you deployed a three replica portal profile, then login to just one of the VMs.

2. Copy the FFM directory from the management VM to your portal VM.
3. Ensure that the FFM directory is set first in your **PATH** variable:

   ```
   export PATH=<FFM directory>:$PATH
   ```

   Note: The API Connect VMs have an executable that is called apic in the **PATH** variable. The toolkit CLI apic must come before it in the **PATH** so that the restore scripts run correctly.

4. Run the restore portal sites script:

   ```
   python3 restore_portal_db.py -n default
   ```

Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration

Verify that the target system is in a healthy state and fully configured.

Before you begin

Complete Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

About this task

Check the health of the target system, complete any optional configuration, and validate data, APIs, and URLs.

Procedure

1. Use the **health_check_post_migration.py** script to health check the target system.
   Examples:

   - When all the subsystems are in the same namespace, and the deployments uses username/password authentication:

     ```
     python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -n NAMESPACE
     ```

   - When all the subsystems are in the same namespace, and the deployments uses username/password authentication, with use of the optional flag **-check_portal_site_health** to check the health of Portal sites:

     ```
     python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD  -n NAMESPACE -check_portal_site_health
     ```

   - When subsystems are present in different namespaces, and the deployment uses username/password authentication

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD  -mgmt_ns
NAMESPACE -gw_ns NAMESPACE
```

- When all subsystems are in different namespaces, and the deployment uses username/password authentication:

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD  -mgmt_ns
NAMESPACE -gw_ns NAMESPACE -ptl_s NAMESPACE -a7s_ns NAMESPACE
```

- When all subsystems are in the same namespace, and the deployment uses SSO authentication:

```
python3 health_check_post_migration.py -n NAMESPACE --sso -s PLATFORM_API_HOSTNAME
```

- When all subsystems are in the same namespace, and the deployment uses SSO authentication silent mode:

```
python3 health_check_post_migration.py -n NAMESPACE --sso -s PLATFORM_API_HOSTNAME -api_key API_KEY_VALUE
```

- When there are multiple subsystems across namespaces:

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -n
"namespace1|namespace2|namespace3"
```

2. Complete any optional configuration steps needed for your deployment:
   a. If necessary, update redirect URLS in the authorization server.
      If OIDC or SSO authentication is being used, the redirect URLS must be updated in the authorization server after migration. For example, for Google OIDC, you must to add the new redirect URLs in Google Developer Console. The new redirect URLs can be found in the user registry in Cloud Manager.
   b. If necessary, complete configuration for Analytics.
      If the Analytics service is present on the target system, backups must be configured. Also, use the Cloud Manager UI to manually associate the Analytics with the Gateways, as needed.
   c. If the target system is Cloud Pak for Integration, you must use the password from the target API Connect system to log in to Platform Navigator.
   d. If necessary, update Portal and Gateway services names in scripts or utilities.
      The migrated Portal and Gateway services will have new names (old_name + "new"). Any scripts and utilities written using the apic toolkit must be updated if they are using names as input parameter and not the ids. This is applicable to only Portal and Gateway names.
3. Validate configuration data:
   a. Validate the data in the target API Connect system by logging into Cloud Manager and API Manager UIs.
   b. Validate the APIs published in the Gateways.
   c. Validate the Portal site URLs
   d. If necessary, update the DNS mapping info.
      Once all of the APIs are verified, you may need to update the DNS mapping info, to redirect the calls to the new Gateways and Portals.

   The v10 migration is now complete.
4. After migration is finished, and verification of the target system is complete, you can uninstall API Connect on the source system.
   See Uninstalling API Connect.

Verifying the target system on VMware

Verify that the target system is in a healthy state and fully configured.

Before you begin

Complete Restoring the target system on VMware.

About this task

Check the health of the target system, complete any optional configuration, and validate data, APIs, and URLs.

Procedure

1. Login to your target management VM with **SSH**, and switch to the root user:

   ```
   ssh apicadm@<management hostname>
   ```

   ```
   sudo -i
   ```

   If you deployed a three replica management profile, then login to just one of the VMs.
2. Run the health check script:

   ```
   python3 health_check_post_migration.py -s <platform API endpoint> -u admin -p <password> -r admin/default-idp-1 -n default
   ```

   where
   - *<platform API endpoint>* is defined in the apiconnect-up-v10.yml file in your project directory.
   - *<password>* is the admin password that is used on your source system.

Migrating from OpenShift to Cloud Pak for Integration on the same cluster

Migrate your API Connect v10 deployment from OpenShift to Cloud Pak for Integration, while remaining on the same cluster.

Before you begin

Your API Connect instance must use the top-level CR. Direct migration of individual API Connect subsystem installations to Cloud Pak for Integration by the steps described here is not supported. Alternative methods of migration if you are not using the top-level CR are:

- If the same subsystem endpoints can be used, deploy a new top-level CR API Connect and restore disaster recovery backups from your existing installation, see Backing up, restoring, and disaster recovery. The new top-level CR deployment can then be migrated to Cloud Pak for Integration following the steps here.
- If different subsystem endpoints need to be used, migrate your API Connect deployment to a new top-level CR OpenShift cluster first. Follow the form factor migration steps Migrating from v10 to v10 on a different form factor, and then return here to complete the OpenShift top-level CR to Cloud Pak for Integration migration.

About this task

V10.0.6.0 Only: Migration from OpenShift to Cloud Pak for Integration on the same cluster results in changes to the Management subsystem API endpoint URIs, as shown in these examples.

- apiManager endpoint changes from

  `https://topcr-mgmt-api-manager-apic.example.com/manager`

  to

  `https://cpd-apic.example.com/integration/apis/apic/topcr/manager`

- cloudManager endpoint changes from

  `https://topcr-mgmt-admin-apic.example.com/admin`

  to

  `https://cpd-apic.example.com/integration/apis/apic/topcr/admin`

- platformAPI endpoint changes from

  `https://topcr-mgmt-platform-api-apic.example.com/`

  to

  `https://cpd-apic.example.com/integration/apis/apic/topcr/api`

- consumerAPI endpoint changes from

  `https://topcr-mgmt-consumer-api-apic.example.com/`

  to

  `https://cpd-apic.example.com/integration/apis/apic/topcr/consumer-api`

Procedure

1. Update your `<TOP_CR_NAME>-mgmt-admin-pass` secret with your current Cloud Manager admin password:
   a. Check whether the `<TOP_CR_NAME>-mgmt-admin-pass` password already matches your Cloud Manager admin password with:

   ```
   oc get secret -n <APIC-namespace> | grep mgmt-admin-pass

   oc get secret -n <APIC-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d &&
   echo ""
   ```

   If the passwords match then skip to 2.
   b. From where you run OpenShift CLI commands, use the base64 command to encode your Cloud Manager admin password.

   ```
   echo -n '<password>' | base64
   ```

   Note: If the `base64` command is not available, alternative commands or tools can be used.
   c. Edit the `<TOP_CR_NAME>-mgmt-admin-pass` secret:

   ```
   oc edit secret <TOP_CR_NAME>-mgmt-admin-pass -n <namespace>
   ```

   d. Replace the `data.password` value with your base64 encoded value from 1.b.

   ```
   ...
   data:
     email: ZXhhbXBsZUBleGFtcGxlLmNvbQ==
     password: <base64 encoded password>
   kind: Secret
   metadata:
   ...
   ```

   Note: The password in `<TOP_CR_NAME>-mgmt-admin-pass` is only used on API Connect installation, form factor migration, and disaster recovery. It does not need to be kept in sync with the Cloud Manager during normal API Connect usage.
2. Install IBM Cloud Pak Platform UI and create an instance of it.
3. Restart the `apiconnect` operator pod.
   The restarted operator pod detects Cloud Pak for Integration and reconciles the subsystems with it. Wait for the subsystems to be healthy.
4. Log in to Cloud Manager and check the services under the topology section.
   Known issue: If you see an additional Analytics service with a different name for the same Analytics endpoint, you must delete the newly created Analytics service.
5. Check that the configurator job is complete: :

```
oc get pods -n <namespace>
...
NAME                                                READY   STATUS      RESTARTS   AGE
<instance name>-configurator-<random string>        0/1     Completed   0          2h
...
```

Complete the following validation checks:

- Verify you are able to login to the Cloud Pak for Integration Platform UI, and can see your API Connect instance.
- Verify you are able to login to Cloud Manager UI, API Manager UI, and your portal sites.
- Test that your APIs are running, and analytics data is logged.
- Test lifecycle operations such as a product publish or delete, or an app creation.

v10 migration troubleshooting

Troubleshoot problems with v10 migration.

Topics:

- Script help
- Restarting migration
- Factory reset of portal subsystem
- Avoid error when a gateway is already registered to another API manager

Script help

```
python3 <SCRIPT_FILE_NAME> --help
```

Restarting migration

On the target system, after running **register_gateway_portals_in_target.py** or **update_to_new_portals.py** or **update_to_new_gateways.py** script:

- If you want to restore the Management database and try the steps again:
  - Run the restore Management db (Step 2 on Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration) with the **-reset_gateway_portal** flag as shown

    ```
    python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
    ```

    If running on a Kubernetes environment, supply the Cloud Manager admin password by using the **-p** flag. After this, continue with next steps of migration.
- If you deleted the data directory after registering Gateways or Portals, but want to use the same target API Connect system which you already installed, then:
  1. Complete Preparing the source system to create the data directory.
  2. Run the restore management db (Step 2 on Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration) with the **-reset_gateway_portal** flag as shown

     ```
     python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
     ```

     If running on a Kubernetes environment, supply the Cloud Manager admin password by using the **-p** flag. After this, continue with next steps of migration.

Factory reset of portal subsystem

You can do a factory reset of the Portal subsystem by either manually or by using a migration script.

- Using migration script
  The script will restore the Management database and will factory reset the Portal subsystem, and also delete Gateway pods. The gateway pods will get restarted.

  The script will factory reset the Portal subsystem and also delete Gateway pods. When Gateway pods are deleted, they are also restarted.

  ```
  python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
  ```

  If using a Kubernetes environment, you must also supply the Cloud Manager admin password by using the **-p** flag. After this command, you must run the remaining steps of migration, starting with Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

  ```
  python3 register_gateway_portals_in_target.py -n NAMESPACE -u USERNAME -p PASSWORD -s HOSTNAME -r REALM_NAME -reset_gateway_portal
  ```

- **Manual steps**
  1. Log in to the Portal www pod:

     ```
     kubectl exec -it PORTAL_WWW_POD_NAME -c admin -n NAMESPACE -- bash
     ```

  2. Run the command :

     ```
     curl -X DELETE -k --cert /etc/nginx/ssl/portal-director-client-both.pem  https://localhost:3009/v2/portal/factory-reset
     ```

  3. If any sites are there, use the **list_sites** command to check if all sites are deleted.
  4. Check health of the Portal subsystem.

Avoid error when a gateway is already registered to another API manager

Error messages

```
Error: An error occurred communicating with the gateways subsystem at 'some_url' (status: 400, response: '"Unable to perform
initial registration for API Management.
Error: The API Connect Gateway Service is already registered to another API Manager instance"
```

You can fix the error condition manually, or use a script:

- Manual step, when Gateway is in a Kubernetes or OpenShift cluster:
  Restart all the gateway pods.
- Using the migration script when Gateway is in a Kubernetes or OpenShift cluster:
  The script will restore the Management database, factory reset the Portal subsystem, and delete the Gateway pods. Once deleted, Gateway pods get restarted.
  1. Run the following script:

     ```
     python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
     ```

     If using a Kubernetes environment, you must also supply the Cloud Manager admin password by using the **-p** flag.

  2. After this command, you must run the remaining steps of migration, starting with Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Gateway is on an Appliance
  Reboot all the Gateway appliances.

Shutting down the Postgres database

V10.0.6 only. Shutdown the Postgres database to ensure no changes are made to the database during migration.

Instructions:

- Shutting down Postgres database in Management subsystem on Kubernetes or VMware
- Shutting down Postgres database in Management subsystem on OpenShift

Shutting down Postgres database in Management subsystem on Kubernetes or VMware

When using s3 backup configuration for the Management subsystem, the following steps should be run on the source system, before the target API Connect system is installed.

1. If on a VMware appliance deployment, connect to the Management node and log in as root user (`sudo -i`), so that you can run `kubectl`.
2. Enable pgo client:

   ```
   kubectl set env deploy/ibm-apiconnect ENABLE_PGO_CLIENT="true" -n OPERATOR_NAMESPACE
   ```

3. Wait for `pgo-client` pod to come up.
4. Bring down the apic operator:

   ```
   kubectl scale deploy ibm-apiconnect --replicas=0 -n OPERATOR_NAMESPACE
   ```

5. Scale down deployments.
   Before scaling down the deployments, make a note of the current replicas:

   ```
   kubectl get deployment -n namespace
   ```

   - Standard deployments :
     - juhu
     - portal-proxy
     - apim
     - lur
     - taskmanager
     - hub (when Test and Monitor is enabled)

   a. Scale down:

   ```
   kubectl scale deploy <deployment_name> --replicas=0 -n NAMESPACE
   ```

   b. To get the name of the Postgres cluster:

   ```
   kubectl get pgcluster -n NAMESPACE
   ```

   c. Connect to pgo client pod and run:

   ```
   pgo update cluster PG_CLUSTER_NAME --shutdown -n NAMEPSACE
   ```

Shutting down Postgres database in Management subsystem on OpenShift

When using s3 configuration, the following steps should be run on the source system, before the target API Connect system is installed.

1. Change to operator namespace:

   ```
   oc project "{OPERATOR NS}"
   ```

2. `oc edit csv ibm-apiconnect.v2.4.0`
   a. Search for `APPLIANCE` and add these two lines above it:

   ```
   - name: ENABLE_PGO_CLIENT
     value: "true"
   ```

b. Save and wait for the pgo-client pod to come up.

3. `oc scale deploy ibm-apiconnect --replicas=0`
4. Bring down apiconnect operator pod:

   ```
   oc scale deploy ibm-apiconnect --replicas=0
   ```

5. Change to the namespace where API Connect is installed:

   ```
   oc project "{APIC NS}"
   ```

6. Scale down the following deployments: juhu, portal-proxy, apim, lur, taskmanager

   ```
   oc scale deploy JUHU_DEPLOYMENT_NAME --replicas=0
   oc scale deploy PORTAL_PROXY_DEPLOYMENT_NAME --replicas=0
   oc scale deploy APIM_DEPLOYMENT_NAME --replicas=0
   oc scale deploy LUR_DEPLOYMENT_NAME --replicas=0
   oc scale deploy TASKMANAGER_DEPLOYMENT_NAME --replicas=0
   ```

7. To get the name of the pg cluster:

   ```
   oc get pgcluster
   ```

8. Log in to pgo client pod:

   ```
   oc exec -it $(oc get po|grep pgo|awk '{print $1}') -- bash
   ```

9. Shutdown Postgres database:

   ```
   pgo update cluster PG_CLUSTER_NAME --shutdown -n NAMESPACE
   ```

Starting the Postgres database in the Management subsystem on Kubernetes and OVA

Use these steps when you are moving back to the source system because the migration failed, and you want to bring up the Postgres database, if it was shutdown.

1. If on an appliance (VMware), connect to the Management node and log in as root user (`sudo -i`), so that you can run the `kubectl` commands.
2. Get the name of the Postgres cluster:

   ```
   kubectl get pgcluster -n NAMESPACE
   ```

3. Connect to the pgo client pod and run the command:

   ```
   pgo update cluster PG_CLUSTER_NAME --startup -n NAMESPACE
   ```

4. Scale up the deployments that use Postgres.
   Standard deployments : juhu, portal-proxy, apim, lur, taskmanager, hub (when test and monitor is enabled)

   ```
   kubectl scale deploy DEPLOYMENT_NAME --replicas=N -n NAMEPSACE
   ```

   The value of `N` is from the `kubectl get deployment -n namespace` output that you got before shutting down the Postgres database. It is 1 if using n1 profile, and 3 when using n3 profile.

5. Bring up the apic operator:

   ```
   kubectl scale deploy ibm-apiconnect --replicas=1 -n OPERATOR_NAMESPACE
   ```

6. If s3 backups are used, perform a Management restore with the backup that was taken as part of Preparing the source system.
   Note: Any backups that are taken on the target system are not valid for the source system. The backups must not be used during restoration.
7. Ensure that all subsystems are healthy.

Starting postgres database on the Management subsystem on OpenShift

Use these steps when you are moving back to the source system because the migration failed, and you want to bring up the Postgres database, if it was shutdown.

1. Change to the project where the top-level CR (apic) is installed:

   ```
   oc project APIC_NAMESPACE
   ```

2. Get the name of the Postgres cluster:

   ```
   oc get pgcluster
   ```

3. Log in to pgo client pod:

   ```
   oc exec -it $(oc get po|grep pgo|awk '{print $1}') -- bash
   ```

4. Start the postgres database:

   ```
   pgo update cluster PG_CLUSTER_NAME --startup -n NAMESPACE
   ```

5. Scale up the deployments: juhu, portal-proxy, apim, lur, and taskmanager. Use the following commands, where `N` is the value of replicas. If an n1 profile being used the value is 1, and if an n3 profile is being used the value is 3.
   - `oc scale deploy JUHU_DEPLOYMENT_NAME --replicas=N`
   - `oc scale deploy PORTAL_PROXY_DEPLOYMENT_NAME --replicas=N`
   - `oc scale deploy APIM_DEPLOYMENT_NAME --replicas=N`
   - `oc scale deploy LUR_DEPLOYMENT_NAME --replicas=N`
   - `oc scale deploy TASKMANAGER_DEPLOYMENT_NAME --replicas=N`
6. Bring down the apiconnect operator pod:

   ```
   oc scale deploy ibm-apiconnect --replicas=1 -n OPERATOR_NAMESPACE
   ```

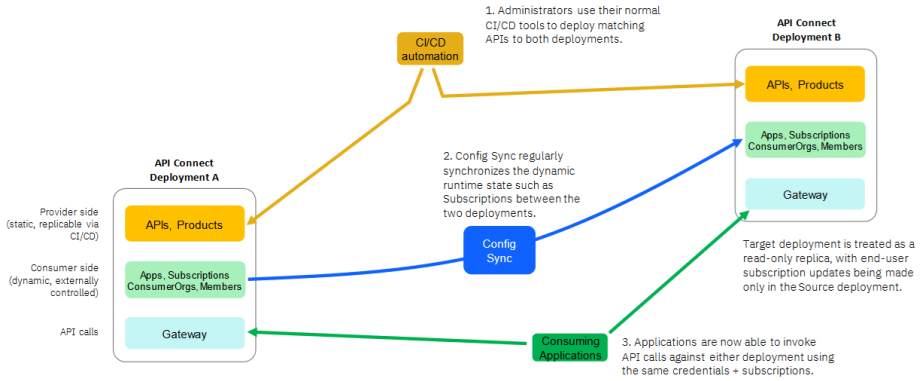
7. If s3 backups are used, perform a Management restore with the backup that was taken as part of Preparing the source system.
   Note: Any backups that are taken on the target system are not valid for the source system. The backups must not be used during restoration.
8. Ensure that all subsystems are healthy.

[Technical Preview] Using Config Sync to replicate consumer-side catalog data

Use the API Connect Config Sync utility to replicate consumer-side data from a source catalog in an API Connect cluster to a target catalog in a different API Connect cluster, so that API calls can be served by either API Connect cluster interchangeably to enable hybrid deployments and high-availability style scenarios.

API Connect Config Sync (apic-configsync) can be run either as a standalone binary, or a schedule with a Kubernetes cronjob, to facilitate the unidirectional replication of consumer-side data (consumer organizations, members, apps, subscriptions, credentials) from a catalog in a source API Connect cluster to a corresponding catalog in a separate, target API Connect cluster.

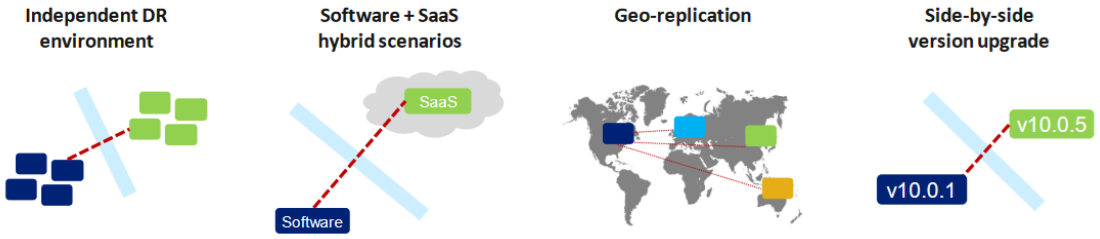
The following image shows how you can use Config Sync to replicate consumer-side data from a source deployment to a target deployment:



Config Sync can be run as frequently as required, and detects the differences between the replicated resource types in the source and target catalogs so that it efficiently replicates only the new changes that have been made in the source instance.

As shown in the following image, Config Sync helps to enable a range of hybrid cloud API topologies such as:

- Independent disaster recovery instances
- Software and SaaS hybrid scenarios
- Geo-replication
- Side-by-side version upgrade



This feature is provided as a Technical Preview

As such, the feature might not be fully functional in your environment and support is limited. In addition, the feature's appearance and functionality are subject to change both in this release and in later releases of API Connect. For more information, see https://ibm.biz/api-connect-config-sync.

Requirements

For API Connect Config Sync to run successfully, the following requirements that must be satisfied:

- You are responsible for configuring the API Connect the target deployment to appropriately match the source deployment, so that replication of consumer-side data can take place:
  - The target API Connect deployment must be configured correctly including topology setup, provider organization creation, and catalog creation.
  - The APIs and Products in the source catalog must be replicated in the target catalog using either CI/CD or manual procedures.
  - The target catalog settings (including any spaces if they are enabled in the source catalog) must be configured to match the configuration of the source catalog. This includes compatible gateways and any extensions, user registries, and any other relevant catalog settings (such as lifecycle approvals, application lifecycle, and so on).
  - Compatible onboarding User Registries must be configured in the target catalog (the user registry name and type must match that of the corresponding source user registry, that is, the source and target catalog names must match if you are using the default user registry).
  - All OAuth providers must be configured on the target catalog and spaces.
  - All API User Registries must be configured on the target catalog and spaces.
  - All TLS client profiles must be configured on the target catalog and spaces.
- The Config Sync utility makes use of the API Connect Provider REST API, so you must have connectivity (into both the source and target clusters) with sufficient provider organization user permissions.
- The `metadata.source_id` key is reserved for use by Config Sync.

    - Because the underlying creation of resources in the target catalog uses the API Connect Provider REST API, the IDs and URLs associated with resources in the target catalog will be different from their corresponding resources in the source catalog (only the cluster-agnostic data of a resource is synchronized).
    - To track which resources in the source catalog map to which resources in the target catalog, Config Sync uses the `metadata` field of a particular resource. When a new resource is created in the target catalog, the `metadata` field of that resource is set to contain a key named `source_id` with a value equal to the ID of the corresponding resource in the source catalog that is being synchronized.
- API Connect Config Sync also uses the `name` field of some resources to determine a match. This is typically done for resources that are not synchronized by the utility but are needed in the target catalog for the synchronization to be successful; for example, User Registries, Consumer Org Groups, Roles, and published Products (the `name` and `version` fields are used for product matching).

Note: The first time API Connect Config Sync runs, it might take longer to complete than subsequent runs require (depending on the number of resources to synchronize). The first run of the utility creates all new resources in the target cluster; subsequent runs only perform synchronization of any data that was added, updated, or deleted since the last run of the utility.

Limitations

API Connect Config Sync has the following limitations:

- Config Sync does not back up data; it merely replicates the contents of a source catalog to a target catalog. You must still perform periodic backups to ensure the safety of your data.
- The target catalog is a read-only replica: only unidirectional synchronization of data from the source catalog to the target catalog is supported. Subsequent changes made in the target catalog cannot be synchronized back to the source.
- Source and target deployments operate independently of each other:
    - API rate limiting on Plans is counted independently in the source catalog and the target catalog.
    - OIDC tokens are not replicated. OIDC tokens generated in the source cluster are not valid within the target cluster.
    - Local User Registry (LUR) passwords are not replicated. Consumer organization members belonging to a Local User Registry (LUR) must reset their password in the target cluster.
    - Analytics data is tracked independently in the source cluster and the target cluster. Analytics data is not replicated or aggregated across clusters.
    - Developer portal configuration is not replicated. If you want to enable consumer organization access in the target catalog, you must replicate your Developer Portal site for consistency (restore the site with UUID/URL update where needed).
- Config Sync operates on a single source-target catalog pair at a time.
  If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

Supported versions of API Connect

Config Sync can synchronize consumer-side resources across different versions of API Connect clusters. The target API Connect cluster version must always be greater or equal to the source API Connect cluster version. Table 1 shows the supported version combinations:

Table 1. Supported source and target version combinations of API Connect

Source version	Target Version	Release Stream
10.0.1.15	10.0.5+	Earlier LTS -> Current LTS
10.0.5+	10.0.5+	Current LTS -> Current LTS
10.0.5+	10.0.7	Current LTS -> Current CD
10.0.7	10.0.7	Current CD -> Current CD

- **Downloading the API Connect Config Sync utility**
  Download and extract the API Connect Config Sync utility from the Early Access Program site.
- **Setting environment variables for Config Sync**
  Configure environment variables that can be used by the API Connect Config Sync utility.
- **Running Config Sync as a standalone binary**
  The pre-built binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.
- **Running Config Sync as a cronjob on OpenShift**
  Running the apic-configsync utility as a cronjob on Red Hat OpenShift or IBM Cloud Pak for Integration enables the utility to be run on a timed basis, such as every 10 minutes.
- **Running Config Sync as a cronjob on Kubernetes**
  Running the apic-configsync utility as a cronjob on Kubernetes enables the utility to be run on a timed basis, such as every 10 minutes.
- **Running Config Sync as a cronjob on VMware**
  Running the apic-configsync utility as a cronjob on VMware enables the utility to be run on a timed basis, such as every 10 minutes.

Downloading the API Connect Config Sync utility

Download and extract the API Connect Config Sync utility from the Early Access Program site.

About this task

The apic-configsync.tar.gz file contains the following artifacts:

- A binaries directory with sub-directories containing the apic-configsync utility for each of the supported client platforms (Mac, Windows, and Linux x86).
- A helper_files directory containing YAML files for configuring cronjobs if you want to run the utility on a schedule.
- An ibm-apic-configsync-image.tar.gz file containing the Docker image for running the utility on a schedule in a Kubernetes cluster with a cronjob.

Procedure

1. Sign up to the API Connect Config Sync Early Access Program at the following location: https://ibm.biz/api-connect-config-sync.

2. Agree to the terms.
3. Download the apic-configsync.tar.gz file.
4. Extract the apic-configsync.tar.gz package by running the following command:

```
tar xf apic-configsync.tar.gz
```

Setting environment variables for Config Sync

Configure environment variables that can be used by the API Connect Config Sync utility.

API Connect Config Sync consumes a set of configuration properties required to connect to and perform REST calls against the source and target API Connect clusters. The configuration properties are passed to the utility with environment variables.

The following environment variables must be set to the appropriate values for the source and target API Connect cluster:

```
# Properties for source catalog
export SOURCE_MGMT_SERVER=https://yoursourcehostname.com/path
export SOURCE_ORG=sourceporg
export SOURCE_REALM=provider/default-idp-2
export SOURCE_ADMIN_USER=sourceadmin
export SOURCE_ADMIN_PASSWORD=sourceadminpassword
#export SOURCE_ADMIN_APIKEY=1010101010101010
export SOURCE_CATALOG=sourcecatalog
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=00000000-0000-0000-0000-000000000000
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=11111111-1111-1111-1111-111111111111

# Properties for target catalog
export TARGET_MGMT_SERVER=https://yourtargethostname.com/path
export TARGET_ORG=targetporg
export TARGET_REALM=provider/default-idp-2
export TARGET_ADMIN_USER=targetadmin
export TARGET_ADMIN_PASSWORD=targetadminpassword
#export TARGET_ADMIN_APIKEY=2020202020202020
export TARGET_CATALOG=targetcatalog
export TARGET_TOOLKIT_CREDENTIALS_CLIENTID=22222222-2222-2222-2222-222222222222
export TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=33333333-3333-3333-3333-333333333333
```

Download the Toolkit credentials file

A number of the required configuration properties can be obtained from the Toolkit credentials file that can be downloaded from the API manager UI for the API Connect cluster.

1. Log in to the API Manager UI.
2. From the Home page, select the Download Toolkit tile.
3. In "Step 2" of the Download dialog box, select Toolkit credentials - Download.
4. Open the resulting credentials.json file in a text editor so that you can locate and copy settings as explained in the next section.

Locating information for the environment variables

The following list explains how to obtain the setting for each of the environment variables.

`*_MGMT_SERVER`
: This property specifies the hostname and path that provides access to the REST API endpoint for your catalog. Locate **`toolkit.endpoint`** property in the toolkit **`credentials.json`** file, and set the **`*_MGMT_SERVER`** variable to the value of the **`toolkit.endpoint`** property.
The value might look like the following example:

  ```
  https://platform-api.hostname.com/api
  ```

`*_TOOLKIT_CREDENTIALS_CLIENTID, *_TOOLKIT_CREDENTIALS_CLIENTSECRET`
: The toolkit credentials **`clientID`** and **`clientSecret`** are used to authenticate the utility to be able to make REST API calls against the API Connect cluster. Locate following properties in the toolkit **`credentials.json`** file, and set the environment variables as shown:

  - Set the **`*_TOOLKIT_CREDENTIALS_CLIENTID`** variable to the value of the **`toolkit.client_id`** property
  - Set the **`*_TOOLKIT_CREDENTIALS_CLIENTSECRET`** variable to the value of the **`toolkit.client_secret`** property

`*_ORG`
: This is the short name of the provider organization in which your catalog is hosted. Set the **`*_ORG`** variable to the value of the provider organization's **`Name`** property. To locate the provider organization name, complete the following steps:

  1. Log in to the API Manager.
  2. From the Home tab, select Manage settings.
  3. On the Settings page, click the Overview tab and locate the value of the **`Name`** property (not the **`Title`**).

`*_REALM`
: This property specifies the identity provider realm of the API Manager registry for your instance of API Connect. Set the **`*_REALM`** variable to the value of the realm name. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see **`*_API_KEY`** for details).
To obtain the realm name, run the following toolkit CLI command:

  ```
  apic identity-providers:list --scope provider --server <mgmt_endpoint_url> --fields title,realm
  ```

  where ***`<mgmt_endpoint_url>`*** is the API Manager URL with any segments (for example, **`/manage`**) removed from the end of the URL. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in Viewing platform and UI endpoints.

The following example shows a response listing the available realms for a deployment:

```
apic identity-providers:list --scope provider --server <mgmt_endpoint_url> --fields title,realm

total_results: 2
results:
  - title: 'API Manager User Registry'
    realm: 'provider/default-idp-2'
  - title: 'Common Services User Registry'
    realm: 'provider/common-services'
```

In the example, the realm for the API Manager registry is **provider/default-idp-2**.

For more information on obtaining the realm name, see How to determine the identity provider.

***_CATALOG**
This property indicates the name of the Catalog that you want to synchronize. Set the ***_CATALOG** variable to the value of the catalog's **Name** property.
To locate the catalog name, complete the following steps:

1. Log in to the API Manager UI.
2. From the Home tab, select Manage catalogs.
3. Select the tile for the catalog you want to synchronize.
4. Click the Catalog settings tab.
5. On the Settings page, locate the value of the catalog's **Name** property (not the **Title**).

***_ADMIN_USER**
This property is the name of the user account under which you will authenticate to the catalog. Set the ***_ADMIN_USER** variable to the value of the username that the utility will log in with to perform the synchronization task. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see ***_API_KEY** for details).
In the source catalog, the user must be a Catalog Administrator or Organization Administrator with the ability to create consumer objects on behalf of the end users.
In the target catalog, the user must have authorization to Update the catalog settings and enable or disable the **hash_client_secret** property.

To confirm the username, complete the following steps:

1. Log in to the API Manager UI with the user account you will use to synchronize the catalog.
2. Click the username in the page header.
3. Select My account.
4. Locate the value of the Username property.

***_ADMIN_PASSWORD**
In most cases you will authenticate to the API Manager with the password associated to your username. Set the ***_ADMIN_PASSWORD** property to your password, being careful with any non-alphanumeric characters that may be in your password. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see ***_API_KEY** for details).
Attention: If you set the ***_ADMIN_PASSWORD** variable, then skip the ***_ADMIN_APIKEY** variable. Do not set both variables when synchronizing a particular catalog.

***_ADMIN_APIKEY**
In API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example API Connect Enterprise as a Service), you must authenticate using an API key instead of your password.
To locate your API key, complete the following steps:

1. Log in to the API Manager UI using your IBM ID.
2. In the page header, click and select My API Keys.
3. On the My API Keys page, click Add.
4. Set a title and description for your new API key and click Create.
5. Copy the new API key from the dialog box.

Attention: If you set the ***_ADMIN_APIKEY** variable, then skip the ***_ADMIN_PASSWORD** variable. Do not set both variables when synchronizing a particular catalog.

Setting the environment variables

- Mac and Linux x86:
  On Mac or Linux x86, you can either export the environment variables individually on the command line directly or create a script to export the environment variables and source that file from the command line, as in the following example:

```
# Properties for source catalog
export SOURCE_MGMT_SERVER=https://yoursourcehostname.com/path
export SOURCE_ORG=sourceporg
export SOURCE_REALM=provider/default-idp-2
export SOURCE_ADMIN_USER=sourceadmin
export SOURCE_ADMIN_PASSWORD=sourceadminpassword
#export SOURCE_ADMIN_APIKEY=1010101010101010
export SOURCE_CATALOG=sourcecatalog
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=00000000-0000-0000-0000-000000000000
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=11111111-1111-1111-1111-111111111111

# Properties for target catalog
export TARGET_MGMT_SERVER=https://yourtargethostname.com/path
export TARGET_ORG=targetporg
export TARGET_REALM=provider/default-idp-2
export TARGET_ADMIN_USER=targetadmin
export TARGET_ADMIN_PASSWORD=targetadminpassword
#export TARGET_ADMIN_APIKEY=2020202020202020
export TARGET_CATALOG=targetcatalog
export TARGET_TOOLKIT_CREDENTIALS_CLIENTID=22222222-2222-2222-2222-222222222222
export TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=33333333-3333-3333-3333-333333333333
```

In the example, notice that the command to set the ***_ADMIN_APIKEY** variable is commented out because the ***_ADMIN_PASSWORD** is used instead.

- Windows:
  On Windows, you can set each environment variable individually by opening a command window and running the following command for each variable:

  ```
  setx <variable_name> "<variable_value>"
  ```

  where:
  - ***<variable_name>*** is the name of the environment variable to set
  - ***<variable_value>*** is the value to set for the specified variable name

  Alternatively, you can create a batch file that uses the **setx** command to set the environment variables, as in the following example:

  ```
  REM Properties for source catalog
  setx SOURCE_MGMT_SERVER "https://yoursourcehostname.com/path"
  setx SOURCE_ORG "sourceporg"
  setx SOURCE_REALM "provider/default-idp-2"
  setx SOURCE_ADMIN_USER "sourceadmin"
  setx SOURCE_ADMIN_PASSWORD "sourceadminpassword"
  REM setx SOURCE_ADMIN_APIKEY "1010101010101010"
  setx SOURCE_CATALOG "sourcecatalog"
  setx SOURCE_TOOLKIT_CREDENTIALS_CLIENTID "00000000-0000-0000-0000-000000000000"
  setx SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET "11111111-1111-1111-1111-111111111111"

  REM Properties for target catalog
  setx TARGET_MGMT_SERVER "https://yourtargethostname.com/path"
  setx TARGET_ORG "targetporg"
  setx TARGET_REALM "provider/default-idp-2"
  setx TARGET_ADMIN_USER "targetadmin"
  setx TARGET_ADMIN_PASSWORD "targetadminpassword"
  REM setx TARGET_ADMIN_APIKEY "2020202020202020"
  setx TARGET_CATALOG "targetcatalog"
  setx TARGET_TOOLKIT_CREDENTIALS_CLIENTID "22222222-2222-2222-2222-222222222222"
  setx TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET "33333333-3333-3333-3333-333333333333"
  ```

  In the example batch file, notice that the command to set the ***_ADMIN_APIKEY** variable is commented out because the ***_ADMIN_PASSWORD** is used instead.

Running Config Sync as a standalone binary

The pre-built binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.

About this task

Running a standalone invocation of apic-configsync using one of the pre-built binaries is the most flexible option. For optimal performance, apic-configsync should run as close to the target cluster as possible.

Complete the following steps to configure environment variables and run the standalone binary.

Procedure

1. Download and extract the API Connect Config Sync package.
2. In the extracted package, navigate to the /binaries/*<platform>* directory that contains the appropriate version of the apic-configsync utility for your platform.
3. Define the environment variables for the source and target catalogs.
4. Run the utility with the following command:
   - Mac and Linux x86: `./apic-configsync`
   - Windows: `apic-configsync.exe`

Running Config Sync as a cronjob on OpenShift

Running the apic-configsync utility as a cronjob on Red Hat OpenShift or IBM Cloud Pak for Integration enables the utility to be run on a timed basis, such as every 10 minutes.

Before you begin

Ensure that the following prerequisites are satisfied before attempting to configure the cronjob:

- Ensure that you have a tool available for copying the image into your image registry.
  The examples in this topic use **skopeo** to copy the image to the target registry, but you could use equivalent **docker** or **podman** commands instead.
- Expose the OpenShift registry with **defaultRoute** by running the following command:

  ```
  oc patch configs.imageregistry.operator.openshift.io/cluster --patch '{"spec":{"defaultRoute":true}}' --type=merge
  ```

  For more information, see Exposing the registry in the OpenShift documentation. It is not necessary to perform step 5 (the "podman login" step) in the instructions.
- Set the **REGISTRY_HOST** environment variable to the OpenShift registry by running the following command:

  ```
  REGISTRY_HOST=$(oc get route default-route -n openshift-image-registry --template='{{`{{ .spec.host }}`}}')
  ```

- Set the **APIC_PROJECT** environment variable to the namespace (project) where you intend to run the cronjob. For optimal performance, the cronjob should run within the same OpenShift environment as the target API Connect cluster.

About this task

You can configure the apic-configsync utility to run as a cronjob in an API Connect deployment running on OpenShift or Cloud Pak for Integration. The apic-configsync utility should run as close to the target cluster as possible, so the cronjob should be configured to run within the same OpenShift environment as the target API Connect cluster.

Procedure

1. Download and extract the API Connect Config Sync package.
2. Extract the Config Sync image from the extracted API Connect Config Sync package by running the following command:

   ```
   tar xf ibm-apic-configsync-image.tar.gz
   ```

3. Copy the extracted Config Sync image to the target registry.
   For example, if you use skopeo, run the following command:

   ```
   skopeo copy --dest-tls-verify=false --dest-registry-token=$(oc whoami -t) dir:./ibm-apic-configsync/ibm-apic-configsync-<version>/<tag> docker://$REGISTRY_HOST/$APIC_PROJECT/ibm-apic-configsync-<version>:<tag>
   ```

   Replace ***<version>*** and ***<tag>*** with their actual values. To ensure that you use the most recent values, copy them from the README file located in the root of the extracted API Connect Config Sync package.

4. Define the environment variables for the source and target catalogs.
5. Create secrets to host configuration details for the source cluster and the target cluster.
   a. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

   ```
   oc create secret --namespace $APIC_PROJECT generic source-catalog-details \
       --from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \
       --from-literal=SOURCE_ORG=$SOURCE_ORG \
       --from-literal=SOURCE_REALM=$SOURCE_REALM \
       --from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \
       --from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \
       --from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \
       --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \
       --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
   ```

   b. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

   ```
   oc create secret --namespace $APIC_PROJECT generic target-catalog-details \
       --from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \
       --from-literal=TARGET_ORG=$TARGET_ORG \
       --from-literal=TARGET_REALM=$TARGET_REALM \
       --from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \
       --from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \
       --from-literal=TARGET_CATALOG=$TARGET_CATALOG \
       --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \
       --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
   ```

6. Create the cronjob:
   a. Open the `helper_files/configsync-cronjob-ocp.yaml` file located in the extracted API Connect Config Sync package.
   b. Modify the `schedule` property to specify how frequently the job will run.
   The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.

   c. Set the `concurrencyPolicy` to `Forbid`.
   Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

   d. In the `image` property, replace the ***<APIC_PROJECT>*** variable with the namespace (project) where you will run the cronjob.
   e. Create the cronjob resource in the cluster by running the following command:

   ```
   oc --namespace $APIC_PROJECT apply -f helper_files/configsync-cronjob-ocp.yaml
   ```

Running Config Sync as a cronjob on Kubernetes

Running the apic-configsync utility as a cronjob on Kubernetes enables the utility to be run on a timed basis, such as every 10 minutes.

Before you begin

Ensure that the following prerequisites are satisfied before attempting to configure the cronjob:

- Ensure that you have a tool available for copying the image into your image registry.
  The examples in this topic use `skopeo` to copy the image to the target registry, but you could use equivalent `docker` or `podman` commands instead.

About this task

You can configure the apic-configsync utility to run as a cronjob in an API Connect deployment running on Kubernetes. The apic-configsync utility should run as close to the target cluster as possible, so the cronjob should be configured to run within the same Kubernetes environment as the target API Connect cluster.

Procedure

1. Download and extract the API Connect Config Sync package.
2. Extract the Config Sync image from the extracted API Connect Config Sync package by running the following command:

   ```
   tar xf ibm-apic-configsync-image.tar.gz
   ```

3. Copy the extracted Config Sync image to the target registry.
   For example, if you use skopeo, run the following command:

   ```
   skopeo copy dir:./ibm-apic-configsync/ibm-apic-configsync-<version>/<tag> docker://<registry>/ibm-apic-configsync/ibm-apic-configsync-<version>:<tag>
   ```

   Replace ***<version>*** and ***<tag>*** with their actual values. To ensure that you use the most recent values, copy them from the README file located in the root of the extracted API Connect Config Sync package.

   Replace ***<registry>*** with the actual registry value for your image registry. Refer to the skopeo documentation on configuring credentials for your destination registry.

4. Define the environment variables for the source and target catalogs.
5. Create secrets to host configuration details for the source cluster and the target cluster.
   a. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

   ```
   kubectl create secret --namespace <namespace> generic source-catalog-details \
       --from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \
       --from-literal=SOURCE_ORG=$SOURCE_ORG \
       --from-literal=SOURCE_REALM=$SOURCE_REALM \
       --from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \
       --from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \
       --from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \
       --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \
       --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
   ```

   b. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

   ```
   kubectl create secret --namespace <namespace> generic target-catalog-details \
       --from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \
       --from-literal=TARGET_ORG=$TARGET_ORG \
       --from-literal=TARGET_REALM=$TARGET_REALM \
       --from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \
       --from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \
       --from-literal=TARGET_CATALOG=$TARGET_CATALOG \
       --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \
       --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
   ```

6. Create the cronjob:
   a. Open the `helper_files/configsync-cronjob-k8s.yaml` file located in the extracted API Connect Config Sync package.
   b. Modify the `schedule` property to specify how frequently the job will run.
   The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.

   c. Set the `concurrencyPolicy` to `Forbid`.
   Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

   d. In the `image` property, replace the ***<registry>*** variable with the actual registry value for your image registry.
   e. Create the cronjob resource in the cluster by running the following command:

   ```
   kubectl --namespace <namespace> apply -f helper_files/configsync-cronjob-k8s.yaml
   ```

Running Config Sync as a cronjob on VMware

Running the apic-configsync utility as a cronjob on VMware enables the utility to be run on a timed basis, such as every 10 minutes.

About this task

You can configure the apic-configsync utility to run as a cronjob in an API Connect deployment running on VMware. The apic-configsync utility should run as close to the target cluster as possible, so the cronjob should be configured to run from the management subsystem virtual machines in the target API Connect cluster.

Ensure that your virtual machines have enough resources available (CPU/Memory) for the cronjob to run the apic-configsync utility.

Procedure

1. Download and extract the API Connect Config Sync package.
2. Define the environment variables for the source and target catalogs.
3. For each node in the management subsystem:
   a. In the extracted apic-configsync.tar.gz package, locate the `ibm-apic-configsync-image.tar.gz` file.
   b. Upload the `ibm-apic-configsync-image.tar.gz` file using the following command:

   ```
   scp ibm-apic-configsync-image.tar.gz apicadm@<hostname>:~
   ```

   where ***<hostname>*** is the hostname or IP address of the node.

   c. SSH into the node and become root with `sudo -i`.
   d. Switch into the registry directory with the following command:

```
cd /var/lib/apiconnect-subsystem/registry/
```

e. Extract the image from the tar.gz file with the following command:

```
tar xf /home/apicadm/ibm-apic-configsync-image.tar.gz
```

Extracting the file creates the following directory:

```
/var/lib/apiconnect-subsystem/registry/ibm-apic-configsync/ibm-apic-configsync-<version>/<tag>
```

where ***<version>*** is the current version of the apic-configsync utility and ***<tag>*** is the tag of the built image.

f. Restart the appliance-manager by running the following command:

```
systemctl restart appliance-manager
```

4. Create secrets to host configuration details for the source cluster and the target cluster.
   a. SSH into one of the nodes in the management subsystem and become root with `sudo -i`.
   b. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

```
kubectl create secret generic source-catalog-details \
    --from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \
    --from-literal=SOURCE_ORG=$SOURCE_ORG \
    --from-literal=SOURCE_REALM=$SOURCE_REALM \
    --from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \
    --from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \
    --from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \
    --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \
    --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

   c. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

```
kubectl create secret generic target-catalog-details \
    --from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \
    --from-literal=TARGET_ORG=$TARGET_ORG \
    --from-literal=TARGET_REALM=$TARGET_REALM \
    --from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \
    --from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \
    --from-literal=TARGET_CATALOG=$TARGET_CATALOG \
    --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \
    --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

5. Create the cronjob:
   a. Open the `helper_files/configsync-cronjob-ova.yaml` file located in the extracted API Connect Config Sync package.
   b. Modify the `schedule` property to specify how frequently the job will run.
   The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.

   c. Set the `concurrencyPolicy` to `Forbid`.
   Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

   d. Upload the `helper_files/configsync-cronjob-ova.yaml` file to one of the management nodes.
   To upload the file, run the following command:

```
scp helper_files/configsync-cronjob-ova.yaml apicadm@<hostname>:~
```

   Replace ***<hostname>*** with the host name or IP of one of the nodes in the management subsystem.

   e. SSH into one of the nodes in the management subsystem and become root with `sudo -i`.
   f. Create the cronjob resource in the cluster by running the following command:

```
kubectl apply -f /home/apicadm/configsync-cronjob-ova.yaml
```

The API Connect operations tool: apicops

Use the apicops operations tool to check the health, troubleshoot, and run maintenance operations on your API Connect installation.

The API Connect apicops tool is in active development and is available to download from github.com. It is available for Linux® and macOS. All suggestions, feedback, and bug reports can be raised in this repository.

Installing

Download the binary for your operating system from latest release. Rename the file to **apicops**, and give it execute permission: `chmod +x apicops`.

Running apicops

Apicops requires access to your Kubernetes or OpenShift environment. For more information about using apicops, see: Requirements for running apicops.

Configuring and managing your server environment

You configure and manage the servers that comprise your IBM® API Connect on-premises cloud by using the Cloud Manager user interface.

The Cloud Manager user interface is the part of IBM API Connect that enables a Cloud Administrator to define and manage the API Connect on-premises cloud.

You can use the Cloud Manager to define the API Connect cloud by performing the following tasks:

- Create Provider organizations and invite users to serve as the owner
- Create and manage user roles and role defaults
- Create availability zones for services
- Register the relevant servers that will provide the gateway, analytics, and portal services
- Associate an analytics service with a gateway to enable reports for API Events
- Configure resources for user authentication, TLS security, and OAuth providers and make the resources visible to all or selected provider organizations
- Connect to an existing SMTP mail server and edit templates for system-generated emails
- Set the default gateway service for catalogs

- **Cloud Manager configuration checklist**
  A summary, with links, of the key initial configuration tasks that you must complete in the Cloud Manager user interface after installing and deploying IBM API Connect, and further supplementary tasks.
- **Activating your Cloud Manager user account**
  If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.
- **Accessing the Cloud Manager user interface**
  How to navigate to and login to the Cloud Manager user interface.
- **Defining your Cloud Manager topology**
  To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. A Default Availability Zone is provided on installation.
- **Managing authentication and security**
  Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.
- **Configuring the cloud settings**
  Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.
- **Configuring API governance in the Cloud Manager**
  How to add API governance rulesets in the Cloud Manager, to validate and enforce organizational governance policies and best practices across your API development process.
- **Administering provider organizations**
  Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.
- **Administering members and roles**
  Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.
- **Monitoring the cloud**
  API Connect generates events to monitor the status of your cloud.
- **Changing your Cloud Manager password and profile information**
  You can change your Cloud Manager password and update your profile information.
- **Resolving login problems by increasing HTTP header size**
  You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.
- **Onboarding a new admin for Cloud Pak for Integration**
  Use the API Connect toolkit CLI to create a new admin account for use with Cloud Pak for Integration.
- **Extending the Gateway server behavior**
  To support your enterprise requirements, you can extend the Gateway servers within IBM API Connect to provide extra enforcement behavior.
- **Cloud Manager Tutorials**
  Tutorials for using the Cloud Manager user interface in IBM API Connect.

Cloud Manager configuration checklist

A summary, with links, of the key initial configuration tasks that you must complete in the Cloud Manager user interface after installing and deploying IBM® API Connect, and further supplementary tasks.

Key initial tasks

Task	Description
Log in to the Cloud Manager user interface	A default admin user account is provided for you to begin your configuration tasks.
Configure an email server for notifications	The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service.
Specify your email server as the notification server	Select the email server to be used as the notification server, and configure the sender name and email address to be included in the emails.
Register a Gateway service	A Gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting.
Register an Analytics service	The Analytics service collects API event data from the Gateway service.
Associate the Analytics service with a Gateway service	You must associate an Analytics service with each of the Gateway services from which you want to collect API event data.
Register a Portal service	The Portal service provides a developer portal used by application developers to discover APIs and onboard consumers.

Task	Description
Create a provider organization	For developers to be able to publish APIs, and for API managers to be able to manage the API lifecycle, they must be a member of a provider organization. You must create a least one provider organization specifying the owner, who can add further members.

Further supplementary tasks

Task	Description
Configure authentication and security	API Connect provides default local user registries, but you can configure your own user registries, of various types, for user interface and API access control. You can also configure TLS profiles for securing data transmission over HTTPS, and OAuth providers for securing third-party website or application access to APIs.
Create an Availability Zone	An Availability Zone is a logical grouping of one or more API Connect services. A default Availability Zone is provided on installation, but you can add further Availability Zones to reflect your data center topology.
Administer members and roles	You can add further users as members of the administration organization, and control their permissions by assigning predefined roles. You can also create your own custom roles.
Monitor your API Connect cloud	API Connect generates events to allow you to monitor the status of your cloud.

Activating your Cloud Manager user account

If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.

Before you begin

A cloud administrator invited you to join API Connect .

Procedure

1. Complete the following steps to activate your Cloud Manager account:

   If the Identity Provider uses LDAP
   : An invitation email with an activation link is sent. Click the activation link, or paste it in a browser, to log in directly with your LDAP user credentials. Upon authentication, the API Connect user record is updated from the backend identity provider.

   If the Identity Provider uses a local registry
   : An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your first name, last name and password. Passwords must have a minimum of 8 characters and contain characters from at least three of the four following categories:
     - Uppercase letters
     - Lowercase letters
     - Numbers
     - Special characters (for example: ! # $ %)

     Note:
     - The email address that you enter on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails.
     - If you previously had an account that was removed, and you are being invited again, you must re-activate your account by using the Sign In option on the page, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail.

   If the Identity Provider uses an authentication URL
   : An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your credentials, which then become your user name and password. Upon authentication, the API Connect user record is updated from the backend identity provider.

   If multiple user registries are available for selection on the sign up page, then make sure that the correct registry for your Cloud Manager account is selected. You might need to ask your administrator which user registry is appropriate for your account.

   For information on configuring user registries and making them available for Cloud Manager login, see User registries overview and Selecting user registries for Cloud Manager and API Manager.

2. Click Sign up to complete your registration, then click Sign in to open the Cloud Manager login page.

Results

You have created your API Connect administrator account.

What to do next

Log in to the Cloud Manager user interface and, depending on your role, start to manage the cloud topology, and work with provider organizations and cloud resources.

To access the Cloud Manager login page in the future, use the following URL:

`https://host/admin`

where *host* is the fully qualified host name or IP address of the Management server.

Related tasks

- Accessing the Cloud Manager user interface
- Defining your Cloud Manager topology
- Administering provider organizations
- Administering members and roles

Accessing the Cloud Manager user interface

How to navigate to and login to the Cloud Manager user interface.

Procedure

1. Open a browser and enter the URL for the cloud-admin-ui endpoint followed by /admin. Note that this is a secure connection that uses HTTPs, for example: **`https://<cloud-admin-ui>/admin`**.
   - VMware installations: The cloud-admin-ui endpoint was set during installation of the Management subsystem by the following command: **`apicup subsys set mgmt cloud-admin-ui <endpoint>`**. Append **`/admin`** to this value.
   - Kubernetes, OpenShift, Cloud Pak for Integration installations: The cloud-admin-ui endpoint is specified in the Management subsystem CR, in the **`Endpoints`** section, for example:

     ```
     Endpoints:
       ...
       Name:   admin
       Type:   UI
       Uri:    https://example.com/admin
       ...
     ```

2. Enter the Cloud Administrator user name and password.
   - Kubernetes, VMware, and OpenShift individual Management subsystem install:
     If you are logging in for the first time, enter `admin` for the user name and `7iron-hide` for the password. Otherwise, enter `admin` for the user name and your own password.
   - OpenShift top-level CR install:
     The default user name is `admin`. If you are logging in for the first time, run the following commands to retrieve the initial password, which is generated automatically during deployment:

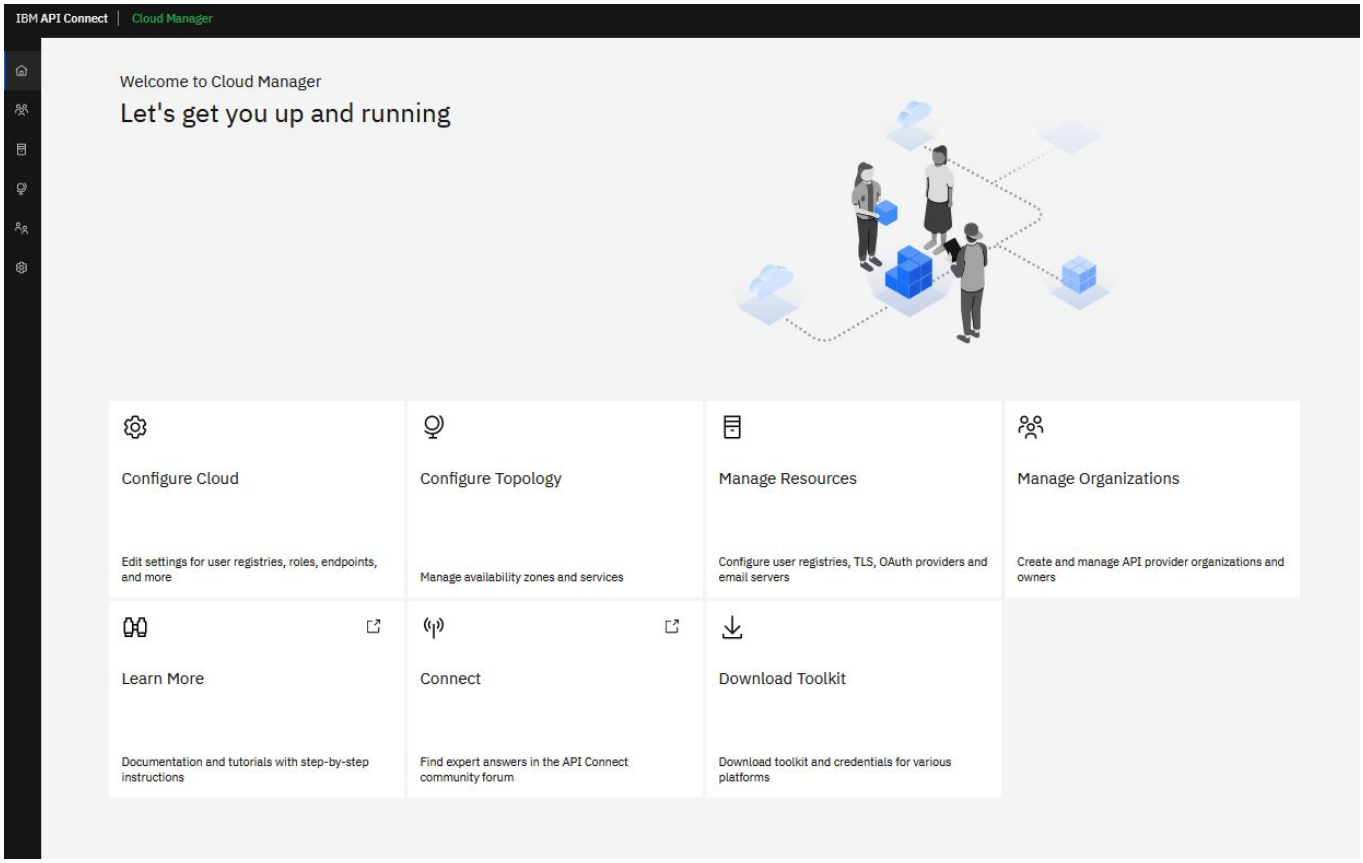
     ```
     oc get secret -n <namespace> | grep mgmt-admin-pass

     oc get secret -n <namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d && echo ""
     ```

3. If your cloud contains multiple user registries, as configured on the Settings > User Registries screen, then choose the user registry that contains your login credentials. You might need to ask your administrator which user registry is appropriate for your account.
4. Click Sign In.
   Important: The first time that you access the cloud console, you must, for security reasons, enter a new password and your email address. If you forget your password and request a password reset, the notification email is sent to this email address. The email is sent by the email server that is configured in the **Notifications** section of the cloud **Settings**.

Results

The Cloud Manager user interface opens to the home page, as shown in the following screen capture:



What to do next

Configure the email server so you can reset your password if needed and send other notifications. See Tutorial: Configuring the Cloud.

Configure your topology by registering services. See Tutorial: Configuring the Cloud.

Create a Provider Organization. See Tutorial: Creating a Provider Organization.

Related tasks

- Changing your Cloud Manager password and profile information

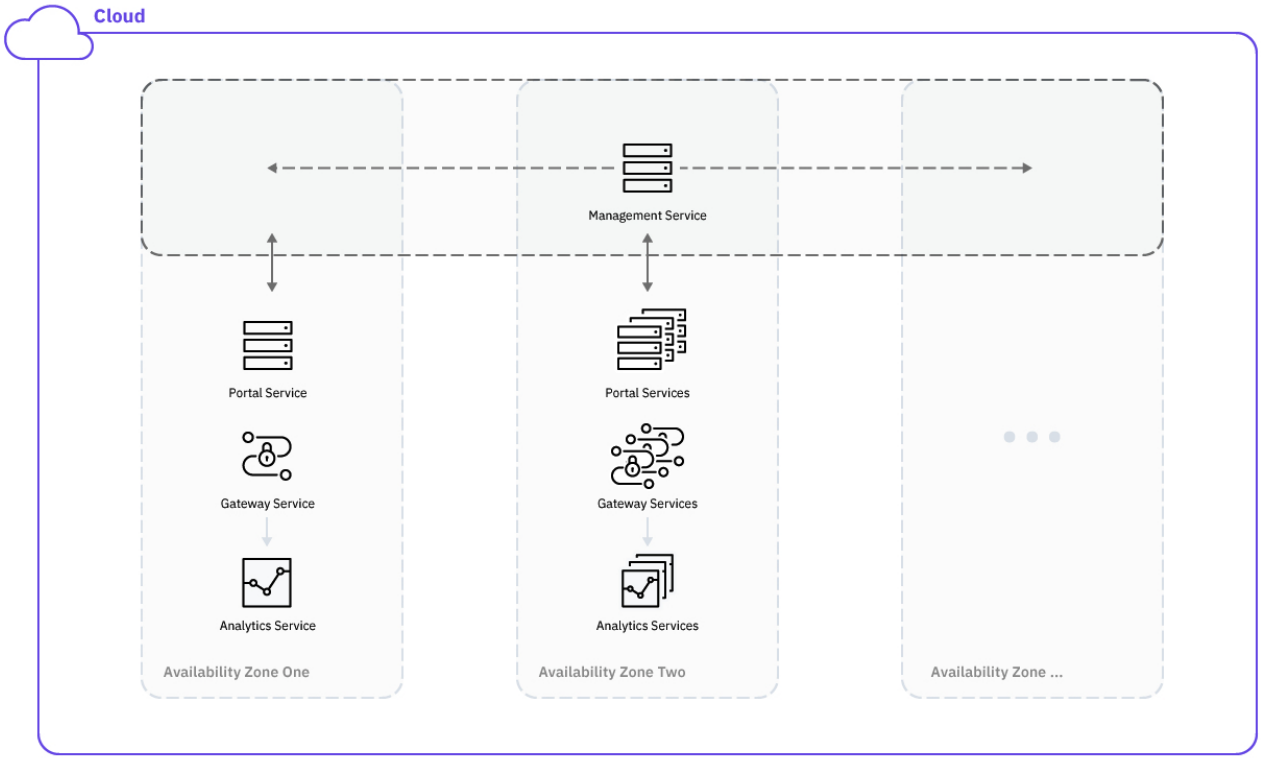
Defining your Cloud Manager topology

To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. A Default Availability Zone is provided on installation.

About this task

The Cloud Manager topology consists of Availability Zones that contain the API Connect services. Availability Zones can contain one or more gateway services, analytics services, and portal services.

The following diagram illustrates the topology for services and Availability Zones in an API Connect network:



One of the following roles is required to register and manage services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Following are the tasks involved in defining the API Connect topology:

- Create one or more Availability Zones.
- Register one or more Gateway, Analytics, and Portal services in each Availability Zone
- Associate an Analytics service with each Gateway service
- Set the visibility for the services

Once the cloud is defined and an email server has been configured, you invite other users to access API Manager to create APIs. You expose these APIs to the development community through the Developer Portal user interface.

To define the API Connect cloud, complete the following tasks:

- **Creating an availability zone**
  An Availability Zone is a logical group of one or more API Connect services. The Default Availability Zone is created during installation.
- **Registering a gateway service**
  A gateway service is required to handle incoming traffic for APIs.
- **Registering an analytics service**
  Configure at least one analytics service in your API Connect on-premises cloud. The analytics service is always associated with a gateway service, from which it collects API event data.
- **Registering a portal service**
  Define one or more Portal services in your API Connect on-premises cloud.
- **Associating an analytics service with a gateway service**
  To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.
- **Setting visibility for a service**
  The visibility setting determines which provider organizations can access a service.

Related concepts

- Configuring and managing your server environment

Creating an availability zone

An Availability Zone is a logical group of one or more API Connect services. The Default Availability Zone is created during installation.

About this task

Availability zones allow you to logically group API Connect services to suit your environment. For example, you can group gateway services according to the region or data center they are located in.

The Default Availability Zone is created during the installation process.

When you create an availability zone, you should provide a descriptive title; a name is generated automatically for internal identification. For example:

Table 1. Example availability zones

Title	Name
US Availability Zone	us-availability-zone
Hampshire Availability Zone	hampshire-availability-zone
Newport Availability Zone	newport-availability-zone
London South Availability Zone	london-south-availability-zone

One of the following roles is required to add and manage Availability Zones:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Procedure

Follow these steps to add one or more additional Availability Zones to your on-premises cloud:

1. In the Cloud Manager, click Topology.
2. You will see the current Availability Zones configured in your cloud. The Default Availability Zone is created at installation. To add another Availability Zone, choose Create Availability Zone.
3. Enter the following values:

Field	Description
Title (required)	Enter a descriptive title for the availability zone. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Summary (optional)	Enter a brief description.

4. Click Create to complete the operation.

Results

The availability zone will be added on the Topology page. You can now add gateway, analytics, and portal services to the availability zone.

Related tasks

- Registering a portal service

Registering a gateway service

A gateway service is required to handle incoming traffic for APIs.

Before you begin

Before registering a Gateway service in Cloud Manager, the DataPower® API Connect Gateway Service has to either be installed as a subsystem in your Kubernetes cluster or enabled on the DataPower appliance. For a Kubernetes environment, see DataPower Gateway subsystem on Kubernetes. For appliances, see *Configuring the API Connect Gateway Service* in the appropriate version of the DataPower documentation.

About this task

A Gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting.

One of the following roles is required to register and manage a gateway services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Note: You can also register, and manage, gateway services by using the developer toolkit CLI; for details, see apic gateway-services.

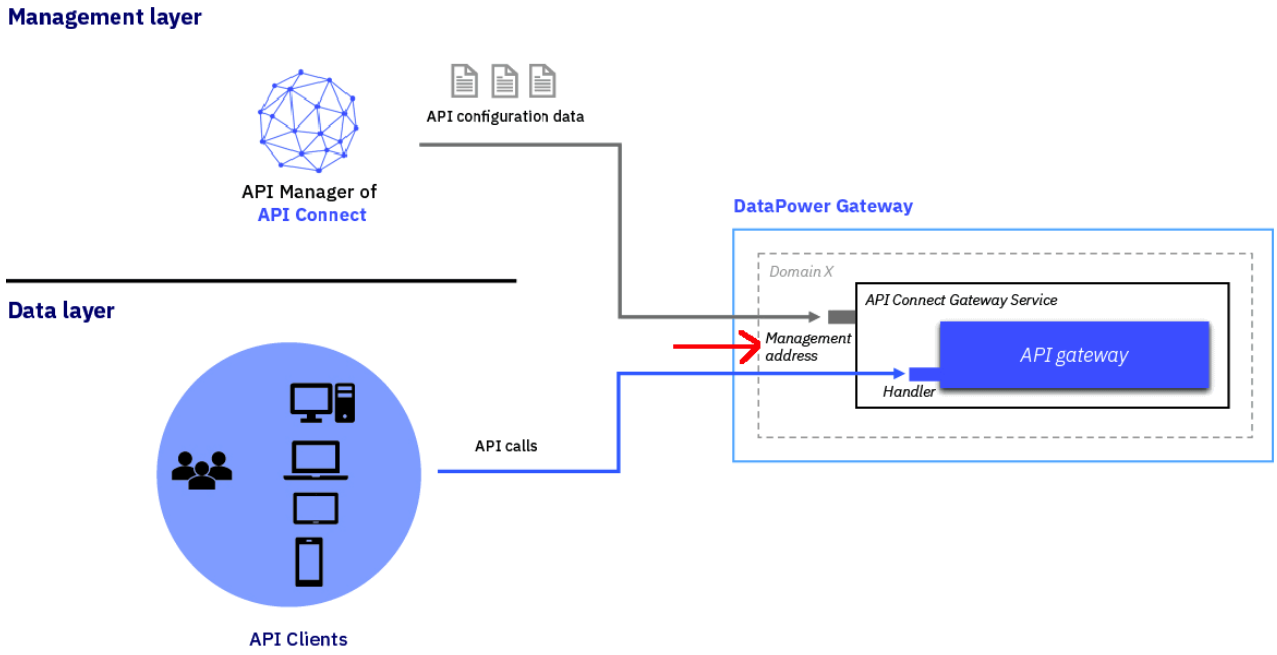
Procedure

Complete the following steps to configure a Gateway service for your cloud:

1. In the Cloud Manager, click Topology.
2. From the Availability Zone that will contain the Gateway service, select Register Service.
3. On the Configure Service page, select DataPower Gateway as the service type. Select the Gateway type that you want to create, either DataPower Gateway (v5 compatible) or DataPower API Gateway. For a description of the gateway types, see API Connect gateway types
4. Enter the values to configure the Gateway service. You will need to obtain the endpoints from your deployment configuration. For a Kubernetes environment, the endpoints are configured by the following values in the CR (custom resource) file. For an appliance, the endpoint is configured in DataPower.

Field	Description
Title (required)	Enter a descriptive title for the gateway service. This title will be displayed on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Summary (optional)	Enter a brief description.
Management endpoint on the gateway service: Endpoint (required)	Enter the API Connect Gateway Service endpoint. • For a Kubernetes environment, the Management Endpoint is the endpoint created in the CR (custom resource). See DataPower Gateway subsystem on Kubernetes for more information. • For an appliance, the Management Endpoint is the *Management address* to the API Connect Gateway Service shown in the gateway service connection diagram. For one gateway, this takes the form *https://<ip-address-for-gateway>:3000*. For multiple gateways, it would be the address:port of the load balancer • If you are using **`in-cluster`** communication, set this to the service endpoint URL for the gateway, which has the format: **`https://<name>.<namespace>.svc`** where: ◦ *<name>* is the **`name`** property from the gateway subsystem CR. If you are using the top-level CR this is **`<apic instance name>-gw`** ◦ *<namespace>* is the namespace that the gateway CR exists in.
Management endpoint on the gateway service: TLS client profile (required)	Specify the TLS client profile to use when the management subsystem initiates communication with the gateway. The client profile contains the TLS client certificate that is presented to the gateway when establishing a secure connection. Important: • Do not leave this property unset. You must specify a client profile for secure management to gateway communication (mTLS). If you do not want to use mTLS, then you can configure JWT instead: ◦ Use JWT instead of mTLS on VMware. ◦ Use JWT instead of mTLS on Kubernetes and OpenShift. • The default profile to use is Gateway management client TLS client profile:1.0.0. On a Kubernetes or OpenShift deployment where the management and gateway subsystems are in the same namespace, the gateway service is automatically configured (during installation) to trust the Gateway management client TLS client profile:1.0.0. • If you want to use a different client certificate, do not update the Gateway management client TLS client profile:1.0.0, create a new client profile that uses the certificate you want. See Creating a TLS Client Profile. • If you are registering a gateway appliance, then configure your gateway to trust the client profile that you select. For more information about configuring TLS on your gateway appliance, see ◦ Configuring DataPower API Gateway. ◦ Configuring DataPower Gateway (v5 compatible). Do not configure your gateway appliances with client authentication disabled.
Management endpoint on the gateway service: Use **`in-cluster`** communication switch	If you want to use **`in-cluster`** communication between the management and gateway subsystems, then enable this switch. For more information about this option, see In-cluster or external communication between subsystems. If you are not sure, then leave this switch disabled (the default).
Management endpoint on the gateway service: Use JWT for gateway authentication to analytics service	If you plan to associate an analytics service with this gateway, and you want to use JWT authentication between the gateway and analytics service, then enable this switch. If this switch is not enabled, then mutual TLS authentication is used between the gateway and analytics service. For more information about JWT security, see Enable JWT security instead of mTLS
API invocation endpoint: API endpoint base (required)	Enter the base portion of the URL that maps to the base portion of the URL for incoming API traffic. It is a public FQDN with additional paths that are specific to your API calls. For example: **https://api.mycompany.com** Note: If you are using the DataPower API Gateway, HTTP/2 is enabled automatically on the API invocation endpoint. If you are using the DataPower Gateway (v5 compatible), HTTP/2 is not supported on the API invocation endpoint.
API invocation endpoint: Server Name Indication (SNI) - Host name	For supporting Server Name Indication (SNI) at the API Endpoint Base. The default hostname of '*' is required to allow all hosts. Enter other host names as needed. Wild card format is supported. The SNI capability enables you to serve multiple TLS secure host names through the same Gateway service, using the same IP address and port, without requiring them to use the same TLS profile. Note: To allow requests from clients that don't support SNI, you **must** include a host name value of '*'.
API invocation endpoint: Server Name Indication (SNI) - TLS server profile	The TLS server profile that supports the given hostname for SNI. The server profile that is selected here contains the server certificate that is presented to callers of the APIs you publish on the gateway. By default this profile is set to Default TLS server profile. Best practice is to create your own TLS server profile that contains the certificate you want on your API invocation endpoint. For more information about configuring TLS server profiles, see TLS profiles overview. Restriction: If you are using the DataPower API Gateway, HTTP/2 is enabled automatically on the API invocation endpoint. Therefore, using a TLS server profile that supports only TLS protocol version 1.3 is not supported and will result in the gateway being unable to receive API traffic. You must use a TLS server profile that includes TLS protocol version 1.2 as one of its supported protocols. This restriction does not apply if you are using the DataPower Gateway (v5 compatible), which does not support HTTP/2.
OAuth shared secret (optional)	For sites using native OAuth providers, enter the shared secret that will be used by all API calls going through the gateway. Note: The specified shared secret must be 64 characters (64 bytes) in length, prefixed with **`0x`**, and must consist only of hexadecimal characters. For example: **`0xa354282f227c10250511ae9c9e8c7ed9f4f1bd0d7c04cb6d5bd178f8c62296e3`**

The following diagram illustrates the gateway service connection:



5. When you are finished, click Save.

Results

The Gateway service is added to the appropriate Availability Zone for your cloud.

What to do next

Add additional gateway services. Add one or more analytics services. Add one or more portal services. Associate the gateway service with an analytics service. Set the visibility for the gateway.

Related tasks

- Registering a portal service
- Registering an analytics service
- Associating an analytics service with a gateway service
- Setting visibility for a service

Registering an analytics service

Configure at least one analytics service in your API Connect on-premises cloud. The analytics service is always associated with a gateway service, from which it collects API event data.

Before you begin

You must complete the following tasks:

- Creating an availability zone
- Registering a gateway service

About this task

The analytics service collects API event data from the gateway service. In Cloud Manager, you configure the analytics service and then associate it with one or more gateways. Multiple gateways can be associated with a single analytics service, but each gateway can be associated with only one analytics service.
One of the following roles is required to register and manage analytics services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

When you register the analytics service, you must select from one of three inter-subsystem communication methods. Before you decide which method to use, familiarize yourself with the difference between **`external`** and **`in-cluster`** communication: In-cluster or external communication between subsystems. If you are an OVA user, or are in doubt as to what communication method to use, then use the default **`external`** setting.

The analytics subsystem has two separate communication flows:

- Management to analytics. The management service communicates with the analytics subsystem to query for analytics data to present in the UI dashboards. This flow is known as "analytics queries".
- Gateway to analytics. The gateway sends API event data to the analytics service. This flow is known as "analytics ingestion".

What you select depends on what is most suitable for your network configuration. The options are:

Use `external` communication for both ingestion and queries
: This option is the default, and is what is used for analytics services that are upgraded from a pre-10.0.5.3 release. For OVA deployments, or if your analytics subsystem is in a different environment then `external` is the only option that you can use. Both the gateway and the management service communicate with the analytics service by using the external endpoint, which is a Kubernetes `ingress` or OpenShift `route` depending on your platform.

Use `in-cluster` communication for both ingestion and queries
: You can select `in-cluster` if you have a Kubernetes or OpenShift deployment where all subsystems are within the same cluster. When this option is selected, the management, gateway, and analytics subsystems communicate with each other through internal service endpoints rather than externally accessible `ingresses` (Kubernetes) or `routes` (OpenShift).

Use `in-cluster` for ingestion and `external` for queries, or vice versa
: You can select this option if you have a Kubernetes or OpenShift deployment and you have some of your subsystems installed in the same cluster. When this option is selected, you can use different communication methods for the different analytics communication flows. For example, the management to analytics communication can use `in-cluster`, and the gateway to analytics can use `external`. You might choose this configuration if your gateway is in a different cluster to the rest of your subsystems.

Procedure

Complete the following steps to configure the analytics services for your cloud:

1. In the Cloud Manager, click Topology.
2. Select Register Services > Analytics in the Availability Zone where you have the gateways you want to associate with the analytics service.
3. Enter the values to configure the analytics service:

Field	Description
Title	Enter a descriptive title for the analytics service.
Name	This field is auto-populated by the system and used as the internal field name.
Summary	Enter a brief description.
Service endpoint configuration: Communication method.	Select your communication method, for more information on the options see, Communication types. If your API Connect deployment is OVA then you must select the first option: Use `external` communication for both ingestion and queries.

Service endpoint configuration: `External` analytics endpoint.	Enter the fully qualified domain name for the analytics ingestion endpoint that you defined during installation. To determine the endpoint, run the following command:
	• Kubernetes
	`kubectl get ingress -n <namespace>`
	The endpoint has `-ai-` in its name:
	`NAME CLASS HOSTS ADDRESS PORTS AGE`
	`def-analytics-ai-endpoint nginx a7s-in.example.com 80, 443 87d`
	• OpenShift
	`oc get routes -n <namespace>`
	The endpoint has `-ai-` in its name:
	`NAME CLASS HOSTS ADDRESS PORTS AGE`
	`def-analytics-ai-endpoint nginx a7s-in.example.com 80, 443 87d`
	• VMware
	`apicup subsys get <analytics subsystem>`
	The endpoint is the value of property `analytics-ingestion`.
	This field is disabled if "Use `in-cluster` communication for both ingestion and queries" is set as the communication type.

Service endpoint configuration: TLS client profile for `external` analytics endpoint.	Select the TLS Client Profile to use for management to analytics subsystem communication. The Client Profile applies to the endpoint that you specified in the previous row. The default is "Analytics Ingestion TLS client profile". This field is disabled if "Use `in-cluster` communication for both ingestion and queries" is set as the communication type.
Service endpoint configuration: `In-cluster` analytics endpoint.	Enter the fully qualified domain name for the analytics ingestion service endpoint. The format of the service endpoint is `https://<name>.<namespace>.svc` where: • *<name>* is the `name` property from the analytics subsystem CR. If you are using the top-level CR this is `<apic instance name>-a7s`. • *<namespace>* is the namespace that the analytics CR exists in. This field is disabled if Use `external` communication for both ingestion and queries is set as the communication type.

Field	Description
Service endpoint configuration: TLS client profile for `in-cluster` endpoint.	Select the TLS Client Profile to use for management to analytics subsystem communication. The Client Profile applies to the Endpoint that you specified in the previous row. The default is "Analytics Ingestion TLS client profile". This field is disabled if Use `external` communication for both ingestion and queries is set as the communication type.
Service endpoint configuration: Use `in-cluster` endpoint for analytics queries.	If you want the management subsystem to use the `in-cluster` service endpoint to communicate with the analytics subsystem, then select this option. If this option is not selected, then the management subsystem uses the `external` endpoint. Selection of `external` or `in-cluster` communication between the gateway and analytics subsystem is done when the gateway is associated with the analytics service, see Associating an analytics service with a gateway service. This setting is enabled when "Use `in-cluster` for ingestion and `external` for queries, or vice versa" is selected.

4. Click Save to complete the operation.

Results

The analytics service is added to your cloud settings.

What to do next

- Associate the analytics service with one or more gateway services: Associating an analytics service with a gateway service.
- Set preferred retention and rollover settings for the new analytics service: Retention and rollover.

Related tasks

- Registering a gateway service
- Registering a portal service

Registering a portal service

Define one or more Portal services in your API Connect on-premises cloud.

Before you begin

You must complete the following tasks:

- Creating an availability zone
- Registering a gateway service
- Configuring an email server for notifications
- Setting up notifications

Note:
When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the `portal-www` pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully.
To disable the endpoint check, complete one of the following updates depending on your platform:

On Kubernetes, OpenShift, and IBM® Cloud Pak for Integration

Add the following section to the Portal custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

On VMware

In your `apicup` project, create a file called ptl-extra-values.yaml (or edit the file if one already exists), and add the following section:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

Run the following commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>

apicup subsys install <ptl_subsys>
```

About this task

Each Availability Zone contains one or more Portal services. The Portal service provides a Developer Portal used by application developers to discover APIs and onboard consumers. An email server must be configured and set as the email server for the cloud before registering a Portal service.
One of the following roles is required to register and manage Portal services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Important: It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a Portal site for every Catalog, for example Catalogs that are only for API Developers don't need a Portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services.

Procedure

Complete the following steps to configure the Portal services for your cloud:

1. In the Cloud Manager, click Topology.
2. In the Availability Zone that will contain the Portal service, select Register Services > Portal.
3. Enter the values to configure the Portal service.

Field	Description
Title (required)	Enter a descriptive title for the portal service. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Summary (optional)	Enter a brief description.
Management endpoint on the portal service: Endpoint (required)	Enter the IP address, fully-qualified host name, service, or ingress name. Used for communication with API Manager. • In a Kubernetes deployment, the endpoint is defined in the CR by `api.portal.$STACK_HOST` . See Developer Portal subsystem on Kubernetes. • If configured during installation in a VMware environment, it is the `apicup subsys set portal portal-admin` value. • If you are using `in-cluster` communication, set this to the service endpoint URL for the portal, which has the format: `https://<name>.<namespace>.svc` where: ◦ *<name>* is the `name` property from the portal subsystem CR. If you are using the top-level CR this is `<apic instance name>-ptl` ◦ *<namespace>* is the namespace that the portal CR exists in.
Management endpoint on the portal service: TLS client profile (optional)	Select the TLS Client Profile that will be used to communicate with the portal service. The profile applies to the Management Endpoint. Note: TLS protocol version 1.3 is not supported.
Management endpoint on the portal service: Use `in-cluster` communication switch	If you want to use `in-cluster` communication between the management and portal subsystems, then enable this switch. For more information about this option, see In-cluster or external communication between subsystems. If you are not sure, then leave this switch disabled (the default).
Portal website URL (required)	The URL that will be used for public access to the portal. • In a Kubernetes deployment, the endpoint is defined in the CR by `portal.$STACK_HOST` . See Developer Portal subsystem on Kubernetes. • If configured during installation in a VMware environment, it is the `apicup subsys set portal portal-www <portal>.<hostname>.<domainname>` value. Multiple portal-www endpoints may be configured, as described here in these topics: Defining multiple portal endpoints for a Kubernetes environment and Defining multiple portal endpoints for a VMware environment.

4. When you are finished, click Save.

Results

The Portal service is configured in your cloud and can be used to publish APIs.

Related tasks

Associating an analytics service with a gateway service

To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.

About this task

The associated analytics service receives API event data from the gateway service.

To associate an analytics service with a gateway, you must first configure at least one analytics service and one gateway service.

One of the following roles is required to associate an analytics service with a gateway service:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Follow these steps to associate an analytics service with a gateway service:

Procedure

1. In the Cloud Manager, click Topology.
2. In the section for the Availability Zone you want to work on, locate the gateway service that requires an analytics service in the SERVICE column.
3. Locate the ASSOCIATED ANALYTICS SERVICE column.
4. If an analytics service is configured, the Associate Analytics service link is enabled for each gateway service. Click Associate Analytics Service in the same row as the gateway service that requires an analytics service.
5. In Associate Analytics Service, you see the name of the gateway service and a list of analytics services that have been configured in your cloud.
6. Select the analytics service to associate with the gateway service by adding a checkmark next to the analytics services.
7. If you specified `in-cluster` communication when you registered the analytics service, you can enable the gateway to send API event data to the internal analytics endpoint. Enable the "Use internal endpoint for ingestion of analytics data from the gateway service" switch. For more information about `in-cluster` communication, see Communication types.
8. Click Associate.
9. To remove the associated analytics service, select Unassociate analytics service from the actions menu. The gateway stops sending API event data to the analytics service.

Results

The analytics service is associated with a gateway service and starts to receive API event data from that gateway.

Setting visibility for a service

The visibility setting determines which provider organizations can access a service.

Before you begin

You must complete the following tasks:

- Create additional availability zones if needed, see Creating an availability zone
- Register at least one gateway service, see Registering a gateway service
- Register other services.

About this task

The visibility setting controls which provider organizations can use a service. The default visibility setting is Public.

One of the following roles is required to set the visibility for services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Procedure

Follow these steps to set the visibility for the services in your on-premises cloud:

1. In the Cloud Manager, click Topology.
2. From the list of Services, choose Set visibility from the actions menu next to the name of the service that requires the visibility setting.
3. Select the visibility setting for the service. The options are:
    - Private - the service is not visible and cannot be used by any provider organization

- Public - the service is visible and can be used by all provider organizations
- Custom - the service is visible only to the provider organizations designated by you

4. For Custom visibility, select the provider organizations that will be able to use the service.
5. Click Make visible to complete the operation.

Results

For Private, the service cannot be used by any provider organizations. For Public, the service can be used by all provider organizations. For Custom, the service can be used by the provider organizations that you designate.

Managing authentication and security

Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.

As Cloud Administrator or Topology Administrator (or with a custom role that contains the `Settings:Manage` permission), you can configure the following authentication and security mechanisms:

- User registries to authenticate users of Cloud Manager and API Manager and of your Catalogs and APIs.
- OAuth providers to provide protection for APIs.
- TLS profiles to secure transmission of data through the Gateway to external web sites and among web servers.

The following topics describe how to configure user registries, OAuth providers, and TLS profiles:

- **User registries overview**
  API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.
- **TLS profiles overview**
  API Connect supports TLS Profiles for securing data transmission over HTTPS.
- **OAuth Provider overview**
  API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

Related concepts

- User registries overview
- OAuth Provider overview
- TLS profiles overview

User registries overview

API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.

Introduction to user registries

A user registry holds unique user account credentials, primarily usernames and passwords, which are accessed during authentication for logging into Cloud Manager, API Manager, the Developer Portal, and also for calling APIs (if the API is configured to use Basic Authentication in the Security Definition). The Cloud Administrator configures user registries to ensure that all users are successful at logging in.

User registries also provide security when calling APIs. For information on configuring Security Definitions for APIs, see Creating a basic authentication security definition.

User registries are configured as Resources. Once the user registry has been configured as a resource in Resources > User registries, the next step is indicate the active user registries for your cloud in Settings > User registries. The user registry must be made active in your cloud in order to make it available for authentication. When a user logs into Cloud Manager or API Manager, the specified user registry is queried for credentials to confirm the user's identity. To make a user registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings > Onboarding; for more information see Creating and configuring Catalogs.

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access. In Cloud Manager and API Manager, a registry cannot be changed after a user is invited to be the owner of a provider organization, even if the invitation is not yet accepted.

User registries in API Connect serve the following primary functions:

- To authenticate a user at login time based upon username and password.
- To store basic profile information such as first name, last name, and email address.
- To provide secure access to Catalogs.
- To provide Basic Authentication for APIs when called by an application.

In order to log in to Cloud Manager, API Manager, the Developer Portal, or access a catalog, a user must have valid credentials (username and password) stored in a user registry that is configured in API Connect.

The Security Definition for an API can be configured to require a username and password, called the Basic Authentication method. With Basic Authentication, the username and password are included in the HTTP authorization header, and the credentials are verified through user registry.

User registries that are configured in Cloud Manager have the following characteristics:

- They are available to Cloud Manager, API Manager, the Developer Portal, and for Basic Authentication for APIs.
- They are available to provider organizations, as determined by the visibility setting.
- They can be edited and deleted only in Cloud Manager.

User registries that are configured in API Manager have the following characteristics:

- They are available to the Developer Portal (for Catalogs) and for Basic Authentication for APIs.
- They are available only to the Provider Organization that created them.

User registries supported by API Connect

API Connect integrates with several types of user registries to accommodate all security solutions. You can use your corporate LDAP registry, an Authentication URL, or an LUR to provide secure access to Cloud Manager, API Manager, the Developer Portal, and APIs. API Connect includes two internal databases that serve as local user registries, or LURs. The Providers LUR supports credentials for Provider organizations and the Admin LUR supports credentials for the Administrator organization. Multiple registries may be configured.

The following user registry types can serve as a resource in API Connect:

- Local user registry (LUR) - An internal database of usernames and passwords stored on the local server. Contains the Admin user account which may not be modified or deleted.
- LDAP - A user registry definition that points to an existing corporate LDAP directory. May be set up as case-sensitive.
- Authentication URL - Accesses a URL that points to a service for validating user credentials.
- OpenID Connect (OIDC).

- **Configuring an Authentication URL user registry**
  An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.
- **Configuring a shared custom user registry**
  You can configure a custom user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal.
- **Configuring an LDAP user registry in the Cloud Manager**
  You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.
- **Configuring a Local User Registry**
  A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.
- **Configuring an OIDC user registry in Cloud Manager**
  Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.
- **Setting visibility for a user registry**
  The visibility setting determines which provider organizations can access a resource, for example, user registries.
- **Deleting a user registry**
  As the Cloud Manager administrator, you can delete user registries.
- **Removing a user from a user registry**
  As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

- Configuring an LDAP user registry in the Cloud Manager
- Setting visibility for a user registry

Configuring an Authentication URL user registry

An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.

About this task

This topic describes how to configure a new Authentication URL user registry as a Resource in your cloud. After the user registry is configured, you must select it for use in your cloud in Settings > User Registries. See Selecting user registries for Cloud Manager and API Manager.

One of the following roles is required to configure user registries.:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:
API Connect issues an HTTP **`GET`** call to the Authentication URL endpoint, sending the user's credential. The following example shows a call made to an Authentication URL identity provider with an endpoint defined as **`https://myauthurl.example.com/user/authenticate`**:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
```

If the Authentication URL endpoint returns an HTTP status code of **`200`**, the user authenticates successfully. An HTTP status code other than **`200`** indicates a failed login attempt. API Connect forwards any HTTP Header starting with **`X-`** (with the exception of **`X-Client-Certificate`**), and Cookie to the Authentication URL identity

provider, to aid the authentication decision; for example:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
 X-Forwarded-For: 8.8.9.9
 X-Custom-Header-From-Customer: special
 Cookie: MyCookie=VGhpc0lzV2lja2VkQW1hemluZw==
```

When a user is presented with the form for completing their API Connect user registration, which fields are pre-populated depends on which fields are returned in the response from the Authentication URL identity provider. If any of the following fields are returned, they will be pre-populated in the registration form:

- `username`
- `email`
- `first_name`
- `last_name`

If the `username` field is not returned, the registration form displays the user name that was provided by the user. The pre-population capability requires that the response from the Authentication URL identity provider satisfies the following conditions:

- The `Content-Type` must be `application/json`.
- The response body format must be JSON.

A sample response is as follows:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
  "username":"myuser",
  "email":"myuser@example.com",
  "first_name":"My",
  "last_name":"User"
}
```

Procedure

1. In the Cloud Manager, click .
2. Select User Registries to see the list of current user registries in your cloud.
3. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. Select Authentication URL User Registry and enter the following parameters:

Field	Description
Title (required)	Enter a descriptive name to use on the screen.
Name (required)	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see apic user-registries.
Summary (optional)	Enter a brief description.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the `Title` of the User Registries when rendering them at the login page, rather than the `Display Name`.
URL (required)	Enter the URL for the authentication service. When establishing authentication, API Connect makes a GET call to the URL. The call includes the user name and password it has collected from the user in its authorization header. Either `200 OK` or `401 Unauthorized` will be returned.
TLS Client Profile (optional)	Select a TLS Client Profile to allow secure authentication with a specific web server.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend Authentication URL server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

5. Click Save.

Results

The Authentication URL user registry is saved and is available to be selected as a user registry for Cloud Manager or API Manager by selecting it in Settings > User Registries. It can also be used for Basic Authentication in the Security Definition for an API.

Configuring a shared custom user registry

You can configure a custom user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal.

Before you begin

To configure a custom user registry as a resource in the Cloud Manager, the external user directory must be created and available to use with your API Connect ecosystem.

Custom user registries can be used for authenticating users to the Cloud Manager, the API Manager, and the Developer Portal, but cannot be used to secure APIs.

One of the following roles is required to configure a custom user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create a custom user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific custom user registry can be used for authenticating Developer Portal users, while a shared custom user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure a shared custom user registry. If you want to create an organization-specific registry, see Creating an organization-specific custom user registry for more information. Note also that the visibility of a user registry is set to **`shared`** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see Setting visibility for a user registry.
Note:

- You can also create custom user registries by using the API Connect REST APIs (see the API Connect REST API documentation).

You can use the following instructions to create a writable or a read-only custom user registry.

API Connect provides two methods for creating a shared custom user registry in the Cloud Manager, as described in the following sections:

- Creating a shared custom user registry by using the Cloud Manager UI
- Creating a shared custom user registry by using the developer toolkit CLI

Creating a shared custom user registry by using the Cloud Manager UI

You configure a custom user registry by first creating a custom user registry type that defines your external user registry, and then creating a new custom user registry resource that references the custom user registry type that you just created. To make the registry available for user authentication, you need to add the registry to the Cloud Manager, or to the API Manager, or both, depending on your requirements. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the custom user registry type.

Creating a custom user registry type

Use the following instructions to create a custom user registry type that defines your external user registry.

1. In the Cloud Manager, click Resources.
2. Click Create in the User registry type section.
3. Enter the following information:

Property	Description
Title	A descriptive name of the custom user registry type to display in the UI. For example, *My custom user registry type*.
Name	The name of the user registry type. This name is auto-generated, and is used in CLI commands.
Version	The version number of the custom user registry type.
Summary	A brief description of the custom user registry type.
Properties	Enter the properties of your external user registry. Must include the property: **`remote: true`** This property must be set to **`true`** to indicate that this is an external user registry.

Property	Description
Secured Endpoint	Denotes the external registry secured endpoint section of the custom user registry type.
URL	The secure endpoint of your external user registry interface, where your platform REST API is located. It is made up of the URL and port, for example: `https://custom.ms.com:8888` API Connect will make REST calls to this endpoint for the user registry actions.
TLS Client Profile	Optionally set the TLS Client Profile URL that the custom server requires.
Headers	Optionally complete the user-defined header section to your external registry specification.
Configuration schema	Optionally complete the user-defined configuration schema section to your external registry specification.

4. Click Create. A new user registry with a Type of Custom is displayed in the User registry type list.

Creating a custom user registry resource

Use the following instructions to create a new custom user registry resource that references the custom user registry type that you just created.

1. Click Create in the User Registries section of Resources.
2. Click the Custom user registry tile.
3. Enter the following information:

Property	Description
Custom type	The name of the custom user registry type that you just created. For example, *my-custom-user-registry-type*. Use the drop-down arrow to select different custom user registry types.
Title	A descriptive name to display in the UI.
Name	The name of the custom user registry. This name is auto-generated, and is used in CLI commands.
Summary	A brief description of the custom user registry.
Endpoint	Optional endpoint information.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: • The Developer Portal does not support case sensitive usernames. • After at least one user has been onboarded into the registry, you cannot change this setting.
User registry managed	Determines whether API Connect manages your user registry. Valid values are: • `true` - select the checkbox • `false` - clear the checkbox
User managed	Determines whether your user registry is writable or not. Select the checkbox to set to `true` for writable. Clear the checkbox for the non-writable option.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Create. The new user registry is displayed in the User registries list.

Adding your custom user registry to the Cloud Manager or API Manager login

To make the custom user registry available for user authentication in the Cloud Manager or the API Manager, you must set it as active in the Settings > User Registries section of the Cloud Manager UI. See Selecting user registries for Cloud Manager and API Manager for more information.
If you want to make the custom user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Catalog settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see Creating and configuring Catalogs.

Creating a shared custom user registry by using the developer toolkit CLI

You configure a custom user registry by first configuring an integration document that defines your external user registry, and then creating a new custom user registry resource that references the integration document that you just created. You use developer toolkit CLI commands to create the integration document, and then the custom user registry. Finally, to make the registry available for user authentication, you need to configure the registry in the management server, or in the appropriate Catalog, or both, depending on your requirements. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the integration document.

Logging in to the management server CLI

Before you can define the custom user registry, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your integration document

You define the configuration of your external user registry in an ***integration_file*.yaml** document, as shown in the following example.

```
integration: '1.0.0'
integration_type: 'user_registry'
info:
  name: 'custom_user_registry'
  version: '1.0.0'
  title: 'Custom External User Registry'
  summary: 'Configure External User Registry'
properties:
  remote: true
secured_endpoint:
  endpoint:  'https://custom.ms.com:8888'
  tls_client_profile_url: {$tslClientProfileUrl}
headers:
  key1: value1
  key2: value2
configuration_schema:
  option_config1:
     type: string
  option_config2:
     type: boolean
```

The integration document properties are described in the following table:

Property	Description
integration_type	The type of integration, which in this case is **user_registry**.
info	Denotes the information section for the integration document.
name	The name of the user registry type, for example ***custom_user_registry***. This name is used in the user registry file to denote the registry type.
version	The version number of the integration document.
title	A descriptive name to display in a graphical user interface.
summary	A brief description of the integration document.
properties	Denotes the property section of the integration document.
remote	Indicates that this is an external user registry. Must be set to **true**.
secured_endpoint	Denotes the external registry endpoint section of the integration document.
endpoint	The secure endpoint of your external user registry interface, where your platform REST API is located. It is made up of the url and port, for example: ***https://custom.ms.com:8888*** API Connect will make REST calls to this endpoint for the user registry actions.
tls_client_profile_url	Optionally set the TLS Client Profile URL that the custom server requires.
headers	Complete the user-defined header section to your external registry specification.
configuration_schema	Complete the user-defined configuration schema section to your external registry specification.

Save your ***integration_file*.yaml** so it can be accessed by the **integrations:create** command in the following section.

Creating your custom integration

To create your custom user registry integration, run the following CLI command:

apic integrations:create --server *mgmt_endpoint_url* --subcollection user-registry *integration_file*.yaml

where:

- ***mgmt_endpoint_url*** is the management platform API endpoint URL.
- ***integration_file*** is the name of the YAML file that defines the configuration of your external user registry.

At this point API Connect makes a REST request call to the **endpoint** that is configured in the integration document, and the external platform REST API will need to return the requested information.
On completion of the integration creation, the command displays the following summary details:

integration_name custom_integration_url

The ***integration_name*** is derived from the **name** property in the configuration YAML file. The ***custom_integration_url*** is the URL with which the integration can be accessed. Both properties are needed when defining your custom user registry in the next section.

After your custom integration has completed successfully, you can continue to create the custom user registry.

Defining your custom user registry

You define the configuration of your custom user registry in a ***custom_config_file*.yaml** file, as shown in the following example.

```
name: 'custom_registry_name'
title: 'display_title'
registry_type: 'custom_user_registry'
integration_url: custom_integration_url
case_sensitive: true_or_false
user_managed: true_or_false
user_registry_managed: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: 'provider_title'
configuration:
  custom_config1: 'value1'
  customize: true
```

The registry properties are described in the following table:

Property	Description
name	The name of the custom user registry. This name is used in the CLI commands.
title	A descriptive name to display in a graphical user interface.
registry_type	The registry type that you configured in the **name** property in the integration document, for example ***custom_user_registry***.
integration_url	The custom integration URL in your API Connect configuration. You can determine the custom integration URL by using the following CLI command: **apic integrations:list --server *mgmt_endpoint_url* --subcollection user-registry** Or you can copy and paste from the summary of the integration creation.
case_sensitive	Determines whether your user registry is case-sensitive. Valid values are: • **true** • **false** To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set **case_sensitive** to **true** if your backend LDAP server supports case-sensitivity. • Set **case_sensitive** to **false** if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
user_managed	Determines whether your user registry is writable or not. Must be set to **true** for writable. Set to **false** if you don't want the registry to be writable.
user_registry_managed	Determines whether API Connect manages your user registry. Valid values are: • **true** • **false**
email_required	Determines whether an email address is required as part of the user onboarding process. Valid values are: • **true** • **false** If set to **true**, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
email_unique_if_exist	Determines whether email addresses must be unique within the user registry. Valid values are: • **true** • **false** Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
identity_providers	An array containing the details of your custom server, where: • **name** - is the name of the custom server and is the name that is used in CLI commands • **title** - is the display name of the custom server
configuration	The user-defined configuration based on the **configuration_schema** that is defined in the integration document.

Save your ***custom_config_file*.yaml** so it can be accessed by the **user-registries:create** command in the following section.

Creating your custom user registry

To create your shared custom user registry, run the following CLI command:

apic user-registries:create --server *mgmt_endpoint_url* --org admin *custom_config_file*.yaml

where:

- ***mgmt_endpoint_url*** is the platform API endpoint URL.

- `--org admin` means that the registry will be created in the admin organization, which is required for a user registry to be shared.
- *`custom_config_file`* is the name of the YAML file that defines the configuration of your custom user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The *`registry_name`* is derived from the `name` property in the custom user registry YAML file. The *`registry_url`* is the URL with which the custom registry resource can be accessed.
Your shared custom user registry is now created; see the following sections for instructions on how to make the registry available to users.

Configuring your custom registry for Cloud Manager or API Manager login

If you want to make your custom registry available for authenticating Cloud Manager and API Manager users, you must configure it on the management server.

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Determine what the current user registries are, because you will need to confirm these as well as add your new custom registry:

   ```
   apic user-registry-settings:get --server mgmt_endpoint_url --output -
   ```

   This command outputs a list of all the current user registries in your environment, similar to the following example:

   ```
   type: user_registry_setting
   api_version: 2.0.0
   name: user-registry-setting
   admin_user_registry_default_url: >-
     https://server.com/api/user-registries/xxxxx/xxxxx-1234
   admin_user_registry_urls:
     - >-
       https://server.com/api/user-registries/xxxxx/xxxxx-1234
   provider_user_registry_default_url: >-
     https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
   provider_user_registry_urls:
     - >-
       https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
   created_at: '2019-09-30T12:22:19.467Z'
   updated_at: '2019-10-17T10:05:37.867Z'
   url: 'https://server.com/api/cloud/settings/user-registries'
   ```

3. Enter the following command to update your user registries (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic user-registry-settings:update --server mgmt_endpoint_url -
   ```

   The following message is output:

   ```
   Reading USER_REGISTRY_SETTING_FILE arg from stdin
   ```

4. If you want to make your custom registry available for authenticating Cloud Manager users, enter the following data, followed by a new line:

   ```
   admin_user_registry_urls:
     - >-
       current_admin_user_registry_urls
     - new_custom_user_registry_url
   ```

   where:
   - *`current_admin_user_registry_urls`* are the current admin user registry URLs, as listed in Step 2 in the `admin_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *`new_custom_user_registry_url`* is the URL of your new custom user registry, as determined in Step 1.
5. If you want to make your custom registry available for authenticating API Manager users, enter the following data, followed by a new line:

   ```
   provider_user_registry_urls:
     - >-
       current_provider_user_registry_urls
     - new_custom_user_registry_url
   ```

   where:
   - *`current_provider_user_registry_urls`* are the current provider organization user registry URLs, as listed in Step 2 in the `provider_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *`new_custom_user_registry_url`* is the URL of your new custom user registry, as determined in Step 1.
6. Press `CTRL D` to terminate the input. A confirmation message is output, for example:

   ```
   user-registry-setting   https://server.com/api/cloud/settings/user-registries
   ```

   where *`server.com`* is your management server endpoint.

Configuring your custom registry in a Catalog

If you want to make your custom registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Log in to the management server as a member of a provider organization by entering the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

For full details of the `apic login` command, see Logging in to a management server.

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *`catalog_name`* is the value of the `name` property of the required Catalog. The command returns:

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

4. Enter the following data, followed by a new line:

   ```
   user_registry_url: custom_registry_url
   ```

   where *`custom_registry_url`* is the URL of your custom registry, obtained in step 1.
5. Press `CTRL D` to terminate the input.

Configuring an LDAP user registry in the Cloud Manager

You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a shared resource in the Cloud Manager, the LDAP directory must be created for use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, to authenticate users to the Cloud Manager and the API Manager, or for securing a Catalog to authenticate Developer Portal users.
Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used across the Cloud Manager, the API Manager, and the Developer Portal components in your environment.

This topic describes how to configure a shared LDAP user registry that is available to all of the provider organizations in your API Connect environment. If you want to create an organization-specific registry, see Creating an LDAP user registry in API Manager for more information. Note also that the visibility of a user registry is set to **`shared`** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see Setting visibility for a user registry.
Note:

- If you configure your LDAP user registry to be writable (by selecting the User Managed check box on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create and manage LDAP user registries by using the developer toolkit CLI (see Using the CLI to configure a shared LDAP user registry), and by using the API Connect REST APIs (see the API Connect REST API documentation).
- You can map external LDAP groups to API Connect user roles to enable greater control of user access, but this configuration can be done only by using the developer toolkit CLI; see Using the CLI to configure a shared LDAP user registry for details.

You create an LDAP user registry by configuring a set of properties in the Cloud Manager UI. If you want to enable writable LDAP, you must complete the Attribute Mapping section by selecting the User Managed checkbox, and providing the mapping of your source LDAP attribute names to the target API Connect values. You can also change a registry to be read-only again by clearing the User Managed checkbox. After configuring the user registry, you must set it as active in Settings > User Registries. To make the registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions.

For general information about authenticating with LDAP, see LDAP authentication.

Procedure

Follow these steps to configure a new LDAP user registry as a shared resource in the Cloud Manager UI.

1. In the Cloud Manager, click Resources.
2. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the

catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

3. Select LDAP User Registry for the user registry type, and enter the following information:

Field	Description
Title	Enter a descriptive name to display on the screen.
Name	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see apic user-registries.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Address	Enter the IP address or host name of the LDAP server.
Port	Enter the Port number that API Connect can use to communicate with the LDAP registry. For example, `389`.
Select a TLS Client Profile (optional)	Select the TLS Client Profile that the LDAP server requires.
Select an LDAP protocol version	Select the version number for the LDAP protocol that you are using.
Remote directory is Microsoft Active Directory	Select this option if you use Active Directory.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** select Case sensitive if your backend LDAP server supports case-sensitivity. • Do **not** select Case sensitive if your backend LDAP server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Enable External Group Mapping	Enable this property if you want user to use this user registry to map external LDAP groups to API Connect user roles to enable more control of user authorization.
Email required	Select this check box if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this check box if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Next and enter the authentication information, which will vary depending on the selected Authentication Method. The choices are:
   - Compose DN - Select this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, **`uid=<username>,ou=People,dc=company,dc=com`** is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, Compose DN is not supported with the DataPower API Gateway.
   - Compose UPN - Select this format if your LDAP directory supports binding with User Principal Names such as **`john@acme.com`**. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
     Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
   - Search DN - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.
     Optionally select a scope to specify which part of the directory information tree is examined:
     - Whole subtree (default)
     - Base object
     - Single level

   For all of the authentication methods:

   If you are creating an LDAP registry to authenticate users of an API, you can specify an LDAP authorization group to restrict API access. To be able to call an API that is secured by the LDAP registry, a user must successfully authenticate with their LDAP user ID and password **and** they must be a member of the specified authorization group. The authorization group can be a Static Group or Dynamic Group. A static group is one in which the individual members of the group are explicitly listed. A dynamic group is one which is defined according to the set of attributes that the group members share in common.

5. For authentication method Compose DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Specify the prefix to the DN. For example `(uid=`.
Suffix	Specify the suffix to the DN. For example `)`.
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

6. For authentication method Compose UPN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.

Field	Description
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Suffix	Enter the domain part of the user principal name. For example, `@acme.com`.
Use group authentication (optional)	Enter the Filter condition for the group.

7. For authentication method Search DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Specify the prefix to the DN. For example `(uid=`.
Suffix	Specify the suffix to the DN. For example `)`.
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

8. Optional: Click Test configuration to test the settings for your LDAP user registry. Enter valid credentials to ensure that you can access the LDAP database.
9. Optional: If you want to make your LDAP user registry writable, select the User Managed checkbox in the Attribute Mapping section, and provide the mapping of your source LDAP attribute names to the target API Connect values. Click Add to add each name/value pair, specified as follows:
   - LDAP ATTRIBUTE NAME - is the name of the source LDAP attribute.
   - API CONNECT VALUE - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.

   The default user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`, as shown in the following example:

LDAP ATTRIBUTE NAME	API CONNECT VALUE
`dn`	`uid=[username],ou=users,dc=company,dc=com`
`cn`	`[first_name] [last_name]`
`sn`	`[last_name]`
`mail`	`[email]`
`userPassword`	`[password]`

   You must ensure that you enter the correct attribute mapping values for your LDAP configuration, to enable API Connect to access the LDAP database. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
10. Click Create.
    Your new LDAP registry is shown in the list of User Registries on the Resources page.

What to do next

To make the LDAP registry available for user authentication in the Cloud Manager and the API Manager, you must set it as active in the Settings > User Registries section. See Selecting user registries for Cloud Manager and API Manager for more information.
If you want to make the LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see Creating and configuring Catalogs.

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Creating a basic authentication security definition.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

- **Using the CLI to configure a shared LDAP user registry**
  You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Using the CLI to configure a shared LDAP user registry

You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a resource in the Cloud Manager, the LDAP directory must be created and available to use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for authenticating users to the Cloud Manager, the API Manager, and the Developer Portal.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for onboarding and authenticating Developer Portal users, while a shared LDAP user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure a shared LDAP user registry. If you want to create an organization-specific registry, see Using the CLI to create an organization-specific LDAP user registry for more information. Note also that the visibility of a user registry is set to **`shared`** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see Setting visibility for a user registry.
Note:

- If the LDAP user registry is configured as writable (by enabling the **`user-managed`** property on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create LDAP user registries by using the Cloud Manager UI (see Configuring an LDAP user registry in the Cloud Manager), and by using the API Connect REST APIs (see the API Connect REST API documentation).
- If you are using the DataPower® API Gateway, LDAP group authentication is not supported.
- You can map external LDAP groups to API Connect user roles to enable more control of user authorization by using the developer toolkit CLI. The following instructions explain how to set the **`external_group_mapping_enabled`** configuration on your LDAP user registry resource. For information about how to set external role mapping on your API Connect user roles, see Configuring LDAP group mappings on Cloud Manager user roles.

You configure an LDAP user registry by first defining the registry details in a configuration file. You then use a developer toolkit CLI command to create the registry, passing the configuration file as a parameter. Finally, to make the registry available for user authentication, you need to configure the registry in the management server, or in the appropriate Catalog, or both, depending on your requirements. To secure APIs with an LDAP registry, you must configure security definitions. You can use the following instructions to create a writable or a read-only LDAP user registry.

For general information about authenticating with LDAP, see LDAP authentication.

Logging in to the management server CLI

Before you can define the LDAP user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **`default-idp-1`**.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your LDAP configuration

You define the configuration of your LDAP user registry in an ***`ldap_config_file`*`.yaml`** file, as shown in the following example. Note that the actual contents of your YAML file will vary depending on the authentication method of your LDAP server, and this is explained in the following tables.

```
name: registry_name
title: "display_title"
integration_url: LDAP_integration_url
```

```
user_managed: true_or_false
user_registry_managed: false
directory_type: ad
external_group_mapping_enabled: true_or_false
case_sensitive: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: provider_title
endpoint:
  endpoint: "ldap_server_url_and_port"
configuration:
  authentication_method: authentication_method
  authenticated_bind: "true_or_false"
  admin_dn: "admin_dn"
  admin_password: admin_password
  search_dn_base: "search_dn_base"
  search_dn_scope: search_dn_scope
  search_dn_filter_prefix: prefix
  search_dn_filter_suffix: suffix
  attribute_mapping:
    dn: "distinguished_name"
    cn: "common_name"
    sn: "last_name"
    mail: "email_address"
    userPassword: "password"
```

The registry properties that are common to each authentication method are described in the following table:

Property	Description
`name`	The name of the registry. This name is used in CLI commands.
`title`	A descriptive name to display in a graphical user interface.
`integration_url`	The LDAP integration URL in your API Connect configuration. You can determine the LDAP integration URL by using the following CLI command: `apic integrations:list --server mgmt_endpoint_url --subcollection user-registry`
`user_managed`	Determines whether your user registry is writable or not. Must be set to `true` for writable LDAP. You can change this setting to `false` if you don't want the registry to be writable; see the Switching your LDAP registry between writable and read-only section at the end of this topic for details. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
`user_registry_managed`	Must be set to `false` for LDAP. Determines whether API Connect manages your user registry. Only LUR registries are managed by API Connect.
`directory`	Specify one of the of following values for the directory type: • `ad` - Indicates that the LDAP is Microsoft Active Directory • `standard` - (Default value) Indicates any other LDAP
`external_group_mapping_enabled`	Determines whether your user registry supports LDAP group mapping. Valid values are: • `true` • `false` The default value is `false`.
`case_sensitive`	Determines whether your user registry is case-sensitive. Valid values are: • `true` • `false` To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set `case_sensitive` to `true` if your backend LDAP server supports case-sensitivity. • Set `case_sensitive` to `false` if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
`email_required`	Determines whether an email address is required as part of the user onboarding process. Valid values are: • `true` • `false` If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
`email_unique_if_exist`	Determines whether email addresses must be unique within the user registry. Valid values are: • `true` • `false` Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
`identity_providers`	An array containing the details of your LDAP server, where: • `name` - is the name of the LDAP server and is the name that is used in CLI commands • `title` - is the display name of the LDAP server
`endpoint`	The endpoint of your LDAP server, made up of the url and port, for example: `"ldap://server.com:389"`
`tls_profile`	Optionally set the TLS Client Profile that the LDAP server requires.

Property	Description
`protocol_version`	Optionally set the version number for the LDAP protocol that you are using. Valid values are: • `2` • `3` Defaults to `3` if not explicitly set.

The properties in the configuration section will vary depending on the selected authentication method. The three authentication methods are:

- `compose_dn` - Set this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, `compose_dn` is not supported with the DataPower API Gateway.
- `compose_upn` - Set this format if your LDAP directory supports binding with User Principal Names such as `john@acme.com`. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
  Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
- `search_dn` - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For authentication method `compose_dn`, set the following configuration properties:

Properties	Description
`authentication_method`	`compose_dn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`search_dn_base`	Optionally set a base DN, for example: `"dc=company,dc=com"`
`bind_prefix`	Set the prefix to the DN, for example: `(uid=`
`bind_suffix`	Set the suffix to the DN, for example: `)`

`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:
	`ldap_registry_attribute_name``: "`*`apic_ldap_attribute_value`*`"`
	Where:
	• *ldap_registry_attribute_name* - is the name of the source LDAP attribute
	• *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.
	The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping:
	`attribute_mapping:`
	`  dn: "uid=[username],ou=users,dc=company,dc=com"`
	`  cn: "[first_name] [last_name]"`
	`  sn: "[last_name]"`
	`  mail: "[email]"`
	`  userPassword: "[password]"`

For authentication method `compose_upn`, set the following configuration properties:

Properties	Description
`authentication_method`	`compose_upn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`bind_suffix`	Enter the domain part of the user principal name. For example: `@acme.com`

Properties	Description

`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:
	
	`ldap_registry_attribute_name: "apic_ldap_attribute_value"`
	
	Where:
	
	• *ldap_registry_attribute_name* - is the name of the source LDAP attribute
	• *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.
	
	The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping:
	
	`attribute_mapping:`
	`  dn: "uid=[username],ou=users,dc=company,dc=com"`
	`  cn: "[first_name] [last_name]"`
	`  sn: "[last_name]"`
	`  mail: "[email]"`
	`  userPassword: "[password]"`

For authentication method `search_dn`, set the following configuration properties:

Property	Description
`authentication_method`	`search_dn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`search_dn_base`	Optionally set a base DN, for example: `"dc=company,dc=com"`
`search_dn_scope`	Optionally set the search DN scope. The scope determines which part of the directory information tree is examined. Possible values are: • `base` • `one` • `sub` (default value)
`search_dn_filter_prefix`	Set the prefix to the DN, for example: `(uid=`
`search_dn_filter_suffix`	Set the suffix to the DN, for example: `)`

`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:
	
	`ldap_registry_attribute_name: "apic_ldap_attribute_value"`
	
	Where:
	
	• *ldap_registry_attribute_name* - is the name of the source LDAP attribute
	• *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.
	
	The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping:
	
	`attribute_mapping:`
	`  dn: "uid=[username],ou=users,dc=company,dc=com"`
	`  cn: "[first_name] [last_name]"`
	`  sn: "[last_name]"`
	`  mail: "[email]"`
	`  userPassword: "[password]"`

Save your `ldap_config_file.yaml` so it can be accessed by the `user-registries:create` command in the following section. See the Example section for an example configuration file.

Creating your LDAP user registry

To create your shared LDAP user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin ldap_config_file.yaml
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL.
- `--org admin` means that the registry will be created in the admin organization, which is required for a user registry to be shared.
- `ldap_config_file` is the name of the YAML file that defines the configuration of your LDAP user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The *registry_name* is derived from the `name` property in the configuration YAML file. The *registry_url* is the URL with which the registry resource can be accessed. Your shared LDAP user registry is now created; see the following sections for instructions on how to make the registry available to users.

Configuring your LDAP registry for Cloud Manager or API Manager login

If you want to make your LDAP registry available for authenticating Cloud Manager and API Manager users, you must configure it on the management server.

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Determine what the current user registries are, because you will need to confirm these as well as add your new LDAP registry:

   ```
   apic user-registry-settings:get --server mgmt_endpoint_url --output -
   ```

   This command outputs a list of all the current user registries in your environment, similar to the following example:

   ```
   type: user_registry_setting
   api_version: 2.0.0
   name: user-registry-setting
   admin_user_registry_default_url: >-
     https://server.com/api/user-registries/xxxxx/xxxxx-1234
   admin_user_registry_urls:
     - >-
       https://server.com/api/user-registries/xxxxx/xxxxx-1234
   provider_user_registry_default_url: >-
     https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
   provider_user_registry_urls:
     - >-
       https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
   created_at: '2019-09-30T12:22:19.467Z'
   updated_at: '2019-10-17T10:05:37.867Z'
   url: 'https://server.com/api/cloud/settings/user-registries'
   ```

3. Enter the following command to update your user registries (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic user-registry-settings:update --server mgmt_endpoint_url -
   ```

   The following message is output:

   ```
   Reading USER_REGISTRY_SETTING_FILE arg from stdin
   ```

4. If you want to make your LDAP registry available for authenticating Cloud Manager users, enter the following data, followed by a new line:

   ```
   admin_user_registry_urls:
     - >-
       current_admin_user_registry_urls
     - new_ldap_user_registry_url
   ```

   where:
   - *current_admin_user_registry_urls* are the current admin user registry URLs, as listed in Step 2 in the `admin_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *new_ldap_user_registry_url* is the URL of your new LDAP user registry, as determined in Step 1.

5. If you want to make your LDAP registry available for authenticating API Manager users, enter the following data, followed by a new line:

   ```
   provider_user_registry_urls:
     - >-
       current_provider_user_registry_urls
     - new_ldap_user_registry_url
   ```

   where:
   - *current_provider_user_registry_urls* are the current provider organization user registry URLs, as listed in Step 2 in the `provider_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *new_ldap_user_registry_url* is the URL of your new LDAP user registry, as determined in Step 1.

6. Press `CTRL D` to terminate the input. A confirmation message is output, for example:

   ```
   user-registry-setting   https://server.com/api/cloud/settings/user-registries
   ```

   where *server.com* is your management server endpoint.

Configuring your LDAP registry in a Catalog

If you want to make your LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Log in to the management server as a member of a provider organization by entering the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   For full details of the `apic login` command, see Logging in to a management server.

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
```

where *catalog_name* is the value of the `name` property of the required Catalog. The command returns:

```
Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
```

4. Enter the following data, followed by a new line:

```
user_registry_url: ldap_registry_url
```

where *ldap_registry_url* is the URL of your LDAP registry, obtained in step 1.
5. Press `CTRL D` to terminate the input.

Switching your LDAP registry between writable and read-only

After an LDAP user registry has been created, it can be switched between writable and read-only by updating the `user_managed` property in the registry configuration. Complete the following steps.

1. Determine the name or ID of the LDAP user registry that you want to update, by running the following command (or you can use the summary from the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

The command returns a list of all the user registries on that server, shown by name followed by their registry URL. The registry ID is located at the end of the URL, for example `https://company.com/api/user-registries/x-x-x-x-x/registry_id`.
2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic user-registries:update --server mgmt_endpoint_url --org admin registry_name_or_id -
```

where `registry_name_or_id` is the name or ID of the LDAP user registry that you want to update (as determined in the previous step). The command returns:

```
Reading USER_REGISTRY_FILE arg from stdin
```

3. Enter the following data, followed by a new line:

```
user_managed: true_or_false
```

where `true` makes the registry writable, and `false` makes the registry read-only.
4. Press `CTRL D` to terminate the input.

Note that if you are changing your registry from read-only to writable, you must also set the `attribute_mapping` configuration, as described in the previous registry property tables.

Using an LDAP user registry to secure APIs

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Creating a basic authentication security definition.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

For details of all the `apic user-registries` and `apic configured-catalog-user-registries` commands, see apic user-registries and apic configured-catalog-user-registries.

Example

The following example shows a configuration file that uses the Search DN authentication method for setting up writable LDAP:

```
name: sdn-ldap
title: "SDN LDAP User Registry"
integration_url: https://mycompany.com/api/cloud/integrations/user-registry/xxx-xxx-xxx
user_managed: true
user_registry_managed: false
directory_type: standard
case_sensitive: false
identity_providers:
  - name: ldap
    title: "SDN LDAP Identity Provider"
endpoint:
  endpoint: "ldap://mycompany.com:389"
configuration:
  authentication_method: search_dn
  authenticated_bind: "true"
  admin_dn: "cn=admin,dc=company,dc=com"
  admin_password: xxxx
  search_dn_base: "dc=company,dc=com"
  search_dn_scope: sub
  search_dn_filter_prefix: (uid=
  search_dn_filter_suffix: )
  attribute_mapping:
    dn: "uid=[username],ou=users,dc=company,dc=com"
    cn: "[first_name] [last_name]"
    sn: "[last_name]"
    mail: "[email]"
    userPassword: "[password]"
```

Configuring a Local User Registry

A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.

About this task

Local User Registries (LURs) are the default user registries included in API Connect. LURs are local databases included with API Connect. Two default LURs are installed and configured during installation of API Connect. They cannot be deleted. The default Admin user account is stored in the Provider LUR.

You can create and configure a new LUR. After you create it, you must set it as active in Settings > User Registries. See Selecting user registries for Cloud Manager and API Manager.

One of the following roles is required to configure user registries:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

Procedure

Follow these steps to configure a new LUR:

1. In the Cloud Manager, click .
2. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
3. Select Local User Registry as the type for the user registry and enter the following information:

Field	Description
Title (required)	Enter a descriptive name for use on the screen.
Name (required)	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see apic user-registries.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Case sensitive	Select this setting if user names are case-sensitive. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. For new Local User Registries, this setting is always selected; so if email addresses are contained in the user record, they must be unique. However, for existing Local User Registries this setting can be edited. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Save.

Results

The user registry is saved and is available to be configured for user authentication in Cloud Manager or API Manager by selecting it in Settings > User Registries. See Selecting user registries for Cloud Manager and API Manager.

Configuring an OIDC user registry in Cloud Manager

Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.

You can create an OIDC user registry that is specific to a provider organization, or that is shared and available to all the provider organizations in your API Connect environment. An organization-specific OIDC user registry is used for onboarding and authenticating Developer Portal users, while a shared OIDC user registry can be used for onboarding and authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to create a shared registry. For information on how to create an organization-specific registry, see Creating an OIDC user registry in API Manager.

Important: If you are using X (formerly known as Twitter) as your OIDC provider, API Connect supports only the OAuth 1.0a method, so your X application must be configured to use OAuth 1.0a. Other OIDC providers support OAuth 2.0.
API Connect provides two methods for creating an OIDC user registry in Cloud Manager, as described in the following sections:

- Using the UI to configure an OIDC user registry
- Using the CLI to configure an OIDC user registry

Using the UI to configure an OIDC user registry

Use the Cloud Manager application's user interface to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

1. In the Cloud Manager navigation pane, click Resources.
2. Click User Registries.
3. Click Create and select OIDC User Registry.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. On the Create OIDC User Registry page, use the fields in each of the following sections to configure the registry settings, and then click Create.
   Many of the registry settings are preconfigured to simplify the configuration steps.

   Provider Type
   : Use the settings in Table 1 to define the provider type.

Table 1. Provider Type settings

Field	Description
Provider Type	OIDC provider. Select one of the following supported OIDC providers: • Facebook • GitHub • Google • LinkedIn • Slack • Twitter • Windows Live • Standard OIDC (default value allows you to specify another provider)
Title	Provide a descriptive name for display purposes.
Name	Automatically generated. This name is used in CLI commands to reference the registry. For details of the CLI commands for managing user registries, see the apic user-registries topic in the Command Line tool reference section of this documentation.
Summary	Provide a brief description of the new registry.
Email required	Select this check box if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this check box if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

   Provider Endpoint
   : Automatically generated for most supported providers. In the Authorization Endpoint field, type the URL of the provider's authorization endpoint.

   Token Endpoint
   : Fill in the settings as described in Table 2.

Table 2. Token Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's token endpoint.
TLS	Select the TLS Client Profile for the token endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

   UserInfo Endpoint
   : Fill in the settings as described in Table 3.

Table 3. UserInfo Endpoint settings

Field	Description

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's userinfo endpoint. For LinkedIn, the endpoint changed and now uses the following value: `https://api.linkedin.com/v2/me` If you previously configure the OIDC registry using the legacy LinkedIn OIDC protocol, you do not need to specify this endpoint.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Email Endpoint

Required for the legacy LinkedIn OIDC protocol.
Due to changes in LinkedIn, the configuration settings for the OIDC registry in API Connect also changed. If you are configuring a new OIDC registry for LinkedIn, you can leave the Email Endpoint field blank.

If you previously configured an OIDC registry for use with the legacy LinkedIn OIDC protocol, update your configuration by providing the Email endpoint settings as described in Table 4. The new setting is required for the legacy LinkedIn OIDC protocol.

Table 4. Email Endpoint settings

Field	Description
URL	For the legacy LinkedIn OIDC protocol, this field defaults to the following value: `https://api.linkedin.com/v2/emailAddress?q=members&projection=(elements*(handle~))` You can override the setting by typing in a new value.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

JWKS Endpoint

Fill in the settings as described in Table 5.

Table 5. JWKS Endpoint settings

Field	Description
URL	Type the URL of the read-only endpoint that contains the public keys' information in JWKS format.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Logout

Fill in the settings as described in Table 6.

Table 6. Logout

Field	Description
Logout redirect	Optionally, give a logout redirect URL, allowing APIC to initiate an https 302 redirect to the configured endpoint. Note: When the Developer Portal uses this feature, it does not retain control afterwards. Instead, the content is presented from the redirected endpoint.

Client Information

Fill in the settings as described in Table 7.

Table 7. Client Information settings

Field	Description
Client ID	Provide the client ID of the application that is registered with the selected OIDC provider.
Client Secret	Provide the client secret of the application that is registered with the selected OIDC provider. This field is optional when you create an OIDC directory of type Standard and set the Client Authentication Method to Data encoded form body. If you do not use the Client Secret, make sure that mutual TLS is possible with the OIDC provider.
Response Type	Preconfigured for most of the supported OIDC providers. Specify the data type of the response that will be received from the OIDC provider.
Scopes	Preconfigured for most of the supported OIDC providers. Specify the access scope for the OIDC provider.
Client Authentication Method	Preconfigured for most of the supported OIDC providers. Select the authentication method to be used with the OIDC provider. Options are: • HTTP Basic authentication schema • Data encoded form body

Additional Support

Optional. Select the additional security parameters described in Table 8.

Table 8. Additional security options

Security parameter	Setting name for CLI	Description
NONCE	`nonce`	Enable the NONCE extension to prevent compromised requests from being used again (replayed).
Proof Key for Code Exchange (PKCE)	`pkce`	Enable the PKCE extension to allow public clients to mitigate the threat of having the authorization code intercepted.

Advanced Features

Optional. Select the advanced features described in Table 9.

Table 9. Advanced features

Feature / UI Label	Setting name for CLI	Description
Auto onboard	`auto_onboard`	Allow users to executes calls to APIs without logging in first, provided they present a valid token issued by the OIDC provider. Note: Does not apply to consumer organizations.
Always use the userinfo endpoint	`userinfo`	Configures the OIDC user registry to always fetch user data from the userinfo endpoint, if populated.
Use Portal as Endpoint for external OIDC provider traffic	`proxy_redirect`	When authenticating users, redirect the external OIDC provider to communicate with the Developer Portal instead of API Manager.

Feature / UI Label	Setting name for CLI	Description
Return third-party access token	`proxy_access_token`	Include the third-party OIDC access token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error.
Return third-party id_token	`proxy_id_token`	Include the third-party OIDC id_token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error.
Token Relay	`token_relay`	Allow `access_token/refresh_token` to send in 302 redirect for logout
Userinfo POST	`post_userinfo`	If supported by your OIDC provider, by using HTTP POST method when contacting userinfo endpoint. Note: Not all OIDC providers support POST. Ensure that your OIDC provider supports this before you enable the feature.
Use IBM APIC token expiration setting from cloud	`override_provider_ttl`	Override the OIDC provider's token expiration setting with the access token and refresh token expiration settings that are configured in API Connect. For information on configuring the access token and refresh token expiration settings in API Connect, see Configuring timeouts for access tokens and refresh tokens.
Disable hash verification (CLI only)	`disable_hash_verification`	Disable `at_hash`, `c_hash`

User Mapping

Fill in the settings as described in Table 10.
Note: The User Mapping fields are preconfigured for most of the supported OIDC providers to minimize potential errors; use care when changing the settings. For the Standard OIDC option, contact your OIDC provider to obtain the details of the fields.

Table 10. User mapping settings

Field	Description
Username	The name of the field in the response token that contains the user's user name. Note: The Username field must be unique for this OIDC registry, because it identifies the user in the system and cannot be changed.
Email	The name of the field in the response token that contains the user's email address.
First name	The name of the field in the response token that contains the user's given name.
Last name	The name of the field in the response token that contains the user's surname.

Redirect URI

The Redirect URI section lists the endpoints to which the OIDC authorization server will redirect the authorization code. There is one endpoint for each API Connect organization type: Cloud administration, Provider organization, and Consumer organization. The redirect endpoint is required when a user registers their application with the OIDC provider. For example, if this OIDC user registry is used by a provider organization, the user must register the provider organization's redirect endpoint with the OIDC provider. These read-only fields are provided for you to copy the endpoint values as required.

Enabling the OIDC user registry

Complete the following steps to enable the new user registry for Cloud Manager, API Designer, or both.

1. On the navigation pane, click Settings.
2. Click User Registries > Edit.
3. Click Edit in the section that corresponds to the application for which you are enabling the new user registry.
4. Select the new OIDC user registry.
5. When you have finished enabling the registry, click Save.

Using the CLI to configure an OIDC user registry

Use the developer toolkit CLI to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

Configure an OIDC user registry by first defining the registry details in a configuration file. You then use a CLI command to create the registry, passing the configuration file as parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated catalog.
Note:

- An OIDC registry cannot be used to secure APIs on the gateway.
- Because the interaction with the third-party OIDC provider is handled by the Management server, the Management server is the application from the point of view of the third-party OIDC provider. Your OIDC redirection endpoint is used by the authorization server to send the token to the Management server, so it must be accessible to the OIDC provider through your firewall. When you register your application with the third-party OIDC provider, you are required to supply the associated OIDC redirect URI, `https://consumer.mycompany.com/consumer-api/oauth2/redirect` for example. However, this information is not available until you have created your OIDC user registry in API Connect. You must first register your application without this information and then update it later, as detailed in the instructions on this page.

Logging in to the Management server

Before you can create an OIDC user registry, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
For full details of the **apic login** command, see Logging in to a management server.

Defining your OIDC registry configuration

Define the configuration of your OIDC user registry in a YAML file. At a minimum, the YAML file must include the settings from the following list. For additional settings, see the tables provided with the UI version of the procedure in this topic.

```
title: registry_title
integration_url: oidc_integration_url
case_sensitive: case_sensitivity_setting
email_required: true_or_false
email_unique_if_exist: true_or_false
configuration:
  client_id: 'app_client_id'
  client_secret: 'my-client-secret'
  provider_type: oidc_provider_type
```

where:

- *registry_title* is your chosen descriptive title for the user registry.
- *oidc_integration_url* is the OIDC integration URL in your API Connect configuration. You can determine the OIDC integration URL by using the following CLI command:

  ```
  apic integrations:list --server mgmt_endpoint_url --subcollection user-registry
  ```

- *case_sensitivity_setting* determines whether your user registry is case-sensitive. Valid values are:
  - **true**
  - **false**

  To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on the backend OIDC provider:
  - Only set **case_sensitive** to **true** if the backend OIDC provider supports case-sensitivity.
  - Set **case_sensitive** to **false** if the backend OIDC provider does not support case-sensitivity.

  Note: After at least one user has been added to the registry, you cannot change this setting.
- *email_required* determines whether an email address is required as part of the user onboarding process. Valid values are:
  - **true**
  - **false**

  If set to **true**, the source identity provider must supply the email address as part of the authentication process during onboarding.
  Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
- *email_unique_if_exist* determines whether email addresses must be unique within the user registry. Valid values are:
  - **true**
  - **false**

  Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
- *app_client_id* is the client ID of the application that is registered with the OIDC server, and must be in string format.
- *my-client-secret* is the client secret of the application that is registered with the OIDC server, and must be in string format.
- *oidc_provider_type* is the type of OIDC provider; specify one of the following values:
  - **facebook**
  - **github**
  - **google**
  - **linkedin**
  - **slack**
  - **twitter**
  - **windows_live**
  - **standard**

    Note:
    - Use the **twitter** provider type if your OIDC provider is X (formerly known as Twitter).
    - Use the **standard** provider type for any OIDC provider that is compliant with the OIDC standard.
      If the provider type is **standard**, you must include the following additional properties in the **configuration** section of your YAML file:

      ```
      authorization_endpoint: 'oidc_auth_endpoint'
      token_endpoint:
        endpoint: 'oidc_token_endpoint'
      ```

      where:
      - *oidc_auth_endpoint* is the authorization endpoint on the OIDC server, and must be in string format.
      - *oidc_token_endpoint* is the token endpoint on the OIDC server, and must be in string format.

Default OIDC configurations

For each OIDC provider type, API Connect assumes a default configuration, but you can override the default configuration properties in your YAML file.

Note: Endpoints are subject to change; when you create a registry you must verify the default endpoint provided by API Connect.
API Connect makes the best effort to update endpoints for the known OIDC user registry types. However the OIDC provider can change the endpoint at any time. It is the customer's responsibility to confirm that the endpoints provided by API Connect are supported by the OIDC provider and to update the OIDC configuration as needed.

The default configurations are as follows:

- Facebook

```
authorization_endpoint: 'https://www.facebook.com/v3.1/dialog/oauth'
token_endpoint:
  endpoint: 'https://graph.facebook.com/v3.1/oauth/access_token'
userinfo_endpoint:
  endpoint: 'https://graph.facebook.com/me'
scope: email public_profile
field_mapping:
  username: email
  email: email
  last_name: last_name
  first_name: first_name
```

- GitHub

```
authorization_endpoint: 'https://github.com/login/oauth/authorize'
token_endpoint:
  endpoint: 'https://github.com/login/oauth/access_token'
userinfo_endpoint:
  endpoint: 'https://api.github.com/user'
scope: 'read:user user:email'
field_mapping:
  username: login
  email: email
  last_name: name
  first_name: name
```

- Google

```
authorization_endpoint: 'https://accounts.google.com/o/oauth2/v2/auth'
token_endpoint:
  endpoint: 'https://www.googleapis.com/oauth2/v4/token'
scope: openid profile email
field_mapping:
  username: email
  email: email
  last_name: family_name
  first_name: given_name
```

- LinkedIn
  Some settings differ between the legacy configuration and the newer configuration. Be sure to use the correct settings for the LinkedIn protocol that you are using.

  - New OIDC protocol:

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
  credential_location: form_body
  field_mapping:
    email: email
    username: name
    first_name: given_name
    last_name: family_name
  scope: openid profile email
  token_endpoint:
    endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
  userinfo_endpoint:
    endpoint: 'https://api.linkedin.com/v2/me'
```

  - Legacy OIDC protocol:

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
token_endpoint:
  endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
userinfo_endpoint:
  endpoint: 'https://api.linkedin.com/v1/people/~:(id,first-name,last-name,picture-url,public-profile-url,email-
address)?format=json'
scope: r_basicprofile r_emailaddress
field_mapping:
  username: emailAddress
  email: emailAddress
  last_name: lastName
  first_name: firstName
credential_location: form_body
```

- Slack

```
authorization_endpoint: 'https://slack.com/oauth/authorize'
token_endpoint:
  endpoint: 'https://slack.com/api/oauth.access'
userinfo_endpoint:
  endpoint: 'https://slack.com/api/users.identity'
scope: identity.basic identity.email
field_mapping:
  username: user.email
  email: user.email
  last_name: user.name
  first_name: user.name
```

- X (formerly known as Twitter)
  Although Twitter re-branded to X, the URL for the OIDC endpoint remains twitter.com.

```
request_endpoint: https://api.twitter.com/oauth/request_token'
authorization_endpoint: https://api.twitter.com/oauth/authenticate'
token_endpoint:
    endpoint: 'https://api.twitter.com/oauth/access_token'
```

```
userinfo_endpoint:
    endpoint: 'https://api.twitter.com/1.1/account/verify_credentials.json'
oauth_signature_method: 'HMAC-SHA1'
field_mapping:
    email: email
    first_name: name
    last_name: name
    username: screen_name
```

- Windows Live

```
authorization_endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/authorize'
token_endpoint:
  endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/token'
scope: openid offline_access profile email
field_mapping:
  email: email
  username: preferred_username
  first_name: name
  last_name: name
```

- Standard

```
response_type: code
scope: openid
field_mapping:
  username: sub
  email: email
  last_name: family_name
  first_name: given_name
credential_location: auth_header
```

  Although this is the default configuration for the **standard** provider type, you should contact your OIDC provider to obtain the details of the fields that you need to define.

Creating your OIDC user registry

To create your OIDC user registry, use the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin oidc_config_file
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization_name* is the value of the **name** property of your provider organization.
- *oidc_config_file* is the name of the YAML file that defines the configuration of your OIDC user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

By default, the *registry_name* is derived from the **title** property in the configuration YAML file but you can override this by including a **name** property in the file. The *registry_url* is an internal URL that API Connect assigns to the registry.
After you have created your OIDC user registry, you must update your application registration with the third party OIDC provider to include the OIDC redirect URI; you can obtain this information by using the following command, which displays the details of the registry in the command window:

```
apic user-registries:get --server mgmt_endpoint_url --org organization_name registry_name --output -
```

The required **oidc_redirect_uri** value is in the **consumer:** section; for example:

```
consumer:
  oidc_redirect_uri: https://consumer.mycompany.com/consumer-api/oauth2/redirect
```

Enabling your OIDC registry in a Catalog

If you want to make your OIDC registry available for onboarding and authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your OIDC user registry by using the following command:

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Log in to the Management server as a member of a provider organization; enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   For full details of the **apic login** command, see Logging in to a management server.
3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

4. Enter the following data, followed by a new line:

   ```
   user_registry_url: oidc_registry_url
   ```

   where *oidc_registry_url* is the URL of your OIDC registry, obtained in step 1.
5. Press **CTRL D** to terminate the input.

For details of all the **apic user-registries** and **apic configured-catalog-user-registries** commands, see apic user-registries and apic configured-catalog-user-registries.

You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Setting visibility for a user registry

The visibility setting determines which provider organizations can access a resource, for example, user registries.

Before you begin

You must complete the following tasks:

- Creating an availability zone
- Registering a gateway service

About this task

The user registry visibility setting controls which provider organizations are able to use that registry for authenticating Developer Portal users, or for securing APIs. For details on how to specify the user registries that can be used for authenticating users of the Cloud Manager and API Manager user interfaces, see Selecting user registries for Cloud Manager and API Manager.

Procedure

Follow these steps to set the visibility for the resources (user registries) in your on-premises cloud:

1. In the Cloud Manager, click Resources.
2. Select User Registries as the resource to view.
3. From the list of user registries, choose Edit visibility from the actions menu next to the name of the user registry you are working with.
4. Select the visibility setting for the user registry. The options are:
   - Private - the user registry is not visible and cannot be used by any provider organization
   - Public - the user registry is visible and can be used by all provider organizations
   - Custom - the user registry is visible only to the provider organizations designated by you
5. For Custom visibility, select the provider organizations that you want to have access to the user registry.
6. Click Make visible to complete the operation.

Results

For Private, the user registry cannot be used by any provider organizations. For Public, the user registry can be used by all provider organizations. For Custom, the user registry can be used by the provider organizations that you designate.

Deleting a user registry

As the Cloud Manager administrator, you can delete user registries.

About this task

Complete the following steps to delete a user registry. All users within the user registry will be deleted. The pre-configured user registries (API Manager Local User Registry and Cloud Manager Local User Registry) may not be deleted. Any user registry marked as the Default in Settings > User Registries also may not be deleted.

One of the following roles is required to delete a user registry:

- Administrator
- Owner

Procedure

1. In the Cloud Manager, click .
2. Select User Registries to see the list of current user registries in your cloud.
3. Choose Delete from the overflow menu that is adjacent to the user registry you want to delete.
4. Optionally, you can delete multiple user registries by marking the checkboxes and selecting Delete Selected User Registries from the overflow menu for the list.
5. Confirm the deletion.

Results

The user registry is deleted and removed from the User Registries list in Cloud Manager. All user accounts contained in the user registry are deleted.

Removing a user from a user registry

As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

For details on how to remove a user from a user registry, see the following subtopics:

- **Removing yourself from a user registry**
  As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.
- **Removing another user from a user registry**
  You can remove a user from an API Connect user registry by using the developer toolkit CLI.

Removing yourself from a user registry

As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.

Before you begin

You cannot remove yourself from a user registry if you are a member of a provider organization. Before removing yourself from a user registry, ensure that you have been deleted from any provider organizations. For more information, see Removing a user from an organization.

Procedure

1. Log in to the management server as the user that you want to remove.
   The format of the login command depends on whether you are a user in the Cloud Manager admin organization, or you are a user in a provider organization.

   If you are a Cloud Manager admin user, enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   If you are a provider organization user, enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   If you want to log in as a member of the cloud administration organization, or as a member of a provider organization, you can help determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope scope --server mgmt_endpoint_url --fields title,realm
   ```

   where *scope* has the value `admin` or `provider` depending on whether you want to log in as a member of the cloud administration organization, or as a member of a provider organization. The output lists the names and titles of all identity providers, for example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`, and the default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

   Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and you have access to both, when you remove yourself from the user registry you will lose access to both user interfaces regardless of which organization you log in to.
2. Remove yourself from the user registry. Enter the following command:

   ```
   apic me:delete --server mgmt_endpoint_url
   ```

   For example:

   ```
   apic me:delete --server platform-api.myserver.com.com
   ```

   The command confirms successful removal by returning the details of the deleted user; for example:

   ```
   user1    [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
   0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
   ```

Removing another user from a user registry

You can remove a user from an API Connect user registry by using the developer toolkit CLI.

Before you begin

To complete this task, you must have Administrator access to your API Connect cloud, or be the owner of a provider organization, depending on the scope of the user registry.

You cannot remove a user from a user registry if that user is a member of the Cloud Manager admin organization, a provider organization, or a consumer organization, and that user registry is used for the associated login. Before removing a user from a user registry, ensure that they have been deleted from any organizations for which that user registry is used for login. For more information, see Deleting a member or Removing a user from an organization.

Procedure

1. Log in to the management server.
   - If the user registry is defined at the cloud administration level, and therefore available to all provider organizations, you must log in as a member of the Cloud Manager admin organization.
   - If the user registry is defined at a provider organization level, and therefore specific to that provider organization, you must log in as the organization owner.

   For full details of the **apic login** command, see Logging in to a management server.

   Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and the user has access to both, when you remove them from the user registry they will lose access to both even though you are logging in to the admin organization.
2. Identify the name of the user registry from which you want to remove the user. Enter the following command:

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

   where *organization_name* has the value **admin** if you are logged in as a member of the Cloud Manager admin organization, or is the name of the provider organization if you are logged in as an organization owner.
   For example:

   ```
   apic user-registries:list --server platform-api.myserver.com.com --org admin
   ```

   The command returns a list of all user registries, with the registry name displayed first; for example:

   ```
   api-manager-lur     https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-
   0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245
   cloud-manager-lur   https://platform-api.myserver.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/3adbf524-
   cd74-4051-99c0-89ce5ffcc9c0
   my-ldap             https://platform-api.myserver.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/29eae413-
   cd74-4051-99c0-89ce5ffcc9c0
   ```

3. Identify the name of the user, from the required user registry, that you want to remove. Enter the following command:

   ```
   apic users:list --server mgmt_endpoint_url --org organization_name --user-registry user_registry_name
   ```

   For example:

   ```
   apic users:list --server platform-api.myserver.com.com --org admin --user-registry my-ldap
   ```

   The command returns a list of all users in the user registry, with the user name displayed first; for example:

   ```
   user1     [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
   0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
   user2     [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
   0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/12f1aa82-d9f0-4670-99f1-7500d1fb6583
   ```

4. Remove the required user from the user registry. Enter the following command:

   ```
   apic users:delete user_name --server mgmt_endpoint_url --org organization_name --user-registry user_registry_name
   ```

   For example:

   ```
   apic users:delete user1 --server platform-api.myserver.com.com --org admin --user-registry my-ldap
   ```

   The command confirms successful removal by returning the details of the deleted user; for example:

   ```
   user1    [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
   0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
   ```

TLS profiles overview

API Connect supports TLS Profiles for securing data transmission over HTTPS.

Introduction to TLS profiles

Important: API Connect includes several default TLS profiles to help you get started working with the application. The default profiles should not be used in a production environment. It is important to create your own profiles to ensure a secure network.
API Connect may need to transmit data across an untrusted network, for example, when accessing the Gateway, email server, or LDAP server. TLS provides secure network layer transportation of data between two parties.

There are two types of TLS Profiles: a TLS Server Profile and a TLS Client Profile. A TLS Server Profile is used by the Gateway to configure its endpoint for use during API execution. A TLS Client profile is used whenever the system needs to communicate with another endpoint over TLS.

The components of a TLS Profile are:

- TLS Protocol version indicates the versions of the Transport Layer Security Protocol required for the profile. TLS Protocol versions 1.0, 1.1, 1.2, and 1.3 are supported.
- Optional support for mutual authentication and renegotiation for Server Profiles.
- Optional support for weak server connections and Server Name Indication for Client Profiles.
- Cipher suites to secure HTTPs communication within the API Connect ecosystem.
- Keystores containing public and private key pairs.
- Truststores containing public keys for trusted third party services, such as Google, Facebook, or Verisign.

Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

- **Viewing TLS Profiles, Keystores, and Truststores**
  The current list of TLS profiles, Keystores, and Truststores can be viewed on the main TLS screen.
- **Creating a TLS Server Profile**
  In Cloud Manager, you can configure the profile that is used on the gateway when it acts as a TLS server.
- **Creating a TLS Client Profile**
  In Cloud Manager, TLS profiles are configured as a Resource to provide secure transmission of data over HTTPs.
- **Creating a Keystore**
  Each keystore contain a matched pair of a public certificates and its private keys. These artifacts provide identity information during a TLS handshake.
- **Creating a Truststore**
  A truststore contains a list of certificates. The certificates are used to verify the peer during a TLS handshake.
- **Viewing certificate details and adding certificates to a keystore or truststore**
  You can view details for the certificates in an existing keystore or truststore and add additional certificates.
- **Generating a self-signed certificate using OpenSSL**
  OpenSSL is an open source implementation of the SSL and TLS protocols. It provides the transport layer security over the normal communications layer, allowing it to be intertwined with many network applications and services.
- **Generating a PKCS#12 file for Certificate Authority**
  PKCS#12 (P12) files define an archive file format for storing cryptographic objects as a single file. API Connect supports the P12 file format for uploading a keystore and truststore. The keystore should contain both a private and public key along with intermediate CA certificates.
- **Setting the API invocation certificate for a gateway service**
  Configure the TLS certificate for the API invocation endpoint on your gateway service.
- **Updating the PKCS#12 certificate for a TLS server profile**
  A server certificate bound to a gateway service can be invalidated if the host name in the digital certificate of the server does not match the URL specified by the client, or because it has expired. When this happens, you must update the TLS profile with a new CA certificate or PKCS#12 (P12) file.

Viewing TLS Profiles, Keystores, and Truststores

The current list of TLS profiles, Keystores, and Truststores can be viewed on the main TLS screen.

Before you begin

Important: API Connect includes several default TLS profiles to help you get started working with the application. The default profiles should not be used in a production environment. It is important to create your own profiles to ensure a secure network.
One of the following roles is required to view TLS Server Profiles:

- Administrator
- Owner
- Topology Administrator
- Viewer
- Custom role with the `Settings: Manage` or `Settings: view` permissions

About this task

The TLS list screen provides a list of TLS Profiles, Keystores and Truststores configured for your cloud. Users with view permissions can use this screen as a reference for the TLS Profiles.

Users with manage permissions can create new Profiles, Keystores, and Truststores; edit existing ones; and delete items that are no longer needed. Users can view the Keystores and Truststores assigned to the profiles.

Users can view and set the visibility for Client Profiles. For more information on visibility, see Setting visibility for a TLS Client Profile

Procedure

Following are the tasks you can perform using the list screen as a base:

1. In the Cloud Manager, click Resources.
2. Select TLS.
3. Complete your management task:
   - To create a new item, click Create next to the table for the type of item you want to create.
   - To edit an existing item, either click the Title of the item, or click the options menu ⋮ and then click Edit.
   - To set the visibility of a TLS Client Profile, click the options menu ⋮ for the profile, and then click Edit Visibility.
   - To delete an existing item, click the options menu ⋮ for the profile, and then click Delete.

Creating a TLS Server Profile

In Cloud Manager, you can configure the profile that is used on the gateway when it acts as a TLS server.

Before you begin

Important: API Connect includes several default TLS profiles to help you get started. The default profiles should not be used in a production environment. It is important to create your own profiles to secure your network.
One of the following roles is required to configure TLS Server Profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

About this task

The Server profile is for the gateway when it is acting as the TLS server.

Procedure

Perform the following steps to create a TLS Server profile:

1. In the Cloud Manager, click Resources.
2. Select TLS.
3. Click Create in the TLS Server Profile table.
4. Enter the fields to configure the TLS Server Profile:

Field	Description
Title (required)	Enter a Title for the profile. The title is displayed on the screen.
Name (required)	The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage TLS Server Profiles, see apic tls-server-profiles.
Version (required)	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, *MyProfile 1.0* and *MyProfile 1.1*.
Summary (optional)	Enter a description of the profile.
Protocols (required)	Select one or more supported TLS protocol versions. The default is 1.2.
Mutual Authentication (required)	Determines the level of two-way authentication for the server profile. In two-way authentication, the server responds to a client by sending a request for the client certificate. • None (default) No support for mutual authentication. • Request Enable this option to request client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the certificate is not checked on the gateway. • Require Enable this option to require client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the TLS handshake fails and the request is blocked.
Limit Renegotiation (optional)	Client-initiated renegotiation allows the connection to be retried. The default is to prevent renegotiation. Remove the checkmark to allow renegotiation.
Keystore (required)	A keystore is a repository containing a public and private key pair. The Server Profile requires a keystore in order to securely identify the system. When an application sends an API request, the keystore is used to verify a matching certificate. Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.
Truststore (optional)	A truststore is a repository containing certificates. The certificates are used to verify the peer during a TLS handshake. If, in addition to a keystore, a truststore is specified, the certificate is further checked for validity by ensuring that is signed by the root certificate, which must be in the truststore. Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.
Ciphers (required)	Cipher suites are encryption/decryption algorithms used to secure HTTPs communication within the API Connect ecosystem. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, **all** the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are **not** added to the list of ciphers supported by the profile.

5. Click Save.

Creating a TLS Client Profile

In Cloud Manager, TLS profiles are configured as a Resource to provide secure transmission of data over HTTPs.

Before you begin

One of the following roles is required to configure TLS Profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

API Connect uses both TLS Server and TLS Client profiles. A TLS Server profile is presented when a communication request is received. The Server profile validates the request against the Keystore and protocol version to determine whether the connection is secure. The Client profile is presented to initiate communication with another system. Client Profiles may be made visible for use by provider organizations in policies in API Manager. See Setting visibility for a TLS Client Profile.

Procedure

Perform the following steps to create a TLS Client profile:

1. In the Cloud Manager, click Resources.
2. Select TLS.
3. Click Create in the TLS Client Profile table.
4. Enter the fields to configure the TLS Client Profile:

Field	Description
Title (required)	Enter a Title for the profile. The title is displayed on the screen.
Name (required)	The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage a TLS Client Profile, see apic tls-client-profiles.
Version (required)	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, *MyProfile 1.0* and *MyProfile 1.1*.
Summary (optional)	Enter a description of the profile.
Protocols (required)	Select one or more supported TLS protocol versions. The default is 1.2.
Server Connection (optional)	Specify whether to support weak or insecure credentials. • Allow insecure server connections - Insecure server connections may result from self-signed certificates, expired or corrupted certificates, or certificates from an unknown or untrusted source. Check this box to allow the connection to proceed with an insecure connection. The default is to not allow insecure server connections. • Support Server Name Indication (SNI) - Check this box to enable SNI. SNI allows support for multiple certificates presented on the same IP address using different host names. The client profile sends the name of a virtual domain as part of the TLS negotiation. The default is to enable SNI.
Keystore (optional)	A Keystore is a repository containing public and private key pairs. Select the keystore where you will store the certificates for the profile. Default keystores are provided, and you can also create your own. Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your uploaded certificates before they expire.
Truststore (optional)	A Truststore is a repository containing verified public keys, which are usually obtained from a third-party certificate authority. Truststores provide list of certificates to verify a peer's certificate. If used in a TLSServerProfile, a truststore is used when mutual authentication is enabled. Select a truststore for the profile. Default truststores are provided, and you can also create your own. Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your uploaded certificates before they expire.
Ciphers (required)	Cipher suites are encryption/decryption algorithms used to secure HTTPs communication within the API Connect ecosystem. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, **all** the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are **not** added to the list of ciphers supported by the profile.

5. Click Save.

Setting visibility for a TLS Client Profile

The visibility setting determines which provider organizations can access a resource.

Before you begin

You must complete the following task:

- Creating a TLS Client Profile

About this task

The visibility setting gives you control over the resources that are available to provider organizations.

Procedure

Follow these steps to set the visibility for the resources in your on-premises cloud:

1. In the Cloud Manager, click Resources.
2. Select TLS as the resource to view.
3. From the table of TLS Client Profiles, choose Edit visibility from the ⋮ options menu next to the name of the profile you are managing.
4. Select the visibility setting for the profile. The options are:
   - Private - the profile is visible only in Cloud Manager and cannot be used by any provider organization
   - Public - the profile is visible and can be used by all provider organizations
   - Custom - the profile is visible only to the provider organizations designated by you
5. For Custom visibility, select the provider organizations that you want to have access to the profile.
6. Click Save to complete the operation.

Results

For Private, the profile cannot be used by any provider organizations. For Public, the profile can be used by all provider organizations. For Custom, the profile can be used by the provider organizations that you designate. If visible, the profiles will be available in API Manager.

Defining elliptic curve cryptographic schemes for a TLS client profile

You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

About this task

To define elliptic curve cryptographic schemes for a TLS client profile, you include **`elliptic_curve_auto_negotiation`** and **`elliptic_curve`** properties in a YAML file definition for the TLS client profile. The **`elliptic_curve`** property lists the required elliptic curve cryptographic schemes. For example:

```
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - secp521r1
  - secp384r1
  - prime256v1
```

You then use the developer toolkit CLI to create the TLS client profile in API Connect.

When **`elliptic_curve_auto_negotiation`** is set to **`true`**, the system negotiates the Elliptic-curve Diffie-Hellman (ECDH) key agreement automatically with its peer, and any **`elliptic_curve`** property settings are ignored.

The following example shows a complete YAML file for a TLS client profile:

```
type: tls_client_profile
name: my-tls-client-profile
version: 1.0.0
title: My TLS client profile
protocols:
  - tls_v1.2
ciphers:
  - ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - sect163k1
insecure_server_connections: false
server_name_indication: true
```

Note:

- The **elliptic_curve_auto_negotiation** option is not supported by any of the API Connect gateway types. If the TLS client profile is targeted for an API Connect gateway; this setting is ignored by the gateway.
- The elliptic curve cryptographic schemes shown in each row of the following table are equivalent. However, API Connect recognizes only one or the other depending on how the TLS profile is used, as indicated in the table.

  Table 1.

API enforcement on the gateway	API Connect server access security
secp192r1	prime192v1
secp256r1	prime256v1

  Therefore, if you want to use either of these schemes and are unsure whether you are targeting the TLS client profile to the API Connect gateway for API enforcement, whether you are using it to secure user access to the API Connect servers, or whether it will be used for both purposes, specify both equivalent schemes; API Connect will simply ignore the non-relevant scheme. For example:

```
elliptic_curve:
        .
        .
        .
  - secp256r1
  - prime256v1
        .
        .
        .
```

Procedure

To create a TLS client profile with elliptic curve cryptographic schemes defined. complete the following steps:

1. Create a YAML file definition for your TLS client profile, with the required **elliptic_curve** property.
2. Log in to the management server from the developer toolkit CLI. Log in either as a member of the cloud administration organization or as a member of a provider organization, depending on where you want to create the TLS client profile. For details, see Logging in to a management server.
3. Create the TLS client profile by using the following command:

   ```
   apic tls-client-profiles:create --server mgmt_endpoint_url --org organization_name tls_client_profile_yaml_file
   ```

   where:
   - *mgmt_endpoint_url* is the platform API endpoint URL, and is the same as that which was used when you logged in at step 2.
   - *organization_name* is either **admin**, for the cloud administration organization, or the name of your provider organization, and is the same as that which was used when you logged in at step 2.
   - *tls_client_profile_yaml_file* is the name of the YAML file that contains the definition for your TLS client profile.

   Note: When you install IBM® API Connect, the API Connect gateway has a pre-supplied default TLS client profile that is used for API enforcement if you do not configure a TLS client profile; you cannot configure this default TLS client profile on the gateway.
   For reference details of all the **apic tls-client-profiles** commands, see apic tls-client-profiles.

   You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Creating a Keystore

Each keystore contain a matched pair of a public certificates and its private keys. These artifacts provide identity information during a TLS handshake.

Before you begin

Cloud Manager and API Manager both support and use TLS certificates, but they do not themselves produce strong encryption keys or manage your encryption keys. Encryption keys are generated and managed according to your own procedures. For more information, see Generating a PKCS#12 file for Certificate Authority and Generating a self-signed certificate using OpenSSL.

One of the following roles is required to configure Keystores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

API Connect includes pre-configured Keystores which may be used for testing purposes. For production environments, we suggest creating a new, secure Keystore.

Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

Procedure

Perform the following steps to create a TLS Client profile:

1. In the Cloud Manager, click Resources.
2. Select TLS.
3. Click Create in the Keystore table.

Field	Description
Title (required)	Enter a Title for the Keystore. The title is displayed on the screen.
Name (required)	The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage keystores, see apic keystores.
Summary (optional)	Enter a brief description.
Private Key & Public Key: Step 1: Upload private key	Upload the file containing the private key certificate. If necessary, you can click Browse to locate the file. If the file contains both the private and public keys, upload it in Step 1. Private and public keys are always uploaded in pairs, either in a single file or separate files.
Private key password (optional)	Enter the password for the private key if it has a password.
Private Key & Public Key: Step 2: Upload public key	If the public key is contained in a separate file, upload it in Step 2. Private and Public keys are always uploaded in pairs, either in a single file or separate files.

4. Click Save.
   Note: After they have been uploaded, private keys cannot be downloaded from API Connect.

1. In the Cloud Manager, click Resources.
2. Select TLS.
3. Click Create in the Truststore table.

Field	
Title (required)	Enter a Title for the Truststore. The title is displayed on the screen.
Name (required)	The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage truststores, see apic truststores.
Summary (optional)	Enter a brief description.
Public Keys	Upload the file containing the public key certificate. If necessary you can click Browse to locate the file.

4. Click Save.

Viewing certificate details and adding certificates to a keystore or truststore

You can view details for the certificates in an existing keystore or truststore and add additional certificates.

Before you begin

One of the following roles is required to edit Keystores and Truststores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

API Connect includes pre-configured Keystores and Truststores which you can use for testing purposes. For production environments, we suggest creating a new, secure Keystore or Truststore. From an existing Keystore or Truststore, you can edit the title, view the details of the certificates, and add new certificates.
Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

Procedure

To work with existing keystores and truststores:

1. In the Cloud Manager, click Resources.
2. Select TLS.
3. Click the name of the keystore or truststore.
4. Edit the name and summary if needed.
5. The Subject, Finger Print, and Expiration date is shown for each certificate in the keystore or truststore. Click > to view the certificate details.
6. Add additional private and/or public keys if needed.
7. Click Save.
   Note: After they have been uploaded, private keys cannot be downloaded from API Connect.

Generating a self-signed certificate using OpenSSL

OpenSSL is an open source implementation of the SSL and TLS protocols. It provides the transport layer security over the normal communications layer, allowing it to be intertwined with many network applications and services.

Before you begin

One of the following roles is required to complete this task:

- Administrator
- Owner
- Topology Administrator

- Custom role with the `Settings: Manage` permissions

About this task

This topic tells you how to generate a self-signed SSL certificate request using the OpenSSL toolkit to enable HTTPS connections.

Procedure

To generate a self-signed SSL certificate using the OpenSSL, complete the following steps:

1. Write down the Common Name (CN) for your SSL Certificate. The CN is the fully qualified name for the system that uses the certificate. For static DNS, use the hostname or IP address set in your Gateway Cluster (for example. **`192.16.183.131`** or **`dp1.acme.com`**).
2. Run the following OpenSSL command to generate your private key and public certificate. Answer the questions and enter the Common Name when prompted.

   ```
   openssl req -newkey rsa:2048 -nodes -keyout key.pem -x509 -days 365 -out certificate.pem
   ```

3. Review the created certificate:

   ```
   openssl x509 -text -noout -in certificate.pem
   ```

4. Combine your key and certificate in a PKCS#12 (P12) bundle:

   ```
   openssl pkcs12 -inkey key.pem -in certificate.pem -export -out certificate.p12
   ```

5. Validate your P2 file.

   ```
   openssl pkcs12 -in certificate.p12 -noout -info
   ```

   Once the certificate file is created, it can be uploaded to a keystore.
6. In the Cloud Manager, click Resources.
7. Select TLS.
8. Click Create in the Keystore table.
9. Create a Keystore and upload the certificate file following the instructions at Creating a Keystore.
   Note:
   - API Connect supports only the P12 (PKCS12) format file for the present certificate.
   - Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
   - Your P12 file can contain a maximum of 10 intermediate certificates.
10. Click Save.

Generating a PKCS#12 file for Certificate Authority

PKCS#12 (P12) files define an archive file format for storing cryptographic objects as a single file. API Connect supports the P12 file format for uploading a keystore and truststore. The keystore should contain both a private and public key along with intermediate CA certificates.

Before you begin

One of the following roles is required to add a key to a keystore or truststore:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

Before you can generate a P12 file, you must have a private key (for example: *key.pem*), a signed certificate by a Certificate Authority (for example *certificate.pem*) and one or more certificates from the CA authority.
Note: If your certificate file contains more than one certificate, you must manually split the file and create a single file for each entry. Each entry must be bound by the following markers:

```
-----BEGIN CERTIFICATE-----

-----END CERTIFICATE-------
```

Procedure

1. If you have intermediate certificates from your CA, concatenate them into a single .pem file to build your **`caChain`**. Be sure to enter a new line following each certificate's data.

```
cat ca1.pem ca2.pem ca3.pem > caChain.pem
cat caChain.pem
-----BEGIN CERTIFICATE-----
MIIEpjCCA46gAwIBAgIQEOd26KZabjd+BQMG1Dwl6jANBgkqhkiG9w0BAQUFADCB
...
lQX7CkTJn6lAJUsyEa8H/gjVQnHp4VOLFR/dKgeVcCRvZF7Tt5AuiyHY
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIEPDCCAySgAwIBAgIQSEus8arH1xND0aJ0NUmXJTANBgkqhkiG9w0BAQUFADBv
...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIENjCCAx6gAwIBAgIBATANBgkqhkiG9w0BAQUFADBvMQswCQYDVQQGEwJTRTEU
...
-----END CERTIFICATE-----
```

2. Create the P12 file including the private key, the signed certificate and the CA file you created in step 1, if applicable. Omit the `-CAfile` option if you don't have CA certificates to include.
   The following command uses OpenSSL, an open source implementation of the SSL and TLS protocols.

   ```
   openssl pkcs12 -inkey key.pem -in certificate.pem -export -out certificate.p12 -CAfile caChain.pem -chain
   ```

   Once the certificate file is created, it can be uploaded to a keystore.
3. In the Cloud Manager, click Resources.
4. Select TLS.
5. Click Create in the Keystore table.
6. Create a Keystore and upload the certificate file following the instructions at Creating a Keystore.
   Notes:
   - API Connect supports only the P12 (PKCS12) format file for the present certificate.
   - Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
   - Your P12 file can contain a maximum of 10 intermediate certificates.
7. Click Save.

Setting the API invocation certificate for a gateway service

Configure the TLS certificate for the API invocation endpoint on your gateway service.

Before you begin

One of the following roles is required:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Topology: Manage` permissions

For more information on which user roles have access, see Adding members to the admin organization.

About this task

To set the API invocation certificate for a gateway service, you must add the certificate to a TLS server profile, and then update your gateway service to use this TLS server profile.

Important: API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

Procedure

1. Create or update the TLS server profile that contains the certificate you want for your API invocation endpoint. See Creating a TLS Server Profile.
2. In the Cloud Manager user interface, click Topology, then select the gateway service where you want to set the API invocation certificate.
3. Scroll down to the API Invocation Endpoint section, and under Server Name Indication (SNI) select the TLS server profile that you configured in step 1.
   You can also set the TLS server profile during the initial registration of a gateway service; see Registering a gateway service.
4. Click Save when done.

Updating the PKCS#12 certificate for a TLS server profile

A server certificate bound to a gateway service can be invalidated if the host name in the digital certificate of the server does not match the URL specified by the client, or because it has expired. When this happens, you must update the TLS profile with a new CA certificate or PKCS#12 (P12) file.

Before you begin

One of the following roles is required:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

If the expiration date of a certificate or a P12 file is approaching, or if a certificate is invalidated, use the steps in this topic to update a TLS profile bound to a gateway service. CA certificate and P12 file expiration dates are displayed in the details of the containing keystore; see step 3.

You update the certificate for a TLS server profile by replacing the certificate in the keystore that is associated with the TLS server profile.

Complete the following steps to update a TLS profile that has an invalidated or expired certificate or P12 file.

Procedure

1. In the Cloud Manager user interface, click Resources, then click TLS.
2. To identify the keystore that is associated with the TLS server profile, complete the following steps:
   a. In the TLS Server Profile section, select the required profile.
   b. In the Keystore/Truststore section, note the selected keystore, then click Cancel to close the TLS server profile details page.
3. In the Keystore section, select the required keystore.
   The Certificates section displays the expiration date of a certificate. You can expand a certificate to see further details.
4. Click Browse and select the required P12 file.
   Note:
   - API Connect supports only the P12 (PKCS12) format file for the present certificate.
   - Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
   - Your P12 file can contain a maximum of 10 intermediate certificates.
5. Click Save when done.

OAuth Provider overview

API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

Introduction to OAuth

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information. In API Connect, you can secure an API with OAuth.

In Cloud Manager, you configure both Native and Third party OAuth providers that can be made visible to selected Provider organizations. The OAuth Provider configuration is based on the OAuth 2.0 Specification, which is available at https://tools.ietf.org/html/rfc6749. Knowledge of the OAuth 2.0 specification is required to implement an OAuth Provider in API Connect.

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- **Configuring a native OAuth provider**
  Native OAuth providers are configured and managed by you within your cloud.
- **Configuring a third-party OAuth provider**
  Enter the secure endpoints to provide OAuth authentication from a third party.
- **Setting the visibility for OAuth providers**
  The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.
- **OAuth concepts for API Connect**

Configuring a native OAuth provider

Native OAuth providers are configured and managed by you within your cloud.

About this task

A native OAuth provider object provides settings for OAuth processing operations such as generating and validating OAuth tokens. An OAuth provider object is referenced by an OAuth security definition to protect an API. When a native OAuth provider is used, the OAuth operations are performed natively by API Connect.

Every OAuth provider object has a backing API. Your configuration here automatically updates the OpenAPI document of the API. You can edit the OpenAPI document directly by navigating to the Resources > OAuth Providers page, selecting your OAuth provider, then clicking API Editor.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the **`oauth-provider-settings-ref`** field in each OAuth assembly action.

When a published API references an OAuth provider object, the backing API is automatically made available in the gateway.

Token requests and client_id checks:
If you are calling an OAuth endpoint, the sequence of **`client_id`** checks in the token request is as follows:

1. Check both body and query.
   - If found in only the body, validate and return a **`200`** or appropriate return code.
   - If found in only the query, return a **`wrong location`** error.
   - If found in both the body and the query, return a **`more than one location`** error.
2. When not found in the body or the query, check the **`Authorization`** header.
   - If found in this header, validate and return a **`200`** or appropriate return code.
3. Not found, return the appropriate error and code.

The best location for the **`client_id`** is in the request body.
One of the following roles is required to configure a native OAuth provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:

- The OAuth provider logs analytics data for failure cases, but does not log successful cases. Activity log policies that call for logging of analytics data upon success do not apply for the OAuth provider.
- You must ensure the OAuth Provider is configured in the Sandbox Catalog before using the OAuth Provider in a non-Sandbox Catalog.

Procedure

OAuth provider configuration uses a series of screens. The first set of screens controls a basic OAuth provider configuration. Perform the following steps to configure a native OAuth Provider for your cloud:

1. In the Cloud Manager, click Resources.
2. Click OAuth Providers > Add > Native OAuth provider.
   a. Complete the following parameters for the first screen, then click Next.

Field	Description
Title	Enter a title for the native OAuth provider.
Name	This field is auto-populated by the system.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path must be unique for a given catalog. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
Gateway Type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. In the next screen, enter the following additional configuration parameters, then click Next.

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to login to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.

Field	Description

Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step.
	• Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security.
	• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."
	• Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.
	• API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.
	Note: To use the Resource owner - JWT option, complete the following steps:
	  • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT.
	  • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type.
	  For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).

Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

c. Enter the scopes in the next screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

d. Enter the parameters for User Security in the next screen. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application grant type. Click Next when done.

Field	Description
Identity Extraction	Determines how the user credential is extracted: • Basic Authentication - HTTP basic authentication (requires no additional configuration) • Default HTML Form - Use default login form for user name and password • API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here API Connect context variables Note: DataPower API Gateway only. Not available for DataPower Gateway (v5 compatible). • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security. • Redirect - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL. • API Gateway only Disabled - do not collect the user credential Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the `state_nonce` query parameter, otherwise the authorization fails.
Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry. For a DataPower API Gateway, you have the option to disable authentication with a user registry.
Authorization	The following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use default HTML form to authorize. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML authorization form for user security. • API Gateway only Disabled - Disable authorization.

3. Review the Summary for the native OAuth provider configuration.
4. Click Back to make changes.
5. Click Finish to save the basic configurations and to proceed to the Advanced Parameters for a native OAuth Provider.
   If you want to specify the native OAuth Provider in your Catalog, see Specifying the OAuth Providers.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

- **Configuring basic settings for a native OAuth provider**
  You can update the identification details and basic configuration settings for a native OAuth provider.
- **Configuring scopes for a native OAuth provider**
  Access tokens contain authorization for specific scopes.
- **Configuring user security for a native OAuth provider**
  Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.
- **Configuring tokens for a native OAuth provider**
  Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.
- **Configuring token management and revocation for a native OAuth provider**
  Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.
- **Configuring introspection for a native OAuth provider**
  Define an introspection path to allow the metadata for an access token to be examined.
- **Configuring metadata for a native OAuth provider**
  Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Configuring the OIDC parameters for a native OAuth provider**
  Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.

- **Editing a native OAuth provider by using the API Editor**
  You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

Configuring basic settings for a native OAuth provider

You can update the identification details and basic configuration settings for a native OAuth provider.

About this task

One of the following roles is required to configure the basic settings for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the basis settings pages for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the basic settings for an existing native OAuth provider. If you want to update the basic settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. To modify the identification details, click Info in the sidebar menu, then update the following fields as required:

Field	Description
Title	Enter a title for the native OAuth provider.
Name	This field is auto-populated by the system.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path must be unique for a given catalog. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.

2. To modify the basic configuration settings, click Configuration in the sidebar menu, then update the following fields as required:

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to login to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.

Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step.
	• Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security.
	• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."
	• Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.
	• API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.
	Note: To use the Resource owner - JWT option, complete the following steps:
	  • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT.
	  • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type.
	  For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).
	
	Tip: If you plan to configure OpenID Connect (OIDC) for a Native OAuth provider, include at least one of the following grant types: Implicit, Access code.

Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

DataPower Gateway (v5 compatible) only Note: If the gateway type is DataPower® Gateway (v5 compatible) and, when the native OAuth provider was created, only the Application grant type was selected, you cannot add further grant types until you configure the user security settings. In particular, you must specify the user registry for authenticating application users. To configure the user security settings, complete the following steps:
   a. Click User Security in the sidebar menu, then click Edit.
   b. Update the user security settings as required; for more details, see Configuring user security for a native OAuth provider.
   c. Click Save when done.
3. Click Save when done.

Configuring scopes for a native OAuth provider

Access tokens contain authorization for specific scopes.

About this task

Client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth protected API is invoked, the gateway checks the scopes carried in the access tokens against the list of allowed scopes in the security definition for the API to determine whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The final scope permission that is granted by the access token is the result of all scope checks.

Per IETF RFC 6749, the value of the scope parameter is a list of space-delimited, case-sensitive strings. For more information, see The OAuth 2.0 Authorization Framework.

One of the following roles is required to configure scopes for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the scope settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the scope settings for an existing native OAuth provider. If you want to update the scope settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure the scopes for the access token:

1. Click Scopes in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

   In the Default scopes section, select the default scopes to be used if the API request doesn't contain any scopes. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.
   If the user authorization method is set to Default HTML Form in the User Security settings, all scopes specified here are added automatically to the authorization consent form.

2. Advanced scope check before token generation. This setting specifies the scope check endpoint where additional scope verification is performed in addition to the basic scopes. The advanced scope check URLs are invoked after application authentication or after owner authentication based on which URLs are configured. The scopes are included in the token and will overwrite any previous scopes.

Field	Description
Application scope check	Allow extra verification by running a scope check from an endpoint. Enter the endpoint and an optional TLS Profile to use for an application scope check.
Owner scope check	Further refine the scope with an additional check. Enter the endpoint and an optional TLS Profile to use for an owner scope check.

   For more information about scope, see Scope
3. Advanced scope check after token generation. This setting specifies an additional scope check at the API consumer level to verify compliance with the scope requirements of the API.

Field	Description
Enabled	Select the check box to enable the advanced scope check after token validation. Enter an optional default validator endpoint.
Use endpoint from API	Select the check box to use the endpoint from the API, or clear the check box to override the endpoint from the API.

   For more information about scope, see Scope
4. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider with the specified scopes can be used to secure the APIs in catalog.

Configuring user security for a native OAuth provider

Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.

About this task

User security authenticates the user. It is required for the Implicit, Access code, and Resource owner - Password grant types. It is not used for the Application or Resource owner - JWT grant types.

One of the following roles is required to configure user security for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator

- Custom role with the `Settings:Manage` permissions

You can select the user security settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the user security settings for an existing native OAuth provider. If you want to update the user security settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure the user security settings for the OAuth Provider:

1. Click User Security in the sidebar menu.
2. Specify the following parameters for User Security. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application or Resource owner - JWT grant types. Click Next when done.

Field	Description
Identity Extraction	Determines how the user credential is extracted: • Basic Authentication - HTTP basic authentication (requires no additional configuration) • Default HTML Form - Use default login form for user name and password • API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here API Connect context variables • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security. • Redirect - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL. • API Gateway only Disabled - do not collect the user credential Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the **`state_nonce`** query parameter, otherwise the authorization fails.
Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry.
Authorization	Various methods may be used to authorize application users. For a DataPower® API Gateway, the following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use default HTML form to authorize. If you select the Default HTML Form method, all scopes that are specified in the Scopes settings are added automatically to the authorization consent form. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. • API Gateway only Disabled - Disable authorization.

3. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Related information

Configuring tokens for a native OAuth provider

Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.

About this task

Access tokens are granted to the client application to allow the application to access resources on behalf of the application user. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or more narrow scope. You can also specify how long the consent given by the combination of any number of access and refresh token remains valid.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token settings for an existing native OAuth provider. If you want to update the token settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.

2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure tokens for the native OAuth provider:

1. Click Tokens in the sidebar menu.
2. Define the settings to configure tokens.

Field	Description
Access tokens time to live	Enter the expiration time period in seconds for access tokens.
API Gateway only One time use access token	Click the check box to enable one time use for the access token. Access tokens are multiple use by default which allows them to be used for multiple requests. When one time use is enabled, the access token will be consumed after one use. The OAuth flow will need to be repeated to obtain another access token. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Refresh tokens	Click the check box to enable Refresh tokens. Set the Count to limit the number of times a refresh token can be issued. Set the Refresh Token Time to Live value to determine the time to live, or expiration time period, for each refresh token in seconds.
One time use refresh token	Clear the check box to disable one time use for the refresh tokens. Refresh tokens are one time use by default which allows them to be used one time only to generate an access token and a new refresh token. When refresh token one time use is disabled then the refresh token count is limited to one and the refresh token can be used multiple times to generate new access tokens, however, another refresh token will not be generated unless the initial OAuth flow (Authorization Code or Password) is repeated. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Maximum consent	Click the check box to enable Maximum consent and enter the Maximum Consent Time to Live value in seconds. This is the time to live, or expiration time period, for all tokens, both access and refresh.
API Gateway only Token secret	Click the check box to select the Shared Secret which was configured for the gateway. If no Shared Secret was entered in the Gateway Configuration, then enter an key name and key value to use as the token secret.
API Gateway only Proof Key for Code Exchange	Proof Key for Code Exchange (PKCE) is a method to protect OAuth 2.0 public clients from an authorization code interception attack when they use Authorization Code grant requests. You can enable this extension when deploying with the DataPower® API Gateway. For more information, see RFC 7636. Select the options for your OAuth Providers: • Enable proof key for code exchange If selected, enforces PKCE when submitted in Authorization Code grant requests. • Always required If selected, requires PKCE in all Authorization Code grant requests. • Allow plain Select this check box to allow the plain challenge method in Authorization Code grant requests.

3. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring token management and revocation for a native OAuth provider

Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.

About this task

Token management enables you to prevent replay attacks by configuring token revocation. API Connect supports token revocation using a native gateway (DataPower) or a third party endpoint. For a native gateway, quota enforcement is used to manage tokens. For a third-party endpoint, a URL to an external service is used to manage tokens.

For more information, see the IETF RFC 7009 OAuth 2.0 Token Revocation.

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

One of the following roles is required to configure token management and revocation for a native OAuth Provider:

- Administrator

- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token management settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token management settings for an existing native OAuth provider. If you want to update the token management settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure revocation settings for tokens:

1. Select Token Management in the sidebar menu.
2. Enable token management by selecting the check box.
3. From the Type list, select either Native or External. Native points to DataPower as the token storage location; External points to a revocation URL for token storage.
   Note: If you are using the API Manager user interface then, for the External option to be available, you must be using DataPower® API Gateway Version 10.0.1.0 or later, and the gateway service must be enabled in the Sandbox Catalog; for details on how to enable a gateway service in a Catalog, see Creating and configuring Catalogs
4. For Native, select one or both of the Resource owner revocation path and Client revocation path.
   - Resource owner revocation path - Uses the standard OAuth revocation path to allow the resource owner (end user) to revoke the application permission.
   - Client revocation path - Uses the standard OAuth revocation path to allow the client (application) to revoke a single token when the application closes.

   For more information about managing tokens with the Native DataPower Gateway, see Token management with the native DataPower Gateway.
5. For External, the settings depend on the gateway type, as follows:
   DataPower API Gateway:
   - Endpoint - the URL of the external management endpoint.
   - TLS Client Profile (optional) - the TLS client profile to secure connections.
   - Security - how to secure connections. The only supported method is basic authentication.
   - Basic authentication username (optional) - the user name for authentication.
   - Basic authentication password (optional) - the password for authentication.
   - Basic authentication request header name (optional) - the request header that contains the authentication string; if you supply both a request header name and user name/password, the request header authentication method is used.
   - Custom header pattern (optional) - the name pattern of the headers to use for sending additional information to the external management service.
   - Cache type - the cache type to control whether and how to cache positive responses. If you select Time to live, specify how long to keep responses in the cache; the default value is 900 seconds.
   - Fail on error - if selected, processing is stopped if the connection to the external management service fails.

   Note: For details of the JSON format that is required when exchanging messages with the external management service, see JSON format to exchange messages with the external management service.
   DataPower Gateway (v5 compatible):
   - Endpoint - Enter the URL to an external web server that contains information about access or refresh tokens. API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing. For more information see Token revocation.
   - TLS Client Profile - Select a TLS profile to verify the external endpoint.
6. Click Save when done.

Results

Depending on the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring introspection for a native OAuth provider

Define an introspection path to allow the metadata for an access token to be examined.

About this task

Token introspection allows an authorized holder of an access token to examine the contents of tokens using an introspection path. The access token to introspect must be obtained through the native OAuth provider. Introspection provides context for the token by allowing an authorized protected resource to query the authorization server to determine the set of metadata for a given token. The metadata includes whether or not the token is currently active, the scopes assigned to the token, and the authorization context in which the token was granted (including who authorized the token and which client it was issued to). API Connect token introspection conforms to IETF RFC 7662. See OAuth 2.0 Token Introspection.

One of the following roles is required to enable introspection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the introspection settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the introspection settings for an existing native OAuth provider. If you want to update the introspection settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to enable introspection:

1. Click Introspection in the sidebar menu.
2. Select the check box to enable Introspection. The OAuth standard path for introspection, /oauth2/introspect is automatically entered. This path will be used when another entity inspects the token contents.
3. Click Save when done.

Results

Tokens will be queried using the /oauth2/introspect path. Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring metadata for a native OAuth provider

Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

About this task

Configure an Authentication URL or an External URL from which custom metadata is collected for inclusion in the token. The metadata is either stored inside the access token or it is sent along with the access token to the client application. For more information about how the metadata is collected, see OAuth external URL and authentication URL.

Following are examples of metadata that can be included with the access token:

- Metadata about the authenticated resource owner
- Grant type that was used to obtain the token
- A confirmation code to be provided to the client application

One of the following roles is required to configure metadata collection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the metadata settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the metadata settings for an existing native OAuth provider. If you want to update the metadata settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure metadata collection:

1. Click Metadata in the sidebar menu.
2. Select Collect metadata to enable metadata collection.
3. The Authentication URL user registry is selected by default and is required. For more information about the Authentication URL, see Authentication URL user registry.
4. Select the External URL to collect metadata from an external URL. Enter the endpoint and an option TLS Client Profile.
5. API Gateway only If required, override the default Header name token value. The value of this header, if returned in the response from the OAuth endpoint, is placed in the response payload and indicated as **`metadata`**.
6. API Gateway only If required, override the default Header name payload value. The value of this header, if returned in the response from the OAuth endpoint, is placed within the access token and indicated as **`miscinfo`**.
7. Save the OAuth Provider.
8. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring the OIDC parameters for a native OAuth provider

Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.

About this task

When you enable OpenID connect, a template is provided for generating ID tokens along with access tokens and the required assembly policies are automatically created. You can customize the policies to suit your needs in the API Editor. The sample key provided is for test purposes only and is used to sign the JWT token.

One of the following roles is required to configure an OIDC template for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note: You can configure OIDC parameters only if the selected grant types for the native OAuth provider include at least one of the Implicit or Access code grant types; see Configuring basic settings for a native OAuth provider.
You can select the OIDC settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the OIDC settings for an existing native OAuth provider. If you want to update the OIDC settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure an OIDC template:

1. Click OpenID Connect in the sidebar menu.
2. Select the initial check box to configure an OIDC Template. Enter the following parameters:

Field	Description
API Gateway only Support hybrid response types (optional)	Select the response types for the OpenID Connect hybrid flow to be supported by this OAuth provider.
API Gateway only Auto Generate OIDC API Assembly	Select this option to generate the full OIDC assembly. Leave this option unselected to simply enable OIDC support in the OAuth provider and allow the developer to implement their own assembly.
DataPower Gateway (v5 compatible) only ID token issuer	Descriptive text to indicate the source of the key.
DataPower Gateway (v5 compatible) only ID token signing key	Specify the JSON Web Key (JWK) to be used to sign the ID token.
DataPower Gateway (v5 compatible) only ID token signing algorithm	Select the algorithm used to sign the token.

3. Click Save when done. You can edit the policies by using the API Editor.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Editing a native OAuth provider by using the API Editor

You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

About this task

If you have configured an OIDC template, you can customize it in API Editor. In the API Editor, the Source tab allows you to edit the code for the configuration using a text editor. The API Assemble tab provides a graphical drag-and-drop editor (identical to the one in API Manager) that allows you to add additional elements to the assembly for the OAuth Provider.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the **`oauth-provider-settings-ref`** field in each OAuth assembly action.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can modify the native OAuth provider configuration by selecting the API Editor page immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the configuration for an existing native OAuth provider. If you want to update the configuration for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to edit the OAuth configuration:

1. Click API Editor in the sidebar menu.
2. In the Source tab, view and edit the policies to customize the behavior for the OAuth provider.
3. In the API Assemble tab, use the drag and drop editor to add additional policies to the OIDC behavior.
   Note: If you add a policy that references a TLS profile, an **invoke** policy for example, then when you publish an API that uses this OAuth provider, you must ensure that the TLS profile is enabled for the Catalog to which you publish the API. For details on how to enable a TLS profile in a Catalog, see Creating and configuring Catalogs.
4. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring a third-party OAuth provider

Enter the secure endpoints to provide OAuth authentication from a third party.

About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Procedure

Complete the following steps to configure a third party OAuth provider:

1. In the Cloud Manager, click Resources.
2. Select OAuth Providers > Add > Third party OAuth Provider.
   a. Complete the following parameters for the first screen and click Next.

Field	Description
Title	Enter a descriptive title for the gateway service. This title will be displayed on the screen.
Name	This field is auto-populated by the system and used as the internal field name.
Supported grant types	Select from the following options: • Implicit: An access token is returned immediately without an extra authorization code exchange step. • Application: Application to application. Corresponds to the OAuth grant type Client Credentials. Does not require User Security. • Access code: An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type Authorization Code. • Resource owner - Password: The user's username and password are exchanged directly for an access token, so can only be used by first-party clients. • Resource owner - JWT: a JSON Web Token (JWT) Bearer Token is used as a means for requesting an OAuth 2.0 access token, and for client authentication, as defined by the JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants. Note: To use the Resource owner - JWT option, complete the following steps: ◦ In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT. ◦ Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type. For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).
Gateway type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. Specify configuration settings for the endpoints, and then click Next.

Field	Description
Authorization URL	An authorization URL where the resource owner grants authorization to the client application to access a protected resource. Example: `https://example.com/oauth2/authorize`
Token URL	A token request URL where the client application exchanges an authorization grant for an access token. Example: `https://example.com/oauth2/token`
Introspect URL	The introspection URL is where the API gateway validates the access tokens that are issued by the third party provider. Example: `https://example.com/oauth2/introspect` For more information on integrating third party OAuth providers for introspection, see OAuth introspection for third-party OAuth providers.

Field	Description
API Gateway only Introspect cache type	The cache type determines how long responses from the third party provider are cached, if at all. Select one of the following options: • No cache (default): Responses are not cached. • Protocol: Defined by the **`cache-control`** header in the provider response. • Time to live: Defined by the provider.
API Gateway only Cache Time to Live	The length of time, in seconds, for which provider responses are cached, if the Introspect cache type is set to Time to live. The default value is 900.
TLS Profile (optional)	Select an optional TLS profile for communicating with the third party provider.
Security	Default is Basic Authentication.
Basic authentication request header name	The `x-introspect-basic-authorization-header` is available to provide a user-configured HTTP Basic authorization header.
API Gateway only Basic authentication username (optional)	The default user name for HTTP Basic authentication.
API Gateway only Basic authentication password (optional)	The default password for HTTP Basic authentication.
API Gateway only Token validation	Specifies the method used to determine the success of the introspection request that is sent to the third party service to validate the provided token. Select one of the following options: • Connected: The query is successful if the status return code is **`200`**. • Active (default): The query is successful if the status return code is **`200`** and the response JSON body includes the property **`active: true`**.
API Gateway only Custom header pattern (optional)	A regular expression for request headers that are to be passed to the third-party provider; for example, `x-Introspect-*`.
API Gateway only Authorization header pass through	Select this check box if you want to retain the **`Authorization`** header for a bearer token. The default behavior is to remove this header.

c. Enter the scopes in the third screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
sample_scope_2	Scope for token
additional scopes	Scope for token

d. Review the settings on the Summary panel.

3. Click Save and Edit to complete the configuration.
   If you want to specify the third party OAuth Provider in your Catalog, see Specifying the OAuth Providers.

Setting the visibility for OAuth providers

The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.

About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Procedure

Follow these steps to set the visibility for the OAuth providers in your on-premises cloud:

1. In the Cloud Manager, click Resources.
2. Select OAuth Providers.
3. Choose Edit visibility from the actions menu next to the name of the OAuth provider that requires a visibility setting.
4. Select the visibility setting for the OAuth provider. The options are:
   - Private - the OAuth provider is not visible and cannot be used by any provider organization. It is accessible only to the admin organization in Cloud Manager.
   - Public - the OAuth provider is visible and can be used by all provider organizations
   - Custom - the OAuth provider is visible only to the provider organizations that you designate
5. For Custom visibility, select the provider organizations that you want to have access to the OAuth provider.
6. Click Save to complete the operation.

Results

For Private, the OAuth provider is not visible and cannot be used by any provider organizations. For Public, the OAuth provider is visible and can be used by all provider organizations. For Custom, the OAuth provider is visible only to the provider organizations designated by you.

OAuth concepts for API Connect

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- **OAuth user scenario**
  Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.
- **OAuth introspection for third-party OAuth providers**
  OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by IBM API Connect. IBM API Connect can use this feature along with the mentioned provider to protect access to the API.
- **OAuth external URL and authentication URL**
  You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Scope**
  Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.
- **Tokens**
  Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.
- **Authentication URL user registry**
  You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.
- **Custom forms for user security**
  You can create custom forms for the authorization and identity extraction phase of OAuth.
- **Securing an API with a JSON Web Token**
  There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM API Connect.
- **Troubleshooting OAuth**
  You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

- The OAuth 2.0 Framework

OAuth user scenario

Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.

Scenario overview

In this scenario, Alice is a user of an application. Alice can grant permission for an application to access specific information about Alice in a third-party system that is using OAuth. Depending on the type of OAuth that is supported by the target service, Alice does not enter her user name and password into the application. Instead, the application receives an access token that represents her credentials (user name and password). The application can now access the information about Alice in the target system.

For example, Alice maintains a list of books that she reads on a service that is provided by mybooks.com. Following the purchase of a smartphone, Alice installs an application on her new phone to display the book details. The phone application wants to call an API provided by mybooks.com, which can access the information. The mybooks.com API is secured by using the OAuth protocol.

To access the book details, the application must complete a two-step process:

1. The application must first obtain permission from Alice.
2. The application then uses that permission to call the target service and obtain the list of books.

In the first step, the application typically directs Alice to the provider of the target service, mybooks.com. Alice provides her user name and password, and gives permission for the application to access her information. It is important that Alice trusts that she is providing her credentials to the provider of the target service and not to an untrusted proxy application. For example, by checking that the security certificate of the website where Alice enters her credentials matches what Alice expects from the provider of the target service.

The result of this step is the access token that the application can use to call the API. The application then generates the appropriately formatted OAuth request. For example, the Authorization header, or HTTP query parameters, which includes the access token, consumer key, and signature method that are required by OAuth. This OAuth request is used to invoke the API proxy operation.

Scenario within API Connect

No changes to the definition of your API operation are required to support this scenario.

1. Alice grants permission for the application to access her information *before* the invocation of the API.
2. When the application provides the Authorization header, or query parameters, containing the OAuth details about the call to the operation endpoint, the header is automatically passed through to the target service without any additional configuration.

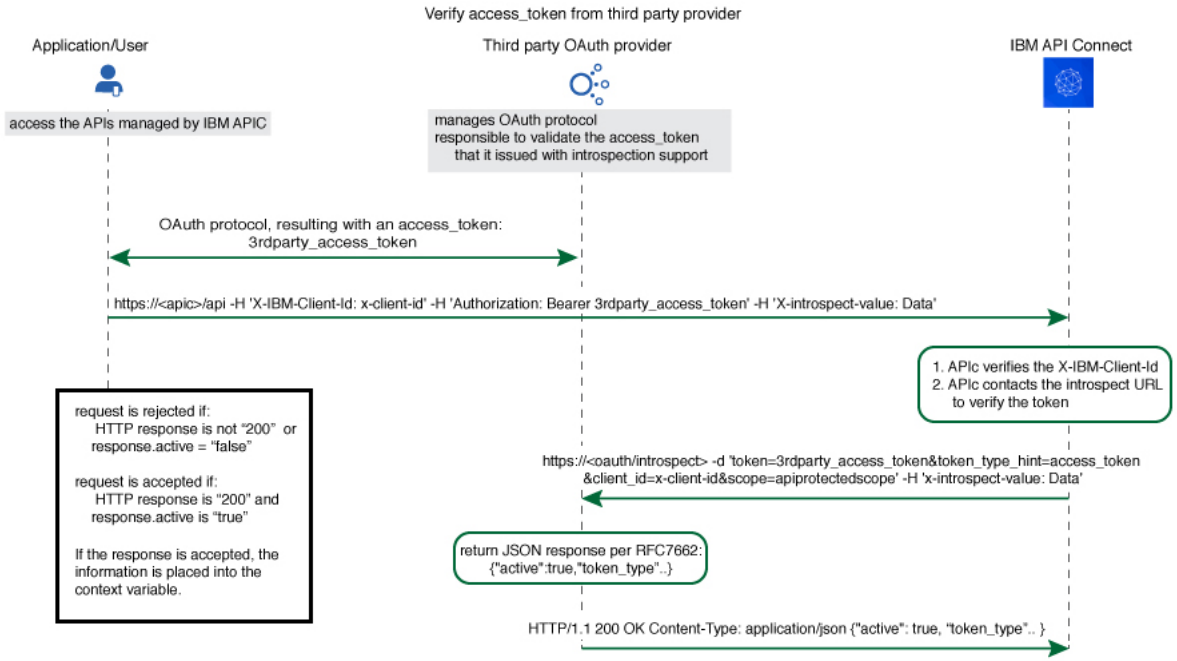
OAuth introspection for third-party OAuth providers

OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by IBM API Connect. IBM® API Connect can use this feature along with the mentioned provider to protect access to the API.

You can use API Connect to protect an API that is secured by using the third-party OAuth access token in accordance with Introspection specification as defined in RFC 7662. In addition to the specification, the **`x-Introspect-`** header is provided to pass other content to the third party as you require.

Authentication information can be carried in the request by configuring a basic authentication request header.

The following sequence diagram depicts the overall flow of request and response. The purpose of this diagram is only to provide a general visualization of the nature of the flow; for the precise details, refer to the explanatory information after the diagram.



The Introspect URL is configured in the Third Party OAuth provider configuration. See Configuring a third-party OAuth provider.

When an API is protected by a third-party OAuth provider, API Connect will extract the bearer token and issue an HTTP POST request to the endpoint specified in the Introspect URL field.

The GET request is protected by API Connect with this feature.

You can use a header prefix to pass information to the third-party provider. The header prefix can include a regular expression and specifies the name pattern of the headers to use for sending additional information, such as **`x-introspect-*`**.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
Authorization: Bearer tGzv3JOkF0XG5Qx2TlKWIA
x-IBM-Client-Id: xxx-xxx
```

However, if you want to use a different header prefix, specify the required value in the Custom header pattern field in the third party OAuth provider configuration. For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider. The Custom header pattern feature is available only with the DataPower® API Gateway, if you are using the DataPower Gateway (v5 compatible) the header prefix must be **`x-Introspect-`**.

API Connect will issue this POST request to the introspection endpoint specified in **`x-tokenIntrospect`**, as illustrated in the code sample:

```
POST /oauth/introspectURL HTTP/1.1
Host: apiconnect.ibm.com
Content-Type: application/x-www-form-urlencoded
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
token_type_hint=access_token&token=tGzv3JOkF0XG5Qx2TlKWIA
```

The third party OAuth/OIDC provider will respond with `HTTP 200` indicating the request was successful and that payload contains the token information. API Connect honors the active claim as defined in the RFC specification.

If the value of the active claim is `true`, the token is treated as valid.

```
HTTP/1.1 200 OK
 Content-Type: application/json;charset=UTF-8
 Cache-Control: no-store
 Pragma: no-cache
```

```
{ "active":true,
   "token_type":"bearer",
   "client_id":"xxx-xxx",
   "username":"John Smith",
   ...
}
```

If the value of the active claim is `false`, the token is treated as invalid.

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
  "active":false
}
```

A response code other than **`HTTP 200`** indicates failure to process the request.

When the OAuth token is valid and active, context variables are populated with information from the introspect JSON response. For more information, see API Connect context variables.

When contacting the introspection endpoint, API Connect uses **`client_id`**/**`appId`** and **`client_secret`**/**`appSecret`** to construct the HTTP Basic authorization header.

By default, if **`x-introspect-basic-authorization-header`** exists in the request, the value is used for the HTTP Basic authentication header when the introspection endpoint is contacted. API Connect verifies that the HTTP Basic authentication header value is Base64 encoded before it is sent, and encodes it if necessary as shown in the following example. If the header is already encoded, it is sent without modification.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-introspect-basic-authorization-header: user:password
```

API Connect issues the following:

```
POST ..
Authorization: Basic M3JkLXBhcnR5LWNsaWVudF9pZDozcmQtcGFydHlfY2xpZW50X3NlY3JldA==token_type_hint=access_token&token= ..
```

If you are using the DataPower API Gateway, you can specify your own value for the HTTP Basic authentication header by providing the required value in the Basic authentication request header name field in the third party OAuth provider configuration. The following rules determine what authentication data is passed to the introspection endpoint:

- If there is a basic authentication header in the request, the specified credentials are used. The value must be either a string in the format ***`user:password`***, or the Base64 encoded equivalent; API Connect will Base64 encode the value if necessary before sending the request to the introspection endpoint.
- If there is no basic authentication header in the request but there are values specified in the Basic authentication username and Basic authentication password fields in the third party OAuth provider configuration, those values are used.
- If there is no basic authentication header in the request, and user name and password details are not supplied in the third party OAuth provider configuration, but **`client_id`** and **`client_secret`** values are supplied in the body of the request, these are used.
- Otherwise, an error is returned.

For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider.
If either, or both, of scope and **`scope validate url`** are configured, and if the response is an active token with a scope claim from the third-party OAuth Provider introspection endpoint, API Connect will further enforce the scope validation in the following order:

1. If **`scope`** is configured for the OAuth API protection, verify the third-party scope against the scope that is configured.
2. If **`scope validation url`** is configured, verify the third-party scope against the scope validation URL.
3. If the third-party OAuth provider introspection endpoint does not return a scope, the Gateway will not check the scope defined in the security definition of the API where the third-party OAuth provider resource is used. For details on configuring an OAuth security definition in an API, see Creating an OAuth security definition.

For more information, see Scope.

DataPower Gateway (v5 compatible) only By default the API Connect client ID and scope are sent to the third party OAuth provider. You can suppress this behavior in either of the following ways:

- Supply a **`suppress-parameters`** header as follows:

  `suppress-parameters: client_id`

  `suppress-parameters: scope`

  or

  `suppress-parameters: client_id scope`

  depending on which parameters you want to suppress.
- Define an API property called **`suppress-parameters`** in the API definition itself, with one of the following string values:

  `client_id`

  `scope`

  or

  `client_id scope`

  depending on which parameters you want to suppress. For information on how to define API properties, see Setting API properties.

OAuth external URL and authentication URL

You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

Including custom metadata in a token

In many scenarios, custom metadata needs to be included during the access token generation process. The metadata is either stored inside the access token or it is sent along with the access token to the client application. The client application can then send that access token, or the metadata in the payload, in a subsequent request to IBM® API Connect where the metadata is retrieved, validated, or sent to the downstream systems as required.

Examples include, but are not limited to:

- When resource owners are authenticated, metadata about the authenticated resource owner needs to be stored within the access token.
- The grant type that was used to obtain the token is another example of metadata stored within the access token.
- A confirmation code that needs to be sent to the client application along with access token is stored as metadata within the access token.

Configuring External URL or Authentication URL in API Connect to obtain metadata

Metadata can be set by using either or both of the following URLs:

- External URL - When you call the External URL, an HTTP GET request is sent and API Connect expects an HTTP 200 OK along with an optional set of the specified response headers.
- Authentication URL - When you call the Authentication URL, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.
  See: Authentication URL.

The External URL endpoint is entered in the Metadata section when you configure an OAuth Provider in the Cloud Manager or API Manager UI.

Use the following HTTP headers in the response, depending on the type of gateway you are using:

- DataPower® API Gateway:

  `X-API-OAUTH-METADATA-FOR-PAYLOAD`

  `X-API-OAUTH-METADATA-FOR-ACCESSTOKEN`

  Note: These are the default header names for the DataPower API Gateway but you can override them; see Configuring metadata for a native OAuth provider.
- DataPower Gateway (v5 compatible):

  `API-OAUTH-METADATA-FOR-PAYLOAD`

  `API-OAUTH-METADATA-FOR-ACCESSTOKEN`

The response header value from **`X-API-OAUTH-METADATA-FOR-PAYLOAD`** or **`API-OAUTH-METADATA-FOR-PAYLOAD`** is placed in the response payload and indicated as **`metadata`**.

The response header value from **`X-API-OAUTH-METADATA-FOR-ACCESSTOKEN`** or **`API-OAUTH-METADATA-FOR-ACCESSTOKEN`** is placed within the access token and indicated as **`miscinfo`**.

The two metadata response headers are case insensitive and you must escape any special characters in the string value content.

An example response payload that contains metadata along with the access token:

```
{
"token_type":  "bearer",
"access_token":  "AAEkNzhjDHYyyYy...cL0Mv6ctl37w7ZU",
"metadata":  "m:metadata-for-payload_content"
"expires_in":  3600,
"scope":  "read",
"refresh_token":  "AAEnj5SynCMybF...oEZ6JjxYax_HdNg",
}
```

This example output from the token introspection endpoint shows the contents of the access token with `"miscinfo"` containing the metadata information.

```
{
"active":  true,
"token_type":  "bearer",
"client_id":  "78c2f10f-799a-4e1f-8e0a-098634997a35",
"username":  "Fred Smith",
"sub":  "fred",
"exp":  1479850049,
"expstr":  "2016-11-22T21:27:29Z",
"iat":  1479846449,
"nbf":  1479846449,
"nbfstr":  2016-11-22T20:27:29Z",
"scope":  "read",
"miscinfo":  "m:metadata-for-accesstoken_content",
"client_name":  "MobileApp"
}
```

Input to the External URL

The following request headers are sent to the External URL.
Note: Any existing metadata values that were previously sent from the Authentication URL are also sent in the two request headers **`x-existing-metadata-for-payload`** and **`x-existing-metadata-for-access-token`**. The Metadata URL can make use of this information to create a new set of metadata values.
The two request headers that are sent to the Metadata URL are displayed in bold text.

```
X-existing-metadata-for-payload     payload-from-auth-url
X-existing-metadata-for-access-token     token-from-auth-url
X-URI-in     /org/env/miscinfo/oauth2/token (the URL that was sent to APIConnect for this particular token request)
X-METHOD-in     POST
X-POST-Body-in     client_id=client_id&grant_type=password&scope=read&username=name&password=password
X-X-Client-IP     IP_address
X-X-Global-Transaction-ID     ID_number
...
```

Note: If you are using the DataPower API Gateway rather than the DataPower Gateway (v5 compatible), the **X-POST-Body-in** header is not supported.

Retrieving Metadata in API Connect

As described in the previous example scenarios, the metadata can be retrieved from the access token in the Application API and sent to the downstream systems. Retrieval can be done in the API assembly, which is secured to accept tokens in the security definitions.

In the resource API that accepts an access token, the **miscinfo** field can be accessed in the Assembly with the **oauth.miscinfo** context variable, as in the example.

```
apim.setvariable('message.body',apim.getvariable('oauth.miscinfo'));
```

You can also use token introspection to look at the contents of the access token.

Refresh tokens and metadata

The Authentication URL (if configured for authentication) is invoked first, during authentication of the resource owner. The External URL is invoked as the last step, just before the generation of the access token. The only exception is when access tokens are generated from a refresh token. In cases where refresh tokens are used to generate new access tokens, the External URL is not invoked. The metadata from the refresh token is retained and then copied into the newly generated access token.

Identifying the source of the metadata

The metadata is prefixed with keywords to indicate whether it originated from the External URL or the Authentication URL.

- Metadata from the External URL is prefixed with **m:**
- Metadata from the Authentication URL is prefixed with **a:**

Note: When revocation is enabled, some internal details are also stored in the **miscinfo** field, in brackets within the access token as shown in the following example:

```
"miscinfo": "[tlsprofile@https://api-revoke-url:443/server/revocation-url]m:metadata-for-accesstoken_content"
```

Maximum size of the metadata

Metadata for the access token cannot exceed 512 bytes.

Metadata for the payload does not have a specific size restriction, except for when you use the Authorization code grant type. These restrictions are described in following sections.

Characters are not allowed in metadata in certain scenarios

When you use the Authorization code grant type, or when a consent form is used for implicit grant type, there is a temporary state or code where the metadata from the authentication URL is stored. API Connect internally uses two prefixes - **!ma** and **!mp** to differentiate between payload and token metadata received from the Authentication URL and store them internally in the temporary state/code. Hence these specific character sequences - **!ma** and **!mp** should not be used as the metadata itself.

Grant types and metadata

The OAuth grant types described in the following sections include **authorization code (access code)**, **implicit**, and **client credentials (application)**.

Authorization code grant type

- When metadata is included from an Authentication URL for an Authorization code grant type, as it is a three legged flow, both the content and the payload are stored within the **dp-state** and carried on to the authorization code and to the access token. Note that around 10 characters are used internally to differentiate between the metadata for payload and metadata for the access token when stored in the **dp-state**. In addition, if revocation is enabled, that will also be part of the token metadata. Hence the combined size of the token metadata, the payload metadata (including the 10 characters of internal data), and internal revocation details, cannot exceed 512 bytes in total.

  If the overall size of the metadata exceeds 512 bytes, then the access token generation succeeds, but the metadata fields contain an error message of "`metadata too large`" as shown in the example.

  ```
  "metadata":"m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-payload]"
  "miscinfo":"[r:gateway]m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-token]"
  ```

  This size restriction can be overcome when the metadata is sent from the Metadata URL and not from the Authentication URL, because the metadata is not stored in **dp-state** or in the authorization code.

  Example of the **authorization code (access code)** grant type:

  ```
   $ curl -k -d
  "grant_type=authorization_code&code=$mycode&client_id=$myid&scope=scope_introspect&redirect_uri="
  https://9.70.153.90/fei/sb/introspectp1/oauth2/token
  { "token_type":"bearer",
  "access_token":"AAEkOTh1ZDhhNjYtYTQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ20ZN5Tl_TqYFeIfB7BFf6HFgibEoOjWXXEA84oFsWuE4NY-
  ```

```
RRZVdnGSaXAIYJz7s5vczfk5EV-BIb_6P_1YKm3ahrfhR5kI3sPO0uADEoseIP5-O9anUpEM5yhsayXvZbJ_6VDYz-hyXSJHTNqVj-
PHBialoRkBD5qca6kO0fV2M", "metadata":"a:[Authorization Code-Test-auth-url-payload]", "expires_in":3600,
"scope":"scope_introspect", "refresh_token":"AAFAg1EVMbwicr_L0fTZ4q6HZ-
RcQygniXFC9zbSKO4wd3hcniC4KQX21X0fL2c8cnmzCZgws8xxLzNyfjQhUJNGl5C1GbIe3dwhXJdiWA0Go-
dduhVtCbG26sJRRXyYrMeRxWnJsylBETPI8HQEN4a_D7fmxKcTVRZBvq86byg95qe1ZKyERi0Lhxdd_O4Nvss" }
```

```
$ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
"token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectp1/oauth2/introspect
{ "active":true, "token_type":"bearer", "client_id":"98ed8a66-a45e-4a33-a47d-fa68fd344746", "username":"anyuser",
"sub":"anyuser", "exp":1484766368, "expstr":"2017-01-18T19:06:08Z", "iat":1484762768, "nbf":1484762768,
"nbfstr":"2017-01-18T18:06:08Z", "scope":"scope_introspect", "miscinfo":"[r:gateway]a:[Authorization Code-Test-auth-
url-token]", "client_name":"oauth_app" }
```

Implicit grant type

- When implicit grant type is used, the access token and the metadata are returned in the `location` header as a fragment, as you see in the example.

```
< Location:
 https://localhost#access_token=AAEkOThlZDhhNjYtYTQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ2buS2KfWdq-
nYBJSi4nmPxQBtLae17tKBPRMzwP5BC386nlxpoOTE1G748ZVH6Mq_TJL3GeV3PtXTVIkWOLBJi_7tljiQfpnVfrNkovvZkhUexYmFkcDsmLSdaWxZ6Pc
IMPAC4ojT8qV1sYV-
ChTk36yqOx_NiKimZaDikDk7WTg&expires_in=3600&scope=scope_introspect&token_type=bearer&metadata=a%3A[Implicit-Test-
auth-url-payload]
```

```
$ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
"token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectp1/oauth2/introspect
             { "active":true, "token_type":"bearer", "client_id":"98ed8a66-a45e-4a33-a47d-fa68fd344746",
"username":"anyuser", "sub":"anyuser", "exp":1484768365, "expstr":"2017-01-18T19:39:25Z", "iat":1484764765,
"nbf":1484764765, "nbfstr":"2017-01-18T18:39:25Z", "scope":"scope_introspect", "miscinfo":"[r:gateway]a:[Implicit-
Test-auth-url-token]", "client_name":"oauth_app" }
```

Client credentials grant type

Authentication URL will not be invoked when using client credentials grant type, as there is no resource owner. The metadata from Authentication URL is not available for this grant type. However, content returned from Metadata URL will be included as metadata.

Behavior when retrieving metadata with both an External URL and an Authentication URL

If an External URL is configured and a connection to the external server is successful, the response headers overwrite any existing metadata obtained from the Authentication URL to become the final value. Therefore, you must carefully examine the incoming request headers and create appropriate response headers from the External URL.

If an External URL is configured, but the connection to the External URL fails, then a failure message of "`error on metadata url`" is written for metadata in both the payload and the access token.

If an External URL is configured and the connection is successful, but the remote server does not send any of the specified HTTP response headers, a blank value is written for metadata in both the payload and the access token.
Attention: An External URL overwrites existing values from Authentication URL. This includes blank values.
If no External URL is configured, the metadata that is obtained from the Authorization URL is retained as the final value.

Scope

Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.

In IBM® API Connect, scopes have no inherent meaning. Instead, scopes are defined in the OAuth Provider so that an application can request an access token that is valid for one or more of the scopes. In the secured API, scopes are listed as requirements for an access token to be considered valid. All scopes that are listed by the security definition for the API must be granted by the access token.
Note:

- An OAuth Provider must have at least one scope.
- An OAuth token will not be granted unless a default scope is configured at the provider, or one or more predefined scopes are included in the grant request.
- If no default scope is defined, and the request does not contain a scope, an invalid scope error is returned for the request.

OAuth provider

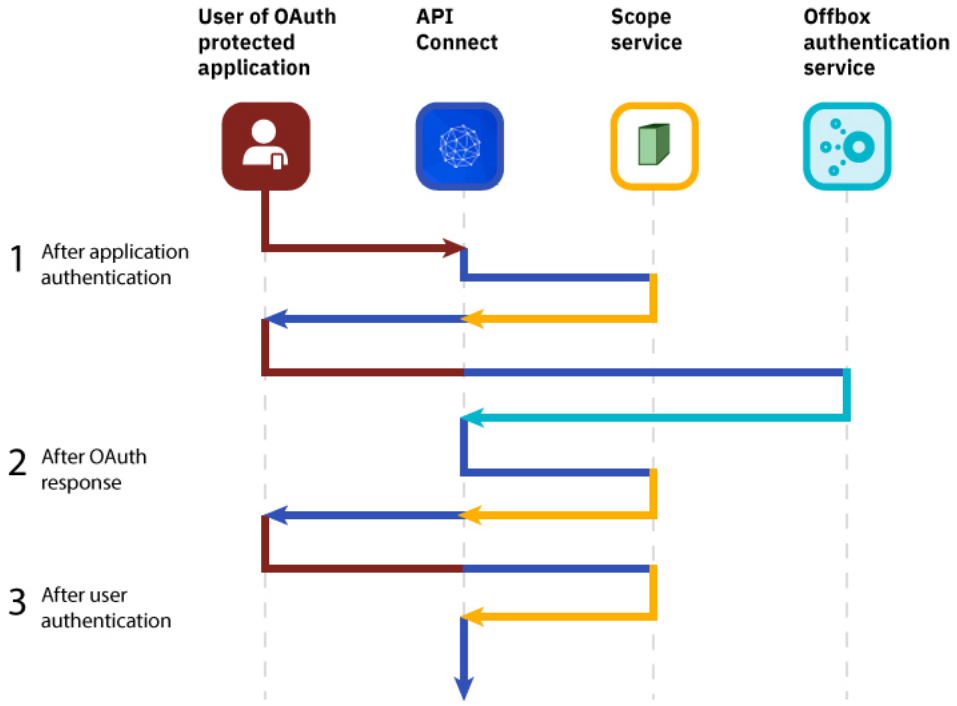
To provide more refined support for the OAuth scope handling, API Connect allows the Authentication URL user registry extension to modify the scope value.

When you define an OAuth provider, the Advanced scope check extensions provide the flexibility to check and override allowed scopes. The optional extensions are Application scope check and Owner scope check.

The scope that is eventually received by the application is determined by the interactions that are described in the three following paragraphs. Scope processing follows the sequence of items 1, 2, and 3 in the following list, offering three opportunities to override the scope value. Figure 1 provides an overview of the process.

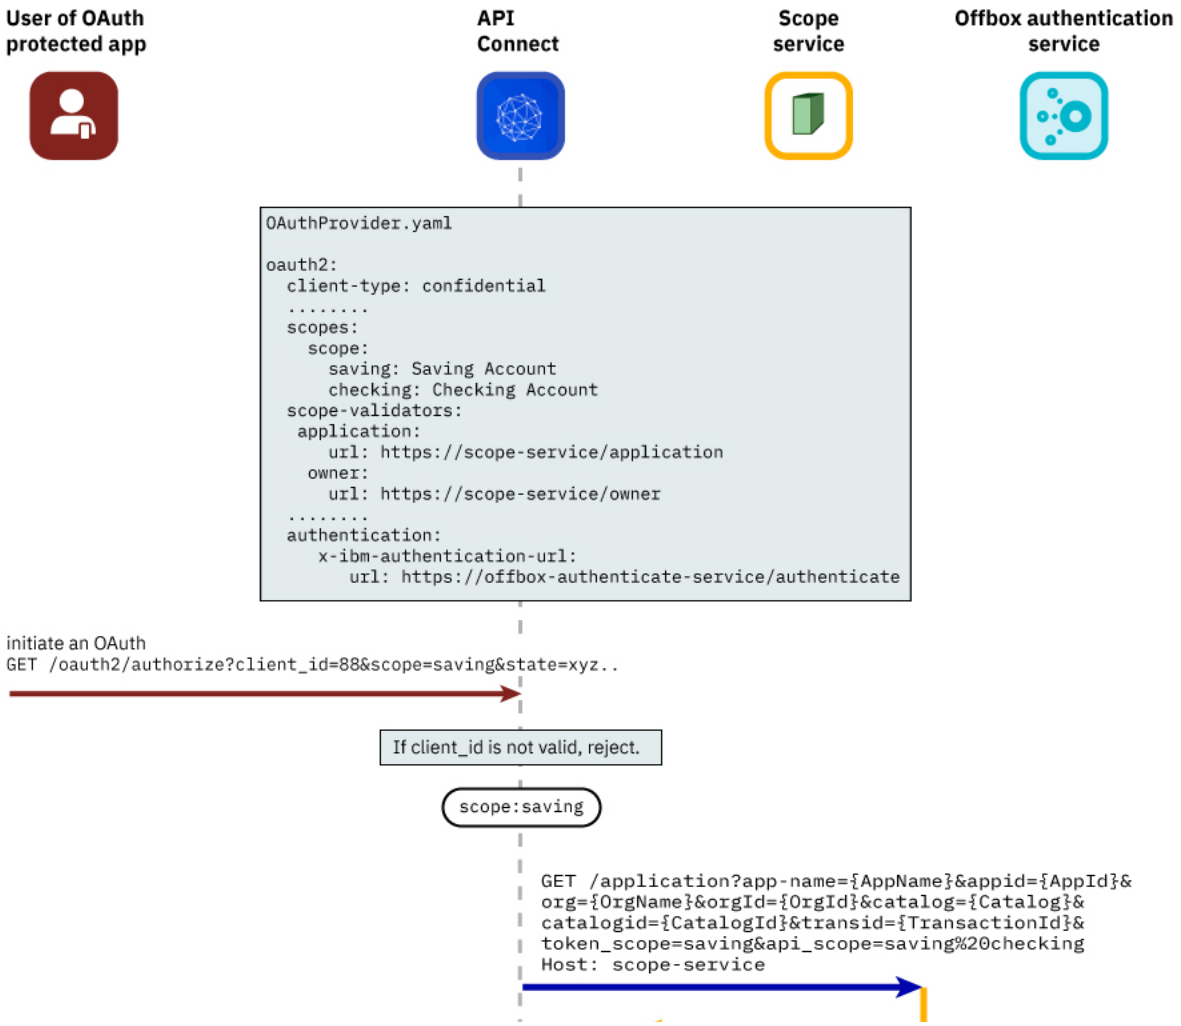
1. After the application successfully authenticates, and if OAuth Native provider > Advanced scope check > Application scope check is configured, API Connect makes a call to allow extra verification and uses the contents of **`x-selected-scope`** to override the scope value that was initially requested by the application. When Application scope check is enabled, the HTTP response header **`x-selected-scope`** must be present, or the call fails.
2. If OAuth Native provider > User Security > Authentication is configured to authenticate application users using an Authentication URL, then API Connect makes a call, as documented in Authentication URL user registry. When the response code is `HTTP 200`, and the response header **`x-selected-scope`** is present, the value that is configured in **`x-selected-scope`** is used as the new scope value, overriding both what the application already requested and what was provided in the Application scope check described in paragraph 1. In the response header, **`x-selected-scope`** is an optional element.
3. After the user successfully authenticates, and if OAuth Native provider > Advanced scope check > Owner scope check is enabled and configured with a valid URL, API Connect makes a call to allow the content of **`x-selected-scope`** to refine the scope value. When Owner scope check is enabled, the HTTP response header **`x-selected-scope`** must be present, or the call fails.

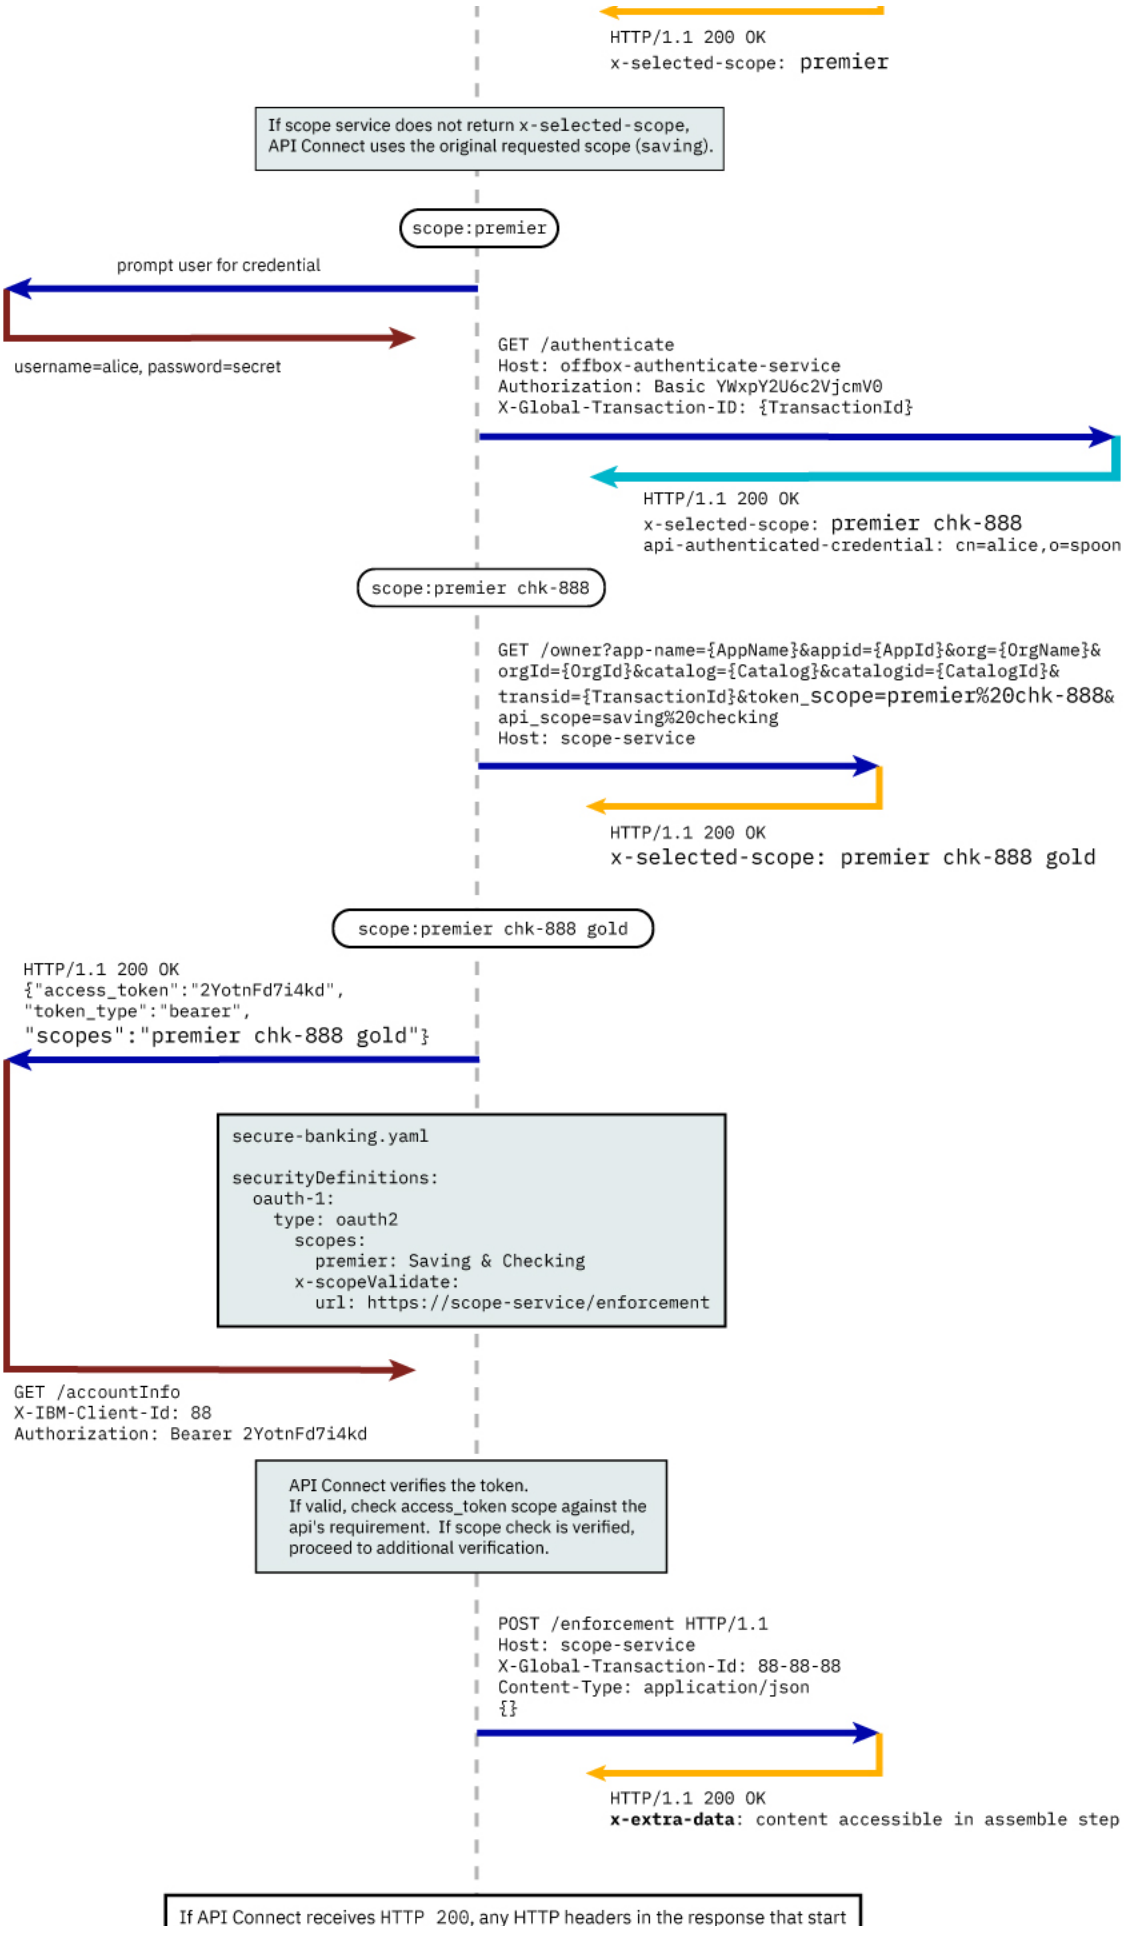
Figure 1. OAuth advanced scope overview



The final scope permission that is granted by the access token is the result of the flow described in items 1, 2, and 3. Figure 2 shows a more detailed view of the transaction flow with examples that show when **`x-selected-scope`** provides a new scope value.

Figure 2. OAuth advanced scope detail





HTTP/1.1 200 OK
x-selected-scope: premier
If scope service does not return x-selected-scope, API Connect uses the original requested scope (saving).
scope:premier
prompt user for credential
username=alice, password=secret
GET /authenticate
Host: offbox-authenticate-service
Authorization: Basic YWxpY2U6c2VjcmV0
X-Global-Transaction-ID: {TransactionId}
HTTP/1.1 200 OK
x-selected-scope: premier chk-888
api-authenticated-credential: cn=alice,o=spoon
scope:premier chk-888
GET /owner?app-name={AppName}&appid={AppId}&org={OrgName}&
orgId={OrgId}&catalog={Catalog}&catalogid={CatalogId}&
transid={TransactionId}&token_scope=premier%20chk-888&
api_scope=saving%20checking
Host: scope-service
HTTP/1.1 200 OK
x-selected-scope: premier chk-888 gold
scope:premier chk-888 gold
HTTP/1.1 200 OK
{"access_token":"2YotnFd7i4kd",
"token_type":"bearer",
"scopes":"premier chk-888 gold"}
secure-banking.yaml
securityDefinitions:
oauth-1:
type: oauth2
scopes:
premier: Saving & Checking
x-scopeValidate:
url: https://scope-service/enforcement
GET /accountInfo
X-IBM-Client-Id: 88
Authorization: Bearer 2YotnFd7i4kd
API Connect verifies the token.
If valid, check access_token scope against the api's requirement. If scope check is verified, proceed to additional verification.
POST /enforcement HTTP/1.1
Host: scope-service
X-Global-Transaction-Id: 88-88-88
Content-Type: application/json
{}
HTTP/1.1 200 OK
x-extra-data: content accessible in assemble step
If API Connect receives HTTP 200, any HTTP headers in the response that start

with "x-" will be accessible at oauth.advanced-consent.<value>
For the above example, x-extra-data is accessible at
oauth.advanced-consent.x-extra-data.
If other than HTTP 200 is returned, it has the same effect as if the access token does not contain neccesary permissions to access the resource.

Consumer API enforcement

Standard scope validation
To access the API /getaccount the application must send a **GET** request with an access token that contains the scope, or scopes, defined in the OAuth provider. If the request doesn't contain a scope, you must specify a default scope to use. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.

```
GET /getaccount
HTTP/1.1
Host: server.example.com
X-IBM-Client-Id: 8888-8888-8888
Authorization: Bearer AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ
```

The following application OpenAPI file secure-banking.yaml defines the scope, or scopes, that must exist in the token to be granted access to the API /getaccount.

```
secure-banking.yaml

securityDefinitions:
   scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
security:
  - scope-only:
      - checking
  - scope-only:
      - saving
      - mutual
```

In the examples, the access token **AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ** is able to access the API because it contains one, or a combination of **scope-only** that is defined in secure-banking.yaml such as:

- **checking**
- **saving mutual**
- **checking saving mutual**

Advanced Scope Check
Administrators can enable an additional scope check by configuring the consumer API property Advanced Scope Check URL that becomes **x-scopeValidate** as shown in the following OpenAPI file example.

```
securityDefinitions:
  advanced-scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
    x-scopeValidate:
      url: 'https://advanced-scope-check.bk.com/validate-scope'
      tls-profile: 'ssl-client'
```

After API Connect successfully verifies the access token against any scope requirement, API Connect will make an **HTTP POST** request to the **x-scopeValidate** endpoint similar to the following example. Response code HTTP 200 from the endpoint indicates a success. Any other response code, or a connection error, is treated as a permission error for the token.

```
     POST /validate-scope?app-name=..&appid=..&org=..&orgid=..&catalog=..&catalogid=..&transid=..
HTTP/1.1
     Host: advanced-scope-check.bk.com
     Content-Type: application/json

   {"context-root" : checking,
    "resource" : accountinfo,
    "method" : GET,
    "api-scope-required" : [jointaccount],
    "access_token" : {"client_id" : "2cd71759-1003-4a1e-becb-0474d73455f3",
                      "not_after" : 174364070,
                      "not_after_text" : "2017-07-11T02:27:50Z",
                      "not_before" : 174360470,
                      "not_before_text" : "2017-07-11T01:27:50Z",
                      "grant_type" : "code",
                      "consented_on" : 1499736470,
                      "consented_on_text" : "2059-07-11T01:27:50Z",
                      "resource_owner" : "cn=spoon,email=spoon@poon.com",
                      "scope" : "jointaccount mutual",
                      "miscinfo" : "[r:gateway]"
```

```
                    }
}
```

An example of successful response follows.

```
    HTTP/1.1 200 OK
    Cache-Control: no-store
    Pragma: no-cache
    X-Custom-For-Assemble-Process: audit
```

Any HTTP response header that begins with "**x-**" is kept as the context variable **oauth.advanced-consent**. Based on the example successful response, **X-Custom-For-Assemble-Process: audit** becomes `oauth.advanced-consent.x-custom-for-assemble-process`, and can be accessed in the assemble step.

Additional validation options
You can optionally use additional fields for validation:

Request Header
: Defines the regular expression to match against **request** headers. Matching headers are included in the request to the advanced scope validation endpoint.

Response Context Variable
: Defines the regular expression to match against **response** headers. Matching headers are saved as context variables in the format **oauth.advanced-consent.***.

Related information

- IETF RFC 6749

Tokens

Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.

This section contains information regarding token management, including refreshing and revoking tokens, redirecting, and managing tokens with the DataPower Gateway.

- **Refresh tokens**
  If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.
- **Token revocation**
  In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.
- **Authenticating and authorizing through a redirect URL**
  You can use a service that is hosted externally from IBM API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.
- **Token management with the DataPower Gateway (v5 compatible)**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.
- **Token management with the DataPower API Gateway**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Refresh tokens

If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.

When you are using OAuth authentication, API requests must include a valid access token, by using the Authorization HTTP header. Access tokens that are issued by the IBM® API Connect Token Endpoint are valid for 3600 seconds (1 hour) by default, as indicated by the expires_in property that is returned on the token request. The following code block shows an example API request with an Authorization header:

```
GET /bankingApi/accountSummary?client_id=32427ce5-bb7c-48a7-9de3-4bb629091103
HTTP/1.1
Accept: application/json
Host: api.ibm.com
Authorization: Bearer AAEFYy1hbGxlhdS5nVX4x6iTL2sb3ymBivQb...
```

After an access token expires, if the option is enabled in the OAuth provider configuration Tokens > Refresh tokens screen, the application uses refresh tokens. Each refresh token is valid for approximately 31 days after it is issued (or for the Time to Live time period specified) and can be used only once to request a new access token. Along with the new access token, a new refresh token is also returned. For details on how to enable refresh tokens, see Configuring a native OAuth provider.

If the access token is expired and the application does not have a refresh token, it must restart the OAuth exchange by using the choice of Grant Type(s) allowed by the OAuth provider.

Token revocation

In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.

Token revocation using an external third party service

This topic describes token revocation using a third party, external service. This option is configured in the Native OAuth provider, using the Token Management > Type = Third party screen. The revocation URL is an endpoint that links to an external service which contains information about access or refresh tokens. API Connect is involved in the initial creation and validation of tokens. When an OAuth revocation URL is present, API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing.

Examples

A number of revocation examples follow. The first shows a sample fetch request and the response from a remote revocation URL.

GET request and response

In this example, an API Gateway server issues a GET request to the Revocation URL and receives a result. It shows that different resource owners (Laura and Emily) can revoke all tokens when using the same application (client ID).

Request:

```
<?xml version="1.0" encoding="UTF-8"?>
GET <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Accept: application/xml; text/xml
```

Response:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>

<!--
Access Tokens and/or Refresh Tokens that are revoked can be individually listed.
To keep this list small, please only include access tokens and refresh tokens that are valid.
For access tokens, any token older than 20 minutes is no longer valid.
For refresh tokens, any token older than 44700 minutes is no longer valid.
-->

<token type="access">AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1...</token>
<token type="refresh">fZaRlVbnPSc1UGTjCRdq4mPbOosD2+aZIKbJ6bTeW...</token>

<!--
If a resource owner has revoked all tokens issued to a given application, please
list them as shown here.
-->

<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">laura</resource-owner>
<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">emily</resource-owner>

</oauth-revocation>
```

POST request and response

The next example shows a post request and response.

Request:

```
POST <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Content-Type: application/xml

<?xmlversion="1.0" encoding="UTF-8"?>
<token>
   <token_type>bearer</token_type>
   <access_token>AAENYy1hbGwtcmVmcmVzaOfNeQKX8ZeojsBY9v0FI7/OerQvzKHq...</access_token>
   <expires_in>3600</expires_in>
   <scope>3600</scope>
   <resource-owner>alice</resource-owner>
   <client_id>83d9cdcd-ba72-4d00-abae-005da8da5fb1</client_id>
</token>
```

Response:

```
HTTP/1.1 200 OK
```

Provide token information on revocation request

In this example, the application calls an API and passes a bearer token. In response, the Gateway fetches the revocation URL and provides information on the token being verified.

Gateway:

```
GET  <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Alternatively, the same process occurs when using a refresh token to issue a new access token. The application sends a refresh request to the token service. The Gateway then fetches the revocation URL, providing information on the refresh token being verified.

Gateway:

```
GET  <revocationURL>GET  HTTP/1.1
refresh-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Note: If you are using a third party OAuth provider then, for API Calls with bearer tokens, when Introspect URL is enabled on the API, the revocation URL is not applicable. Instead, the third party endpoint must validate the token and also check for revocation before returning a `200 OK` response to the Gateway.

Revoking tokens issued to Alice up to and including a specific date

On May 1st, Alice loses her phone and needs to reset her password. As a result, the token provider wants to revoke every token issued before Alice lost her phone. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-05-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

Revoking all tokens issued up to and including a specific date

Under certain catastrophic conditions, you may need to revoke all tokens issued up to and including a specific date, for example, May 1st. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <everytoken before="2015-05-01T09:30:10Z" />
<oauth-revocation>
```

Putting it all together

The following shows the examples contained in this topic executed in a single action:

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
HTTP/1.1 200 OK
Content-Type: application/xml
Cache-Control: public, max-age=120
Date: Fri, 08 May 2015 21:49:03 GMT

<?xml version-"1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-04-08T09:30:10Z">mary</resource-owner>
  <resource-owner before="2015-04-12T09:30:10Z">john</resource-owner>
  <resource-owner before="2015-04-13T09:30:10Z">kevin</resource-owner>
  <resource-owner before="2015-04-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

Notes:

- In the previous example, there are no entries older than one month in the response (the maximum life of a refresh token).
- Each response is cached for up to two minutes according to response's directive.
- The `before` attribute uses the `xs:dateTime` syntax.

Authenticating and authorizing through a redirect URL

You can use a service that is hosted externally from IBM® API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.

Before you begin

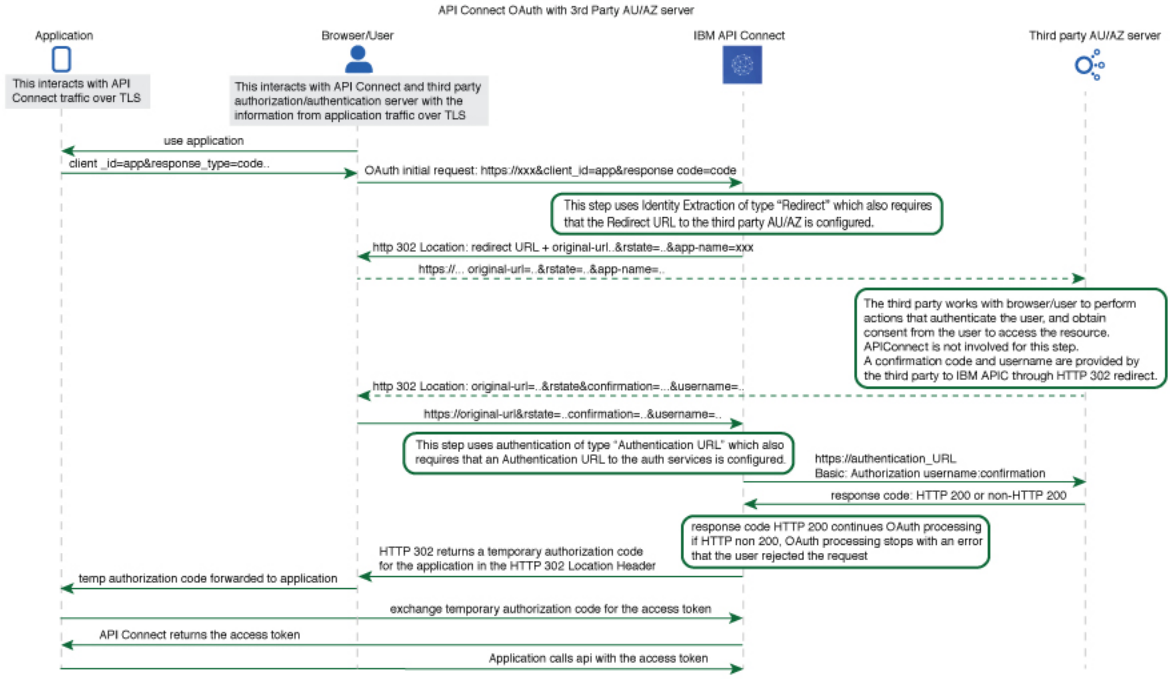
To complete this task, you will need to either create or have created an OAuth security definition that uses Implicit grant type or Access Code (Authorization Code) grant type. For more information, see Creating an OAuth security definition.

About this task

If you use methods for authentication that are not supported by API Connect, you can redirect users to a suitable URL at which they can authenticate. The user is then returned to the OAuth process after authentication and authorization have been confirmed.

The following illustration indicates the transaction flow for third party authentication.

Figure 1. Third party authentication (AU) and authorization (AZ) transaction flow



1. The application initiates a request to access an API protected with a third-party entity. API Connect redirects the application with an **`HTTP 302`** redirect based on **`identity extraction -> redirect -> redirect-url`**, for user authentication (and optional authorization).
2. The application communicates directly with the third-party entity to gather user identity. API Connect is not involved in this communication. After the third-party entity finishes processing authentication (and optional authorization), it returns an **`HTTP 302`** redirect that uses the **`original-url`** from the request, with the username and confirmation code appended.
3. API Connect receives the request that includes the username and confirmation code, and communicates with the authentication URL, based on **`authentication -> x-ibm-authentication-url`**, to confirm user identity before the request is completed.
4. An **`HTTP 200`** response from the third-party entity allows API Connect to continue the OAuth 2.0 request process as if the owner is authenticated. The request is then processed according to the **`grants`** type.
   - **`- accessCode`** returns a temporary code to the application.
   - **`- implicit`** returns the access token to the application.

   For any response other than HTTP 200, the request fails with a statement added to the error log.

Procedure

To create an external form, and to indicate the URL to which API Connect will redirect users, complete the following instructions:

1. Create your service for authentication and authorization. You will use the URL of the landing page of this service as your redirect URL.
   a. To include elements in your form that are provided by API Connect, use the following query parameters from the URL that your user is redirected to.
   Note: With the exception of **`original-url`**, none of these parameters are included in the URL automatically; you must add them as required.

   app-name
   : The name of the application requesting access, as provided through the Developer Portal.

   appid
   : The id of the application requesting access.

   catalog
   : The name of the catalog where the product is being used by the application.

   catalogid
   : The id of the catalog where the product is being used by the application.

   catalogtitle
   : User-friendly display name for the catalog.

   org
   : The name of the consumer organization that hosts the application.

   orgid
   : The id of the consumer organization that hosts the application.

   orgtitle

User-friendly display name for the organization.

original-url
: The original URL that the user was directed to by the application, including query parameters from the original URL that are necessary for standard OAuth 2.0 requests. You can include these parameters in your service to provide information to the user. Additionally the state_nonce is appended. The state_nonce is a hash code generated by API Connect for verification purposes. The URL is URL-encoded and should be decoded before further use, the **`state_nonce`** should remain unchanged.

provider
: The name of the API provider organization.

providerid
: The id of the API provider organization.

providertitle
: User-friendly display name for the provider organization.

requested-scope
: [optional] If Application Scope check is enabled and replaces the **`scope`** from the initial application request, this field holds the **`scope`** value from the initial application request, and the new replacement scope value is put into **`original-url`**.

transid
: transaction id used in the GW for the transaction which trigger this call

The URL to which the user is sent to when they are redirected to your page has the following form:

```
Redirect_URL?original-url=Original_URL&state_nonce=R_State&app-name=Application_Name
```

where all variables are as described previously. The Redirect URL does not have a size limit enforced by API Connect.

b. Create the stages of authentication, authorization, and any intermediate stages that you require to take place before you allow access to the application. Upon completion of these stages, redirect the user to the *Original_URL* and append a user name, their confirmation code, and the application name to be evaluated for access grant or denial by API Connect. The confirmation code does not have a size limit enforced by API Connect.
Original URL requires the following form:

```
Original_URL&username=User_Name&confirmation=Confirmation_Code
```

where all variables are as described previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=spoon&confirmation=12345678
```

c. To send your own error responses after the authentication and authorization service, redirect the user to the *Original_URL* and append an error code. You can also append a user name. Use the following form:

```
Original_URL&username=User_Name&error=Error_Response
```

where *Error_Response* is the message you wish to send and all other variables are described as previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=User&error=access_denied
```

2. Create a service to validate the confirmation code and user name. API Connect makes a GET call to your authentication URL after the user is redirected back to the authorization URL. When the call is made, it includes in its authorization header the user name and confirmation code you supplied previously. Confirm that these are correct and respond with an HTTP success code such as `200 OK` if you want to allow access, or non-`200 HTTP` response code, such as `401 Unauthorized` to deny access.
3. In your OAuth provider configuration, supply the redirect URL that is used in Step 1 and the authentication URL that is used in Step 2.
For more information on configuring an OAuth Provider, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Token management with the DataPower Gateway (v5 compatible)

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

In order to manage tokens with the DataPower® Gateway (v5 compatible), you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Also, the DataPower quota enforcement server must be enabled on the DataPower Gateway to use the distributed cache to manage tokens. See Quota enforcement.

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

When distributed cache support is enabled, replay protection is provided across the gateway cluster through the quota enforcement server. This support ensures that the same token cannot be reused across the members of the quota enforcement peer group.

Important:
If you have a cluster of DataPower Gateway servers, the OAuth data synchronization behavior across the servers depends on whether or not you enable revocation:

- If you enable revocation, API Connect uses the DataPower quota enforcement server, and OAuth data is synchronized across the servers. If an access token is obtained from one server, the OAuth data synchronization ensures that the same authorization code cannot be used to obtain an access code from another server. You must ensure that the DataPower quota enforcement server is configured.

- If you disable revocation, API Connect does **not** use the DataPower quota enforcement server and OAuth data does not synchronize across the cluster of DataPower Gateway servers. Therefore, to prevent the same authorization code being used to obtain an access code from more than one server you must configure DataPower to synchronize OAuth data across the servers, by using the DataPower Gateway console.

To configure DataPower to synchronize OAuth data, ensure that the DataPower quota enforcement server is configured. For more information, see Configuring the quota enforcement server.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user `cn=spoon,o=ibm` with username `spoon` and password `spoon` using a registered administration application of `5287fe53-8747-438a-8262-681ec75b79c5`.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
       Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

[

{

"clientId": "5287fe53-8747-438a-8262-681ec75b79c5", => same client id as request

} => delete second item

]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1
```

```
Host: apic.ibm.com

x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

    { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an **access_token**, or **refresh_token** with **token_type_hint** as shown in the following examples:

Revoke **access_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Revoke **refresh_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Token management with the DataPower API Gateway

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Note: The steps described in this topic are required if you are using the DataPower® OVA or appliance version of the gateway. For the API Connect supplied Kubernetes deployment, the API Security Token Manager is preconfigured provided that, in the gateway service custom resource file, v5 compatibility mode is disabled and the token management service is enabled:

```
      .
      .
      .
spec:
      .
      .
      .
  apicGatewayServiceV5CompatibilityMode: false
```

```
  tokenManagementService:
    enabled: true
      .
      .
      .
```

For more information, see Installing the DataPower Gateway subsystem.
Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

In order to manage tokens with the DataPower API Gateway, you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Note: This setting is also required when you use a third-party OAuth provider and **`Introspect cache type`** is set to **`protocol`** or **`Time to live`**.
For token management with the DataPower API Gateway, you must configure the API Security Token Manager on the gateway. Complete the following steps:

1. Log in to the DataPower administration console, selecting apiconnect for the domain, and WebGUI for the Graphical Interface.
2. In the search box, enter API Security Token Manager, then click on the API Security Token Manager link that displays in the search results.
3. For the Administrative state, select enabled.
4. Click the + icon alongside the Gateway Peering field to create a new gateway peering object.
5. Provide a Name and a Local address.
6. In the Local port and Monitor port fields, provide values that aren't already in use by services for the Local address.
7. Ensure that Peer group mode is selected.
8. Alongside the Peers field, use the add button and accompanying field to add at least two peers, to ensure that quorum is achieved.
9. If the Enable SSL option is selected, select a value for the Identification credentials.
10. For Persistence location, select a setting other than memory.
11. When done, click Apply.
12. Repeat steps 1 to 11 for each DataPower API Gateway in the peer group.
13. When done, click Apply, then click Save Configuration to save your changes.

For more information, see Defining the API security token manager and Creating a gateway peering instance.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user **`cn=spoon,o=ibm`** with username **`spoon`** and password **`spoon`** using a registered administration application of **`5287fe53-8747-438a-8262-681ec75b79c5`**.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5

} => delete second item

]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

    { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an **access_token**, or **refresh_token** with **token_type_hint** as shown in the following examples:

Revoke **access_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Revoke **refresh_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded
```

```
      token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

     { "status": "success" }
```

Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs-in with user name: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes **`cn=spoon,o=eatery`**. The credential is kept in the OAuth **access_token** to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the **`access_token`**.
- Overriding the **`scope`** that the application receives after a successful OAuth protocol processing. By responding with a specific header, the Authentication URL endpoint can replace the **`scope`** value that the application receives. For example, you can provide a specific resource owner an account number within the **`scope`** header response for use in future processing steps.

When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect will use **`cn=spoon,o=eatery`** as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see User Security policy.

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see Example - using multiple OAuth policies in an OAuth provider assembly.

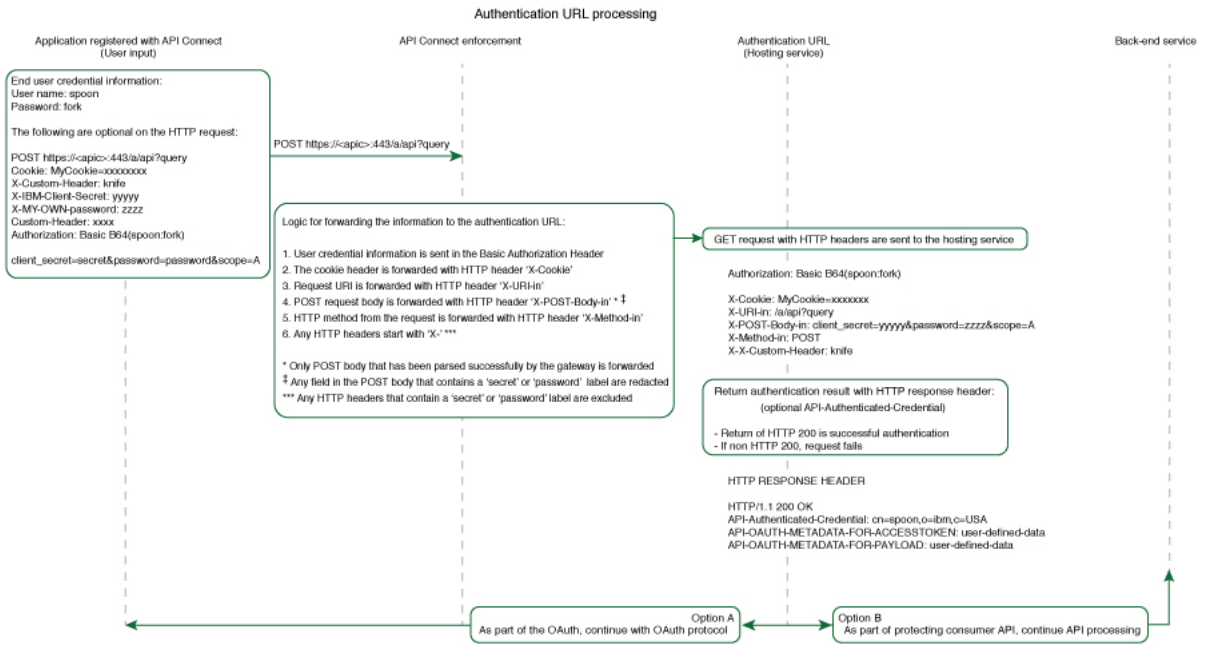
API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see OAuth external URL and authentication URL. The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested **`scope`** from the application. For more information, see Scope. The response header is:

```
x-selected-scope
```



If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Custom forms for user security

You can create custom forms for the authorization and identity extraction phase of OAuth.

About this task

The Native OAuth provider configuration provides the capability for requiring additional authentication and authorization steps for user security. Custom HTML forms may be created to extract the identity of the user and to authorize the user. This capability applies to Implicit, Resource owner password, and Access code grant types.

- **Creating a custom HTML login form for user security**
  Custom HTML forms can be created for user security during the identity extraction stage in OAuth.
- **Creating a custom HTML authorization form for user security**
  Custom HTML forms can be created for user security during the authorization stage in OAuth.

Creating a custom HTML login form for user security

Custom HTML forms can be created for user security during the identity extraction stage in OAuth.

Before you begin

The Native OAuth provider configuration includes Identity Extraction when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to extract the user credential and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. For more information, see Configuring a native OAuth provider. This topic describes how to create the Custom HTML form for identity extraction.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form for signing in to the service provided by the API. You can present a custom form or a default form. Your custom form must fulfill certain requirements.

Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom sign-in form for your Native OAuth provider, complete the following steps:

1. Create a well formed XHTML document that will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example:

   ```
   <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
   ```

3. Create a text input field that is named `username` and create a password input field named `password`.
4. Add the line `<EI-INJECT-HIDDEN-INPUT-FIELDS>`. This third element is a placeholder that API Connect replaces with input fields to complement the user-submitted data.
5. Create a button to initiate the sign-in process.
   For example:

   ```
   <button
   id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.apionprem.doc_oauth_custom_login_form_login_button" type="submit" name="login" value="true">Log in</button>
   ```

6. Optional: Add text that is displayed the first time that the user visits the sign-in page. Use the tag `<EI-LOGINFIRSTTIME>` for the text that you want to display.
7. Optional: Add text that appears when the user is returned to the sign-in page if they fail to authenticate. Use the tag `<EI-LOGINFAILED>` for the text that you want to display.
8. Optional: Have an error message displayed when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<EI-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
9. Optional: You can add elements that are loaded from external sources, such as images or JavaScript.
10. Insert spacing and other features as you require. Completing Steps 1 through to 8 results in a form similar to the following example:

    ```
    <html lang="en" xml:lang="en">
      <head><meta http-equiv="Content-Type" content="text/html; charset=UTF-8"/></head>
      <body>
        <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
          <h1>Please sign in</h1>
          <p>Username </p>
          <p ><input type="text" name="username" required="required" /> </p>
          <p>Password </p>
          <p ><input type="password" name="password" required="required" /> </p>
          <EI-INJECT-HIDDEN-INPUT-FIELDS/>
          <p > <button
    ```

```
id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.apionprem.doc_oauth_custom_login_form_login_bu
tton" type="submit" name="login" value="true">Log in</button> </p>

      <EI-LOGINFIRSTTIME>
        <p>If you have forgotten your user name or password, contact your system administrator.</p>
      </EI-LOGINFIRSTTIME>

      <EI-LOGINFAILED>
        <p >At least one of your entries does not match our records.
          If you have forgotten your user name or password, contact your system administrator.</p>
      </EI-LOGINFAILED>

      <EI-INTERNAL-CUSTOM-FORM-ERROR/>

    </form>
  </body>
</html>
```

11. Make your form available at a URL of your choice.
12. If you have not already done so, configure your Native OAuth provider to use a Custom HTML form for identity extraction and provide the URL at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Creating a custom HTML authorization form for user security

Custom HTML forms can be created for user security during the authorization stage in OAuth.

Before you begin

The Native OAuth provider configuration includes user authorization when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to authorize application users and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. This topic describes how to create the Custom HTML form for authorization.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form through which they grant permission to an application to access their data through the API on their behalf. You can present a custom form or a default form. Your custom form must fulfill certain requirements.
Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom authorization form for your Native OAuth provider, complete the following steps:

1. Create a well-formed XHTML document. This will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example:

   ```
   <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
   ```

3. Add the line `<AZ-INJECT-HIDDEN-INPUT-FIELDS/>`. This line is a placeholder that API Connect will replace with input fields necessary for the completion of the OAuth process.
4. Create two buttons with the following code so that the user can grant or deny permission. Edit the text to suit your preferences.

   ```
   <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
   <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
   ```

5. Optional: Display an error message when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<AZ-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
6. Optional: You can add to the form HTML elements that will load features from external sources, such as images or JavaScript.
   For example, `<script src="http://www.example.com/example.js" />`
7. Insert spacing and additional elements as you require. Completing Steps 1 through to 6 results in a form similar to the following example:

```
<html lang="en" xml:lang="en">
  <head><title>Request for permission</title></head>
  <body class="customconsent">
    <div>
      <div>
        <form method="post" enctype="application/x-www-form-urlencoded" action="authorize">
          <AZ-INJECT-HIDDEN-INPUT-FIELDS/>
```

```
          <p>Greeting..</p><DISPLAY-RESOURCE-OWNER/>
          <p>This app </p><OAUTH-APPLICATION-NAME/><p> would like to access your data.</p>
          <div>
            <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
            <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
          </div>
        </form>
      </div>
      <AZ-INTERNAL-CUSTOM-FORM-ERROR/>
    </div>
  </body>
</html>
```

8. Make your form available at a URL of your choice.
9. If you have not already done so, configure your Native OAuth provider to use a Custom HTML Form for authorization for User Security. Provide the URL as the endpoint at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

- Configuring API security

Securing an API with a JSON Web Token

There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM® API Connect.

About this task

JSON Web Token (JWT) is an OAuth 2.0 compliant method of authentication that can be useful to secure your API in API Connect.

You can secure your API with a JSON Web Token by using either of the following methods:

- Generate a token through the **jwt-generate** command, and then augment the response payload with your generated token replacing the `id` token.
- Use a token that was generated outside of API Connect and include it into the response payload, by using the metadata URL.

Procedure

Create a **jwt-generate** policy in the assembly.

a. In API Manager, open the Assembly tab.
b. Add a jwt-generate policy to the assembly for the API.

Troubleshooting OAuth

You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

You can use the following links to go to the topics:

- OAuth 2.0 support in the developer portal test tool
- OAuth requires quorum in a multi-node cluster

OAuth 2.0 support in the developer portal test tool

OAuth 2.0 support is exposed as an API through the provider OpenAPI definition. You can use the test tool that is included with API Connect to test the OAuth 2.0 configuration. For more information, see Testing an API using the Developer Portal test tool.

OAuth requires quorum in a multi-node cluster

In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

Configuring the cloud settings

Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.

The cloud settings let you define basic configuration for your deployment. To view the current settings, log in to Cloud Manager and click in the navigation pane.

Tip: When you are familiar with the cloud settings, you can modify them using the Toolkit command-line interface instead of the user interface.
Visit the following pages to configure settings:

Overview
: Provide a title and description for your cloud administrator organization. For more information, see Change the name of your cloud.

Onboarding
: Specify time-out settings for onboarding invitations, password resets, access tokens, and refresh tokens. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
For more information on setting timeouts, see the following topics:

  - Configuring invitation timeouts
  - Configuring the password-reset notification and timeout
  - Configuring timeouts for access tokens and refresh tokens

User Registries
: Configure one or more user registries to authenticate users of Cloud Manager or API Manager. The user credentials for all users who login to each applications must be stored in the specified registries. For more information on configuring user registries, see Selecting user registries for Cloud Manager and API Manager.

Roles
: Create roles and assign them to members of the Admin organization to specify which tasks members are authorized to perform. For more information on assigning roles, see Administering members and roles.

Role Defaults
: The Role Defaults for the Admin organization are not configurable, but you can customize the base roles for provider organizations and consumer organizations. For more information on customizing base roles, see Role Defaults overview.

Endpoints
: View the list of endpoints configured for API Manager, provider APIs, and consumer APIs during the installation process.

Notifications
: Select the email server for your on-premises cloud notifications, configure notification settings, and specify the sender name and email address to be included in the emails. You can also preview and customize email templates used for notifications. For more information on setting up notifications, see Setting up notifications.
Note: Be sure to configure the email server, because it is needed for sending invitations and other notifications to users.

Catalog Defaults
: Specify one or more gateway services to be provided to every Catalog by default, so that Products (which contain APIs) can be made available to users. When a new Catalog is created in a provider organization, it is assigned to the default gateway service. Any changes you make to these settings do not affect existing Catalogs.
For more information on selecting gateway services, see Configuring the default gateway services for Catalogs.

Audit Setting
: Configure auditing settings to monitor API calls and log information about the calling users, the time of each call, and the activity involved in each event. The audit focuses on "who" did "what" and "when", including the request payload and the result of the operation. All create, update, and delete operations are audited. Generally, read operations are only audited if the calling user logged in with an OIDC Provider user registry. For more information about configuring the use of auditing, see Configuring audit logging to monitor user operations.

Use the following list to locate instructions for using specific cloud settings:

- **Change the name of your cloud**
  You can change the name of your cloud.
- **Configuring an email server for notifications**
  Connect to an email server in your API Connect on-premises cloud. The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service. Otherwise, the owner of the organization will not receive the email with the details that they require to access the API Manager.
- **Setting up notifications**
  Select an email server and set up the "sent from" information for notifications.
- **Configuring invitation timeouts**
  You can set the time period for when registration invitations for Cloud Settings access and the Admin organization expire.
- **Configuring API key settings**
  You can set the time period for when an API key expires, and optionally authorize it to be used multiple times.
- **Using the CLI to modify cloud settings**
  Use the toolkit CLI to edit the cloud settings.
- **Configuring Base64 encoding for temporary tokens**
  How to enable and disable Base64 encoding for temporary tokens.
- **Configuring the password-reset notification and timeout**
  Configure the time allowed for a user to reset a password, and customize the notification that the user receives.
- **Selecting user registries for Cloud Manager and API Manager**
  Select the user registries to authenticate users for Cloud Manager and API Manager.
- **Configuring timeouts for access tokens and refresh tokens**
  Configure timeout values for the access tokens and refresh tokens for user registries.
- **Viewing platform and UI endpoints**
  A view-only list of platform and UI endpoints is provided.
- **Configuring the default gateway services for Catalogs**
  Configure the list of default gateway services that are available to new Catalogs.
- **Managing the public/private key pairs for signing tokens**
  Manage the public/private key pairs that are used for signing tokens in API Connects.

Change the name of your cloud

You can change the name of your cloud.

About this task

You can change the name of your cloud using the Overview page.

One of the following roles is required to change the name of your cloud:

- Administrator
- Owner
- A custom role with the `cloud settings:manage`

Procedure

Follow these steps to change the name of your cloud:

1. In the Cloud Manager, click Settings.
2. Select Overview..
3. Click Edit to change the name of your cloud.
4. Enter a Title and the name is auto-generated. Enter a brief Summary and click Save.

Configuring an email server for notifications

Connect to an email server in your API Connect on-premises cloud. The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service. Otherwise, the owner of the organization will not receive the email with the details that they require to access the API Manager.

Before you begin

You must complete the tasks in the following section:

1. Defining your Cloud Manager topology

About this task

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator
- Topology Administrator
- Custom role with **`Settings:Manage`** permission

The email server sends invitation emails with activation links and other system messages. More than one email server may be configured in Cloud Manager, but only one email server may be selected as the active server to send notifications at any one time. For instructions on how to select the active email server and to view a list of the email messages that are sent, see Setting up notifications.
Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Procedure

To configure one or more email servers to use for email notifications in Cloud Manager, complete the following steps:

1. In the Cloud Manager, click Resources.
2. Choose Notifications.
3. Enter the values to configure the email server.

Field	Description
Title (required)	Enter a descriptive title for the email server. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Address (required)	IP address for the email server
Port (required)	Port that the email server runs on
Authenticate User	Enter a user name to use for authorization with the SMTP server. The user name is required if the SMTP server requires authentication.
Authenticate Password	Enter the password for the Authenticate User. This password is used for authorization with the SMTP server. The password is required if the SMTP server requires authentication.
TLS Client Profile (optional)	Select an optional TLS Client Profile that will be used to communicate with the email server if the Secure Connection option is selected.
Secure Connection	Select this option to specify that TLS security is used. The following conditions apply: • If this option is not selected then TLS security is not used even if the email server is configured to use the STARTTLS protocol. • If this option is selected and a TLS Client Profile is selected, that profile is used and the STARTTLS protocol configuration on the email server is honored. • If this option is selected and no TLS Client Profile is selected, the Default TLS client profile is used and the STARTTLS protocol configuration on the email server is honored.

4. You can send a test email to confirm that the email server is properly configured. Click Test email in the Test Connection panel to open a dialog window. Enter one or more valid email addresses in the Recipients field. Separate multiple recipients with commas. Click Send test email. Check that the test email was received by the recipients.
5. If the test email is successful, click Save to save the email server configuration. If the test is unsuccessful, check the configuration values and update as needed.

Note: In order to send emails, you must select an email server as your active server in Settings > Notifications.

Results

The email server is configured.

What to do next

You must now select the email server to use as your active email server in Cloud Settings > Notifications. You can enter the sender information, and customize the email templates. For more information, see Setting up notifications.
Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Setting up notifications

Select an email server and set up the "sent from" information for notifications.

Before you begin

You must configure an email server to use for your notifications in Resources > Notifications, before you can set up the notification configuration in Settings > Notifications. See Configuring an email server for notifications for more information.

About this task

In Settings > Notifications, you select the email server that you want to use as the active server to send notification emails. An active email server is required to send email notifications. More than one email server may be configured in Cloud Manager, but only one email server may be selected to send notifications at any one time. The email server must be configured and selected for notifications before adding a Portal Service to your cloud.

You also configure the sender information to be included on all the emails and optionally, edit the standard text for the email templates.

One of the following roles is required to add roles to select the email server, enter the sender information, and edit the email templates:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` permission

Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Notifications.
3. To configure the active email server:
   a. Click Edit in the Sender & Email Server section.
   b. Select an email server in the list; a check mark is displayed next to the currently selected server.
   c. Click Save.
4. To delete an email server from the list, click the options menu next to the server name and select Delete.
5. To change the sender name and email address for notifications:
   a. Click Edit in the Sender & Email Server section.
   b. Fill in the Name and Email address that notifications will be sent from.
   c. Click Save.
6. To preview and edit the notification email templates, see Customizing email notification templates

What to do next

You can now create a provider organization.

- **Customizing email notification templates**
  API Connect includes a set of email templates for invitations and other notification emails. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

Customizing email notification templates

API Connect includes a set of email templates for invitations and other notification emails. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

About this task

The API Connect emails are sent automatically when certain system events occur. The email templates are organized by scope, as explained in Table 1.

Table 1. Notification scopes

Scope	Events that trigger the notification
admin	Admin organization activities such as invitations, portal sign up, and password reset.
catalog	Activities related to Catalogs; for example: such as application life cycle events, invitations to catalogs, product approvals, and subscription approvals.
consumer	Activities to consumer applications and subscription requests in the Developer Portal, invitations to Consumer organizations, and password reset requests for Developer Portal accounts.
provider	Invitations
space	Invitations

Email notifications contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email template being sent, the search can start at the Space level, and then go through the Catalog, Provider Organization, and the Cloud Manager levels. The sender details that are used will be the first set of configured details found during this hierarchical search. To view which search path API Connect takes when looking for the sender details for each notification template, see Configuring sender details for email notifications in the Managing your APIs section.

One of the following roles is required to configure email notifications:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` permission

Note: You can also customize notifications by using the developer toolkit CLI, or by using the API Connect REST APIs. See Using the CLI to modify cloud settings, or API Connect REST APIs, for more information.
If you want to configure the notifications at the Provider Organization level, see Configuring notifications in the Managing your APIs section.

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Notifications.
   On the Notifications page, templates display in a list, sorted by scope. When selecting a template to modify, be sure to select the version that applies to the appropriate scope.
3. To preview the text for a template, select Preview from the actions menu next to the template name.
4. To edit the text for the template, either click the template name, or select Edit in the action menu.
   When a template is opened, an attempt is made to get the language from the browser setting, but if this isn't possible the template defaults to English.

   The text includes variables; for example, `{{catalog}}`. The notification text is based on Handlebars syntax. Most variables are enclosed in double curly braces `{{ }}`, but can be enclosed in triple curly braces `{{{ }}}` to disable HTML escaping, when the variable is a URL link for example. For more information on Handlebars, see https://handlebarsjs.com/.

   To obtain the complete list of variables that are available for a particular notification template, complete the following steps:
   a. Log in to the management server from the command line as a member of the cloud administration organization; for details, see Logging in to a management server. You can use the same management server URL, user name, and password in the login command that you use to log in to the Cloud Manager user interface.
   b. Enter the following command:

   ```
   apic notification-templates:get template_name --server mgmt_endpoint_url --scope cloud --subcollection template_scope
   --fields variables --output -
   ```

   where:
   - *template_name* is the name of the required notification template, as displayed in the Template column in the user interface.
   - *template_scope* is the scope name displayed in the Scope column alongside that template.

   For example:

   ```
   apic notification-templates:get member-invitation --server https://myserver.com --scope cloud --subcollection catalog
   --fields variables --output -
   ```

   The variables that are available for the template are displayed, for example:

   ```
   variables:
     - org
     - catalog
     - activationLink
     - expiresAt
     - originator
     - originatorFirstName
     - originatorLastName
     - originatorEmail
     - username
     - email
     - firstName
     - lastName
   ```

   The `--output -` parameter causes the command output to be written to the command line. You can specify `--output filepath` to have the output written to a .yaml file at the specified location, or omit it altogether to have a file written to the current folder.
5. To view and edit the notification template in a different language, select one of the following supported languages from the View template in drop-down list:
   - Chinese (Simplified)
   - Chinese (Traditional)
   - Czech
   - Dutch
   - English (US English)
   - French
   - German
   - Italian
   - Japanese

- Korean
- Polish
- Portuguese
- Russian
- Spanish
- Turkish

6. Edit the Subject as required.
7. Select the Content type that you want to use for the template, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
8. Edit the body of the template as required.
   For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 2. List of allowed HTML tags and their attributes

HTML tag	Attribute
`<a>`	`"class", "href", "hreflang", "style"`
`<em>`	`"class", "style"`
`<strong>`	`"class", "style"`
`<cite>`	`"class", "style"`
`<blockquote>`	`"class", "cite", "style"`
`<code>`	`"class", "style"`
`<ul>`	`"class", "type", "style"`
`<ol>`	`"class", "start", "type", "style"`
`<li>`	`"class", "style"`
`<dl>`	`"class", "style"`
`<dt>`	`"class", "style"`
`<dd>`	`"class", "style"`
`<h1>`	`"class", "id", "style"`
`<h2>`	`"class", "id", "style"`
`<h3>`	`"class", "id", "style"`
`<h4>`	`"class", "id", "style"`
`<h5>`	`"class", "id", "style"`
`<h6>`	`"class", "id", "style"`
`<p>`	`"class", "style"`
`<div>`	`"class", "style"`
` `	`"class", "style"`
`<span>`	`"class", "style"`
`<img>`	`"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"`
`<table>`	`"class", "id", "style"`
`<tr>`	`"class", "id", "style"`
`<td>`	`"class", "id", "style"`

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
Images can be used by adding a **`<img src="https://path/to/image.png"/>`** tag in the template. The **`src`** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

9. Click Save when done.
   Note: Edits made to a template are saved only for the specific language version that is edited.

Related information

- Configuring notifications

Configuring invitation timeouts

You can set the time period for when registration invitations for Cloud Settings access and the Admin organization expire.

About this task

One of the following roles is required to change the name of your cloud:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

Follow these steps to set the invitation timeout:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the invitation timeout setting that you want to change:
   - Cloud Settings Invitation Timeout
   - Admin Organization Invitation Timeout
4. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.

5. Click Save.

Results

Invitations contain a link, which expires after the specified the timeout. If the user does not register before the expiration, you can send a new invitation.

Configuring API key settings

You can set the time period for when an API key expires, and optionally authorize it to be used multiple times.

About this task

Applications exchange the API key exchange the API key for an access token.

Procedure

Follow these steps to set the API key timeout:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the API Key timeout setting.
4. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
5. Select Multiple use of apikey to allow applications to exchange the API key for an access token multiple times.
   By default, the API key can be used only once.

   To enable this setting with the CLI, set the **api_key_multiple_uses** field to **true**.

6. Click Save.

Results

API Key times out based on the set timeout value.

Using the CLI to modify cloud settings

Use the toolkit CLI to edit the cloud settings.

About this task

Some cloud settings can be modified in the Cloud Manager UI, but all settings can be modified with the toolkit CLI. You can modify the cloud settings configuration file and upload the changes, or issue commands to modify individual settings directly. If multiple people modify the cloud settings, any newer settings overwrite older settings regardless of the method used to update the settings.

For more information about working with the toolkit CLI, see the following topics:

- For details on using **apic** to modify cloud settings, see apic cloud-settings:update.
- For details on all the cloud settings commands, see apic cloud-settings

Procedure

1. Run the following command to log in to a management server as a member of the cloud administration organization:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
   For more information on logging in, see Logging in to a management server.

2. Optionally retrieve the current list of cloud settings with the following command:

   ```
   apic cloud-settings:get --server mgmt_endpoint_url --output -
   ```

   where *mgmt_endpoint_url* is the URL of the server where the cloud settings are stored.

3. Add or modify settings using one of the following methods:
   - Issue each setting from the command line.
     For simple changes, you can issue commands to modify settings without editing the configuration file.
     - Issue the following command to start the update process:

       ```
       apic cloud-settings:update --server mgmt_endpoint_url -
       ```

       where *mgmt_endpoint_url* is the URL of the server where the cloud settings are stored. Include the hyphen at the end of the command to indicate that input follows on the next command line.

     - Type the information for a single setting on one line, and press ENTER to submit it.
       Specify each setting on a single line and use the following format to specify the setting's name and value:

       ```
       setting_name: setting_value
       ```

       For example, the following command updates a single setting:

       ```
       apic cloud-settings:update --server mgmt_endpoint_url -
       refresh_expires_in: expiration time
       Ctrl+D
       ```

     - Type Ctrl+D to indicate that the data entry is complete, as shown in the example.
   - Upload a file containing the settings.
     If you have multiple settings or lengthy values to add or modify, you might prefer to make all of the changes at once by creating or modifying the configuration file and then uploading it.
     - Create a .yaml file with your settings.
       You can choose the file name but must use YAML format. The file can contain as few or as many settings as needed.

       Settings use the following format; notice that the setting's name must be enclosed in quotation marks as shown in the example. The last setting in the file does not end with a comma.

       ```
       "setting_name": setting_value,
       ```

     - Upload the file with the following command:

       ```
       apic cloud-settings:update --server mgmt_endpoint_url my_cloud_settings.yaml
       ```

     For information on using input files with the toolkit CLI, see ../com.ibm.apic.toolkit.doc/rapic_cli_command_line_input.html.

4. When you are ready to log out of the management server, use the following command:

   ```
   apic logout --server mgmt_endpoint_url
   ```

Results

The settings are cached for a maximum of five minutes, so you might experience a delay before your changes take effect.

Configuring Base64 encoding for temporary tokens

How to enable and disable Base64 encoding for temporary tokens.

About this task

You can enable or disable Base64 encoding for temporary tokens. Temporary tokens are invitations, and password reset tokens. When Base64 encoding is enabled, the temporary token is encoded in Base64 format. When Base64 encoding is disabled, the temporary token remains in the JSON Web Token (JWT) format, and means that the length of the URL that the user receives is reduced.

Base64 encoding is enabled by default.

One of the following roles is required to configure Base64 encoding:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

Follow these steps to configure Base64 encoding for temporary tokens:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the Base64 encoding setting.
4. Select Enable to enable Base64 encoding, or Disable to keep temporary tokens in the JSON Web Token (JWT) format.
5. Click Save.

Results

You have successfully enabled or disabled Base64 encoding for temporary tokens.

Configuring the password-reset notification and timeout

Configure the time allowed for a user to reset a password, and customize the notification that the user receives.

Before you begin

Configure an email server that can be used for mailing notifications to users. If you do not configure an email server, a link cannot be send to a user who wants to reset a password. For information on configuring the email server, see Setting up notifications.

About this task

When a user clicks Forgot Password? and provides an email address on the sign-in page, an email is generated with a link where the user can reset the password. When you deploy API Connect, the password-reset settings are configured with default values. You can optionally modify the time-out setting to set a new expiration for resets as well as the notification that is emailed to users.

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Configure the password reset timeout:
   a. In the Settings navigation list, click Onboarding.
   b. Click Edit next to Reset Password Time to Live.
   c. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
   d. Click Save.
4. Customize the notification template for password resets:
   a. In the Settings navigation list, click Notifications.
   b. In the Notifications Templates list, select the appropriate version of the "password-reset" template by clicking the name.
      You can create different versions of the template for different user roles.
   c. Customize the template as explained in Customizing email notification templates.
   d. Click Save.

Results

Password reset notifications contain a link, which expires after the specified the timeout. If the user does not reset the password before the link expires, they can request a new link.

Selecting user registries for Cloud Manager and API Manager

Select the user registries to authenticate users for Cloud Manager and API Manager.

About this task

In Settings > User registries, you select one or more user registries to authenticate users of Cloud Manager and API Manager. The user credentials for all users who login to the applications must be stored in the selected registries.

One of the following roles is required to select the user registries for Cloud Manager and API Manager:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

For details on how to control which user registries can be used by provider organizations for authenticating Developer Portal users, or for securing APIs, see Setting visibility for a user registry.

Procedure

To select the user registries for Cloud Manager and API Manager, follow these steps:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click User Registries.
3. The current list of user registries is displayed for Cloud Manager and for API Manager. To add user registries, click Edit in either the Cloud Manager or API Manager panel.
   Note: The list of user registries is derived from the user registries that were previously configured as a Resource in Resources > User Registries. For more information, see User registries overview
4. Select the user registry by placing a check mark next to the name in the list. Remove a user registry by removing the check mark.

5. Click Save.

Results

The user registry list is updated to reflect the selected user registries available for authenticating users.

What to do next

To set a user registry as the default, click the options menu next to the registry name in the list, and select Set as default.

- **Setting a default user registry for Cloud Manager and API Manager**
  You can select a default user registry for Cloud Manager and and for API Manager.

Related tasks

- Configuring a Local User Registry

Setting a default user registry for Cloud Manager and API Manager

You can select a default user registry for Cloud Manager and and for API Manager.

About this task

In Settings > User registries, you can set a user registry as the default user registry.

One of the following roles is required to select the user registries for Cloud Manager and API Manager:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click User Registries.
3. To set a user registry as the default, click the options menu next to the registry name in the list, and select Set as default.
   Note: The list of user registries is derived from the user registries that were previously configured as resources in Resources > User Registries. For more information, see User registries overview

Results

The user registry list is updated to reflect the default user registry.

Related tasks

- Configuring an LDAP user registry in the Cloud Manager
- Configuring an Authentication URL user registry

Configuring timeouts for access tokens and refresh tokens

Configure timeout values for the access tokens and refresh tokens for user registries.

About this task

IBM® API Connect supports the use of access tokens and refresh tokens for user registries that authenticate users of the Cloud Manager, the API Manager, and the Developer Portal.

Access tokens allow users to sign in and remain logged in for a specified amount of time (the timeout period). Refresh tokens allow the access token to be renewed automatically without requiring the user to sign in again. Access tokens are configured by default, and you can modify the timeout setting. Refresh tokens are disabled by default but are configured with a default timeout when you enable them.

Refresh tokens, when enabled, are generated every time an access token is created. Refresh tokens can be used to obtain a new access token without having to prompt a user to re-login. If you enable the use of refresh tokens, then when the token expires it is refreshed automatically in the background so that the user can continue working without interruption. When the user logs out, the refresh token is revoked and the application can no longer use it.

Note: If users log in with non-OIDC user registries, the use of refresh tokens is supported in API Manager, API Designer, the Developer Portal, and the CLI Toolkit. When the refresh token expires, the user is always redirected to the login page.

If users log in with OIDC user registries:

- If the OIDC providers do not support refresh tokens, API Connect will not issue a refresh_token, regardless of the setting of **refresh_token_enabled** in the cloud settings.
- For more information about OIDC configuration, see Configuring an OIDC user registry in Cloud Manager.

You can configure access tokens and refresh tokens using the Cloud Manager UI, or the Toolkit CLI.

Using the UI to configure tokens

Configure timeout settings for access tokens and refresh tokens in the Cloud Manager Settings pages.

Procedure

1. Click in the navigation pane.
2. Configure the timeout for access tokens:
   a. On the Onboarding page, click Edit next to Access Token Time to Live.
   b. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
   c. Click Save.
3. Configure the timeout for refresh tokens:
   a. On the Onboarding page, click Edit next to Refresh Token Time to Live.
   b. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
   c. Click Save.

Using the CLI to configure tokens

Use the Toolkit CLI to configure timeout settings for access tokens and refresh tokens.

About this task

Use the following properties to specify refresh tokens for cloud settings:

- **access_token_expires_in**
  Integer. Represents the expiration time, in seconds, for access tokens issued by API Connect.
- **refresh_expires_in**
  Integer. Represents the expiration time, in seconds, for refresh tokens issued by API Connect. Must be greater than **access_token_expires_in**.
- **refresh_token_enabled**
  Boolean. Disabled by default. To enable, set to **true**. When enabled, generates a **refresh_token** field in the response to the **/token** API call.

The following extract from a cloud settings file shows example settings for these properties:

```
"type": "cloud_setting",
"api_version": "2.0.0",
"name": "cloud-setting",
"access_token_expires_in": 28800,
.
.
.
"refresh_expires_in": 57600,
"refresh_token_enabled": false,
.
.
.
```

Use the toolkit CLI (**apic**) to update the cloud settings with new values for the properties. You can either specify values as command line arguments, or enter them manually in a configuration file as explained in Using the CLI to modify cloud settings.

Viewing platform and UI endpoints

A view-only list of platform and UI endpoints is provided.

About this task

You can view the list of endpoints configured during the installation process. Included in this view-only list are the following endpoints:

- API Manager URL - the URL for opening the API Manager UI
- Platform REST API endpoint for the Admin and Provider REST APIs - this endpoint handles the REST APIs for Admin and Provider functions.
- Platform REST API endpoint for consumer REST APIs - this endpoint handles the REST APIs for consumer (Portal) functions.

One of the following roles is required to view endpoints:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` or `cloud-settings: view` permissions

Procedure

To view the endpoints, follow these steps:

1. In the Cloud Manager, click Settings.
2. Select Endpoints.
3. View the list of endpoints.

Configuring the default gateway services for Catalogs

Configure the list of default gateway services that are available to new Catalogs.

About this task

One of the following roles is required to configure Catalog Defaults:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

You publish APIs by adding them to a product and then publishing the product to a catalog. To be able to publish products to a catalog, the catalog must be assigned at least one gateway service so that the APIs in the product are available to be called at a gateway service endpoint. You can assign more than one gateway service to a catalog, and they can be of mixed types, DataPower® API Gateway and DataPower Gateway (v5 compatible).

A product is gateway type specific, either DataPower API Gateway or DataPower Gateway (v5 compatible). By default, when you publish a product to a catalog, it is published to all the assigned gateway services of the same gateway type as the product, but you can choose to publish the product only to selected gateway services, of that type, at publish time; see Publishing a draft product for more information. The APIs in the product will be available to be called at all the specified gateway service endpoints.

The procedure described in this topic specifies the gateway services that are assigned by default to newly created catalogs, but you can change the assigned gateway services for a specific catalog; see Creating and configuring catalogs.

Procedure

To configure the gateway services that are assigned to new Catalogs by default, complete the following steps:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Catalog Defaults.
3. Click Edit to change the list of default gateway services.
4. Select the required gateway services, then click Save.

Results

When a new Catalog is created in a provider organization, the default gateway services are automatically assigned to it. Any changes you make to the list of default services affects only the Catalogs that are created after you save your changes. Existing Catalogs are not affected.

Managing the public/private key pairs for signing tokens

Manage the public/private key pairs that are used for signing tokens in API Connects.

API Connect uses public-key cryptography to secure tokens. By default, an API Connect deployment receives one public/private key pair, which is used for signing and verifying tokens. When a token is created, API Connect signs it with the deployment's private key. Any third-party can verify that digital signature with the deployment's public key.

The public/private key pair is generated for you by API Connect on the first start-up after installation, upgrade, or migration. The keys are stored in a keystore object.

Why do you need public/private key pairs?

API Connect uses a public/private key pair to sign and verify the following tokens:

- access_token: Verifies that the user has permission to access resources.
- id_token: Stored within the access token to specifies the user's ID.***Confirm?***
- temporary_token: Provides for short-lived access so that the user can log in and receive an access token. For example, when the user receives a link for resetting a password or to register for an account.

How does APIC use the public/private key pair?

Each API Connect deployment is assigned a public key, which is made openly available, plus a corresponding private key, which can only be accessed by that deployment. To verify a user's access to resources for a transaction, API Connect signs every token with the private key. Any other party can use the openly available public key to verify the signature. Because the private key is not shared, it can be used repeatedly instead of generating a new value for each signature.

When your app accesses an API endpoint, the access_token is in JWT format and includes a 'kid" value that is the new key.

Note: The signature for public/private key schema is larger than for shared secrets, so the access_token that is returned will also be larger. If you encounter issues with headers becoming too large, refer to the following topic: Resolving login problems by increasing HTTP header size.

How can you manage public/private key pairs?

By default, your deployment is assigned one key pair, which is stored in a keystore and never expires. The same key pair is used for signing and verify all tokens. The key pair consists of a public key and a private key:

- key_signing: The private key that API Connect uses for signing tokens
- key_verify: The public key that anyone can access and use for verifying token signatures

API Connect uses the following cloud settings to determine which public/private keystores are used for each type of token:

- access_token_keystore_urls: [*keystore_url_0, keystore_url_n*]
- id_token _keystore_urls: [*keystore_url_0, keystore_url_n*]
- temporary_token _keystore_urls: [*keystore_url_0, keystore_url_n*]

Each setting specifies an array of URLs where the keystores are hosted, with the keystore at position 0 representing the current key pair. You can optionally generate additional key pairs, store them in new keystores, and use them with the tokens to enhance security. Each key pair is stored in its own keystore and can be set to expire at a different time. Providing a different key pair for each type of token is a good practice because it limits the damage if a token is compromised.

If you specify one keystore for a token, that key pair is used for every new token of the same type, and it never expires. If you specify multiple keystores, you can assign a lifetime to each and when the keys in the first keystore expire, the keys are obtained from the next keystore in the list, and so on.

You can use the public/private key pairs and keystores to perform the following operations with tokens:

Sign a token
: The first keystore in the array is the current keystore; use its key_signing key to sign tokens.

Verify a token's signature
: To verify a token's signature, start with the current keystore (the first in the array). If the token doesn't match the key_verify key, move to the older keystores and compare the token with the key_verify value in each.

Add key pairs
: When you create a new key pair, add the keys to a separate keystore, and then add that keystore's URL to the end of the token's keystore array. The first keystore in the array is the "current" keystore, and subsequent keystores in the array are used in turn.

Revoke key pairs
: If you suspect that a token is compromised, you can revoke they keys for signing and verifying it. To revoke a key pair, delete the corresponding keystore from the token's keystore array. Removing a keystore removes the keys that were used for signing and verifying tokens, and invalidates all of the tokens that were issued with that key pair.
: Attention: You must always retain at least one key pair for signing and verifying tokens.

Rotate through keystores to periodically change the key pairs in use
: To rotate through key pairs for a token, configure at least two keystores for the token. Specify the "current" keystore first in the array, followed by the "next" keystores. Make sure that the each keystore's lifetime overlaps that of the next keystore so that keys from the current keystore don't expire before the new key pair takes effect.
: Before you configure the lifetime for a keystore, you can refer to the Onboarding section of the Cloud Settings page to quickly see the lifetime that is configured for each type of token. Then make sure you specify enough keystores, with long enough lifetimes, to span each token's lifetime. For example, if the temporary_token lives for 72 hours and the key used for signing it lives for 24 hours, you need to provide at least 3 sets of keys to span the token's lifetime:
:
: temporary_token: [keystore1, keystore2, keystore3]

- **Configuring public/private key pairs for tokens**
  Configure public/private key pairs for signing and verifying tokens in your API Connect deployment.

Configuring public/private key pairs for tokens

Configure public/private key pairs for signing and verifying tokens in your API Connect deployment.

About this task

By default, an API Connect deployment receives one public/private key pair, which is used repeatedly. The public/private key pair is generated for you the first time you start API Connect after installing or upgrading it. The keys are stored in a keystore object. You can add and revoke keys, and configure a rotation through keys for enhanced security.

You can configure key pairs for tokens in the Cloud Manager user interface, or by using the Toolkit CLI.

Using the Cloud Manager UI to configure public/private key pairs

Use the Cloud Manager user interface to configure key pairs for signing and verifying tokens.

About this task

Manage Keystore assignment and Keystore history for tokens

Procedure

1. In the Cloud Manager, click .
2. In the Settings navigation list, click Signed Token.

The Signed Token page displays the list of supported tokens for signing.

3. Review the current token settings:
   - Click Payload to display the payload code for the set of tokens.
   - Click History log next to a token to view its previous keystore assignments (this history never includes the current keystore assignment). The most recent assignment displays at the top of the list. You can remove any keystore assignment from the history by clicking .
4. To add or change a keystore assignment for a token, complete the following steps:
   a. On the Signed Token page, click Edit.
   b. On the Edit signed token page, select a keystore for the token you want to modify.
   c. Click Save to save your changes and update the keystore history.
   Changes take effect immediately.

   The previously selected keystore is added to the history for the token that you just updated. The history never includes the current keystore assignment.

Using the Toolkit CLI to configure public/private key pairs

Use the Toolkit CLI to configure key pairs for signing and verifying tokens.

About this task

Use the following properties to the keystore URLs that contain the public/private key pair for each type of token. For each setting, the list of keystores is an array of strings, with each string representing the complete URL of a keystore. The first keystore in the array (*keystore_url_0*) is the one that is currently in use.

- access_token:

  `access_token_keystore_urls: [`*`keystore_url_0, keystore_url_n`*`]`

- id_token:

  `id_token_keystore_urls: [`*`keystore_url_0, keystore_url_n`*`]`

- temporary_token:

  `temporary_token_keystore_urls: [`*`keystore_url_0, keystore_url_n`*`]`

The keystore URLs can be lengthy. You can avoid errors by writing the settings in a file and uploading that file. Format the settings as a .yaml file (you can choose the file name) and upload the file using the toolkit CLI. The following example configures a different keystore for each type of token:

```
access_token_keystore_urls:
  - >-
    https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/de5298dd-a00b-45a0-9d08-96c5d93e1273
id_token_keystore_urls:
  - >-
    https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/85a21745-8ac3-499d-929a-2d017bade815
temporary_token_keystore_urls:
  - >-
    https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/63d6462f-c93d-439b-b422-0e604381e97a
```

Procedure

1. Create a YAML file with the keystore settings for each type of token as shown in the example.
   For information on using input files with the toolkit CLI, see Reading input from the command line.

2. Run the following command to log in to a management server as a member of the cloud administration organization:

   `apic login --server `*`mgmt_endpoint_url`***` --username `***`user_id`***` --password `***`password`***` --realm admin/`***`identity_provider`**

   Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

   You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   `apic identity-providers:list --scope admin --server `*`mgmt_endpoint_url`***` --fields title,realm`**

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **`default-idp-1`**.
   For more information on logging in, see Logging in to a management server.

3. Upload the YAML file with the new settings by running the following command:

   `apic cloud-settings:update --server `*`mgmt_endpoint_url my_token_keystore_settings`***`.yaml`**

4. Run the following command to log out of the management server:

   `apic logout --server `*`mgmt_endpoint_url`**

Configuring API governance in the Cloud Manager

How to add API governance rulesets in the Cloud Manager, to validate and enforce organizational governance policies and best practices across your API development process.

Before you begin

Before you can create API governance rulesets, the API governance optional add-on must be enabled on your management subsystem by your system administrator. See Enabling API governance on Kubernetes, and Enabling API governance on VMware for more information. If API governance is enabled in your deployment, the API governance resource is displayed on the Resources page in the Cloud Manager.

The API governance service is available to all user roles.

About this task

API governance is an optional add-on to IBM® API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process. You configure API governance by creating one or more custom rulesets that contain a collection of rules that can then be used to check Swagger, OpenAPI, and AsyncAPI documents. API governance contains the following types of rulesets:

- Global rulesets - these are custom rulesets that you can keep private, or you can make available to some or all of your provider organizations.
- Default rulesets - these are default rulesets that are built-in to API Connect, and contain pre-configured rules that are available to all of your provider organizations, and cannot be edited.

API governance in IBM API Connect is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

Note:

- API governance in IBM API Connect only supports the creation of custom rulesets that contain rules that use the built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions. The use of custom functions, for example rules that use functions that you have created yourself in JavaScript files, is not supported.
- Some of the Spectral rules within the Default rulesets contain the property `recommended: false`, which means that those rules are ignored during validation. However, if you create a new ruleset from one of these rulesets by using the Save as new ruleset option, the `recommended` property isn't transferred to the new ruleset. Therefore all of the rules will be used in the validation, unless you delete those rules from the ruleset. The Spectral ruleset names are prefixed by spectral-.
- You can also configure API governance rulesets directly in a provider organization. For more information, see Configuring API governance in the API Manager.

You can configure API governance rulesets by using the following methods:

- Create a new ruleset using the UI
- Import a ruleset
- Create a ruleset using the CLI

Procedure

- To create a new ruleset using the Cloud Manager UI, complete the following steps.
  1. In the Cloud Manager, click Resources.
  2. In the Resources navigation menu, select API governance.
  3. In the Global rulesets section, click Add > Create from scratch.
     The Create ruleset wizard opens.
  4. Provide the following Ruleset info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the ruleset. This name is displayed in the list of global rulesets.	String
Name	Yes	An auto-generated, sluggified, string that is based on the title. It is not editable.	String
Version	Yes	The version number defaults to 1.0.0, but can be edited. You can have rulesets with the same name, but with different version numbers. The version number must be in the format `major.minor.patch`.	String
Description	No	An optional description of the ruleset.	String

  5. Click Next, and add an initial rule to your ruleset.
  6. Provide the following Rule info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the rule.	String
Name	Yes	A short machine name for the rule. Can contain only alpha-numeric characters, underscores (_), and hyphens (-).	String
Description	Yes	A description of the rule.	String
Message	No	Provide a message to help users understand what the goal of the rule is. If no message is provided, the value of the Description property is used for the message output of the validation scan.	String
Severity	Yes	Select a severity level from the following options: • error • warn • info • hint • off error is selected by default.	String

  7. In the Given section, specify one or more values for the parts of the API document to target. To add more values, click Add. Values must be written in JSONPath.

8. In the Then section, specify the function type and options that will be used to evaluate the target values in the API document. Write this section in YAML syntax.
   In the following example, for a Given value of **$** (which means root level of the document), the Then section uses the Spectral core **truthy** function to check that the **info.contact** property value is not **false**, **""**, **0**, **null**, or **undefined**.

   ```
   - field: info.contact
     function: truthy
   ```

   The Then section can also contain a list of functions to be applied to the Given part of the document. In the following example, for a Given value of **$.info.version** (which refers to the **version** property inside the **info** property at the root level of the document), the Then section uses both the **truthy** function, and the Spectral core **pattern** function that checks that the **info.value** matches the regex expression that is given by **functionOptions.match**.

   ```
   - function: truthy
   - function: pattern
     functionOptions:
       match: "^[0-9]+.[0-9]+.[0-9]+(-[a-z0-9+.-]+)?"
   ```

   For a complete list of the Spectral core functions that you can use in your custom rules, along with examples of these functions, see https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.
9. Click Create to create your draft ruleset.
   Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon </>. To return to the design form view, click the Form icon .
10. You now have the following options:
    - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon ⊕ alongside Rules in the navigation pane. Remember to click Save when you finish editing.
    - If you don't want to edit your ruleset further now, click API governance in the breadcrumb trail to return to the API governance overview page.

- To import an existing ruleset, complete the following steps. Remember that the rules in your imported ruleset can contain only built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.
  1. In the Cloud Manager, click Resources.
  2. In the Resources navigation menu, select API governance.
  3. In the Global rulesets section, click Add > Import.
     The Import ruleset wizard opens.
  4. Drag a file into the Upload file box, or click in the Upload file box to select a file to upload. The maximum file size is 100 kb, and the supported file types are YAML, YML, and JSON.
  5. Click Next.
  6. Edit the Ruleset info details as required, and click Import.
     Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon </>. To return to the design form view, click the Form icon .
  7. You now have the following options:
     - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon ⊕ alongside Rules in the navigation pane. Remember to click Save when you finish editing.
     - If you don't want to edit your ruleset further now, click API governance in the breadcrumb trail to return to the API governance overview page.
- To create a ruleset using the API Connect toolkit CLI, complete the following steps.
  1. Create a JSON file containing the new ruleset.
     The following example shows the contents of a Spectral Ruleset file for API Manager:

     ```
     {
       "name": "custom-ruleset",
       "title": "custom-ruleset",
       "description": "Info validation",
       "ruleset_type": "global-custom",
       "ruleset_version": "1.0.0",
       "rules": [
         {
           "name": "contact",
           "severity": "error",
           "formats": [
             "oas2",
             "oas3"
           ],
           "given": [
             "$"
           ],
           "description": "The info object must contain either a contact email or contact url",
           "then": [{
             "field": "info.contact",
             "function": "truthy"
           }]
         },
         {
           "name": "description",
           "severity": "error",
           "formats": [
             "oas2",
             "oas3"
           ],
           "given": [
             "$"
           ],
           "description": "The info object must contain a description",
           "then": [{
             "field": "info.description",
             "function": "truthy"
           }]
     ```

```
    }]
}
```

2. Log in to the toolkit as an Admin.
3. Run the `rulesets:create` toolkit command in `governance` mode:

   ```
   apic -m governance rulesets:create --org <target_org> --server <server_url> RULESET_FILE
   ```

   where:
   - `<target_org>` is the name of the organization that owns the new ruleset.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `RULESET_FILE` is the path and filename of the JSON file that contains the ruleset.

Results

Your draft ruleset is now listed in the table of Global rulesets.

What to do next

You can validate the ruleset against an API document by clicking Validate, selecting the rules that you want to validate, and uploading an API file. The results of the validation are displayed in a scorecard.

When you finish editing your ruleset, you can publish it to your provider organizations. Click the options menu icon ⋮ either next to the ruleset that you want to publish, or from within the ruleset viewer. Select Publish, and then click Publish again to confirm. The status of your ruleset changes from Draft to Published, and can now be used by API developers to validate their API documents. For more information, see Validating an API document by using API governance.

Note:

- After a ruleset is published, the ruleset information and rules can no longer be edited. If you need to update this information, you must create a new version by clicking the options menu icon ⋮ either next to the ruleset that you want to edit, or from within the ruleset viewer, and selecting Save as new ruleset.
- By default, rulesets are published to all of your provider organizations. You must edit the visibility after publishing, if you want to change which provider organizations can use your rulesets.

If you want to change the visibility of your ruleset, click the options menu icon ⋮ either next to the ruleset that you want to edit, or from within the ruleset viewer. Then click Edit visibility, and select from the following visibility options:

- Private - the ruleset is not visible and cannot be used by any provider organization.
- Public - the ruleset is visible and can be used by all provider organizations.
- Custom - the ruleset is visible to and can be used by only the provider organizations that are designated by you.

Click Save to confirm your visibility option.

- **The API governance ruleset lifecycle in the Cloud Manager**
  When you manage your custom API governance rulesets in the Cloud Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.
- **Updating rulesets and rules with the toolkit CLI**
  Use the API Connect toolkit CLI to update a ruleset or individual rules.

The API governance ruleset lifecycle in the Cloud Manager

When you manage your custom API governance rulesets in the Cloud Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.

The following sections describe the various lifecycle states for a custom API governance ruleset.

Note:

- Approval is not required for any of the lifecycle state transitions.
- Default rulesets are built-in to API Connect, and contain pre-configured rules that are available to all of your provider organizations, and cannot be edited. These rulesets are always in the Published state, and their visibility cannot be changed.

Draft

The draft state for a ruleset is when the ruleset is not published, and isn't visible any provider organization. The ruleset can continue to be edited, and its Status is shown as Draft.

Published

When you publish a ruleset, it is made visible to all of your provider organizations, and cannot be changed. The ruleset Status is shown as Published, and the ruleset visibility is shown as Public. If you want to change which provider organizations can use your rulesets, you must edit the visibility after publishing. You can select from the following visibility options:

- Private - the ruleset is not visible and cannot be used by any provider organization.
- Public - the ruleset is visible and can be used by all provider organizations.
- Custom - the ruleset is visible to and can be used by only the provider organizations that are designated by you.

Any other changes require a new version of the ruleset to be created by using the Save as new ruleset option.

Archived

When you archive a ruleset, it becomes a ready-only, fixed version of the ruleset that cannot be used for validation by any provider organization. The ruleset Status is shown as Archived.
Note: If you cannot see your Archived ruleset, ensure that the Edit filters option on the ruleset table is set to include Archived.
You can restore archived rulesets by using the Restore option, after which the Status returns to Published.

Also, you can delete Archived rulesets by using the Delete option.

Updating rulesets and rules with the toolkit CLI

Use the API Connect toolkit CLI to update a ruleset or individual rules.

Updating a ruleset

1. Create a JSON file that defines the updated ruleset.
   The following example shows an updated ruleset:

   ```
   {
       "title": "custom-ruleset-2",
       "description": "short ruleset updated",
       "ruleset_type": "custom"
   }
   ```

   where:
   - `title` is updated to a new title for the ruleset.
   - `description` is updated to a new description for the ruleset.
   - `ruleset_type` is updated to be custom for the ruleset.
2. Log in to the toolkit as an Admin or as the owner of the provider organization that owns the ruleset.
3. Run the `rulesets:update` toolkit command in `governance` mode:

   ```
   apic -m governance rulesets:update --org <target_org> --server <server_url> RULESET RULESET_FILE
   ```

   where:
   - `<target_org>` is the name of the organization that owns the ruleset.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `RULESET_FILE` is the path and filename of the JSON file that contains the updated ruleset.
   - `RULESET` is the name or the unique ID of the updated ruleset.
     To determine the ID of a ruleset, run the following command:

     ```
     apic -m governance rulesets:list --org <target_org> --server <server_url>
     ```

Updating a rule

1. Create a JSON file that defines the updated rule.
   The following example shows an updated rule in a file called:

   ```
   {
     "description": "Updated the rule",
     "message": "Schema of type array must specify maxItems and minItems. {{path}} {{error}}",
     "formats": [
       "oas3"
     ],
     "severity": "warn",
     "recommended": true,
     "given": [
       "$..[?(@.type==\"array\")]"
     ]
   }
   ```

   where:
   - `description` is updated to a new title for the rule
   - `message` is updated to a new message for the rule
   - `formats` array is replaced to have only the format oas3 for the rule
   - `severity` is updated to the warn value for the rule
   - `recommended` is updated to have a new value for the rule
   - `given` array is replaced to have new values for the rule
2. Log in to the toolkit as an Admin or as the owner of the provider organization that owns the rule.
3. Run the `rules:update` toolkit command in `governance` mode.
   There are two ways to specify the updated rule in the command, depending on whether you provide the rule name and version, or the rule ID:

   Specify the rule name and version in the update command

   ```
   apic -m governance rules:update --org <target_org> --server <server_url> --ruleset <ruleset_name or ruleset_id>
   NAME:VERSION RULE_FILE
   ```

   where:
   - `<target_org>` is the name of the organization that owns the rule.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `<ruleset_name or ruleset_id>` is the name or the unique ID of the ruleset to which the updated rule belongs.

- **NAME** is the name of the updated rule.
- **VERSION** is the version of the updated rule; increase the version when you update the rule, using the **major.minor.patch** format as in "1.0.1".
- **RULE_FILE** is the path and filename of the JSON file that contains the updated rule.

Specify the rule ID in the update command

Instead of providing the rule's name and version, you can provide its unique ID instead by running the following command:

```
apic -m governance rules:update --org <target_org> --server <server_url> --ruleset <ruleset_name or ruleset_id> --id <rule_id> RULE_FILE
```

where:

- ***<target_org>*** is the name of the organization that owns the rule.
- ***<server_url>*** is the management server URL that you specified when you logged in to the toolkit.
- ***<ruleset_name or ruleset_id>*** is the name or the unique ID of the ruleset to which the update rule belongs.
- **RULE_FILE** is the path and filename of the JSON file that contains the updated rule.
- ***<rule_id>*** is the value of the updated rule's unique ID.
  To determine the ID of a rule, run the following command:

  ```
  apic -m governance rules:list --org <target_org> --server <server_url> --ruleset <ruleset_name> RULE_NAME
  ```

Administering provider organizations

Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.

About this task

Perform these tasks to manage your provider organizations:

- **Creating a provider organization**
  For developers to publish APIs, they must be a member of a provider organization. The first step is to create a provider organization and specify an organization owner. Then members can be added to the provider organization and can start publishing APIs.
- **Editing a provider organization**
  You can edit the title of a provider organization, and also transfer ownership to a new organization owner.
- **Deleting a provider organization**
  You can delete a provider organization. All Catalogs and Spaces are also removed.
- **Viewing current provider organizations**
  View the list of current provider organizations for your cloud, including organization title, owner's name and email address, and status. From the list screen, you can add new provider organizations and owners, edit and delete provider organizations, send messages, and change owners.
- **Sending messages to provider organization owners**
  You can send an email message to the owner of a provider organization. You can also style the email to match your business theme.

Related tasks

- Creating a provider organization
- Editing a provider organization
- Deleting a provider organization
- Viewing current provider organizations

Creating a provider organization

For developers to publish APIs, they must be a member of a provider organization. The first step is to create a provider organization and specify an organization owner. Then members can be added to the provider organization and can start publishing APIs.

Before you begin

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

You must also complete the following tasks before beginning:

- Configuring an email server for notifications
- Setting up notifications

About this task

Note that an email server must be configured and an active email server must be selected before a provider organization account can be created.

There are two options for creating a provider organization account, as follows:

- Option 1: Create a provider organization and send an email invitation to a new user to register and become the organization owner. Choose the Add > Invite organization owner option.

- Option 2: Create a provider organization and specify the user who will be the organization owner. Choose the Add > Create organization option.

Procedure

- **Option 1:** To create a provider organization and invite a new user to register as the owner, complete the following steps:
  1. In the Cloud Manager, click Provider Organizations.
  2. Click Add > Invite organization owner
  3. Enter a valid email address and click Invite. An email containing an activation link is sent to the email address inviting the person to register. The link opens the registration form. Alternately, you can copy and paste the activation link into an email; click Get Activation Link and click Copy in the pop up window. Note that the email server requires the Authenticate User and Authenticate Password values in order to send invitations. See Configuring an email server for notifications.

     The new provider organization is placed in Pending status, and is changed to Enabled status after the owner completes the registration form to activate their account. The owner can then log in to the API Manager user interface with the API Connect user name that they specified during account activation.

     Note: If you use this option with a Local User Registry, and the user already exists in the registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. This stipulation includes users that were previously provider organization owners but whose organization was deleted.
- **Option 2:** To create a provider organization and specify the user who will be the organization owner, complete the followings steps:
  1. In the Cloud Manager, click Provider Organizations.
  2. Click Add > Create organization.
  3. In the Title field, enter a title for the provider organization. If desired, the title can be edited after the provider organization is created.
  4. The internal Name is automatically generated for you by the system. The Name field contains the string that is included in the organization segment of the URL for API calls. For more information, see Calling an API.
     Tip: The Name field is auto-generated to ensure its validity in the URL.
     The value in the Name field is also used to identify the provider organization in developer toolkit CLI commands. To view the CLI commands to manage provider organizations, see apic orgs.

  5. Select the user registry for the provider organization owner.
     The remaining procedure varies according to the type of the selected user registry, as follows:
     - Local User Registry
       - Select whether the user is an Existing user or a New User.
         - For an existing user, complete the following steps:
           - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
           - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.
         - For a new user, complete the following steps:
           - Enter a unique user name for the new user.
           - Supply an email address, name details, and a password.
           - Click Create. The user account is created, and the provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface with the specified user name and password; the user interface open in the new provider organization.
     - LDAP
       - Enter the name of a user that exists in the selected user registry.
       - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface with their LDAP user name. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.
     - Authentication URL and OIDC
       - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must use the invitation mechanism described in Option 1.
       - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.

What to do next

For details of how an invited organization owner activates their account see Activating your API Manager user account. For details of how to log in to the API Manager user interface, see Accessing the API Manager user interface.

Editing a provider organization

You can edit the title of a provider organization, and also transfer ownership to a new organization owner.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

About this task

If you transfer ownership, the new organization owner can be an existing user, or you can create a new user. When the ownership changes, the new owner is assigned administration privileges for the organization, and the previous owner has their administration privileges removed. Optionally, you can also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner. If required, you can restore the privileges to the previous owner as described in Administering members and roles.

Procedure

To update a provider organization, complete the following tasks:

1. In the Cloud Manager, click Provider Organizations.
2. Click the name of the provider organization that you want to update.
3. To change the title, enter a new title in the Title field, then click Save.
4. To transfer ownership, select the user registry for the provider organization owner you want to transfer ownership to.
   The remaining procedure varies according to the type of the selected user registry, as follows:
   - Local User Registry
     - Select whether the user is an Existing user or a New User.
       - For an existing user, complete the following steps:
         - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
         - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
         - Click Save.
       - For a new user, complete the following steps:
         - Enter a unique user name for the new user.
         - Supply an email address, name details, and a password.
         - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
         - Click Save.
   - LDAP
     - Enter the name of a user that exists in the selected user registry.
     - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
     - Click Save.
   - Authentication URL and OIDC
     - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must ensure they have been invited to the organization first.
     - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
     - Click Save.

Deleting a provider organization

You can delete a provider organization. All Catalogs and Spaces are also removed.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

About this task

The user account for the owner of the deleted provider organization remains in the associated API Connect user registry. The user can still log in to the API Manager user interface; if they are a member of one or more other provider organizations then those organizations are accessible, otherwise only information links are available, with no access to view or manage any resources.
The user can be added again as a provider organization owner at a later time; see Creating a provider organization.

Procedure

To delete a provider organization, complete the following tasks:

1. In the Cloud Manager, click Provider Organizations.
2. Navigate to the provider organization that you want to delete in the list and select Delete from the Actions menu.
3. Confirm that you want to delete the provider organization.
   The provider organization is deleted and removed from the Provider Organizations list.

Results

The provider organization, and its Catalogs and Spaces, are deleted.

Viewing current provider organizations

View the list of current provider organizations for your cloud, including organization title, owner's name and email address, and status. From the list screen, you can add new provider organizations and owners, edit and delete provider organizations, send messages, and change owners.

Before you begin

You must also complete the following tasks before beginning:

- Configuring an email server for notifications
- Setting up notifications
- Creating a provider organization

This task can be completed by users who are assigned one of the following roles:

- All roles
- Custom role with the `Provider-org:Manage` or the `Provider-org:View` permissions

About this task

All roles can view the list of provider organizations. Use the provider organization list screen to manage your provider organizations.

Procedure

1. In the Cloud Manager, click Provider Organizations.
2. View the list of provider organizations and their status. The statuses are as follows:
   - **Pending**: A provider organization is in `Pending` status until the invited owner successfully completes the registration form.
   - **Active**: A provider organization is in `Active` status if the owner is an existing user with an account in a user registry.
3. The Actions menu performs different functions depending on the organization's status.Use the Actions menu to edit or delete an Active organization. For Pending organizations, use the Actions menu to delete the organization and to resend the invitation to the owner
   - For an Enabled organization, you can Edit or Delete the organization.
   - For a Pending organization, you can Resend the Invitation, or Delete the request.
4. Add new provider organizations using the Add menu. See Creating a provider organization

Related tasks

- Creating a provider organization
- Editing a provider organization
- Deleting a provider organization

Sending messages to provider organization owners

You can send an email message to the owner of a provider organization. You can also style the email to match your business theme.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

Note: You can also send email messages by using the developer toolkit CLI, or by using the API Connect REST APIs. See Cloud administration commands, or API Connect REST APIs, for more information.

Procedure

To send a message, complete the following steps:

1. In the Cloud Manager, click Provider Organizations.
2. Click the options icon ⋮ alongside the provider organization that you want to work with, then click Message owner.
   The Send message window opens, and the email address of the provider organization owner is displayed as the recipient.
3. Enter the subject of the message in the Subject field.
4. Select the Content type that you want to use for the entering the content of the message, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
   For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 1. List of allowed HTML tags and their attributes

HTML tag	Attribute
`<a>`	`"class", "href", "hreflang", "style"`
`<em>`	`"class", "style"`

HTML tag	Attribute
`<strong>`	`"class", "style"`
`<cite>`	`"class", "style"`
`<blockquote>`	`"class", "cite", "style"`
`<code>`	`"class", "style"`
`<ul>`	`"class", "type", "style"`
`<ol>`	`"class", "start", "type", "style"`
`<li>`	`"class", "style"`
`<dl>`	`"class", "style"`
`<dt>`	`"class", "style"`
`<dd>`	`"class", "style"`
`<h1>`	`"class", "id", "style"`
`<h2>`	`"class", "id", "style"`
`<h3>`	`"class", "id", "style"`
`<h4>`	`"class", "id", "style"`
`<h5>`	`"class", "id", "style"`
`<h6>`	`"class", "id", "style"`
`<p>`	`"class", "style"`
`<div>`	`"class", "style"`
` `	`"class", "style"`
`<span>`	`"class", "style"`
`<img>`	`"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"`
`<table>`	`"class", "id", "style"`
`<tr>`	`"class", "id", "style"`
`<td>`	`"class", "id", "style"`

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
Images can be used by adding a **`<img src="https://path/to/image.png"/>`** tag in the template. The **`src`** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

5. Enter the content of the message.
6. Click Send.

Administering members and roles

Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.

About this task

To manage roles, add members, and assign roles to member, perform the following tasks:

- **Creating roles in the admin organization**
  Cloud Manager ships with a set of pre-configured roles. As the Cloud Manager administrator, you can create custom roles, add permissions, and assign the roles to members of the Admin organization.
- **Editing roles in the admin organization**
  As the Cloud Manager administrator, you can edit the roles in the Admin Organization. Both pre-configured roles and custom roles may be edited, except for the Owner, Viewer, and Member roles. The Owner, Viewer, and Member roles may not be edited or deleted.
- **Configuring LDAP group mappings on Cloud Manager user roles**
  As a Cloud Manager administrator, you can configure LDAP group mapping on API Connect roles in the Admin organization by using the developer toolkit CLI.
- **Deleting roles in the admin organization**
  Roles can be deleted (except for the Owner, Viewer, and Member roles) from the Admin organization. If there are members assigned to a role that has been deleted, they will be assigned the Viewer role.
- **Viewing members and roles**
  Use the Members page to view the current members of the Admin organization and manage the role assignments.
- **Adding members to the admin organization**
  As the Cloud Manager administrator, you can add and remove members of the Admin organization and assign roles to them. Once removed, a user can no longer access the Cloud Manager.
- **Assigning roles to members**
  As the Cloud Manager administrator, you manage the roles that are assigned to members. A member's role determines the tasks they are authorized to perform in Cloud Manager.
- **Deleting a member**
  As the Cloud Manager administrator, you can delete members of the API Connect cloud administration organization. Once deleted, the user and associated roles are removed, however the user's account still remains in API Connect.
- **Role Defaults overview**
  Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Creating roles in the admin organization

Cloud Manager ships with a set of pre-configured roles. As the Cloud Manager administrator, you can create custom roles, add permissions, and assign the roles to members of the Admin organization.

About this task

If you are assigned a role that has the `Settings: manage` permission, you can create custom roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.
One of the following roles is required to add custom roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Procedure

Perform the following steps to add custom roles to the Admin Organization:

1. In the Cloud Manager, click Settings.
2. Select Roles.
3. Click Add to add a new role.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see User roles and permissions in the Cloud Manager UI.
6. Save the custom role.

Results

The custom role appears in the list of roles and can be assigned to members.

What to do next

Assign the role to a member in the Members list. See Assigning roles to members

Related tasks

- Editing roles in the admin organization

Editing roles in the admin organization

As the Cloud Manager administrator, you can edit the roles in the Admin Organization. Both pre-configured roles and custom roles may be edited, except for the Owner, Viewer, and Member roles. The Owner, Viewer, and Member roles may not be edited or deleted.

About this task

You can customize the per-configured roles (except for the Owner, Viewer, and Member roles) to reflect your business needs.

If you are assigned a role that has the `Settings: manage` permission, you can edit the roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Following are the edits you can perform for a role:

- Change the title
- Add or delete permissions

Procedure

Perform the following steps to edit roles in the Admin organization:

1. In the Cloud Manager, click Settings.
2. Select Roles.
3. Locate the Role you want to edit, and select Edit from the overflow menu.
4. Enter the desired Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see User roles and permissions in the Cloud Manager UI.
6. Save the updated role.

Results

The Role will be updated with a new name and/or permissions. An updated role will affect the members who are assigned the role. If you change the name of a role, you will have to assign it to the members. If you change the permissions for a role, the way that members use the product may change.

Configuring LDAP group mappings on Cloud Manager user roles

As a Cloud Manager administrator, you can configure LDAP group mapping on API Connect roles in the Admin organization by using the developer toolkit CLI.

Before you begin

You must have an LDAP user registry resource in the Cloud Manager that has the **`external_group_mapping_enabled`** configuration set to **`true`**. See Using the CLI to configure a shared LDAP user registry for information.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Note: The Admin organization roles apply only to Cloud Manager users. If you want to apply LDAP group mapping to API Manager users, see Configuring LDAP group mapping on API Manager user roles. LDAP group mapping cannot be applied to Developer Portal users.

About this task

You can map external LDAP groups to the API Connect preconfigured user roles (except for the Owner and Member roles), as well as to any custom user roles, to reflect your business needs.

Notes:

- After LDAP group mapping is enabled on a role, user onboarding always honors the group mappings.
- Once on-boarded, user membership in API Connect is valid throughout the login period (**`access_token_ttl`**), irrespective of any changes in the external LDAP registry. Membership is updated only on the next login, when the LDAP information is fetched and refreshed.
- One or more API Connect roles can be mapped to one or more LDAP groups, and one or more LDAP groups can be mapped to a role.
- When multiple LDAP groups are mapped to a single role, it means that a user from any one of the LDAP groups can log in to API Connect.
- If a user is removed from the external LDAP user registry, then to ensure quick removal from API Connect you must also delete the user membership in API Connect.

You can configure LDAP group mappings using one of the following methods:

- Using the UI to configure LDAP group mappings
- Using the CLI to configure LDAP group mappings

Using the UI to configure LDAP group mappings

Use the Cloud Manager UI to configure LDAP group mappings.

Procedure

1. Login to the Cloud Manager UI as a user with the appropriate permissions.
2. Click Settings > Roles > Add a new Role or edit existing role .
3. Select the following settings:
   - Enable external group mapping - select to enable external group mapping for this role.
   - LDAP user Registry - LDAP user registry list which has external group mapping enabled. User must select one of the LDAP user registry from this list.
   - LDAP group names - add one or more LDAP group names that you want to map to the user role.
   - User group prefix - add the prefix for the LDAP user group.
   - User group suffix - add the suffix for the LDAP user group.
4. Save your changes.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the Cloud Manager, and automatically be assigned the correct access permissions for their role.

Using the CLI to configure LDAP group mappings

Use the toolkit CLI to configure LDAP group mappings.

About this task

For detailed information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Procedure

Perform the following steps to map external LDAP groups to Cloud Manager user roles.

1. Log in to the management server CLI.
   Before you can update the role configuration, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

where *mgmt_endpoint_url* is the platform API endpoint URL.
You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
For full details of the login command, see Logging in to a management server.

2. Run the following command to get the URL of the LDAP user registry resource in the Cloud Manager that you want to map the user roles to:

```
apic user-registries:get  ldap_user_registry --org admin --server mgmt_endpoint_url --output -
```

where:
- *ldap_user_registry* is the name or ID of your LDAP user registry resource.
- **--org admin** means that the registry details are retrieved from the admin organization.
- *mgmt_endpoint_url* is the platform API endpoint URL.

This command outputs the configuration details of your LDAP user registry, and the **url:** is shown at the end of the list, for example:

```
type: user_registry
api_version: 2.0.0
id: 35e75bad-1d89-4a65-a70f-xxxxxx
name: ldap
title: LDAP
integration_url: >-
  https://server.com/api/cloud/integrations/user-registry/147b5fb1-e88e-41e3-90e9-xxxxxx
registry_type: ldap
user_managed: false
user_registry_managed: false
external_group_mapping_enabled: true
...
url: >-
  https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
```

3. Create a role yaml file that contains the following LDAP group mapping configuration properties:

```
external_group_mapping:
  user_registry_url: https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
  ldap_groups:
    - 'cn=apic-administrators,ou=ibmgroups,o=ibm.com'
    - 'cn=apic-developers,ou=ibmgroups,o=ibm.com'
  user_group_filter_prefix: (&(uniquemember=
  user_group_filter_suffix: ))(objectClass=groupOfUniqueNames))
```

Where:
- **user_registry_url** is the URL of your LDAP user registry resource from Step 2.
- **ldap_groups** is a list of the LDAP group names that you want to map to the user role.
- **user_group_filter_prefix** is the prefix for the LDAP user group.
- **user_group_filter_suffix** is the suffix for the LDAP user group.

4. Run the following command to update the user role with the **external_group_mapping** configuration properties:

```
apic roles:update role_name --scope org --org admin --server mgmt_endpoint_url mapping_properties_file
```

Where:
- *role_name* is the name of the user role that you want to add the LDAP group mapping to.
- **--scope** is the organization scope that you want the update to apply to. For this task, the value must be **org**.
- **--org admin** means that the user role is updated on the admin organization.
- *mgmt_endpoint_url* is the platform API endpoint URL.
- *mapping_properties_file* is the name of your mapping properties file from Step 3, for example **role_mapping_file.yaml**.

If you prefer to enter the configuration properties interactively on the command line, you can substitute the *mapping_properties_file* for a terminating hyphen character **-**, and enter the information manually, followed by pressing **CTRL D** to terminate the input.
If you want to create a custom role that includes LDAP group mapping, you can include the **external_group_mapping** configuration section in the **role_file**, and then create the new role by using the **apic roles:create** command.

For more information about the **apic roles** commands, see **apic roles** in the CLI reference section.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the Cloud Manager, and automatically be assigned the correct access permissions for their role.

Deleting roles in the admin organization

Roles can be deleted (except for the Owner, Viewer, and Member roles) from the Admin organization. If there are members assigned to a role that has been deleted, they will be assigned the Viewer role.

About this task

All custom roles may be deleted. Pre-configured roles can also be deleted, except for the Owner, Viewer, and Member roles. Owner, viewer, and Member role cannot be deleted or edited. Members who are assigned a deleted role are given the most limited role, Viewer, with View-only privileges. These members will need to be assigned a new role if they require any other privileges.

If you are assigned a role that has the `Settings: manage` permission, you can delete roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.
One of the following roles is required to delete custom roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Procedure

Perform the following steps to delete roles in the Admin organization:

1. In the Cloud Manager, click Settings.
2. Select Roles.
3. Locate the Role you want to delete, and select Delete from the overflow menu.
4. Confirm that you want to proceed with deleting the role.

Results

The Role will be deleted. Members who had been assigned the role are given the Viewer role.

Viewing members and roles

Use the Members page to view the current members of the Admin organization and manage the role assignments.

Procedure

To view the members of the Admin organization and their roles in Cloud Manager, follow these steps:

1. In the Cloud Manager, click Members.
2. From the Members list, you can scroll through the list of users to see their current roles and their status.
   - **Pending** - The invitation with the activation link has been sent to the user, but they have not yet completed the registration form.
   - **Enabled** - The user has completed the registration form and is now able to login and access the features associated with their role.

   Note: If your role has the proper permissions, you can assign roles, add, and delete members from this list.

What to do next

- To add members, see Adding members to the admin organization
- To change the roles assigned to members see Assigning roles to members
- To delete a member, see Deleting a member

Adding members to the admin organization

As the Cloud Manager administrator, you can add and remove members of the Admin organization and assign roles to them. Once removed, a user can no longer access the Cloud Manager.

About this task

Membership in the Admin organization is required to use Cloud Manager to view and manage the topology of the API Connect cloud, to set up and manage provider organizations, and to manage other features of the cloud. There are two ways to add a member:

- Invite member - send an email invitation to a new user to register as a member of the Admin organization.
- Add member - specify the user and add them as a member of the Admin organization immediately.

One of the following roles is required to add members:

- Administrator

- Owner

Procedure

- To send an email invitation to a new user to register as a member of the Admin organization, complete the following steps:
  1. In the Cloud Manager, click Members.
     The list of current members for the Admin organization is displayed. You can view the owner of the Admin Organization by expanding View Owners.
  2. Click Add > Invite member.
  3. Enter a valid email address.
  4. Select the roles that you want to assign to the user.
  5. Click Invite. An email containing an activation link is sent to the email address inviting the person to register. The link opens the registration form. Alternately, you can copy and paste the activation link into an email; click Get Activation Link and click Copy in the pop up window.
     Note that the email server requires the Authenticate User and Authenticate Password values in order to send invitations. See Configuring an email server for notifications.

     The user is placed in Pending status, and is changed to Enabled status after they complete the registration form to activate their account. They can then log in to the Cloud Manager user interface with the API Connect user name that they specified during account activation.
     Note: If you use this option with a Local User Registry, and the user already exists in the registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. This stipulation includes users that were previously members but were deleted from the admin organization.
- To specify the user and add them as a member of the Admin organization immediately, complete the following steps:
  1. In the Cloud Manager, click Members.
     The list of current members for the Admin organization is displayed. You can view the owner of the Admin Organization by expanding View Owners.
  2. Click Add > Add member.
  3. Select the required user registry
     The remaining procedure varies according to the type of the selected user registry, as follows:
     - Local User Registry
       - Select whether the user is an Existing user or a New User.
         - For an existing user, complete the following steps:
           - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
           - Select the roles that you want to assign to the user, then click Add. The user is added and their membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.
         - For a new user, complete the following steps:
           - Enter a unique user name for the new user.
           - Supply an email address, name details, and a password.
           - Select the roles that you want to assign to the user, then click Add. The user account is created, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.
     - LDAP
       - Enter the name of a user that exists in the selected user registry.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface with their LDAP user name.
     - Authentication URL and OIDC
       - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.

What to do next

The new member can log in and work in Cloud Manager. The member's authorization is defined by the roles assigned to them.
For instructions on assigning roles, see Assigning roles to members. The list of roles and permissions can be viewed at User roles and permissions in the Cloud Manager UI.

Assigning roles to members

As the Cloud Manager administrator, you manage the roles that are assigned to members. A member's role determines the tasks they are authorized to perform in Cloud Manager.

About this task

Members in the Admin organization use Cloud Manager to view and manage the topology of the Cloud, to set up and manage provider organizations, and to work with other features of the API Connect Cloud. The member's role determines what tasks they are authorized to perform.
When assigning roles, you need to be aware that all members always have a basic set of permissions, which are contained in the **Member** role. The Member role is automatically granted to all members and cannot be removed. For this reason, you do not explicitly assign the Member role. You can grant additional permissions by selecting one or more roles. If additional roles are not assigned, then the user will have only the basic Member role.

One of the following roles is required to assign roles to members:

- Administrator
- Owner

Procedure

Perform the following steps to assign one or more roles to a member:

1. In the Cloud Manager, click Members.
2. The list of current members for the Admin organization is displayed.
3. To change the roles assigned to a member, select the roles by marking the check boxes next to their name. The roles will be updated instantly. The list of roles and permissions can be viewed at User roles and permissions in the Cloud Manager UI

Results

The member will be assigned the permissions for the role(s).

What to do next

The new member can work in Cloud Manager. The member's authorization is defined by the roles assigned to them.

Deleting a member

As the Cloud Manager administrator, you can delete members of the API Connect cloud administration organization. Once deleted, the user and associated roles are removed, however the user's account still remains in API Connect.

About this task

One of the following roles is required to delete a member:

- Administrator
- Owner

Note: The user account of the deleted user remains in the associated API Connect user registry. The user can still log in to the Cloud Manager user interface but only information links are available; there is no access to view or manage any resources.
The user can be added again as a member at a later time; see Adding members to the admin organization.

Procedure

To delete a member of the cloud administration organization, complete the following steps:

1. In the Cloud Manager, click Members.
2. Choose Delete from the overflow menu that is adjacent to the member you want to delete.
3. Confirm the deletion.

Results

The member is deleted and removed from the Members list in Cloud Manager.

Role Defaults overview

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Role Defaults concepts

Role Defaults determine the base roles applied to either Provider or Consumer Organizations. The Role Defaults for the Admin organization are not configurable. Role Defaults help to standardize base roles for all organizations. Roles and permissions may be added or modified in the Role Defaults to customize the base roles as needed. Role Defaults are a "point-in-time" configuration, which effects only new organizations. You can add, delete, or modify roles (except for the Owner, Member, and Viewer roles) in the organization to customize the permissions for each organization.

Rules for editing Role Defaults:

- Edits to Role Defaults are not applied retroactively to existing organizations. Edits apply only to new organizations created after the changes are made.
- Role Defaults apply to all new organizations; roles can then be edited at the organization, catalog, and space level.
- Edits made to roles in an organization do not affect the Role Defaults. Role Defaults are the "parent" and organization roles are the "child". The child inherits from the parent, but changes do not filter up from the organization to the Role Default.

- **Managing role defaults for provider organizations**
  Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.
- **Managing role defaults for consumer organizations**
  Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Related tasks

Managing role defaults for provider organizations

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

About this task

If you are assigned a role that has permissions to manage Cloud Settings, you can create manage the Role Defaults for the provider organizations.
One of the following roles is required to add roles to the role defaults:

- Administrator
- Topology Administrator
- Owner

Perform the following steps to add or edit roles to the Roles Defaults for provider organizations:

Procedure

1. In the Cloud Manager, click Settings.
2. Select Role Defaults.
3. Click Add to add a new role.
   a. To edit a role, select Edit from the overflow menu for the role.
   b. To delete a role from the Role Default, select Delete from overflow menu and confirm the deletion. Owner, Member, and Viewer roles cannot be deleted.
   Note: Role deletions apply to new members added after the deletion. If a current member is assigned the role, they will continue to have the permissions connected with the role. You need to manage the deletions for each member in the Members screen.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see User roles and permissions in the Cloud Manager UI.
6. Save the role.

Results

The role appears in the list of roles for the provider organization Role Defaults. It will be included in the roles that can be assigned to members for all new provider organizations. The roles can be edited for individual organizations.

Managing role defaults for consumer organizations

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

About this task

If you are assigned a role that has permissions to manage Cloud Settings, you can create and manage the Role Defaults for consumer organizations.
One of the following roles is required to add roles to the role defaults:

- Administrator
- Topology Administrator
- Owner

Perform the following steps to add or edit roles to the roles defaults for consumer organization:

Procedure

1. In the Cloud Manager, click Settings.

2. Select Role Defaults.
3. Click Add to add a new role.
    a. To edit a role, select Edit from the overflow menu for the role.
    b. To delete a role from the Role Default, select Delete from overflow menu and confirm the deletion. Owner, Member, and Viewer roles cannot be deleted. Note: Role deletions apply to new members added after the deletion. If a current member is assigned the role, they will continue to have the permissions connected with the role. You need to manage the deletions for each member in the Members screen.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see User roles and permissions in the Cloud Manager UI.
6. Save the role.

Results

The role appears in the list of roles for the consumer organization Role Defaults. It will be included in the roles that can be assigned to members for new consumer organizations. The roles can be edited for catalogs, but permissions inherited from the Role Default cannot be deleted. Permissions can be added at the catalog level, but not deleted.

Monitoring the cloud

API Connect generates events to monitor the status of your cloud.

About this task

You can monitor your API Connect cloud and configure destination targets for your analytics data by using the following tasks:

- **Accessing and configuring analytics**
  Monitor the usage and performance of API calls by using the analytics feature to view, filter, sort, and aggregate your API event data.
- **Configuring audit logging to monitor user operations**
  Configure auditing in IBM API Connect to monitor user operations such as who published which product and when.
- **Reviewing a gateway's processing status**
  Review the processing status for the Gateway services that are enabled in your API Connect Catalogs and Spaces.

Accessing and configuring analytics

Monitor the usage and performance of API calls by using the analytics feature to view, filter, sort, and aggregate your API event data.

From the analytics view of the Cloud Manager UI, you can monitor the usage of your published APIs. API events from all catalogs, spaces, and organizations are captured and displayed together in the Cloud Manager analytics view. For more information about the features of the analytics view, see Viewing analytics data in Cloud Manager.

API event records

An API event is logged each time an API operation is invoked on the gateway. The API event record contains information about the API call. When an analytics service is associated with a gateway, all API invocations on that gateway are captured as API event records and sent to the analytics service. The content of the record depends on the logging policy that is set for the operation. For more information about the fields that are displayed in an API event record, see API event record fields.

Analytics configuration options

API Connect offers many configuration options to customize data collection, storage, and retention. For example, you can define filters that refine data to add or remove fields before they are stored. You can choose to offload some, or all, of the data to a third-party storage system. For more information about the analytics configuration options, see Advanced configuration options

Configuring audit logging to monitor user operations

Configure auditing in IBM® API Connect to monitor user operations such as who published which product and when.

Audit logging is useful when you want to monitor the create, read, update, delete, log-in, and log-out activity in your deployment; for example, who made changes, when, and what they changed.

Note: Actions performed by Portal administrators are not captured by the audit feature.

What events are audited?

All create, update, delete, log-in, and log-out operations that are performed by users in the Admin UI, Manager UI, Toolkit, and REST API are captured by this feature. For Portal users, all create, update, and delete operations involving applications are captured.

Beginning in API Connect 10.0.5.3, read operations can also be audited when the **audit_reads** setting is additionally enabled (using the toolkit CLI).

Attention: If you choose to enable auditing of read operations for an HTTP endpoint, be aware of that the response might return large payloads, and might contain sensitive information.
Internal calls and calls between system components are not audited because they are part of the product functionality and are not executed by users.

How are audit events logged?

Audit events are logged by sending the information about operations to one or more endpoints of the following types: HTTP, Syslog UDP, Syslog TCP, or Syslog TLS.

- HTTP endpoints:
  Audit logging messages are sent as HTTP/HTTPS requests and use the payload format defined by the Cloud Auditing Data Federation (CADF). If the endpoint requires authentication, you can configure a header that will be included in the audit logging request. Audit logging requests are issued once only, on the assumption that every endpoint is available to receive the requests. There is no error checking to ensure that requests are received and stored by the endpoints, and failed requests are not re-sent. If you suspect that audit logging requests are not successfully reaching an endpoint, you can check the server logs on the console, where any error messages are recorded.

  There are two modes that control how the auditing is sent to an endpoint: blocking and non-blocking. In non-blocking mode (the default), an audit event is sent to the endpoint and the system does not wait for a response from the endpoint. Non-blocking mode provides the best performance. Blocking mode should be used with caution: when an audit event is sent, the system pauses and waits for a response from the endpoint. Blocking mode has a negative impact on performance.

- Syslog endpoints:
  Audit logging messages are sent as syslog messages. If the endpoint requires mutual TLS, you can configure a TLS profile to send the required client certificates. Audit logging requests are issued once only, on the assumption that every endpoint is available to receive the requests. There is no error checking to ensure that requests are received and stored by the endpoints, and failed requests are not re-sent. If you suspect that audit logging requests are not successfully reaching an endpoint, you can check the server logs on the console, where any error messages are recorded.

  All syslog messages are sent as non-blocking regardless of the auditing mode, since syslog messages are designed to be fire and forget (syslog was originally a UDP protocol, which by its nature does not have any acknowledgment). Blocking is only used for HTTP endpoints.

Note: With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What's included in the audit logging request?

- HTTP endpoints:
  The payload containing the audit logging record includes information about the user who executed the operation, the date and time of the call, the resource affected by the call, the operation performed, and the payload. If you enabled audit logging for read operations, the payload might also contain the properties from the response (based on your configuration settings).

  To see the most recent set of fields that are included in the payload, refer to the OpenAPI schema for the audit logging request in the Provider API, which you can download at https://us-south.functions.cloud.ibm.com/api/v1/web/API%20Connect%20Native_apic-on-prem/default/v10-index.http.

a1be-083ecc699c2c", permission_urls: [<cut>] }
```

- Syslog endpoints:
  The nature of syslog messaging means that the information logged is less structured and shorter than information logged using structured HTTP endpoints. With Syslog, the information is more of a summary.

  The following sample response shows payloads for an audit logging message directed to a syslog endpoint (IDs and users are not real):

```
The user admin:default-idp-1/admin has deleted the resource Org 'alpha (Alpha title)', id 19cf81c7-7cb3-43de-b5e5-
d92cdfb26214 and url https://localhost:3003/api/orgs/19cf81c7-7cb3-43de-b5e5-d92cdfb26214
The user admin:default-idp-1/admin has deleted the resource Gateway Service 'webhook-gw-v5 (Webhook Gateway Service (v5)
title)', id 08b87e25-616d-451e-8766-bad1c7b82a42 and url https://localhost:3003/api/orgs/69c878db-4f11-4c3e-9499-
10daa25f04de/availability-zones/cb2caa3d-d619-4c2e-85f8-709956495a7b/gateway-services/08b87e25-616d-451e-8766-bad1c7b82a42
The user provider:default-idp-2/steve@example.com has created the resource Catalog 'climbon:1.0.1 (The climbon product
description)', id 665036df-28ad-447e-b8de-fe9d6967b66d and url https://localhost:3003/api/catalogs/19cf81c7-7cb3-43de-
b5e5-d92cdfb26214/8641fda7-43f8-4e59-b405-58a4844016c9/products/665036df-28ad-447e-b8de-fe9d6967b66d
The user admin:default-idp-1/admin has read the resource Cloud Setting 'cloud-setting', id settings and url
https://localhost:3003/api/cloud/settings
```

Verifying that the endpoint is receiving audit logging messages

By default, auditing operates in `non_block` mode to ensure best performance. In `non_block` mode, each audit logging message is sent immediately without waiting to ensure that the previous message was received. If you suspect that audit logging messages are not being received by the endpoint, download the server logs from the Kubernetes console and examine the apim microservices file for messages related to the connection state. Review the messages to validate that the connection was successful or to further diagnose issues.

For HTTP endpoints (not available for Syslog endpoints), you can test the connection by issuing a "test-connection" call using either the toolkit or a REST API. A response status of `204` indicates that the call was successful and the endpoint is available. The following example contains the payload from a connection test (IDs and users are not real):

```
{
  "id": "8d8eaaa2-1b46-4dcb-cadf-639d7d1f7f20",
  "typeURI": "http://schemas.dmtf.org/cloud/audit/1.0/event",
  "action": "create",
  "outcome": "success",
  "eventType": "activity",
  "reason": {
    "reasonCode": "200",
    "reasonType": "HTTP"
```

```
  },

      }
    }
  ]
}
```

Tip: To ensure that audit logging messages are not lost due to an unavailable endpoint, verify each endpoint periodically.

- **Configuring the audit settings**
  Use the Cloud Manager UI or the toolkit CLI to enable auditing and configure settings.

Configuring the audit settings

Use the Cloud Manager UI or the toolkit CLI to enable auditing and configure settings.

About this task

The audit feature tracks platform-level changes in API Connect through the use of platform APIs, CLI, and Web UI. For information on tracking run-time API execution, see API Analytics.

You can configure audit settings using either the Cloud Manager UI, or the Toolkit CLI.

Using the Cloud Manager UI to configure audit settings

Use the Cloud Manager user interface to enable auditing of customer API calls.

Before you begin

Configure one or more audit endpoints where logging data can be directed, and validate that every endpoint is available by testing the connection as explained in Configuring audit logging to monitor user operations.

About this task

By default, auditing is disabled. If you enable auditing, the API Connect management node emits audit events as messages and sends them to the endpoint for storage.

Note: Auditing for read operations can only be enabled and configured using the CLI.

Procedure

1. In the Cloud Manager, click Settings > Audit Setting > Edit.
2. Click Enable to enable the audit feature, or Disable to disable it.
3. Select an audit mode:

- Non-blocking - Default value, offers the best performance. Each request is passed immediately without waiting for a response to the previous request. This is susceptible to errors if a request is dependent on the results of an earlier request whose response is not received before the new request is sent.
- Blocking - If you select this mode, expect a degradation in performance. Each request is allowed to finish execution before the next request is sent. This mode results in fewer errors when requests are dependent on the responses of earlier operations, but the delayed requests slow the network.
  Note: Blocking mode is only applied to HTTP endpoints and is ignored for Syslog endpoints.

4. Click Add and select the type of endpoint that you want to add (you must add at least one endpoint).
   Endpoints can be of the following types: HTTP, Syslog UDP, Syslog TCP, or Syslog TLS.

5. In the Endpoints section, fill in the fields to describe the new endpoint:

   HTTP
   - URL - Required, must not be empty. The URL of the server where audit logging messages will be sent.
     If you previously saved the audit settings with an empty URL and experienced problems, you can edit the URL to correct it.
   - TLS client profile - Optional. The URL of the server where the endpoint's TLS client profile is stored.
   - Header name and Header value - Optional. Multiple headers are allowed (click Add to add another header). For each header, specify the header name and the header value.

   Syslog UDP
   - Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com.
     Do not include the **`syslog://`** protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.
   - Port - Optional. The port number where audit logging messages should be directed.

   Syslog TCP
   - Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com.
     Do not include the **`syslog://`** protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.
   - Port - Optional. The port number where audit logging messages should be directed.

   Syslog TLS
   - Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com.
     Do not include the **`syslog://`** protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.
   - Port - Optional. The port number where audit logging messages should be directed.
   - TLS client profile - Optional. The URL of the server where the endpoint's TLS client profile is stored.

6. Verify that you can reach the endpoint by clicking Test.
7. To specify another endpoint, click Add at the beginning of the "Endpoints" section.
8. When you finish adding endpoints, click Save to save your settings.

Results

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What to do next

If you suspect that audit logging messages are not being received by the endpoint, see Verifying that the endpoint is receiving audit logging messages for information on validating the connection.

Using the CLI to configure audit settings

Use the IBM API Connect toolkit CLI to enable auditing of API calls.

Before you begin

Configure one or more audit endpoints where logging data can be directed, and validate that every endpoint is available by testing the connection as explained in Configuring audit logging to monitor user operations.

About this task

By default, auditing is disabled. If you enable auditing, the API Connect management node emits audit events as messages and sends them to the endpoint for storage.

Use the following **`audit_setting`** options to enable auditing with the CLI toolkit:

- **`enable`** - Boolean, defaults to **`false`** (no audit). Set to **`true`** if you want to enable auditing.
- **`mode`** - Enumerated, defaults to **`non_block`**. The audit mode determines how audit requests are timed when they are sent to the endpoint:
  - **`non_block`** - Default value, offers the best performance. Each request is passed immediately without waiting for a response to the previous request. This is susceptible to errors if a request is dependent on the results of an earlier request whose response is not received before the new request is sent.
  - **`block`** - If you select this mode, expect a degradation in performance. Each request is allowed to finish execution before the next request is sent. This mode results in fewer errors when requests are dependent on the responses of earlier operations, but the delayed requests slow the network.
    Note: Block mode is only applied to HTTP endpoints and is ignored for Syslog endpoints.
- **`audit_reads`** - Use this setting to enable auditing of read operations:
  - **`enable`** - Boolean, defaults to **`false`** and no audit events are sent to the endpoint for read operations. Set to **`true`** if you want to enable audit logging for read operations.
  - **`response_data_to_http_endpoints`** - Configure additional settings for HTTP endpoints only (the settings do not apply to Syslog endpoints).
    - **`enable`** - Boolean, defaults to **`false`** and audit events for GET operations are sent to the HTTP endpoint with no response data in the event. Set to **`true`** if you want to include the response data.
      Attention: If you choose to include the response data, be aware that the response might return large payloads, and might contain sensitive information.

- **`list_results_limit`** - Integer, must be 0 or larger. Use this setting to specify the maximum number of results of **`GET list`** operations to include in the audit message (default is 0 results).

  If **`audit_reads`** is enabled, then the audit message for a **`GET`** of *a single object* (for example, **`GET /orgs/admin`**) always includes all of the properties of the response object.

  If the **`list_results_limit`** is set to 0, then the audit message for a **`GET`** to *list objects* (for example, **`GET /orgs`**) does not include any objects from the GET response. If you set the **`list_results_limit`** to a value greater than 0, then the audit message includes all properties from the first **`list_results_limit`** number of objects from the **`GET /orgs`** response.

- **`endpoints`** - Array of strings. You must specify at least one endpoint where the audit logging messages are sent. Endpoints can be of the following types: HTTP, Syslog UDP, Syslog TCP, or Syslog TLS.
  For HTTP and Syslog TLS endpoints, you can optionally include a TLS client profile URL. For HTTP endpoints, you can additionally include one or more optional headers. For example, if the endpoint requires an authorization header, you can include it in the endpoint setting.

  - **`endpoint_type`** - String. Required. Allowed values are: **`http`**, **`syslog_udp`**, **`syslog_tcp`** or **`syslog_tls`**.
  - **`endpoint`** - String. Required, must not be empty or blank. The URL of the server where audit logging messages will be sent. Include the protocol (**`http://`** or **`syslog://`**) and the port, if applicable. For example, **`syslog://<hostname>:<port>`**.
  - **`tls_client_profile_url`** - String. Optional; supported only for HTTP and Syslog TLS endpoints. The URL of the server where the endpoint's TLS client profile is stored.
  - **`headers`** - String. Optional; supported only for HTTP endpoints. Multiple headers are allowed. For each header, specify the header name and the header value using the format shown in the example.

The endpoint setting can be lengthy, so uploading the settings in a file helps to avoid errors. Format the settings as a .yaml file (you can choose the file name) and upload the file using the toolkit CLI. The following example enables auditing in non-blocking mode with multiple endpoints to demonstrate how the settings should be formatted.

```
audit_setting:
  enabled: true
  mode: non_block
  audit_reads:
    enabled: true
    response_data_to_http_endpoints:
      enabled: true
      list_results_limit: 0
  endpoints:
    - endpoint_type: syslog_udp
      endpoint:
        endpoint: syslog://syslog-audit-endpoint.example_1.com:514
    - endpoint_type: syslog_tls
      endpoint:
        endpoint: syslog://syslog-tls-audit-endpoint.example_1.com:1601
        tls_client_profile_url: https://security.tls_example.com/api/orgs/d8eac736-b4e2-3aa6-c7ff-978a4cd19d0b/tls-client-
profiles/19d0f087-b4e2-3aa6-926b-9f6d51d028c3
    - endpoint_type: http
      endpoint:
        endpoint: https://mutt-audit-endpoint.example_1.com/auditing
    - endpoint_type: http
      endpoint:
        endpoint: https://auditing-endpoint.example_1.com/inputs/64e38c02-acd9-6530-76f8-dd0f336d7b11
        tls_client_profile_url: https://security.tls_example.com/api/orgs/d8eac736-b4e2-3aa6-c7ff-978a4cd19d0b/tls-client-
profiles/19d0f087-b4e2-3aa6-926b-9f6d51d028c3
      headers:
        authorization: Basic c3Bvb246c2ltb25rYXRpZXVtYQ==
    - endpoint_type: http
      endpoint:
        endpoint: https://auditing-endpoint.example_2.com/inputs/64e38c02-acd9-6530-76f8-dd0f336d7b11
      headers:
        authorization: Basic c3Bvb246c2ltb24=
        x-header: ForYourEyeOnly
```

Procedure

1. Create a YAML file with the audit settings as shown in the example.
   For information on using input files with the toolkit CLI, see Reading input from the command line.

2. Run the following command to log in to a management server as a member of the cloud administration organization:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

   You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at

creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
For more information on logging in, see Logging in to a management server.

3. Upload the YAML file with the auditing settings by running the following command:

   ```
   apic cloud-settings:update --server mgmt_endpoint_url my_audit_settings.yaml
   ```

4. Run the following command to log out of the management server:

   ```
   apic logout --server mgmt_endpoint_url
   ```

Results

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What to do next

If you suspect that audit logging messages are not being received by the endpoint, see Verifying that the endpoint is receiving audit logging messages for information on validating the connection.

Reviewing a gateway's processing status

Review the processing status for the Gateway services that are enabled in your API Connect Catalogs and Spaces.

About this task

Sometimes you might want to check the status of an API event that is being processed by the gateway. For example, you might want to ensure that a Product was published before and is available on the gateway before you invoke one of its APIs. Or perhaps it appears that API events are being processed too slowly and you want to see if all of the events for a particular gateway service are affected.

You can review a gateway's processing status in the API Manager user interface, or by using the toolkit CLI to retrieve the information.

Notes:

- You can only obtain processing status information for the DataPower® API Gateway. This feature is not supported for the DataPower Gateway (v5 compatible) service.
- Processing information is collected for each Catalog. If you view information for a particular Space, the display shows the results for the entire Catalog instead.

You can view the gateway processing status using the UI or the CLI.

Using the UI to view the gateway processing status

About this task

Use the API Manager user interface to view the processing status for all of the gateway services associated with a particular Catalog or Space.

Procedure

1. Open the Gateway services page:
   a. Log in to API Manager.
   b. In the navigation pane, click Manage.
   c. Select a Catalog.
   d. Click the Catalog settings tab.
   e. On the Settings page, click Gateway services.
   A list of all of the gateway services for the selected Catalog, including all of its Spaces, displays the gateway type and its endpoint URL. In addition, a status icon displays for each service name to provide a quick indication of that service's current status:

   - Normal: Between 0 and 10 events are waiting to be processed
   - Increased: Between 10 and 20 events are waiting to be processed
   - High: More than 20 events are waiting to be processed

   You can view details about a service's status to gain insight into possible issues.

2. On the Gateway services page, click ⋮ next to a service and select View status.
   The Gateway processing status page displays a list of the events that were sent to the gateway. For each event, you can see the following information:

   - Event type: The action performed by the event; for example, subscribing to a product, deleting an application, or creating a new consumer organization.
   - Category: The feature area affected by the event; for example, subscriptions, applications, or consumer organizations.
   - Time: The time when the event was processed by the gateway service.
   - Status: The current event's processing status; for example, Queued (not yet sent for processing), Sent (but not processed yet), or Processed (complete). The number of events in the Queued and Sent states determine the status level for the service.

   The display includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

Using the CLI to obtain a gateway's processing status

About this task

You can use the developer toolkit CLI to obtain information about the processing status for the Gateway services that are enabled in your Catalogs and Spaces.

The processing status information is returned in the following fields:

Field	Description
`service_up_to_date`	If `true` then all outstanding events have been processed by the Gateway service.
`service_state`	An overall status summary of the various states of events and processing by the Gateway service: • `green` indicates normal status with between 0 and 10 events waiting to be processed • `orange` indicates that between 10 and 20 events are waiting to be processed • `red` indicates that more than 20 events are waiting to be processed
`last_processed_event`	Details of the last event that was processed by the Gateway service, helping to provide a timeline of when the last event was processed, and some statistics about how long ago it was and how long the processing took.
`last_sent_event`	Details of the last event that was sent to the gateway service
`number_of_outstanding_sent_events`	The number of events that have been sent but not yet processed by the Gateway service.
`number_of_outstanding_queued_events`	The number of events that have been queued but not yet sent to the Gateway service.

The following example shows a "green" response that includes the status information and the list of sent events:

```
gateway_processing_status:
  service_up_to_date: false
  service_state: green
  last_processed_event:
    event_id: 40e1a564-2aea-429b-9d35-f588218688a1

  queued_events: []
```

The following example shows a "red" response:

```
gateway_processing_status:
  service_up_to_date: false
  service_state: red
  last_processed_event:
    event_id: 07387d98-dbfc-494b-af12-d7db91208e4c
    title: >-
      Update Product (name-version:lts-cat0-product-49:1.0.0, id:
```

```
    25eba540-0cb1-4808-be3d-f22f65540cb2) by user shavon0
  processed_at: '2020-06-02 22:32:10.838+00'
  generated_at: '2020-06-02 22:31:43.38615+00'
  filter: product_del
  event_processing_time: 22597
  elapsed_time_since_last_processed_event: 18427
last_sent_event:
  event_id: 93d0bf8f-ebfb-4a8b-aa22-7f805719d5c8
  title: >-
    Update Product (name-version:lts-cat0-product-11:1.0.0, id:
    d0bf799f-7f3a-4546-b267-a85c6a7f4b10) by user shavon0
  sent_at: '2020-06-02 22:32:28.426+00'
  generated_at: '2020-06-02 22:32:25.505109+00'
number_of_outstanding_sent_events: 37
number_of_outstanding_queued_events: 1
```

The result includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

Procedure

To obtain processing status information for a Gateway service, complete the following steps:

1. Log in to your API Connect Management server as a provider organization member, by using the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   where:
   - *mgmt_endpoint_url* is the platform API endpoint URL.
   - *user_ID* is the user ID of your provider organization account, and is the same as the user ID that you use to log in to the API Manager user interface.
   - *password* is the password for your administrator account.
   - *identity_provider* is the identity provider that is used to authenticate API Manager users.

   For example:

   ```
   apic login --server platform-api.myserver.com --username myuser --password password --realm provider/myldap
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details on how to log in to your management server from the CLI, see Logging in to the management server.

2. Obtain the Gateway processing status for a Gateway service that is enabled in a Catalog by running the following command:

   ```
   apic configured-gateway-services:get --server mgmt_endpoint_url --scope catalog --org organization_name --catalog
   catalog_name gateway_service_name --fields "add(gateway_processing_status)" --output -
   ```

   where:

   - *mgmt_endpoint_url* is the platform API endpoint URL.
   - The `--scope scope` parameter specifies `catalog` as the scope of the request.
   - *organization_name* is the name of the provider organization that contains the Catalog.
   - *catalog_name* is the name of the Catalog in which the Gateway service is enabled.
   - *gateway_service_name* is the name of the Gateway service whose processing status you want to obtain.
   - The `--fields "add(arguments)"` parameter can include either, or both, of the following arguments (separated with a comma):
     - `gateway_processing_status`: returns the total number of sent events, queued events, and processed events
     - `events`: returns lists of sent events with details about each event

   For example:

   ```
   apic configured-gateway-services:get --server platform-api.myserver.com --scope catalog --org myorg --catalog sandbox my-
   gateway-service --fields "add(gateway_processing_status)" --output -
   ```

Changing your Cloud Manager password and profile information

You can change your Cloud Manager password and update your profile information.

Procedure

To change your password or profile information, follow these steps:

1. Log in to the Cloud Manager user interface.

2. Click the User icon , and then select My Account.
3. In the Profile section, enter a new email address and First Name and Last Name for the account owner.
4. Click Save.
5. In the Change password section, enter your current password and your new password, and confirm the new password.
   The password must contain six characters at a minimum. It must contain at least three of the following types of characters:
   - Lowercase letters
   - Uppercase letters
   - Numbers
   - Characters from the following list of allowed punctuation and special characters:

     ```
     !
     \"
     #
     $
     %
     &
     \
     (
     )
     *
     +
     ,(comma)
     - (dash/hyphen)
     .(period)
     /
     :(colon)
     ;(semi-colon)
     <
     =
     >
     ?
     @
     [
     \\
     ]
     ^
     _ (underscore)
     ` (back quote/grave accent)
     {
     | (pipe)
     }
     ~ (tilde)
     ```

   The password cannot contain more than two consecutive repeating characters.
6. Click Save.

Results

Your profile information and password are changed.

- Configuring and managing your server environment

Resolving login problems by increasing HTTP header size

You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.

About this task

Login attempts to the user interface might fail with error **`502 (Bad Gateway)`**. This error can occur when logging in from a browser that has a large number of cookies. The error occurs because size of the login request exceeds the maximum HTTP client header size.

The maximum HTTP client header size is limited for security reasons. To workaround this issue, you can clear the browser cache and cookies, or open an incognito window from the browser, and then retry the login.

Alternatively, you can increase the maximum HTTP client header size. Use caution when increasing the maximum size because larger headers can raise a security risk to your system.

Procedure

1. **`SSH`** to your management system or appliance.
2. Enter the following commands:

   ```
   kubectl get deployment -n namespace  | grep apim
   kubectl edit deployment -n namespace management-apim
   ```

3. In the **`env`** section of the deployment configuration, change **`--max-http-header-size=12000`** to a larger value that works for your environment. For example:

   ```
   - name: NODE_OPTIONS
           value: --max-old-space-size=8094 --max-http-header-size=16000
   ```

4. Save the updated configuration.
5. Run `kubectl get pod -n namespace` a few times until the new `management-apim` pods are up and running.

Onboarding a new admin for Cloud Pak for Integration

Use the API Connect toolkit CLI to create a new admin account for use with Cloud Pak for Integration.

About this task

If you changed the local admin account for Cloud Pak for Integration, you must create a new admin user in API Connect to ensure that the new Cloud Pak for Integration admin can log in to API Connect with the Common Services User Registry.

Procedure

1. Download and install the API Connect toolkit CLI and credentials file as explained in Installing the toolkit.
2. Log in to the toolkit CLI.
   Logging in to the toolkit CLI requires the endpoint URL for your API Connect management server. In Cloud Pak for Integration, the URL indicates the location of the management server within the Cloud Pak for Integration deployment.

   a. Determine the URL to the API Connect management server by running the following command:

   ```
   oc -n APIC_namespace get mgmt APIC_instance -o jsonpath="{.status.zenRoute}" && echo ""
   ```

   The response looks like the following example URL:

   ```
   apic-mgmt-admin-apic.deve-cip-hlag-8e86d3798137c73f524cf9-0000.eu-de.containers.appdomain.cloud
   ```

   b. Log in to the API Connect toolkit CLI by running the following command:

   ```
   apic -s API_Connect_URL login -u admin -p <password> -r admin/default-idp-1
   ```

   where ***API_Connect_URL*** is the URL of the management server in your API Connect instance.

3. Create a new admin account by completing the following steps.
   Use the toolkit CLI to create an admin account in the Common Services User Registry and then add the new admin to the API Connect **administrator** role.

   a. Create a YAML file called newCp4iAdmin.yaml with the following information for the new admin account.

   ```
   username: <new_cp4i_admin_username>
   first_name: CP4I
   last_name: Administrator
   ```

   b. Create the CP4i admin account by running the following command:

   ```
   apic -s API_Connect_URL users:create -o admin --user-registry common-services newCp4iAdmin.yaml
   ```

   c. Verify that the account was created by running the following command:

   ```
   apic -s API_Connect_URL users:get -o admin --user-registry common-services <new_cp4i_admin_username> --output -
   ```

   d. Get the new admin account's URL by running the following command:

   ```
   apic -s API_Connect_URL users:list -o admin --user-registry common-services | grep <new_cp4i_admin_username> | awk
   '{print $4}'
   ```

   e. Get the URL of the API Connect **administrator** role by running the following command:

   ```
   apic -s API_Connect_URL roles:list --scope org -o admin | grep -w administrator | grep -v topology | awk '{print $2}'
   ```

   f. Create a YAML file called newcp4iadminmember.yaml with the following content:

   ```
   name: <new_cp4i_admin_username>
   user:
     url: <user_URL>
   role_urls:
     - <role_URL>
   ```

   g. Use the newcp4iadminmember.yaml file to add the new admin as a member of the API Connect instance's admin organization.
   Create the new member by running the following command:

   ```
   apic -s API_Connect_URL members:create --scope org -o admin newcp4iadminmember.yaml
   ```

   h. Verify that the new admin account works by using it to log in to the Cloud Manager interface in your API Connect instance.

4. Remove the old Cloud Pak for Integration admin user from API Connect.
   After you verify that the new Cloud Pak for Integration admin can log into the API Connect Cloud Manager interface, delete the previous Cloud Pak for Integration admin account.

   a. Remove the previous admin from the membership of the API Connect admin organization by running the following command:

   ```
   apic -s API_Connect_URL members:delete --scope org -o admin cs-admin
   ```

   When you initially deployed API Connect as a component of Cloud Pak for Integration, the admin username was **admin** and the member in the API Connect admin organization was **cs-admin**. If the **cs-admin** member does not exist in the admin organization, then the Cloud Pak for Integration admin user was changed after deployment. In this case, the member uses the same name as admin account's user name. Delete the member with that name:

```
apic -s API_Connect_URL members:delete --scope org -o admin <old_cp4i_admin_username>
```

b. Delete the previous Cloud Pack for Integration admin user account from the Common Services User Registry by running the following command:

```
apic -s API_Connect_URL users:delete -o admin --user-registry common-services <old_cp4i_admin_username>
```

Extending the Gateway server behavior

To support your enterprise requirements, you can extend the Gateway servers within IBM® API Connect to provide extra enforcement behavior.

Before you begin

Before you develop your extensions, consider the guidelines in the following topics depending on which type of gateway you are using:

- Gateway extension guidelines - DataPower Gateway (v5 compatible)
- Gateway extension guidelines - DataPower API Gateway

For information on the different types of gateway, see API Connect gateway types.

About this task

API Connect Gateway servers uses a subset of DataPower® enforcement capabilities. You can supply DataPower Extensions to customize these enforcement capabilities further.

The DataPower extensibility function can be used to perform actions that include schema validation, antivirus scanning, message filtering, authentication, and authorization, token translation, message enrichment, encryption & decryption, digital signing, and validation and message transformation. For more information, see IBM DataPower documentation.

Important: Gateway server extensions must not be used to modify objects that cause the `apic-gw-service` object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the `apic-gw-service` object to restart, lead to unpredictable behavior in the Gateway service.

Procedure

To extend the default enforcement capabilities that are provided in API Connect for the Gateway server, complete the following steps.

1. In your IBM DataPower environment, develop the configuration that you want to add to your Gateway server.
2. Test your enforcement configuration before you add the configuration to the Gateway server.
3. When you complete the IBM DataPower configuration, save the enforcement objects and files as a DataPower exported .zip file.
   The package file is ready to be uploaded to the Gateway server.
4. Copy your exported configuration .zip file to a centralized file system ready for upload to the Gateway server.

What to do next

Upload your extension to the Gateway server; see Configuring your Gateway server extensions.

- **Gateway extension guidelines - DataPower Gateway (v5 compatible)**
  Before you develop your extensions to the DataPower Gateway (v5 compatible), consider these guidelines.
- **Gateway extension guidelines - DataPower API Gateway**
  Before you develop your extensions to the DataPower API Gateway, consider these guidelines.
- **Configuring your Gateway server extensions**
  You can add extra IBM DataPower enforcement capabilities to a Gateway service by uploading a .zip file that defines the required extension behavior, and then enabling the extension in IBM DataPower.

DataPower Gateway (v5 compatible)

Gateway extension guidelines - DataPower Gateway (v5 compatible)

Before you develop your extensions to the DataPower® Gateway (v5 compatible), consider these guidelines.

Note: These guidelines apply to the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Gateway extension guidelines - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

You can download sample gateway extensions from https://github.com/ibm-apiconnect/dp-extensions.

You can create DataPower Processing Rules that can extend the enforcement behavior of the IBM® API Connect Gateway server at the following locations:

- `pre-request` extension:
  - Before the Gateway server begins to use the policies in the assembly to process the request.
- `post-request` extension:
  - After the Gateway server processes all of the policies in the assembly up to the proxy policy, if a proxy policy is used.
  - After the Gateway server processes all policies in the assembly, but before any catch logic is processed, if a proxy policy is not used.
- `post-response` extension:
  - After the Gateway server processes all of the remaining policies in the assembly after the proxy policy (including catch logic), but before the response is returned to the client application, if a proxy policy is used.

    - After the Gateway server processes the catch logic, but before the response is returned to the client application, if a proxy policy is not used.
- **post-error** extension:
    - If an error occurs, then before the Gateway server returns the error response to the client application.

To configure the Gateway server to call your extension Processing Rule, you must create an XML file that indicates the extension location and Processing Rule name. For example,

```
<extensions>
<extension location="pre-request">CustomRule1</extension>
<extension location="post-request">CustomRule2</extension>
<extension location="post-response">CustomRule3</extension>
<extension location="post-error">CustomRule4</extension>
</extensions>
```

The **<extension>** element entries are optional for any of the locations. Refer to the Gateway server Extension schema for the XML file syntax.

An extension Processing Rule can be applied to a specific organization or to all of the organizations and Catalogs. If the **<extension>** element does not have a tenant attribute, then the **<extension>** element is applied to all of the organizations. The following example shows an **<extension>** element without a tenant attribute.

```
<extension location="post-error">gen_error_handling</extension>
```

To apply an extension Processing Rule to a specific organization, enter the organization name as the value for the tenant attribute in the **<extension>** element. The following example shows an <extension> element with a tenant attribute value of *organization1*.

```
<extension location="post-error" tenant="organization1">organization1_error_handling</extension>
```

If you want to exclude a specific organization in an extension Processing Rule, enter the organization name as the value for the tenant attribute in an empty **<extension>** element. Add the empty **<extension>** element immediately after the custom rule **<extension>** element that you want to exclude the organization from. The following example shows an empty <extension> element with a tenant attribute value of *organization1*.

```
<extension location="pre-request">a_specified_CustomRule</extension>
<extension location="pre-request" tenant="organization1"></extension>
```

Important: An extension Processing Rule with a specified tenant attribute takes precedence over an **<extension>** element that applies to all of the organizations. Also, only one extension Processing Rule is applied to each extension location.
This XML file must be saved to the following location and included in your DataPower exported configuration .zip file:

```
local:///ext/extensions.xml
```

There can be only one DataPower exported configuration .zip file added to a Gateway server in API Connect.

CAUTION:

- Do not modify these files directly in the DataPower API Gateway file system, use the gateway extension mechanism described on this page.
- Do not apply gateway extension modifications to configuration in the local:/config-sequence.cfg file.
- Do not use Gateway server extensions to modify objects that cause the **apic-gw-service** object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the **apic-gw-service** object to restart, lead to unpredictable behavior in the Gateway service.

DataPower configuration restrictions

All Processing Rules have read access to the INPUT context.

Processing Rules must not rely on context variables that are created by the IBM Gateway server enforcement configuration, because those configuration variables might change in the future.

All Processing Rules except Before Request can transform or alter the message flowing through the Gateway server. Ensure that the Processing Rule returns the desired message output context back to the Gateway server at the end of processing.

To avoid name conflicts, all DataPower configuration object names prefixed with **webapi** are reserved for IBM use.

The following folders cannot be modified:

- **local:///isp/***
- **local:///gwapi/***

As a best practice, avoid adding asynchronous actions in your custom Processing Rules because they increase the use of memory per transaction.

Gateway extension guidelines - DataPower API Gateway

Before you develop your extensions to the DataPower® API Gateway, consider these guidelines.

Note: These guidelines apply to the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Gateway extension guidelines - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Introduction

You apply an extension to a DataPower API Gateway by uploading one or more .cfg files that define the required extension behavior. These .cfg files contain DataPower API Gateway CLI commands. For details of the full set of CLI commands that are available, see the DataPower API Gateway CLI command documentation.

You package the .cfg files in a .zip file, together with any additional required files that are referenced from CLI commands; for example, a .json file that contains the OpenAPI definition for an API. The .cfg files are processed in alphanumeric order by file name.
Note:

- All the .cfg files must be at the root of the .zip file. If you are attempting to use an API Connect Version 2018 gateway extension that has files in sub-directories, see Gateway extensions manifest for information on how to deploy multiple extensions in a single package.
- On Mac OS X, run the **zip** command on the command line with the following flags:

  ```
  -x ".DS_Store" -x "__MACOSX"
  ```

  Including the flags prevents the auto-generated .DS_Store and __MACOSX files from being added to the zip.

You upload the extension .zip file to an API Connect Gateway service, and enable the extension, as described in Configuring your Gateway server extensions. Gateway server extensions can be deployed without having to restart the DataPower API Gateway.

To control how gateway extensions are applied to the DataPower API Gateway, you can include a Gateway extensions manifest as a manifest.json file. The manifest allows you to deploy multiple extensions of different types in a single package. For more information, see Gateway extensions manifest.

Using CLI commands in a Gateway extension

Although you can use any DataPower API Gateway CLI commands in your extension .cfg files, typically you use commands that modify API Connect objects that have previously been deployed to the DataPower API Gateway.

When API Connect objects are deployed to a DataPower API Gateway, .cfg are created on the Gateway that define the configuration of those objects. By examining those .cfg on the Gateway, you can determine the precise names of API Connect objects that you want to modify, and the current values of the properties of those objects. You can access these .cfg files by completing the following steps:

1. Log in to the DataPower administrative user interface; for the Graphical Interface, select WebGUI rather than Blueprint Console.
2. Switch to the DataPower application domain for API Connect if necessary.
3. Under Files and Administration, click File Management.
4. Expand the temporary: folder to locate the .cfg files. The files for API Connect objects are named according to their containing provider organization and Catalog, as follows:

   20.*provider-org-name_catalog-name*_collection.cfg

   The prefix **20** controls the position of the file in the overall processing sequence, which is in alphanumeric order by file name.
   Restriction:
   - Do not modify these files directly in the DataPower API Gateway file system. Instead, use the gateway extension mechanism described on this page.
   - Do not apply gateway extension modifications to configuration in the local:/config-sequence.cfg file.
   - Do not use Gateway server extensions to modify objects that cause the **apic-gw-service** object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the **apic-gw-service** object to restart, lead to unpredictable behavior in the Gateway service.

Note: Modifying a .cfg file triggers the execution of all other .cfg files that run commands on the same object.

Config-Sequence tracks all of the objects that it manages through the .cfg files. Any change to a .cfg file that causes config-sequence to run commands on an object automatically executes all other .cfg files that run commands on the same object.

Example: If a new product is published to catalog A, then the .cfg file for that collection in temporary://config will be modified by the apic-gw-service to reflect the new product. Because that .cfg file was changed, config-sequence will execute every other .cfg file that also runs operations on catalog A, in the sequence of locations defined in the config-sequence object. If there are 2 .cfg files in the same location that run commands on catalog A, they run in alphabetical order.

Example 1 - change the scope of the rate limit for a Plan

Suppose the DataPower API Gateway configuration for a Plan has the following CLI command:

```
api-plan myorg_sandbox_financial-services_1.0.0_basic
```

The **api-plan** command has the following syntax:

api-plan *plan_name*

and creates a Plan of the specified name, or modifies a Plan of the same name if it already exists. By using the specified name, you can add **api-plan** commands in your Gateway extension .cfg files to modify the Plan.
Note: The names of API Connect objects in the DataPower API Gateway configuration are derived from their configuration in API Connect. For example, a Plan name has the following structure:

provider-org-name_catalog-name_product-name_product-version_plan-name

where:

- *provider-org-name* is the name of the provider organization.
- *catalog-name* is the name of the Catalog in that provider organization.
- *product-name* is the name of the Product that contains the Plan.
- *product-version* is the version of the Product.
- *plan-name* is the name of the Plan.

The default scope to which a Plan rate limit applies is per application. To change this setting on the Plan in this example, so that the rate limit scope is per client ID, add the following command to a .cfg in your Gateway extension:

```
api-plan myorg_sandbox_financial-services_1.0.0_basic
  rate-limit-scope per-client-id
exit
```

For more information on configuring Plans by using DataPower API Gateway CLI commands, see API Plan commands.

Example 2 - add a path to an API definition

The .cfg file in this example performs the following actions:

1. Uses the **top** and **configure terminal** commands to reset CLI processing.
2. Uses the **api-operation** command as follows:
   a. Creates a new operation called `bank_branches_get_operation`.
   b. Uses the **reset** command to set all properties to their default values.
   c. Sets the operation method to `GET`.
3. Uses the **api-path** command as follows:
   a. Creates a new path called `bank_branches_path`.
   b. Uses the **reset** command to set all properties to their default values.
   c. Sets the path URL segment to `/details`.
   d. Adds the previously created operation `bank_branches_get_operation` to the path.
4. Uses the **api-definition** command as follows:
   a. Modifies the existing API definition called `myorg_sandbox_myapi_1.0.0`.
   Note: The name of the API definition was derived from its configuration in API Connect when it was published to the DataPower API Gateway, and has the following structure:

   provider-org-name_catalog-name_api-name_api-version

   where:
   - *provider-org-name* is the name of the provider organization.
   - *catalog-name* is the name of the Catalog in that provider organization.
   - *api-name* is the name of the API definition in API Connect.
   - *api-version* is the version of the API.

   b. Adds the previously created path `bank_branches_path` to the API definition.
   Note: The **reset** command is not used here because that would reset all the current settings on the `myorg_sandbox_myapi_1.0.0` API definition, whereas the requirement is to add a new path to the existing configuration of the API definition.

The .cfg file is as follows:

```
top; configure terminal

api-operation bank_branches_get_operation
  reset
  method GET
exit

api-path bank_branches_path
  reset
  path "/details"
  operation bank_branches_get_operation
exit

api-definition myorg_sandbox_myapi_1.0.0
  path bank_branches_path
exit
```

For more information on the DataPower API Gateway CLI commands used in this example, see the following pages:

- Initial login and common commands
- API Operation commands
- API Path commands
- API Definition commands

Gateway extension limitations

This section details the limitations of the extensions to the DataPower API Gateway.

- If you use an extension to create a user-defined policy and then delete the extension, the extension is removed from the filesystem, but the configuration sequence is not triggered to clean up related files. For the policy to be cleaned up, you must send a modified extension that explicitly removes the user-defined policy from `apic-gw-service`, as in the following example.

  ```
  apic-gw-service
      no user-defined-policies udp-basic_1.0.0
  exit
  ```

- `user-defined-policy-yaml` policies that use or reference another policy can be deployed only after the referenced policy has been advertised to API Manager. The deploy type must be set to `deferred` and the API Connect Gateway Service must be restarted.
- Deleting an extension that is used to create a user-defined policy using a .cfg file does not remove the policy reference in the `apic-gw-service` object. The policy is not removed from the assembly palette until a reboot or restart of the Gateway pod. To properly remove the policy, send an `apic extensions:update` command that explicitly removes the policy from the `apic-gw-service` prior to sending the `apic extensions:delete` command.
- v5 policies that contain files outside of the `/policy` directory are not supported. If multiple v5 policies reference the same file outside the `/policy` directory, the last applied policy will overwrite the file and will be used by all policies that reference it. Removing any policy that contains the file will cause the file to be deleted and may cause errors for the remaining policies that use it.
- If an extension contains or references objects and files that are also referenced by other objects outside of the extension, deleting the extension can cause errors that are difficult to troubleshoot.
- It is possible to delete an extension that is referenced by published APIs. This may cause those API requests to return errors.
- For an extension type of `user-defined-policy`, extra assembly functions may be present in the DataPower import `.zip` file, even if there is no `.yaml` file to indicate their presence. Using these functions without declaring them using a `.yaml` file is not supported. A policy `.yaml` file is required for each policy you want to advertise to API Manager.
- Extension type `user-defined-policy-yaml` may leak generated Gatewayscript `.js` files in temporary:/js/ or `.xslt` files when deleted.

- Extension types that use SOMA imports must use new objects with no overrides. If you override a singleton or shared object using an extension of this type, then the object will not be restored to its previous state when the extension is deleted, and those objects may be missing after the extension is deleted. You must then restore any needed objects.

- **Gateway extensions manifest**
  The gateway extensions manifest controls how gateway extensions are applied to the DataPower API Gateway.
- **v5 policy emulation limitations**
  This page details the limitations of v5 policy emulation for the current release.

Gateway extensions manifest

The gateway extensions manifest controls how gateway extensions are applied to the DataPower® API Gateway.

The gateway extensions manifest enables you to deploy multiple extension implementations in a single package. The manifest is a JSON file that lists the extensions `.zip` files to be applied and when they are to be deployed. You can also use the manifest to enable v5 policy emulation for the API Connect gateway service. V5 policy emulation enables you to deploy supported v5 built-in policies and custom policies, and manage them from API Manager without having to rewrite them for DataPower API Gateway. V5 policy emulation is supported only for policies that are applied to the Gateway service scope.

The `manifest.json` file must be at the root level of the extensions `.zip` file, along with the gateway extension files specified in the manifest. For example:

```
manifest.json
jws-sign-policy.zip
add_udp.zip
```

The `manifest.json` file contains the following sections.

`properties` section

The properties section determines whether to enable the v5 framework to deploy supported v5 built-in policies and custom policies and manage them from API Manager without having to rewrite them for DataPower API Gateway.

Table 1. `properties` section properties

Property	Description
`deploy-policy-emulator`	Determines whether to enable v5 framework emulation. Valid values are `true` and `false`. v5 framework emulation is enabled for the API Connect Gateway service if `deploy-policy-emulator` set to `true`, if a v5 policy is detected in the files list, or if a `deploy-policies` entry is specified.
`deploy-policies`	Contains a list of built-in policies to advertise for v5 emulation. The following policies are supported. • `activity-log_1.5.0` • `gatewayscript_1.0.0` • `if_1.5.0` • `invoke_1.5.0` • `proxy_1.5.0` • `redact_1.5.0` • `switch_1.5.0` • `validate-usernametoken_1.0.0` • `xslt_1.0.0`
`defer-all-override`	An override toggle to force the deployment property of all extension entries (including V5E) to be deferred. When enabled, the user must restart the `apic-gw-service` object to apply any extension events.

`files` section

The `files` section is an array of file entries that reference extension implementations. Each entry must reference a file that is in the `extension.zip` file (or the extension is rejected).

Table 2. `files` section properties

Property	Description
`filename`	The name of the file that contains the extension implementation. This property is required and cannot be changed while the extension is deployed as part of an update.

Property	Description
`type`	The type of extension implementation to be deployed. This property is required. The following types are supported. **`dp-import`** A DataPower import used to add additional configuration and/or services to a gateway. Like the extension type, but `dp-import` persists the configuration on physical or virtual DataPowers. Note: A `dp-import` file cannot be used to change the `apic-gw-service` object. If it is configured for this purpose, the extension is rejected. **`extension`** A legacy API Gateway extension that can be used to add additional configuration to a gateway. `Extension` should not be used to modify objects created by the API Connect gateway service, see gwd_extension for that use case. For more information, see Gateway extension guidelines - DataPower API Gateway. **`gwd_extension`** A JSON file that allows users to customize objects created by the API Connect gateway service. Only one `gwd_extension` is allowed in the manifest and its deployment is always deferred. For more information about the `gwd_extension`, see GWD extension type. **`policy-v5`** A complete, valid v5 policy implementation. For more information, see Authoring policies for the DataPower Gateway (v5 compatible). **`user-defined-policy`** A native API Gateway policy packaged in a DataPower import zip. Using a DataPower import to apply the policy implementations allows the configuration to persist through restarts and upgrades on virtual and physical forms. The import might contain one or more policy implementations. This policy type is always global scoped. For more information, see Defining, packaging, and publishing a global-scoped policy for the API Gateway. **`user-defined-policy-yaml`** A YAML file that includes an assembly. This policy type is always global scope. If the assembly references another user-defined policy, that policy must already be advertised to the API Manager before it can be deployed. For more information, see Working with global policies. **`v5_extension`** A migrated v5 extension that the migration utility generates. Only certain parts of v5 extensions are usable in API Gateway. For more information, see Migrating gateway extensions. `v5_extension` is reserved for v5 extensions that the migration utility creates. Do not manually create this type of extension. Note: V5E is intended to allow users to migrate from V5 without editing their APIs. V5E type policies cause known performances degradations in the API gateway. To improve performance of V5E policies, it is recommended to convert them to native policies.
`deploy`	When to deploy the extension entry. If you are deploying extensions that might cause a temporary API Connect gateway service outage, it is recommended to use deferred. **`immediate`** Deploy the extension entry immediately when the API Connect gateway service receives it. All gateway nodes apply the extension in parallel. Warning: `immediate` can cause an outage across the cluster, dependent on what the extension does. **`deferred`** A managed deployment strategy that applies the extension entry after the API Connect gateway service is restarted. This value is the default. Using deferred allows the user to do a controlled roll out of the extension across the cluster. When a DRR occurs this property is ignored, and all entries are deployed immediately.
`catalog`	Indicates that a v5 policy is to be used only by certain catalogs and should not be advertised as a gateway service-level user policy. This property is valid only if the file type is `policy-v5`. The `catalog` value must be in the format ***`orgname_catalogname`***.

Example `manifest.json`

The following example `manifest.json` file enables v5 policy emulation and specifies two built-in v5 policies to deploy. The files section lists two v5 policy implementation files and two extension files.

```
{
   "extension":{
      "properties":{
         "deploy-policy-emulator":true,
         "deploy-policies":[
            "invoke_1.5.0"
         ]
      },
      "files":[
         {
            "filename":"proxy_service.zip",
            "deploy":"immediate",
            "type":"dp-import"
         },
         {
            "filename":"add_udp.zip",
            "deploy":"deferred",
            "type":"extension"
         },
         {
            "filename":"override-parse-defaults.json",
            "type":"gwd_extension"
         },
         {
            "filename":"jws-sign-policy.zip",
            "deploy":"immediate",
            "type":"policy-v5"
         },
         {
            "filename":"jwe-decrypt-policy.zip",
            "deploy":"deferred",
            "type":"policy-v5",
```

```
            "catalog":"extension-org_ext-cat-2"
         },
         {
            "filename":"mypolicy.zip",
            "deploy":"immediate",
            "type":"user-defined-policy"
         },
         {
            "filename":"Invoke-Private-Backend-policy.yaml",
            "deploy":"immediate",
            "type":"user-defined-policy-yaml"
         }
      ]
   }
}
```

GWD extension type

The **gwd_extension** type is a JSON map that is used to apply user customizations to objects generated by the API Connect gateway service.

The **gwd_extension** map contains an array of user-defined CLI commands to be run on one or more objects. Only one **gwd_extension** is allowed in the manifest and its deployment is always deferred. Restarting the API Connect gateway service object is required to apply, update, or remove the overrides.

Key features of the **gwd_extension** type:

- The **gwd_extension** type can be used to define overrides at various scope-levels, which means a single array of override commands can be applied to one or more objects of a particular type.
- With some object mappings, you can define instances within a scope so that you can apply the custom CLI commands to all objects in that scope that match a particular name or criteria. For example, you can apply overrides to all catalog instances with the name **MyCatalog** regardless of which organization it belongs to.
- By default, the overrides are applied in order of scope granularity (global → organization → catalog → product → instance).
- Add **"@exclusive": true** to the object at any scope level to signal not to apply the previous scopes. Similarly, using an empty override array in a scope is a signal to not apply all previous scope overrides for that mapping, see tls-client for an example.

The supported scopes are:

- **_global**: Applies customizations to all objects of a particular type. For example, add one or more custom assembly-rate-limits to all **api-collections**.
  - **_instance**: Applies customizations to all objects that match a name or criteria. For example, add one or more custom **assembly-rate-limits** to all **api-collections** with the name **my-restricted-catalog** regardless which organization it belongs to.
- **_organization**: Applies customizations to all objects used in an organization. For example, apply a customization to all TLS client profiles that are used in the organization called **provorg**.
  - **_instance**: Applies customizations to all objects that match a name or criteria. For example, applying a customization to all TLS client profiles with a particular name and version regardless of which catalog is using it.
- **_catalog**: Applies customizations to all objects used in a catalog. For example, apply a customization to all TLS client profiles used in the catalog **myCat** of organization **myOrg**.
  - **_instance**: Applies customizations to all objects that match a name or criteria. For example, applying a customization to all plans in a catalog with a particular name regardless of which product it comes from.
- **_product**: Applies customizations to all objects of a type used in a product. For example, apply a customization to all plans in **product my-prod:1.0.0** published in catalog **myCat** of organization **myOrg**. The product scope is only used by the api-plan **gwd_extension** extension type.
- **_instance**: Applies customizations to a single instance. For example, apply a customization to TLS client profile **my-profile:1.0.0** in catalog **myCat** of organization **myOrg**.

Example **gwd_extension** that shows multiple types of overrides:

```
{
  "parse-settings":{
     "_global":{
        "override":[
           "document-size 4194304"
        ]
     }
  },
  "apigw":{
     "_global":{
        "override":[
           "assembly-rate-limit ratelimit-reject-ALL 10000 5 second on on on off off off \"\" \"1\"",
           "assembly-rate-limit ratelimit-alert-ALL 7500 5 second off on on off off off \"\" \"1\""
        ]
     }
  }
}
```

The **gwd_extension** type supports the following objects:

- **config-sequence**
  The config-sequence object created by **apic-gw-service**, which is used to create all API gateway objects.
- **parse-settings**
  Parse settings used by the API Gateway.
- **analytics-endpoint**
- **front-side-handler**
  FSH and associated SNI Server profiles and objects that are used by the API Gateway.
- **apigw**
  API Gateway object.
- **tls-client**

- **api-collection**
  Catalog objects.
- **api-plan**
  API Plan objects that are created from published products.
- **registry**
  Registry objects used in a catalog.
- **oauth-provider**
  Oauth objects used in a catalog.
- **api-definition**
  The API objects that are published to one or more catalogs.
- **assembly**
  The assembly objects and their associated actions that are used by APIs and global policies.

config-sequence

The config-sequence object created by **apic-gw-service**, which is used to create all API gateway objects.

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "config-sequence":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

parse-settings

Parse settings used by the API Gateway.

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "parse-settings":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

analytics-endpoint

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "analytics-endpoint":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

front-side-handler

FSH and associated SNI Server profiles and objects that are used by the API Gateway.

- Override Key: `source-https`
- Child Objects:
  - `ssl-sni-server`

    - `ssl-sni-map`
    - `ssl-server`
        - Override Key: profile
        - _instance: SNI hostname key
        - Child Objects:
            - `valcred`
            - `idcred`
- Scopes:
    - _global
- Example:

```
{
   "front-side-handler":{
      "_global":{
         "source-https":[
            "summary global my-fsh-override"
         ],
         "ssl-sni-server":[
            "summary global my-sni-server-override"
         ],
         "ssl-sni-map":[
            "summary global my-sni-map-override"
         ],
         "ssl-server":{
            "_instance":{
               "*.myhost.com":{
                  "profile":[
                     "summary sni-host-instance-my-profile-override"
                  ],
                  "valcred":[
                     "summary sni-host-instance-my-valcred-override"
                  ],
                  "idcred":[
                     "summary sni-host-instance-my-idcread-override"
                  ]
               }
            },
            "profile":[
               "summary my-profile-override"
            ],
            "valcred":[
               "summary my-valcred-override"
            ],
            "idcred":[
               "summary my-idcread-override"
            ]
         }
      }
   }
}
```

apigw

API Gateway object.

- Override Key: override
- Scopes:
    - _global
- Example:

```
{
   "apigw":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

tls-client

Profiles that are attached to catalogs.

- Override Key: profile
- Child Objects:
    - Valcred
    - Idcred
- Scopes:
    - _global
        - _instance: *<profileName>*V*<profileVersion>*
    - _organization
        - _instance: *<profileName>*V*<profileVersion>*

    - _catalog
    - _instance: *<profileName>*V*<profileVersion>*
- Example: In this example, an empty array for **valcred** in catalog scope is used. The use of any empty array means the **valcreds** for TLS profiles in that catalog do not get the global or organizational overrides.

```
{
   "tls-client":{
      "_global":{
         "_instance":{
            "my-profileV1.0.0":{
               "profile":[
                  "summary global-instance-profile-override"
               ],
               "valcred":[
                  "summary global-instance-valcred-override"
               ],
               "idcred":[
                  "summary global-instance-idcred-override"
               ]
            }
         },
         "profile":[
            "summary global-profile-override"
         ],
         "valcred":[
            "summary global-valcred-override"
         ],
         "idcred":[
            "summary global-valcred-override"
         ]
      },
      "_organization":{
         "my-org":{
            "profile":[
               "summary org-profile-override"
            ]
         }
      },
      "_catalog":{
         "my-org":{
            "my-catalog":{
               "profile":[
                  "summary cat-profile-override"
               ],
               "valcred":[

               ]
            }
         }
      },
      "_instance":{
         "my-org":{
            "my-catalog":{
               "my-tlsV1.0.0":{
                  "profile":[
                     "summary instance-profile-override"
                  ],
                  "valcred":[
                     "summary instance-valcred-override"
                  ]
               }
            }
         }
      }
   }
}
```

api-collection

Catalog objects.

- Override Key: collection
- Child Objects:
    - **preflow-assembly-function**
    - **preflow-assembly-function-call**
    - **postflow-assembly-function**
    - **postflow-assembly-function-call**
    - **global-assembly-rule**
    - **global-assembly**
    - **global-assembly-function**
    - **global-assembly-function-call**
    - **assembly-function-rule**
- Scopes:
    - _global
        - _instance: *<catalogName>*
    - _organization
    - _catalog

- Example: In the example, global instance is used to apply override to all `api-collections` that have the name `my-catalog`, regardless of what organization they belong to.

```
{
   "api-collection":{
      "_global":{
         "_instance":{
            "my-catalog":{
               "collection":[
                  "summary hello my-catalog"
               ]
            }
         },
         "preflow-assembly-function":[
            "summary hello preflow-assembly-function global scope"
         ],
         "preflow-assembly-function-call":[
            "summary hello preflow-assembly-function-call global scope"
         ],
         "postflow-assembly-function":[
            "summary hello postflow-assembly-function global scope"
         ],
         "postflow-assembly-function-call":[
            "summary hello postflow-assembly-function-call global scope"
         ],
         "global-assembly-rule":[
            "summary hello global-assembly-rule global scope"
         ],
         "global-assembly":[
            "summary hello global-assembly global scope"
         ],
         "global-assembly-function":[
            "summary hello global-assembly-function global scope"
         ],
         "global-assembly-function-call":[
            "summary hello global-assembly-function-call global scope"
         ],
         "assembly-function-rule":[
            "summary hello assembly-function-rule global scope"
         ],
         "collection":[
            "summary hello collection global scope"
         ]
      },
      "_organization":{
         "my-org":{
            "collection":[
               "summary hello collection org scope"
            ]
         }
      },
      "_catalog":{
         "my-org":{
            "my-catalog":{
               "collection":[
                  "summary hello collection cat scope"
               ]
            }
         }
      }
   }
}
```

api-plan

API Plan objects that are created from published products.

- Override Key: override
- Child Objects:
  - `graphql-schema-options`
    - Override Key: override
    - Child Objects:
      - `visibility-list`
  - `rate-limit`
    - Child Object:
      - `rate-limit-definition`
        - Override Key: override
  - `burst-limit`
    - Child Object:
      - `rate-limit-definition`
        - Override Key: override
  - `rate-limit-group`
    - Override Key: override
  - `api-operation-rate-limit`
    - Override Key: override
    - Child Objects:
      - `rate-limit-group`

        - `rate-limit-definition`
    - `assembly-limit`
        - Child Objects:
            - `rate-limit`
            - `burst-limit`
            - `count-limit`
- Scopes:
    - global
        - _instance: *<planName>*.
    - organization
        - _instance: *<planName>*.
    - catalog
        - _instance: *<planName>*.
    - product: *<name>*:*<version>*
    - _instance: *<planName>*.
- Example:

```
{
   "api-plan":{
      "_global":{
         "graphql-schema-options":{
            "visibility-list":[
               "echo hello graphql-schema-options visibility _global"
            ],
            "override":[
               "echo hello graphql-schema-options _global"
            ]
         },
         "rate-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello rate-limit _global"
               ]
            }
         },
         "burst-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello burst-limit _global"
               ]
            }
         },
         "rate-limit-group":{
            "override":[
               "echo hello rate-limit-group _global"
            ]
         },
         "api-operation-rate-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello api-operation-rate-limit _global"
               ]
            },
            "rate-limit-group":{
               "override":[
                  "echo hello api-operation-rate-limit-group _global"
               ]
            },
            "override":[
               "echo hello api-operation-rate-limit _global"
            ]
         },
         "assembly-limit":{
            "rate-limit":{
               "rate-limit-definition":{
                  "override":[
                     "echo hello assemby rate-limit _global"
                  ]
               }
            },
            "burst-limit":{
               "rate-limit-definition":{
                  "override":[
                     "echo hello assebmly burst-limit _global"
                  ]
               }
            },
            "count-limit":{
               "rate-limit-definition":{
                  "override":[
                     "echo hello assebmly count-limit _global"
                  ]
               }
            }
         },
         "override":[
            "echo hello api-plan _global"
         ]
      },
      "_organization":{
         "my-org":{
            "override":[
```

```
            "summary hello api-plan _organization"
         ]
      }
   },
   "_catalog":{
      "my-org":{
         "my-catalog":{
            "override":[
               "summary hello api-plan _catalog"
            ]
         }
      }
   },
   "_product":{
      "my-org-2":{
         "my-cat-2":{
            "my-product:1.0.0":{
               "override":[
                  "summary hello api-plan _product"
               ]
            }
         }
      }
   },
   "_instance":{
      "my-org3":{
         "my-catalog-3":{
            "my-product:1.0.0":{
               "my-plan-1":{
                  "override":[
                     "summary hello api-plan _instance"
                  ]
               }
            }
         }
      }
   }
}
```

registry

Registry objects used in a catalog.

- Registry types:
  - LDAP
    - Override Key: override
    - Child object: `ldap-search-parameters`
  - AuthUrl
    - Override Key: override
- Scopes:
  - _global
  - _organization
  - _catalog
  - _instance: APIM name
- Example:

```
{
   "registry":{
      "ldap":{
         "_global":{
            "override":[
               "ldap-readtimeout 120"
            ],
            "ldap-search-parameters":[
               "summary override parameters global"
            ],
            "_instance":{
               "my-ldap-registry":{
                  "ldap-search-parameters":[
                     "summary override parameters global instance"
                  ],
                  "override":[
                     "ldap-port 636",
                     "ssl-client ldap-ssl-client"
                  ]
               }
            }
         },
         "_organization":{
            "my-org":{
               "override":[

               ],
               "_instance":{
                  "my-ldap-registry":{
                     "override":[
                        "ldap-version v3",
                        "ldap-bind-password mypw",
```

```
                        "ldap-search-param ldap-param",
                        "summary override org instance"
                     ]
                  }
               }
            }
         },
         "_catalog":{
            "my-org":{
               "my-catalog":{
                  "override":[
                     "ldap-host 1.2.3.4",
                     "ldap-bind-dn cn=root,dc=datapower,dc=com",
                     "summary override catalog"
                  ]
               }
            }
         },
         "_instance":{
            "my-org-3":{
               "my-catalog-3":{
                  "my-ldap-reg":{
                     "override":[

                     ],
                     "ldap-search-parameters":[

                     ]
                  }
               }
            }
         }
      },
      "authUrl":{
         "_global":{
            "override":[
               "summary override global"
            ],
            "_instance":{
               "httpbin":{
                  "override":[
                     "summary override global instance"
                  ]
               }
            }
         },
         "_organization":{
            "my-org":{
               "override":[

               ],
               "_instance":{
                  "httpbin":{
                     "override":[
                        "summary override org instance"
                     ]
                  }
               }
            }
         },
         "_catalog":{
            "my-org":{
               "my-catalog":{
                  "_instance":{
                     "httpbin":{
                        "override":[
                           "summary override cat instance",
                           "echo some other override"
                        ]
                     }
                  },
                  "override":[
                     "summary override cat"
                  ]
               }
            }
         },
         "_instance":{
            "my-org-3":{
               "my-catalog-3":{
                  "my-authurl":{
                     "override":[
                        summary override instance
                     ]
                  }
               }
            }
         }
      }
   }
}
```

oauth-provider

Oauth objects used in a catalog.

- Oauth Types
  - Native
    - Override Key: override
  - Third-party
    - Override Key: override
- Scopes:
  - _global
    - _instance: APIM name
  - _organization
    - _instance: APIM name
  - _catalog
  - _instance: APIM name
- Example

```
{
   "oauth-provider":{
      "native":{
         "_global":{
            "override":[
               "apic-access-token-ttl 86400"
            ],
            "_instance":{
               "my-native-oauth":{
                  "override":[
                     "scopes-allowed cmcscope1",
                     "enable-debug-mode on"
                  ]
               }
            }
         },
         "_organization":{
            "my-org-2":{
               "override":[

               ]
            }
         },
         "_instance":{
            "my-org":{
               "my-catalog":{
                  "my-native-oauth-2":{
                     "override":[
                        "apic-enable-introspection on",
                        "apic-auth-code-ttl 600",
                        "apic-enable-refresh-token on "
                     ]
                  }
               }
            }
         }
      },
      "third-party":{
         "_organization":{
            "my-org":{
               "_instance":{
                  "my-third-party-oauth":{
                     "override":[
                        "third-party-introspect-url https://someaddress.com"
                     ]
                  }
               }
            }
         }
      }
   }
}
```

api-definition

The API objects that are published to one or more catalogs.

- Override Key: api-definition
- Child Objects
  - api-schema
  - Security-definition
    - oauth2
      - api-sec-oauth
      - _instance: swagger name
    - apiKey
      - api-sec-apikey
      - _instance: swagger name
    - http
      - api-sec-http-scheme
      - _instance: swagger name

        - basic
            - x-ibm-authentication-url
            - api-sec-basic-auth
            - _instance: swagger name
    - security-requirements
        - api-sec-oauth-req
            - Override Key: override
            - _instance: Datapower object name
        - api-sec-req
    - api-path
        - Override Key: path
        - _instance: *<Path URI>*
        - Child Objects
            - api-operation
                - Override Key: operation
                - _instance: *<Operation Method>*
                - Child Objects
                    - security-requirement
                        - api-sec-oauth-req
                            - Override Key: override
                            - _instance: Datapower object name
                        - api-sec-req
                    - api-schema-request
                    - api-schema-response
                        - Override Key: override
                        - _instance: Datapower object name
                - api-schema-request
    - wsdl-validation-schema-location
    - cors-policy
    - cors-rule
        - Override Key: override
        - _instance: Datapower object name
- Scopes:
    - _global
        - _instance: name:version
    - _organization
        - _instance: name:version
    - _catalog
    - _instance: name:version
- Example: In this example, the **`@exclusive`** flag is used on the instance nick-limits:1.0.0 in my-catalog of my-organization. The **`@exclusive`** flag means that only the CLI commands at the instance level are applied for that API while all other APIs in that catalog still have the global, organization, and catalog CLI commands applied to them.

```

- Scopes:
    - _global
        - _instance: swagger name:version
    - _organization
        - _instance: swagger name:version
    - _catalog
    - _instance: swagger name:version
- Example: In this example, 2 instances are included within the global scope mapping. First is, **`my-global-policy:1.0.0`**, which is a global-policy that is used in some catalogs. Since it is defined at the global scope, the overrides apply anytime an assembly is built from a swagger with the name and version of **`my-global-policy:1.0.0`**. Second is, **`complex-switch:1.0.0`**, which is an API that is published to various catalogs. Similarly, since it is defined as an instance with in the global scope the overrides apply anytime that the assembly is built from a swagger with the name and version of **`complex-switch:1.0.0`**. Also see the **`set-var`** example within global scope for an example of overriding assembly action instances based on the title that is given in APIM or the DataPower object name.

API Gateway

v5 policy emulation limitations

This page details the limitations of v5 policy emulation for the current release.

- The reverse solidus character (\) might be removed from policy property values.
- The source parameter for XSLT and GatewayScript policies is base-64 encoded to preserve escaping. It cannot be easily viewed from the DataPower command line or the DataPower WebGUI.
- Some DataPower service variables (for example, **`var://service/mpgw/skip-backside`**) might not be applicable in API Gateway, depending on how the variables are used.
- User-defined policies that make any alterations to a DataPower context are not supported.
- Execution of a 1.0.0 policy may fail if a previous 2.0.0 policy updates the **`message.body`** content type (for example, from XML to JSON, or JSON to XML).
- A proxy 1.5.0 policy can return an incorrect response if it is the last action within a switch **`case`** or **`otherwise`** property. The response is parsed. The correct behavior is to not parse the response. To work around this issue, set the **`final-action:true`** parameter on the proxy.
- Proxy 1.5.0 and invoke 1.5.0 policies do not preserve the **`gtid`** header.
- The **`cache-putpost-response`** property is not included in the schema for invoke 1.5.0 and proxy 1.5.0 policies.
- Setting HTTP response headers in a v5 user-defined policy, GatewayScript policy, or XSLT policy is not supported.
- Non-UTF-8 characters are not supported.
- JSON data returned in the response of an API running in v10 with v5 emulation is formatted without spaces.
- The v5 user-defined policy emulation feature creates v5 compatible context. After running the user-defined policy, the emulation feature analyzes the context and converts it back to DataPower® API Gateway compatible context. The computations involved in this process might negatively impact the DataPower API Gateway performance. For better performance, use a non-emulated user-defined policy. For more information, see Authoring Policies for DataPower API Gateway.

Configuring your Gateway server extensions

You can add extra IBM® DataPower® enforcement capabilities to a Gateway service by uploading a .zip file that defines the required extension behavior, and then enabling the extension in IBM DataPower.

About this task

You can upload a Gateway server extension to a Gateway service in either of the following ways:

- Use the Cloud Manager user interface
- Use the developer toolkit CLI

Procedure

- To upload a Gateway server extension to a Gateway service by using the Cloud Manager user interface, complete the following steps:
  1. In the Cloud Manager user interface, click Topology.
  2. Alongside the required Gateway service, click the options icon ⋮, then click Configure gateway extension.
  3. Click Add.
     Note: You cannot upload more than one Gateway extension .zip file to the same Gateway service. If a Gateway server extension has previously been uploaded, the Add button is not available; you can replace the previous extension by clicking the options icon ⋮ alongside gateway-extension, then clicking Edit.
  4. Upload the extension as indicated, either by dragging and dropping the .zip file, or by browsing and selecting it.
  5. Click Save when done.
- To upload a Gateway server extension by using the developer toolkit CLI, complete the following steps:
  1. Log in to your API Connect Cloud Manager server as an administrator, using the following command:

     `apic login --server <cloud-manager_endpoint_url> --username <admin_user_ID> --password <admin_password> --realm admin/<identity_provider>`

     where:
     - *<cloud-manager_endpoint_url>* is the Cloud Manager endpoint URL; for example: **`mgmt-admin.<myserver>.com`**.
     - *<admin_user_ID>* is the user ID of your administrator account, and is the same as the user ID that you use to log in to the Cloud Manager user interface.
     - *<admin_password>* is the password for your administrator account.

- *<identity_provider>* is the identity provider that is used to authenticate administrative users.

For example:

```
apic login --server mgmt-admin.myserver.com --username admin --password my-admin-password --realm admin/myldap
```

2. Upload the Gateway extension .zip file by using the following command:

```
apic gateway-extensions:create <extension_zip_file> --scope org --org admin --gateway-service <gateway_service> --
availability-zone <availability-zone> --server <cloud-manager_endpoint_url>
```

where:

- *<extension_zip_file>* is the Gateway extension .zip file that you want to upload.
- *<gateway_service>* is the name of the Gateway service that you want add the extension to.
- *<availability-zone>* is the name of the availability zone that contains the Gateway service.
- *<cloud-manager_endpoint_url>* is the Cloud Manager endpoint URL.

For example:

```
apic gateway-extensions:create myextension.zip --scope org --org admin --gateway-service mygatewayservice --
availability-zone availability-zone-default --server mgt-admin.myserver.com
```

This example uses the default supplied availability zone name of `availability-zone-default`, which will be the required value if you have not configured your own availability zones. To check the names of the currently configured availability zones, use the following command:

```
apic availability-zones:list --org admin --server <cloud-manager_endpoint_url>
```

For details on configuring availability zones, see Creating an availability zone.
To check the names of the currently configured gateway services, use the following command:

```
apic gateway-services:list --org admin --availability-zone <availability-zone> --server <cloud-manager_endpoint_url>
```

You can confirm that the extension has been added to the Gateway service by using the `gateway-extensions:get` command; for example:

```
apic gateway-extensions:get --scope org --org admin --gateway-service mygatewayservice --availability-zone
availability-zone-default --server mgt-admin.myserver.com --output -
```

(the parameter setting `--output -` writes the details of the Gateway extension object to the command window. You can specify the name of an existing folder to have the details written to a `.yaml` file in that folder.)
For reference details of the `apic gateway-extensions` commands, see apic gateway-extensions.

Note: You cannot upload more than one Gateway extension .zip file to the same Gateway service. If you want add further extensions later, update the original .zip file, then use the `apic gateway-extensions:update` command to replace the previous gateway extensions file with the revised one; for example:

```
apic gateway-extensions:update mynewextension.zip --scope org --org admin --gateway-service mygatewayservice --
availability-zone myavailabilityzone --server mgt-admin.myserver.com
```

3. Apply the extension to each server by restarting the API Connect gateway service object; complete the following steps on **each** Gateway server in the Gateway service:
Note: In Kubernetes environments, the following steps can be accomplished by issuing `kubectl delete pod` on **each** gateway pod. Be sure to wait until each pod gets back to the ready state before deleting the next gateway pod.
    a. Remove the Gateway server from the load balancing group.
    b. Disable, then enable the API Connect gateway service object. You can do this by using either the DataPower administrative user interface in a web browser, or by using the DataPower CLI.
        - By using the administrative user interface:
            - Log in to the DataPower administrative user interface; for the Graphical Interface, select WebGUI rather than Blueprint Console.
            - Switch to the DataPower application domain for API Connect if necessary.
            - Search for `API Connect Gateway Service`.
            - Set the Administrative State to disabled.
            - Apply the changes.
            - Set the Administrative State to enabled.
            - Apply the changes.
        - By using the CLI:
            - Enter configuration mode by entering the command `configure`.
            - Navigate to the DataPower application domain for API Connect by entering the command `switch api_connect_domain_name`, where *api_connect_domain_name* is the name of your API Connect application domain.
            - Disable the API Connect gateway service object by entering the following command:

              ```
              apic-gw-service; admin-state disabled; exit
              ```

            - Enable the API Connect gateway service object by entering the following command:

              ```
              apic-gw-service; admin-state enabled; exit
              ```

    c. Ensure that the gateway service object initialization has completed.
    d. Re-add the Gateway server to the load balancing group.
4. Apply the extension to each server by restarting the API Connect gateway service object; complete the following steps on **each** Gateway server in the Gateway service:
Note: In Kubernetes environments, the following steps can be accomplished by issuing `kubectl delete pod` on **each** gateway pod. Be sure to wait until each pod gets back to the ready state before deleting the next gateway pod.

Results

The extension is uploaded and applied to each of the servers in the Gateway service, and the associated enforcement capabilities are applied to all incoming API resource requests.

Warning: DataPower Gateway (v5 compatible) only If you upload an extension to the DataPower Gateway (v5 compatible), a status file called extension_import_response.xml is written to the local:/ext folder in the gateway file system. Do not remove this file, otherwise if your gateway extension is subsequently removed then the referenced objects cannot be reverted to their original state automatically, and you will therefore have to either complete these clean up tasks manually, or re-add the gateway extension to regenerate the extension_import_response.xml file and then remove the gateway extension again. If the extension_import_response.xml exists and there is a cleanup failure for any object, a failure file is written to the local:/ext folder, with the failure details.

Cloud Manager Tutorials

Tutorials for using the Cloud Manager user interface in IBM® API Connect.

Prerequisites

To complete the following tutorials you must be the Cloud Administrator or Cloud Owner of an API Connect instance.

Overview

These tutorials guide you through common tasks performed to set up and maintain the configuration of a cloud.

- **Tutorial: Configuring the Cloud**
  This tutorial shows you how to create a basic cloud configuration, with available gateway, analytics and developer portal services.
- **Tutorial: Creating a Provider Organization**
  This tutorial shows you how to create a Provider Organization.

Tutorial: Configuring the Cloud

This tutorial shows you how to create a basic cloud configuration, with available gateway, analytics and developer portal services.

Before You Begin

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator

You will need the following information to complete this tutorial.

- The IP address or FQDN of the gateway, and the port assigned to accept API requests from clients.
- The IP address or FQDN of the gateway, and the port assigned to communicate with the API Management server. This cannot be the same as the port for API requests.
- The FQDN of the Developer Portal service to accept requests from clients.
- The FQDN of the Developer Portal to communicate with the API Management server.
- The FQDN of the Analytics service to accept requests from clients.
- The address, port and optional login credentials for an SMTP email server.

Note: The port for the **`portal-www`**, **`portal-admin`**, and **`analytics-ingestion`** services is **`443`**, and isn't configurable.

About this tutorial

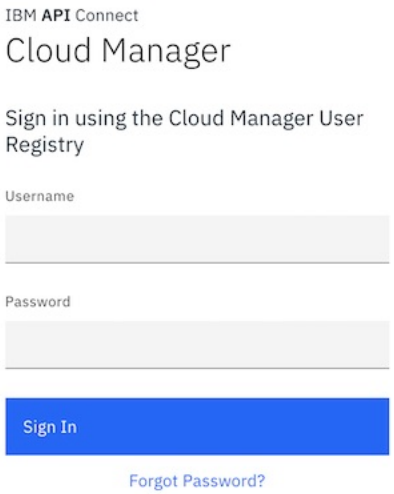
In this tutorial you are going to complete the following lessons:

- Initial Cloud Manager Console login
- Configure an Email Server
- Register a Gateway Service
- Register a Portal Service
- Register an Analytics Service
- Configure a Default Gateway Service

Initial Cloud Manager Console login

Take the following steps to log in to the Cloud Manager user interface for the first time.

1. In a web browser, enter the management service URL. For example, `https://ManagementService.domain/admin` where ManagementService.domain is the fully qualified host name or IP address of the Management service.



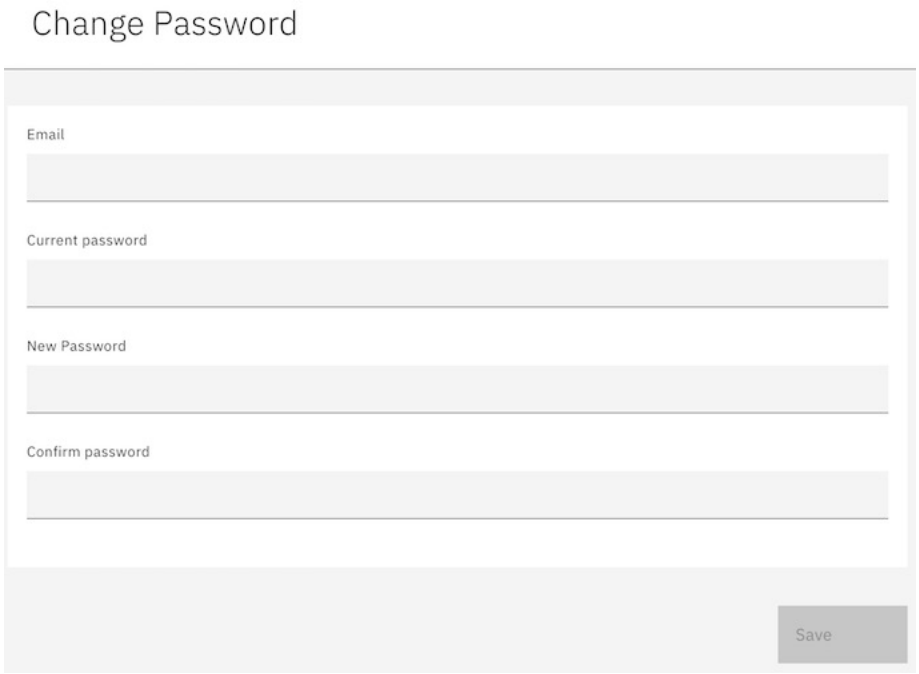
2. Enter the Cloud Administrator user name and password. The default values are `admin` for the user name and `7iron-hide` for the password.

   OpenShift top-level CR install

   If you installed API Connect on OpenShift using the top-level "API Connect Cluster" CR, the default user name is `admin`. If you are logging in for the first time, run the following commands to retrieve the initial password, which is generated automatically during deployment:

   ```
   oc get secret -n <namespace> | grep mgmt-admin-pass
   oc get secret -n <namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d && echo ""
   ```

3. You are immediately required to change the admin password, as well as provide an email address for the cloud administrator. Enter the necessary information. Note: If you forget your password and request a password reset, the notification email is sent to this email address. This action will use the email server set in the Notifications section of the cloud Settings. This tutorial shows you how to set this configuration.

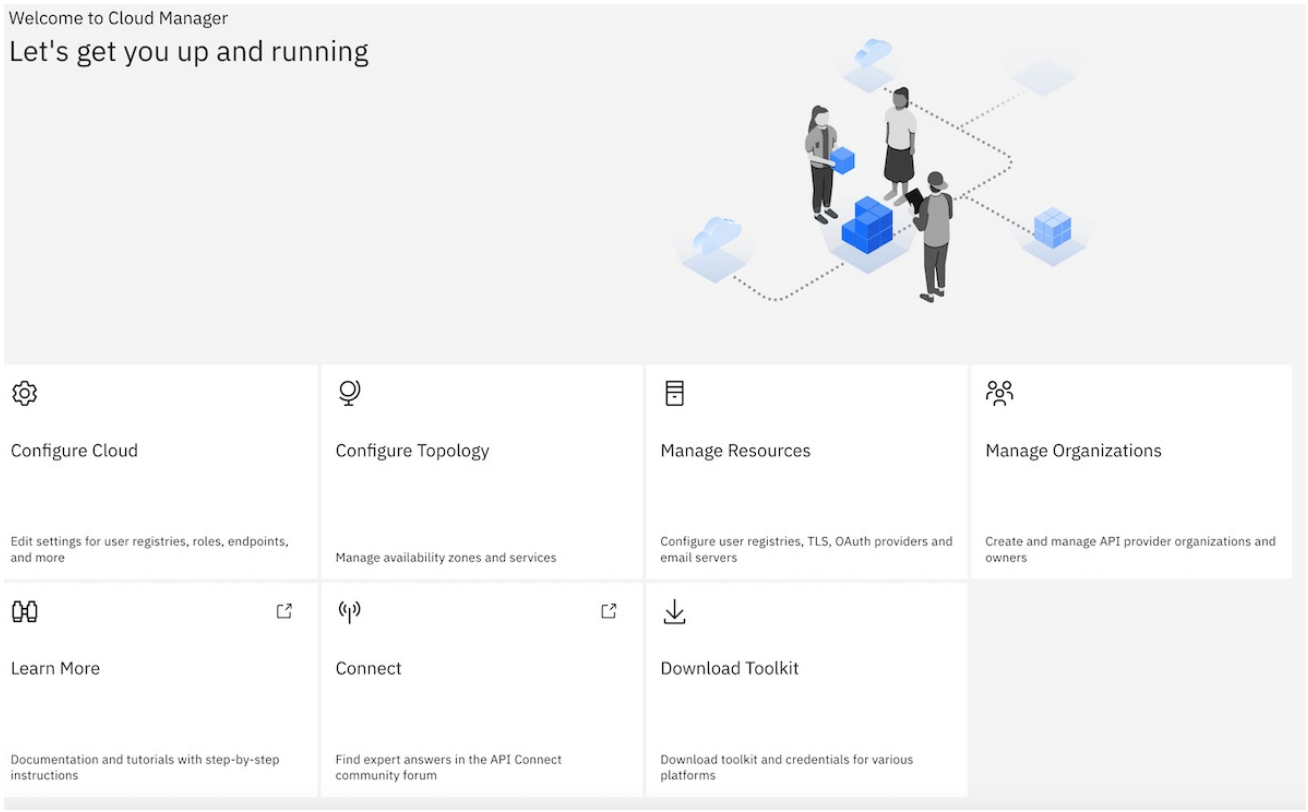


4. Click Save.
5. Log in using the new password.

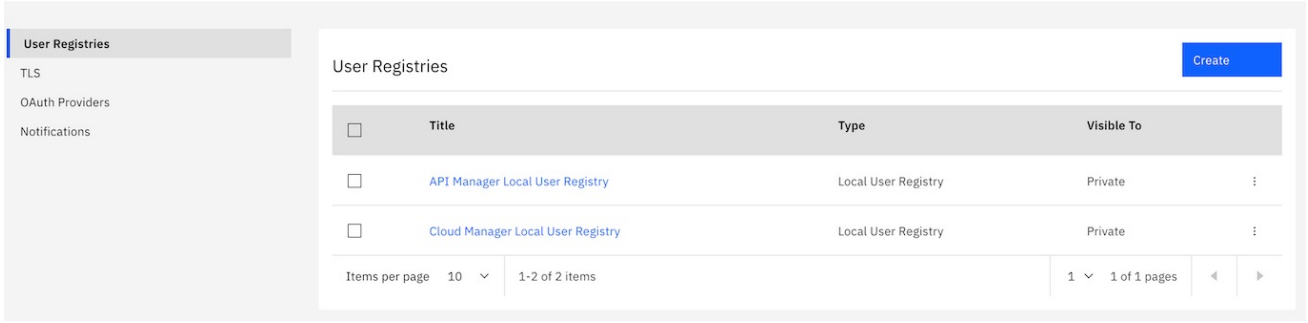
Configure an Email Server

Take the following steps to configure an email server. This configuration allows you to recover the admin password or receive other important notifications.

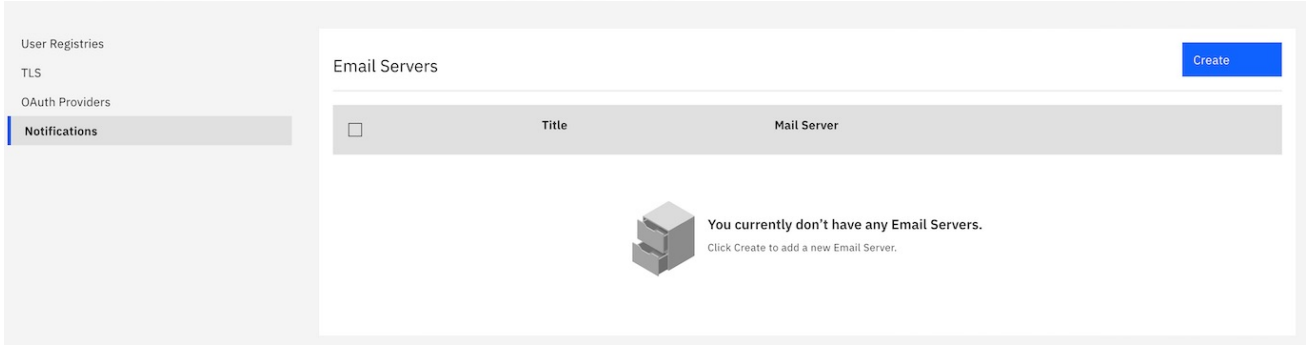
1. Click Resources icon or the Manage Resources tile.



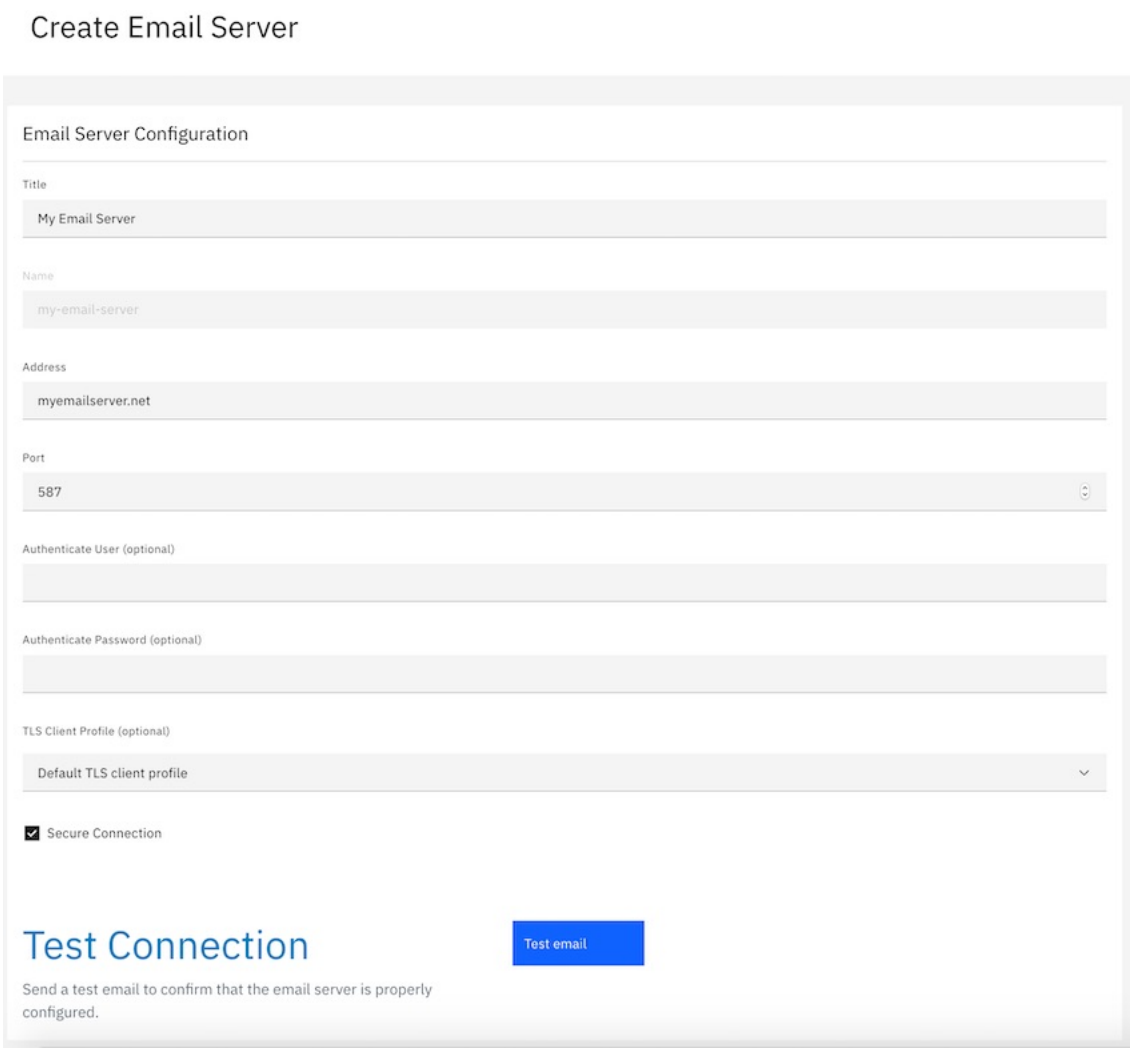
2. Click Notifications.



3. Click Create.



4. Enter the appropriate values in the fields These values vary depending on your site.
5. Click Save.

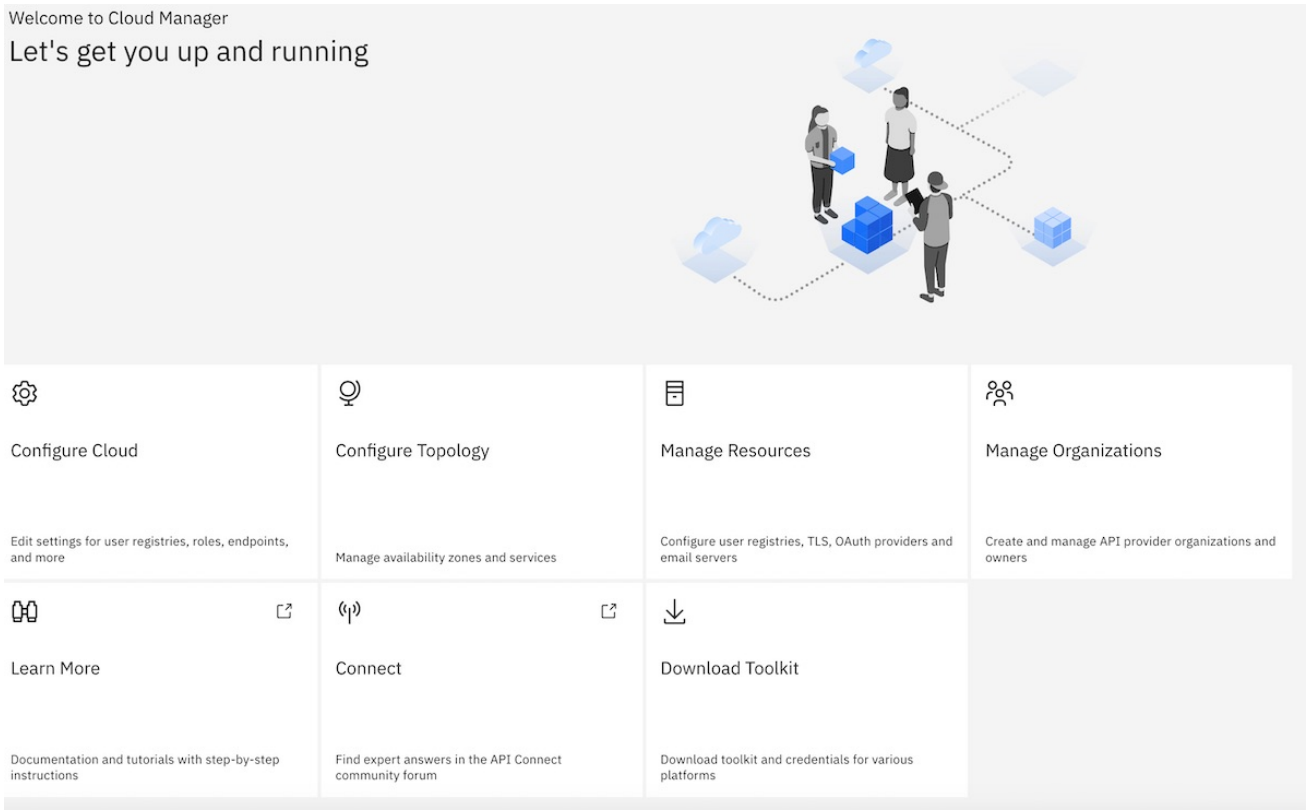


6. Click the Settings icon, then click Notifications > Edit.
7. Ensure your email server is selected, then click Save.
8. Click the Home icon.

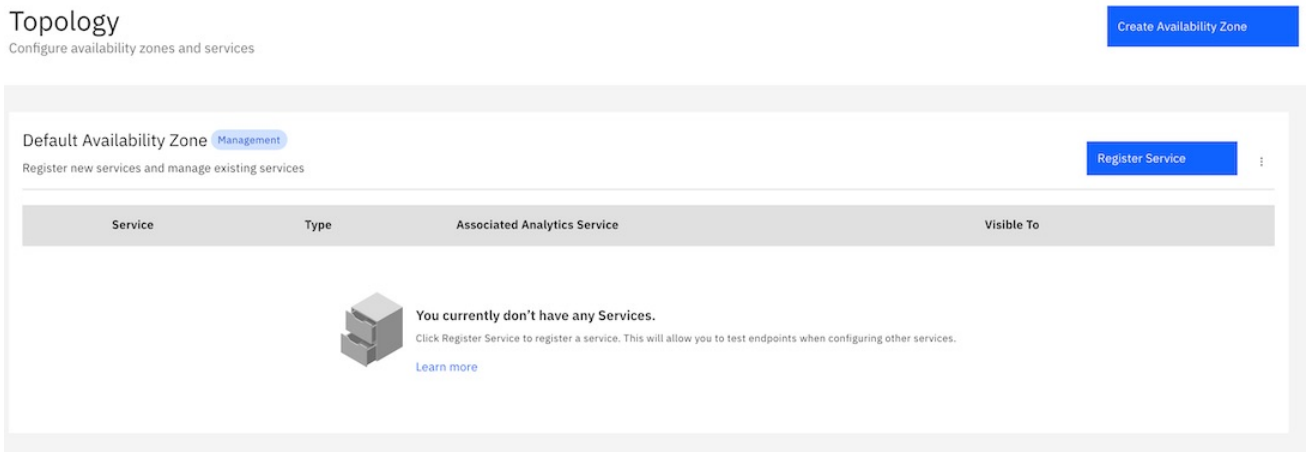
Register a Gateway Service

Take the following steps to register a gateway service.

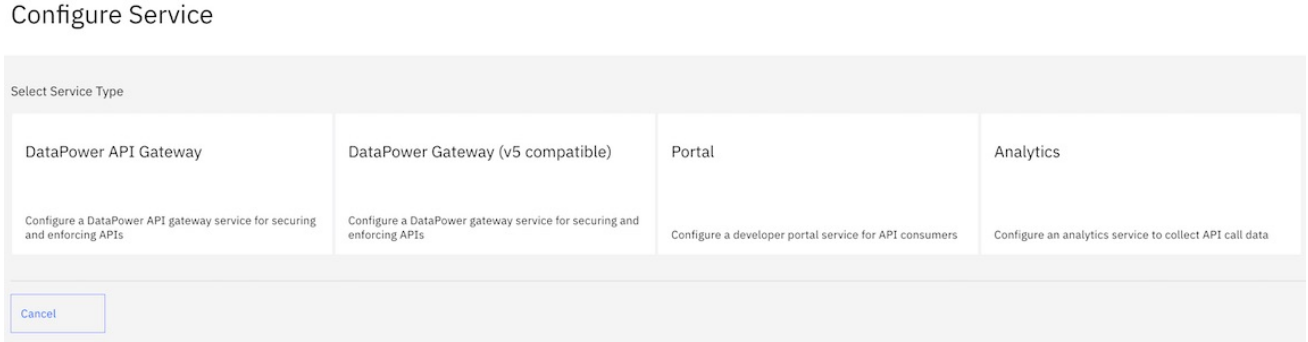
1. Click the Configure Topology tile.



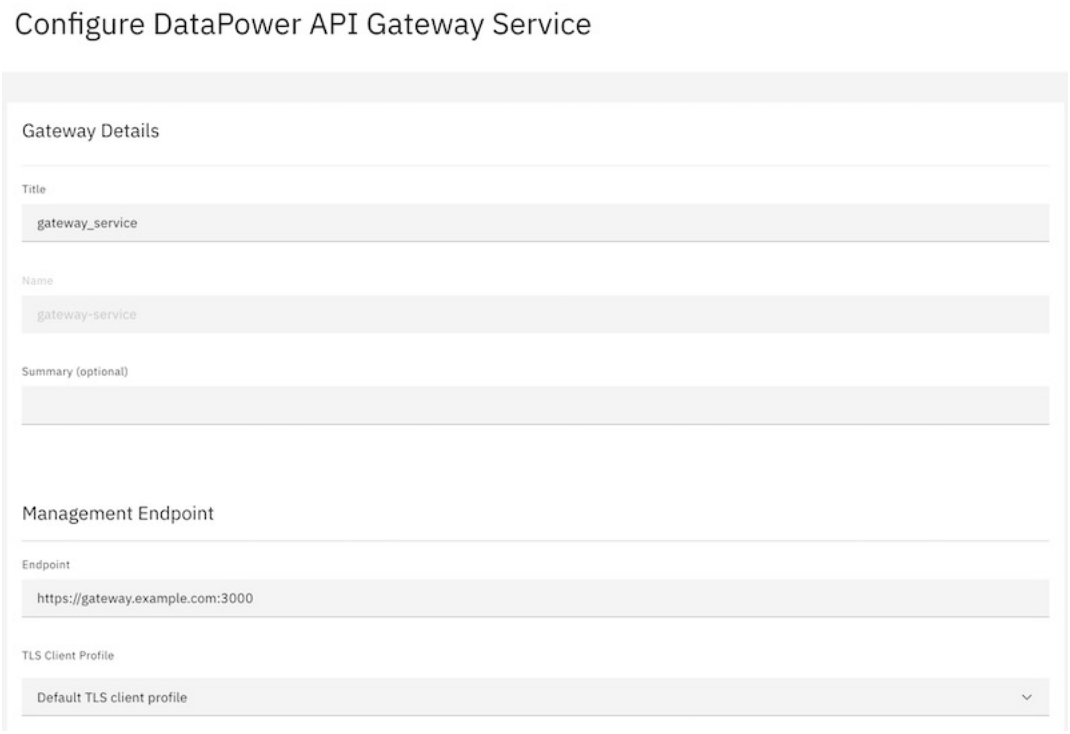
2. Click Register Service.



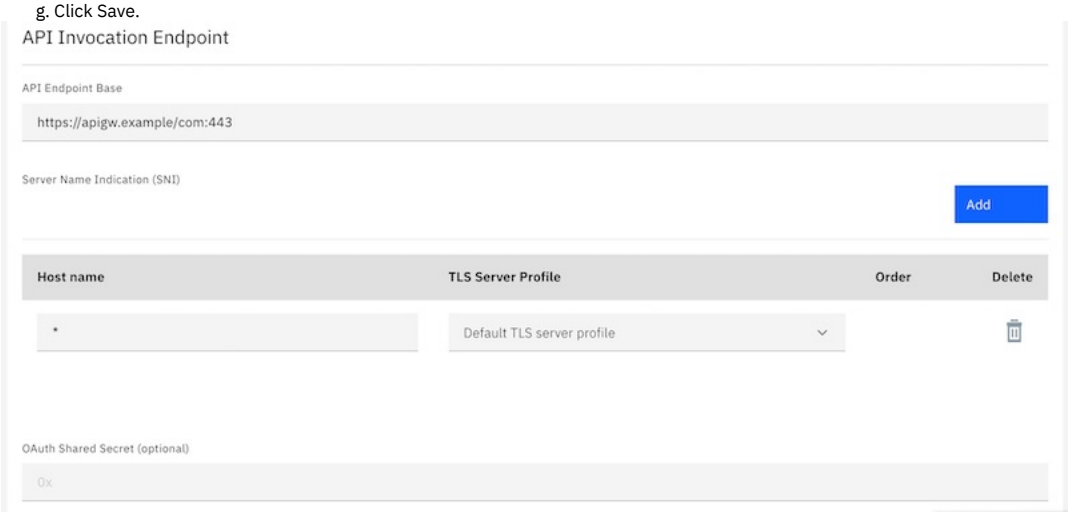
3. Click DataPower API Gateway.



4. Take the following steps.
   a. Enter `gateway_service` in the Title field.
   b. In the Management Endpoint section, enter the URL of the address and port assigned to the management endpoint in the Endpoint field. This is the port used by the API Management server to connect to the gateway.
   c. Leave the remaining values as given to set TLS profiles.



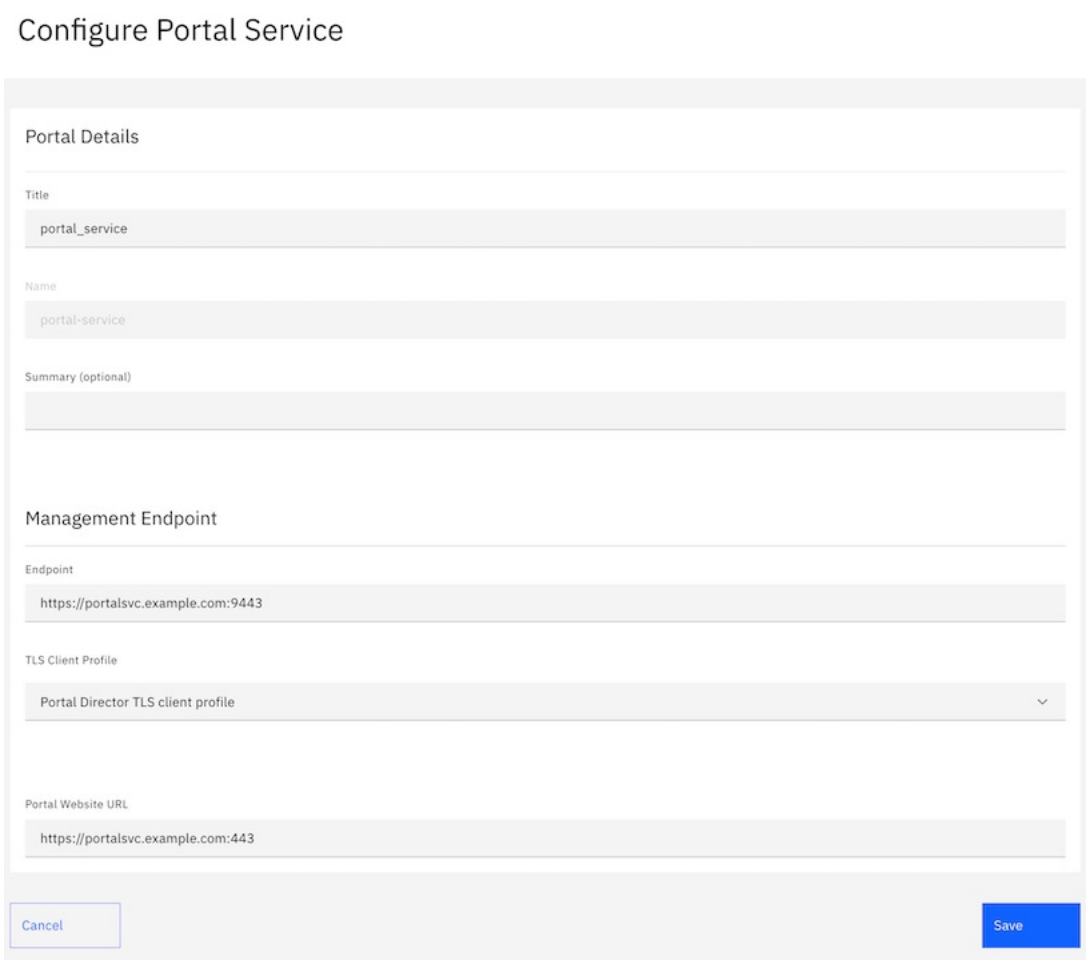
d. In the API Invocation Endpoint section, enter the URL of the gateway address and port assigned to accept API requests from clients in the API Endpoint Base field.
e. Do not change the defaults in the Server Name Indication (SNI) fields. Note that your topology may require specific values in these fields.
f. Optionally enter a hex value in the OAuth Shared Secret field. This must be a 64-bit hex value that begins with "0x". Providing a shared secret value here enables gateways in a cluster to read the OAuth tokens generated by any member of the cluster using the same secret.
g. Click Save.



Register a Portal Service

Take the following steps to register a portal service.

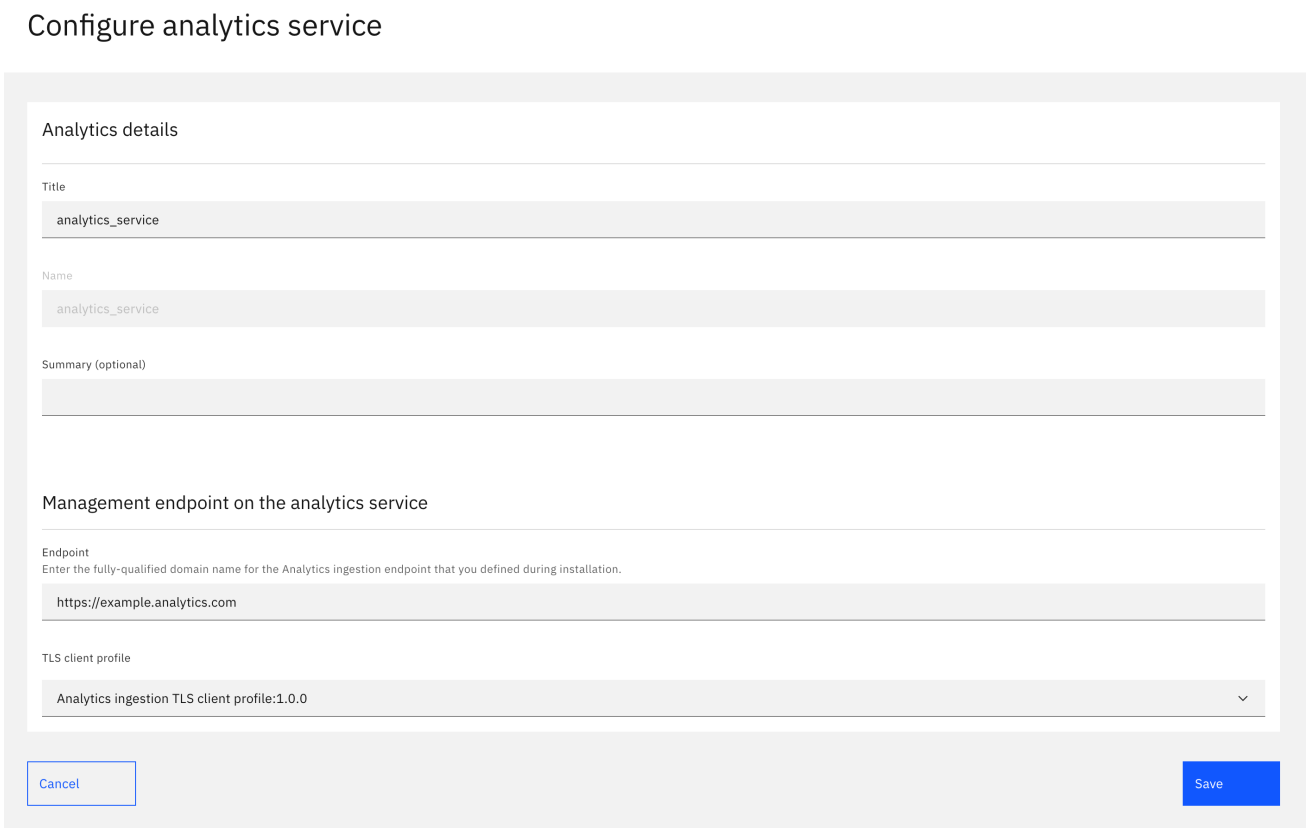
1. Click Register Service.
2. Click Portal.
3. Take the following steps.
   a. Enter `portal_service` in the Title field.
   b. In the Management Endpoint section, enter the URL of the portal address and port assigned to communicate with the management server in the Endpoint field.
   c. Enter the URL of the portal address and port assigned to accept requests from clients in the Portal Website URL field.
   d. Use the reconfigured profile in the TLS Client Profile field.
   e. Click Save.



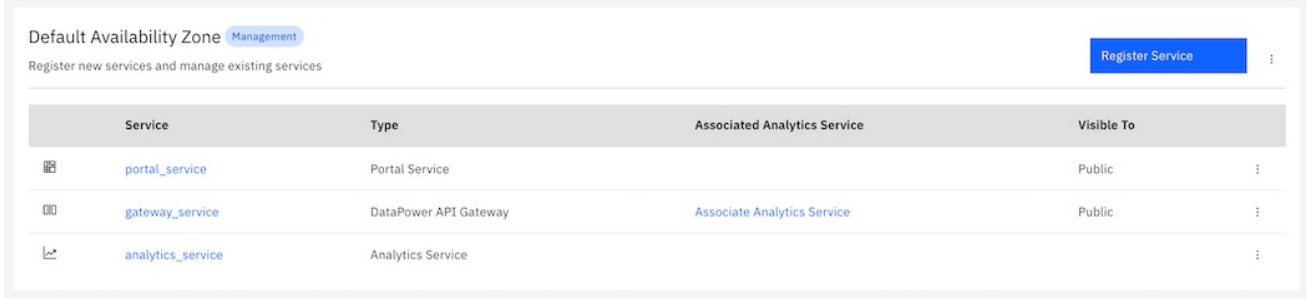
Register an Analytics Service

Take the following steps to register an analytics service.

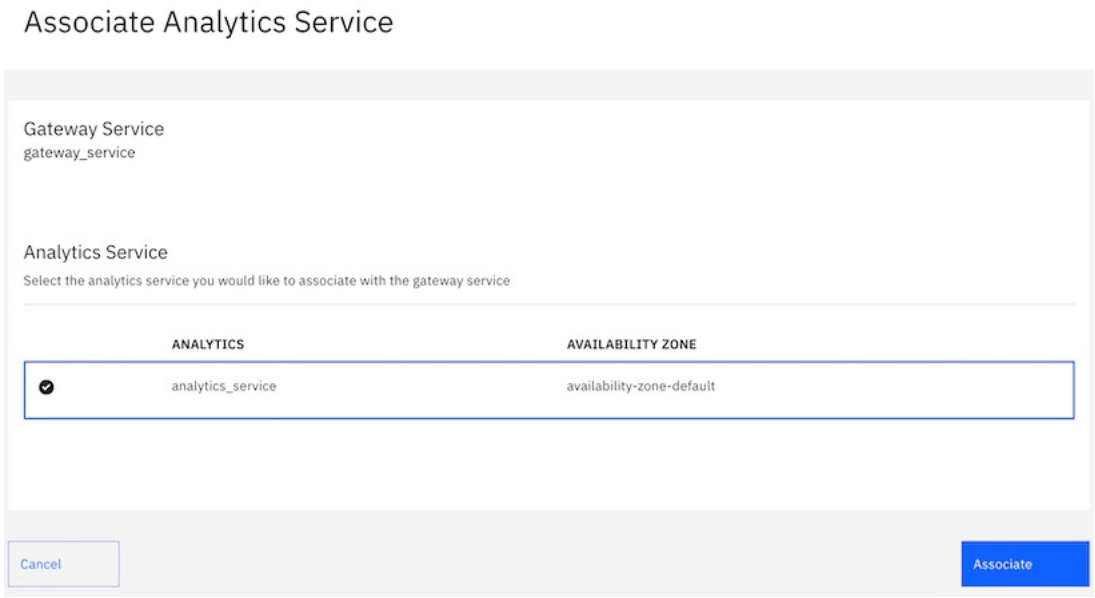
1. Click Register Service
2. Click Analytics.
3. Take the following steps.
   a. Enter `analytics_service` in the Title field.
   b. In the Management Endpoint section, enter the URL of the analytics server address and port assigned to accept requests from clients in the Endpoint field.
   c. Select `Analytics ingestion TLS client profile` in the TLS Client Profile field.
   d. Click Save.



4. Click Associate Analytics Service corresponding to the gateway service listing.



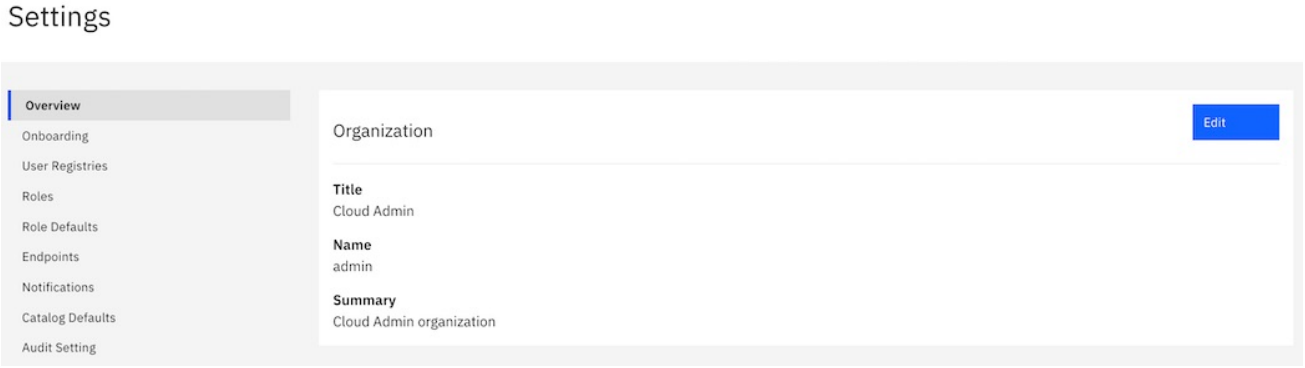
5. Select analytics_service. Click Associate.



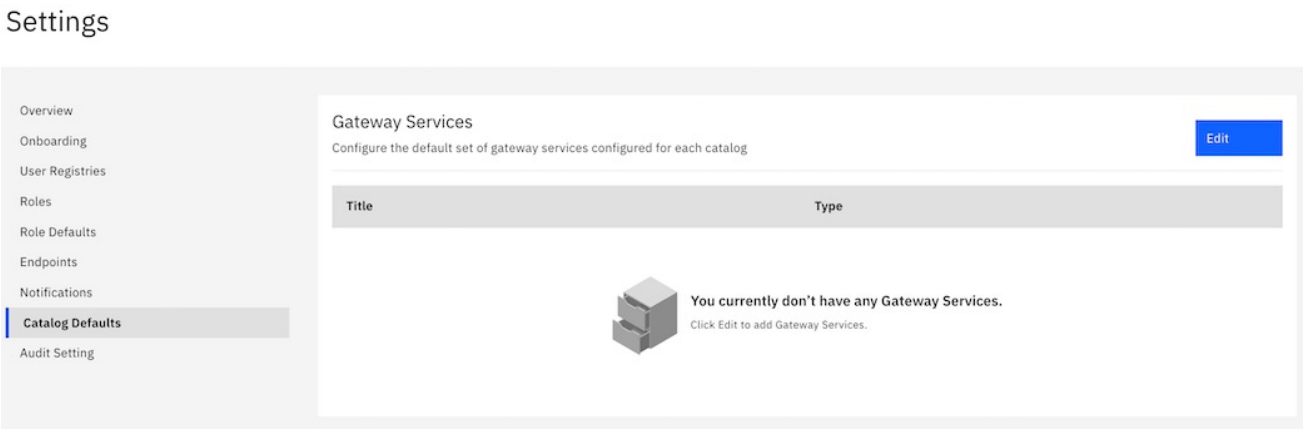
Configure a Default Gateway Service

Take the following steps to configure a default gateway service for every catalog in the cloud.

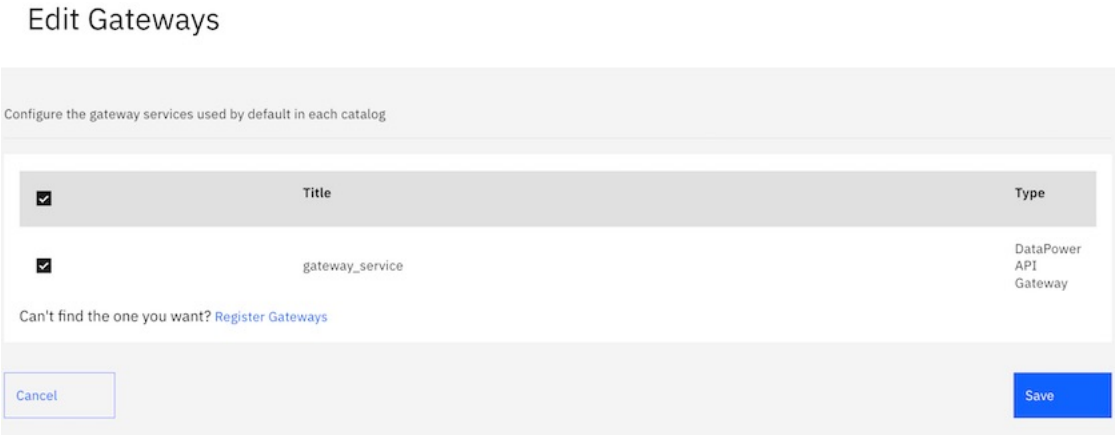
1. Click Settings icon .
2. Click Catalog Defaults.



3. Click Edit.



4. Select an available gateway service.
5. Click Save.



What you did in this tutorial

- Set new Cloud Manager Console login password
- Configured a Gateway Service
- Configured a Developer Portal Service
- Configured an Analytics Service
- Configured a Notifications Email Server
- Configured a Catalog Default Gateway Service

Tutorial: Creating a Provider Organization

This tutorial shows you how to create a Provider Organization.

Before You Begin

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator

You must also complete the following tasks before beginning:

- Configuring an email server for notifications
- Setting up notifications

Note that an email server must be configured and an active email server must be selected before a provider organization account can be created.

About this tutorial

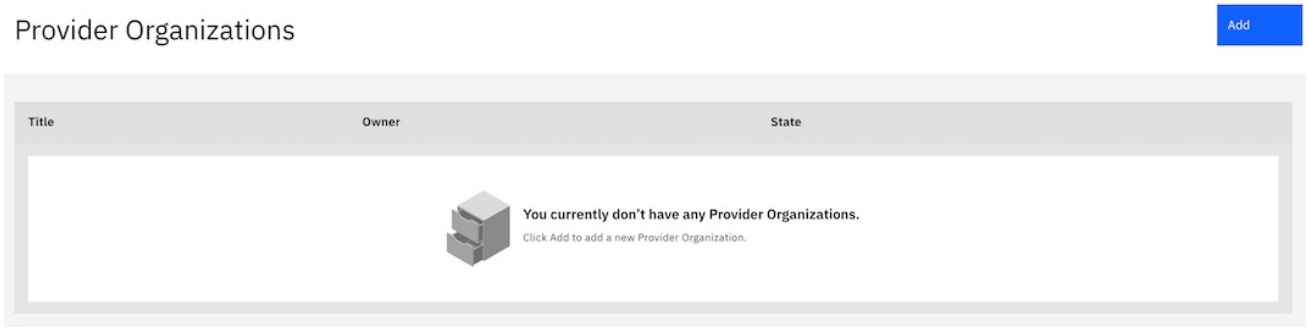
In this tutorial you are going to complete the following lessons:

- Create a Provider Organization

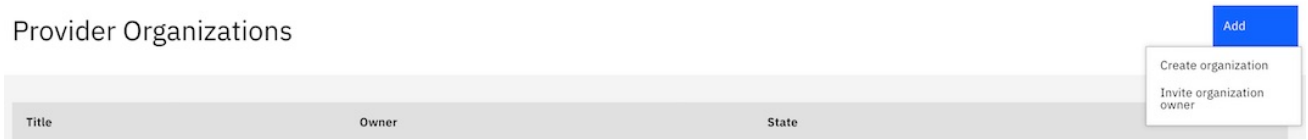
Create a Provider Organization

Take the following steps to create a new Provider Organization.

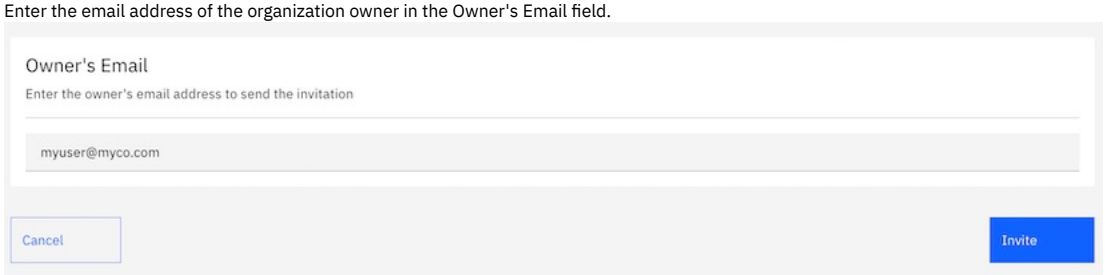
1. Log in to the Cloud Manager.
2. Click Provider Organizations.



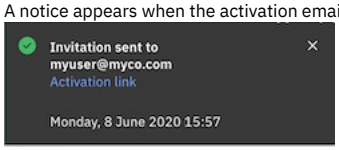
3. Click Add > Invite organization owner.



4. Enter the email address of the organization owner in the Owner's Email field.

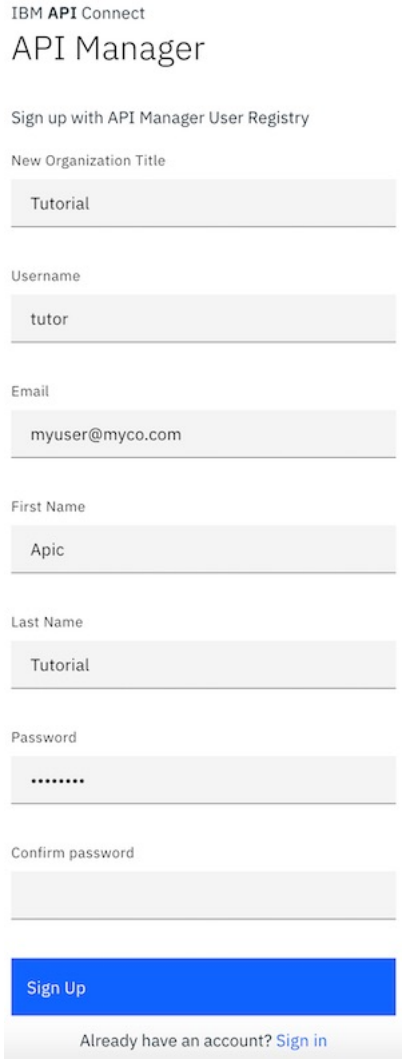


5. Click Invite.
6. A notice appears when the activation email has been sent. Click Activation link..

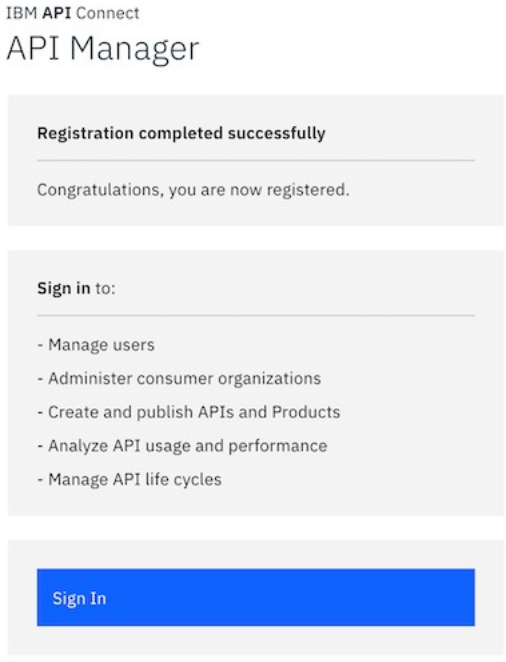


7. A dialog box displays the activation link. Click the Copy to clipboard icon .

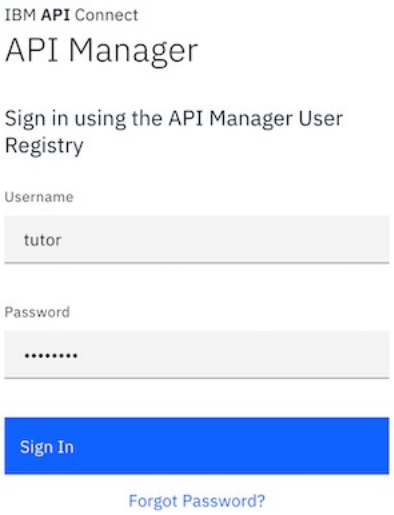
8. Open a new window in your browser. Paste the copied activation link into the Location bar. Optionally, you can click the activation link in the invitation email to open the registration form.
9. Complete fields shown in the form to sign up with the API Manager User Registry. Click Sign up.



10. You see a confirmation of registration. Click Sign in.



11. Enter the username and password you just created. Click Sign in to begin creating APIs and products.



12. Return to the original window of your browser. Click Provider Organizations to refresh the list. Your new organization is listed.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a new Provider Organization.

- Importing an API

Developing your APIs and applications

You develop APIs and LoopBack® applications by using the IBM® API Connect developer toolkit.

The API Connect developer toolkit provides both the API Designer user interface and a command line interface that you can use to develop APIs and LoopBack applications and publish them to API Connect.

You publish APIs by including them in a Product and then publishing the Product. You define your APIs and Products by creating and validating YAML definition files in your local file system. You can then interact with API Connect by using either the API Designer or the toolkit commands.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
The developer toolkit is described in detail in the following subsections:

- **API development checklist**
  A summary, with links, of the key tasks for developing APIs in IBM API Connect.
- **Working with the toolkit**
  Install the developer toolkit by downloading an executable file. You can then use the toolkit commands to interact with IBM API Connect and publish APIs that you have defined in your file system.
- **Managing platform REST API keys**
  Create API keys associated with your user account, and then use them to authenticate when you call the platform REST APIs provided by API Connect.
- **Searching for items in API Manager**
  Use the search feature in IBM API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.
- **Working with API definitions**
  An API definition specifies the complete configuration for an API. You can create and configure your APIs either by using either the API Designer UI application, or by using the browser based API Manager UI.
- **Working with Products**
  In IBM API Connect, Plans and APIs are grouped together in Products, with which you can manage the availability and visibility of APIs and Plans.

- **Creating and validating API and Product definitions by using the CLI**
  The developer toolkit of IBM API Connect provides a command line interface that you can use to create and publish API and Product definitions, and also to validate YAML or JSON definitions.
- **Working with global policies**
  Use global policies to configure policy assemblies that are called just before, or just after, each of your API assemblies is called, or when an error is thrown. You can upload global policies into each of the gateway services in your Catalogs, and then designate, for each gateway service, which global policy should be called before an API assembly is called, after an API assembly is called, or if an error occurs when an API assembly is called. The designated global policies are applied to all the APIs that are deployed to the associated gateway service.
- **Reference**
  Reference information for developing your APIs in API Connect, including context variables, and template variables.

API development checklist

A summary, with links, of the key tasks for developing APIs in IBM® API Connect.

Task	Description
Activate your API Manager user account	For you to be able to connect to a Management server by using either the API Designer or API Manager user interfaces, one or other of the following prerequisites must be satisfied: • Your administrator has created a provider organization, specifying you as the owner; see Creating a provider organization. • You have been added as a member of a provider organization; see Adding provider organization users and assigning roles.
Install the developer toolkit	The developer toolkit provides a command-line environment and an API Designer user interface, both of which enable you to develop and work with your APIs on your local machine; you publish your APIs to the Management server when ready. You can also develop your APIs directly on the Management server by using the API Manager user interface.
Log in to the user interface; see Logging in from API Designer, or Accessing the API Manager user interface, depending on which user interface you want to use.	After you have activated your account, you can log in to your Management server from either user interface. You can also use the API Designer in offline mode, but to be able to test and publish APIs you must be connected to a Management server.
Create your API definitions	You can create API definitions in the following ways: • Create a REST API definition either by composing the API definition, and its operations, from scratch, creating a proxy API that calls an existing endpoint, or importing an OpenAPI definition. • Expose an existing SOAP service as an API. • Create a GraphQL API proxy definition that proxies a backend GraphQL server.
• Secure your APIs (OpenAPI 2.0) • Secure your APIs (OpenAPI 3.0)	You configure security for an API by creating one or more security definitions that you then apply to your API, and to the operations in your API. Security mechanisms include basic authentication through a user registry, and token based authentication with OAuth.
Test your APIs	The user interfaces provide a test tool with which you can test your APIs through the gateway.
Productize and publish your APIs	To make your APIs available to application developers, you include them in a Product that you then publish to the gateway.
Apply visibility controls and rate limiting to your APIs	Visibility settings control which APIs the application developers can subscribe to. Rate limiting controls the usage of your APIs; for example, you can apply a rate limit of 100 calls per minute.
Develop your APIs by using the developer toolkit CLI	You can use the developer toolkit CLI to develop APIs based on OpenAPI definition files in YAML or JSON format.

Working with the toolkit

Install the developer toolkit by downloading an executable file. You can then use the toolkit commands to interact with IBM® API Connect and publish APIs that you have defined in your file system.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
The following subsections describe how to install and use the toolkit:

- **Installing the toolkit**
  You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM API Connect.
- **Logging in from API Designer**
  To log in from the API Designer user interface for IBM API Connect, you will need the host name of the management server and the user name and password associated with your API Manager account.
- **Using the developer toolkit command-line tool**
  The IBM API Connect developer toolkit provides a command-line tool, `apic`, that you can use to perform all API Connect tasks. You can also use the command-line tool to script tasks such as continuous integration and delivery.

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just to need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
   - To download the toolkit from IBM Fix Central, complete the following steps:
     - Open the IBM Fix Central site in your browser.
     - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
     - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
     - In the Text field, enter `toolkit`, then click Continue.
     - Select the toolkit file that you want to download.
     - Click Continue, then follow the instructions to complete the download operation.
   - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
     - Open the Cloud Manager or API Manager user interface.
     - On the welcome page, click the Download Toolkit tile. The two toolkit options are listed.
     - Click your platform alongside either the CLI option or the CLI + LoopBack + Designer option as required, then save the associated compressed file to your local file system.
     - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the designer_credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 6.
     - To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 5.
     - Close the Install API Connect Toolkit window.
2. Extract the contents of the toolkit compressed file to a folder of your choice.
   The contents of the file depend on the your chosen toolkit option and platform, as follows:

   - The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.
   - The apic or apic.exe file is the CLI for IBM API Connect including LoopBack support.
     Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.
   - The api_designer-*platform* file is the API Designer user interface application for the specified platform.
3. Optional: Delete the **`$HOME/.apiconnect/node_clis`** directory.
   You need to do this only if you replaced a version of **`apic`** or apic.exe and are using the **`apic lb4`** command. You need to delete the directory get **`apic`** to unpack the new loopback.

   On Windows, $HOME is defined by environment USERPROFILE.

4. Run the CLI.
   - For the Mac OSX or Linux® platforms, complete the following steps:
     - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Make the CLI file an executable file by entering the following command:

       ```
       chmod +x download_name
       ```

       Where *download_name* is the name of the toolkit file that you downloaded, either apic or apic-slim.
     - Run CLI commands as follows:

       ```
       ./apic command_name_and_parameters
       ```

       or

       ```
       ./apic-slim command_name_and_parameters
       ```

       For details of the CLI commands, see apic.
   - For the Windows platform, complete the following steps:
     - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Run CLI commands as follows:

       ```
       apic command_name_and_parameters
       ```

       or

       ```
       apic-slim command_name_and_parameters
       ```

For details of the CLI commands, see apic.

Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.

5. Install the toolkit credentials.
   If you do not install the toolkit credentials that are provided for download, as detailed previously in the toolkit credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

   ```
   apic client-creds:set toolkit_credentials_file_path/credentials.json
   ```

   where *credentials_file_path* is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.
   Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
   To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

   ```
   apic client-creds:clear
   ```

   For increased security, an administrator can remove the default credentials from the management server by completing the following steps:
   a. Log in to the management server as an administrator; see Logging in to a management server.
   b. Delete the default credentials by running the following commands:

   ```
   apic registrations:delete toolkit --server mgmt_endpoint_url
   apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
   ```

6. Install the API Designer credentials.
   If you do not install the API Designer credentials that are provided for download, as detailed previously in the API Designer credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the **APIC_DESIGNER_CREDENTIALS** environment variable to the credentials download location, using the mechanism appropriate for your operating system.

   After you have set the **APIC_DESIGNER_CREDENTIALS** environment variable, your API Designer uses the new credentials to authenticate with the management server.

   - Windows:
     If you are using Windows, create an environment variable using one of the following methods:

     - Create a permanent environment variable so that you can start API Designer from any location on your computer:
       - Open the Environment Variables page: Click Start > Settings > System and in the "Related Settings" section of the page, click Advanced System Settings.
       - On the Advanced tab of the System Properties dialog box, click Environment Variables.
       - In the "User variables" section, click New and create an environment variables with the following settings:
         - Variable: **APIC_DESIGNER_CREDENTIALS**
         - Value: *<designer_credentials_file_path>*\designer_credentials.json where ***<designer_credentials_file_path>*** is the location where you stored the designer_credentials.json file.
       - Click OK to save the new environment variable, and then exit the dialog box.
     - If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
       - Open the Windows command prompt.
       - Run the following command to set the temporary environment variable:

         ```
         set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
         ```

         where ***<designer_credentials_file_path>*** is the location where you stored the designer_credentials.json file.

         Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.
       - Now run the following command to start API Designer:

         ```
         C:\"Program Files\API Designer\API Designer.exe"
         ```

         By default, API Designer is installed in the C:\"Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

   - Mac:
     If you are using Mac OS X, create an environment variable using one of the following methods:

     - Run the following command to set the global environment variable:

       ```
       launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
       ```

       where ***<designer_credentials_file_path>*** is the location where you stored the API Designer credentials JSON file.
     - Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

       ```
       APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open
       <designer_application_file_path>/'API Designer.app'
       ```

       where:
       - ***<designer_credentials_file_path>*** is the location to which you downloaded the API Designer credentials JSON file.
       - ***<designer_application_file_path>*** is the location to which you downloaded and uncompressed the API Designer application.

7. Start the API Designer application from the location to where you stored the extracted file.
   Note:
   - To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
     - In Windows File Explorer, navigate to the USER_HOME\AppData\Local\Programs\api-designer folder.
     - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.

- To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see Developing your APIs and applications.

For information on using the toolkit CLI, see Using the developer toolkit command-line tool.

Logging in from API Designer

To log in from the API Designer user interface for IBM® API Connect, you will need the host name of the management server and the user name and password associated with your API Manager account.

About this task

API Designer provides a secure login to a management server for staging and publishing APIs and Products. You log in to the same host that was configured for API Manager and use your API Manager user name and password. You will need an account on API Manager and membership in a provider organization to access the API Designer.

You can also use the Explorer tab to see how your APIs look to a consumer in the Developer Portal. You can check the descriptions of the different artifacts, and refine any schemas or examples, and you can also use the Try it tool to test the behavior of the API.

Note:

- Configuration changes that are made in API Manager are not available in API Designer concurrently. You will need to log out of API Designer and log back in to access any updates.
- Set **`SKIP_IBMID_LOGIN=true`** as an environment variable to bypass the IBM ID login screen for API Designer. This applies to users who are working on an internal network, without access to external networks.

Procedure

To log in to API Designer, complete the following steps:

1. Download and extract API Designer, as described in Installing the toolkit.
2. Start the API Designer user interface by running the application from the location where you extracted the contents of the toolkit compressed file.
   Note: If you see a message stating that credentials cannot be found, download new credentials as explained in Downloading the toolkit.
3. Optional: If you see the Accept License page, click the URL read the license agreement, then click the button to accept the license. This prompt appears only one time. It does not appear once you have accepted the license on the current system.
4. Optional: If you see the IBM ID login page, enter your IBM customer ID.
   Note: You won't receive the IBM ID page if you are already authorized, or if you have set the **`SKIP_IBMID_LOGIN`** environment variable to **`true`**.
5. Open a directory on your local file system to store the API and Product specifications that you create in API Designer. The system defaults to a previously-accessed directory.
   If you want to switch to a different directory after logging in, click Switch directory on the menu bar in the header.

   Note: If you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, don't copy the file into your API Designer directory.
   Such an API will **not** be visible in the API Designer user interface if it doesn't contain the API Connect specific sections that are required by API Designer.

   Instead, copy the OpenAPI definition file to another folder, then import it into API Designer; the import operation adds the necessary API Connect specific sections; see Adding a REST API by importing an OpenAPI definition file.

   For more information on the API Connect specific sections in an OpenAPI definition file, see IBM extensions to the OpenAPI specification.

6. If this is the first time you have logged in, establish a connection to API Connect by completing the following steps:
   - Contact your administrator and request the "management endpoint URL" for connecting to API Connect.
     The management endpoint URL looks similar to the following example: https://*<host.domain>* and indicates the location where the API Manager is running.

     Note: If you are using API Connect as a component of Cloud Pak for Integration, the management endpoint URL follows this format:
     https://*cpd-your-company.domain*/integration/apis/*APIC_namespace*/*APIC_instance*

     Example: https://cpd-company.com/integration/apis/apic/production

     Do not add /manager to the URL. If you include /manager at the end of this URL, the connection with Cloud Pak for Integration will fail with a message stating that the host URL is invalid.

   - In the dialog window, enter the management endpoint URL as the Host URL and click Next.
   - Type the user name and password for your API Manager account.
   - Select a User Registry from the list.
   - Click Sign In.
7. For subsequent log ins, select the appropriate cloud where you will be working. You can select from any previous cloud connections.
8. When more than one cloud connection is configured, you can switch clouds when developing APIs and Products. See Switching clouds from API Designer.
   Note: If you are using an OIDC user registry that supports single sign-on (SSO), you cannot switch clouds to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then select the required cloud connection.
9. Click Add Another Cloud to add another cloud connection. Enter the URL, user name and password, and user registry to add the cloud connection.
   Note: If you are using an OIDC user registry that supports single sign-on (SSO), and you are already logged in, you cannot add a new cloud connection to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then add the new cloud

connection.
10. Delete a cloud connection by selecting the trash can icon.
11. API Designer will launch with the organization set to your provider organization in the selected cloud. If you have accounts for multiple provider organizations, it will default to the first organization in alphabetical order.
12. To choose another provider organization, select it from the drop-down list.

- **Setting the locale for API Designer**

Setting the locale for API Designer

How to set one of the supported locales when you start the API Designer application.

About this task

If you want to use a different locale than your current operating system (OS) locale, you can set a locale code by using the **`--lang`** argument when you start the API Designer application. This locale is then effective for the duration that the application is open. If no **`--lang`** argument is set, then the current OS locale is used.

Procedure

To change the locale for API Designer, complete the following instructions.

From the command line, run the following command to start the API Designer application with the **`--lang`** argument:

Mac OS X Mac:

```
open "API Designer.app" --args --lang=locale_code
```

Windows Windows:

```
"API Designer".exe --args --lang=locale_code
```

Where ***`locale_code`*** is one of the following supported locale codes:

Table 1. List of supported locale codes and their associated language

Locale code	Language
`cs`	Czech
`de`	German (Standard)
`en-US`	English (United States)
`es`	Spanish
`fr`	French (Standard)
`it`	Italian (Standard)
`ja`	Japanese
`ko`	Korean
`nl`	Dutch (Standard)
`pl`	Polish
`pt-br`	Portuguese (Brazil)
`ru`	Russian
`tr`	Turkish
`zh-cn`	Chinese (PRC)
`zh-tw`	Chinese (Taiwan)

For example, running the following command on a Mac:

```
open "API Designer.app" --args --lang=es
```

sets the API Designer language to Spanish.

Switching clouds from API Designer

You can switch clouds to work in another cloud in API Designer.

About this task

API Designer allows the flexibility to connect to multiple clouds. For example, your organization may have separate clouds for testing, development, and demos. You select the cloud connection when you log in, but you can also switch clouds when you are developing APIs and Products. Multiple clouds must be configured in order to switch clouds. You must have a valid API Manager account to connect to a cloud.

Note: If you are using an OIDC user registry that supports single sign-on (SSO), you cannot switch clouds to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then select the required cloud connection.

Procedure

To switch clouds for working in API Designer, complete the following steps:

1. Log in to API Designer and select a cloud, or configure a new cloud connection.
2. From the Develop: APIs and Products screen, you can switch to another cloud by selecting it from the Switch Cloud Connection menu.
3. Delete a cloud connection by selecting the trash can icon.

Working offline with API Designer

You can work offline (without a connection to the cloud) with API Designer to create APIs. Some functionality is missing due to the lack of a cloud connection.

About this task

API Designer provides the capability to work in offline mode without a connection to a management server. You can work on APIs with no management server, but some functions will be changed or missing.

The preferred method for working in API Designer is with a Cloud Connection to the management server when logging into API Designer. Working while connected to a management server provides full functionality, with automatic field completion. When working offline, you will need to remember the values to complete the fields that are backfilled from the management server.

Following are the differences when working in offline mode:

- There is no connection to a management server.
- There is no Provider Organization selection.
- Only the Develop APIs and Products tile may be selected. The Learn more and Connect menu tiles are not available.
- When creating an API, the Gateway Type defaults to V5 Gateway and the default policies are loaded.
- Stage and Publish for APIs and Products functions are not available.
- The Sandbox catalog is not available.
- When configuring a Security Definition, there are no selection lists available for the User Registry for a Basic Auth security definition or for the OAuth Provider for an OAuth 2 security definition. You will need to enter the User Registry and OAuth Provider values correctly as text.
- When adding custom Visibility and custom Subscribability values for a product, there is no selection list for the Organization field. You will need to enter the organization name correctly as text.

Procedure

To work in offline mode in API Designer, complete the following steps:

1. Log in to API Designer and open a directory location.
2. To start offline mode, choose Work Offline from the selector in the upper right corner of the Connect to Cloud screen.
3. The Home page appears with the Develop APIs and Products tile. Select Develop APIs and Products to start working in offline mode.
4. To return to online mode, choose Connect to Cloud in the upper right hand corner and select the management server to log in to.

Gathering support information in API Designer

When you report an issue with the API Designer application, enable debug mode and provide as much information as possible.

To report an issue with API Designer, enable debug mode, collect the recommended information, and submit it with your report. Including the information will help IBM resolve the problem more quickly.

- Enabling debug mode on Mac
- Enabling debug mode on Windows
- Enabling debug mode on Linux

- Information to gather for support

Enabling debug mode on Mac

Start API Designer with debug mode enabled:

1. Start a terminal or command prompt.
2. Navigate to the directory where API Designer is installed.
3. Run the following command to start API Designer in debug mode:

   ```
   DESIGNER_DEBUG=true open API/Designer.app/
   ```

   If you add **`DESIGNER_DEBUG=true`** to your .bash_profile, then every time you start API Designer it will open in debug mode.

Enabling debug mode on Windows

Add a Windows environment variable that enables debug mode for API Designer:

1. Type "Environment" in the Windows search bar (on the task bar) and select Edit environment variables for your account.
2. In the Environment Variables dialog box, click New in the "User variables" section.
3. In the New User Variable dialog box, add the following variable settings and then click OK:
   - Variable name: `DESIGNER_DEBUG`

   - Variable value: `True`

4. Click OK to save your change.

Enabling debug mode on Linux

To start API Designer with debug mode enabled, add the following command to your .bash_profile:

```
EXPORT DESIGNER_DEBUG=true
```

Information to gather for support

Gather the following information about your problem and include it with your report.

- Operating system where you are running API Designer (Mac, Windows, or Linux)
- Product versions for API Designer and the API Manager that is connects to:
  1. Open API Designer.
  2. Click the Help icon on the navigation bar.

     
  3. On the Help page, click the Product information tile.
  4. On the Product information page, note down the following values for the following labels on the page:
     - Connected to API Manager Product version
     - Package
- HAR file
  The HAR file contains the information about your browser's interaction with the web, and can be helpful in determining why your problem is happening. Complete the following steps to export the HAR file from the browser where you use API Designer:

  1. Open API Designer.
  2. Open the browser's developer console; for example in Google Chrome, click > More tools > Developer tools.
  3. In the developer console, click the Network tab.
  4. Click to download the HAR file.
- Are you using API Designer in Online mode or Offline mode?
  If you're using Online mode, are you connecting to a local test environment, or to an API Manager server?
- When does the problem happen?
  Provide reproducible steps with optional screen captures or video so the support team can recreate the problem.
- Supporting data.
  Provide any related data that would be useful while examining the problem; for example, a copy of the API or Product that you were using.
- How often does the problem happen?
  Is the problem intermittent? Does it happen constantly? Does it only happen with certain artifacts (for example, only with a particular API)? If the problem is associated with an artifact, try to include it with your report.

Using the developer toolkit command-line tool

The IBM® API Connect developer toolkit provides a command-line tool, **apic**, that you can use to perform all API Connect tasks. You can also use the command-line tool to script tasks such as continuous integration and delivery.

The command line tool is described in detail in the following subtopics. For summary reference material for each of the available commands for the developer toolkit, see Command-line tool reference for the developer toolkit.

- **Overview of the command-line tool**
  The IBM API Connect developer toolkit provides commands for cloud administration and API development and management.
- **Logging in to a management server**
  You log in to a management server from the command line by using the **apic login** command. The parameters that you supply determine the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.
- **Logging in to a management server with an OIDC registry**
  Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.
- **Cloud administration commands**
  A summary of the cloud administration commands in the IBM API Connect developer toolkit.
- **API development and management commands**
  A summary of the core commands in the IBM API Connect developer toolkit.
- **Creating APIs and applications**
  You can develop API proxies and API implementations by using the developer toolkit. In the documentation, *API* refers to the API proxy and *application* refers to the API implementation.
- **Publishing APIs and applications**
  To publish APIs and applications by using the developer toolkit of IBM API Connect, you set configuration variables to define where you want to publish, log in to the target cloud platform, and then use the appropriate publishing commands.
- **Managing API Products**
  Use the **apic products** and **apic apis** commands to manage Products and APIs that have been published to IBM API Connect Catalogs. Use the **--scope space** option to manage Products and APIs that have been published to Spaces within Catalogs.
- **Working with Drafts**
  Co-locate your APIs and applications in your local source code control systems to support typical development activities such as commits, branching, merges, continuous integration, and so on. The developer toolkit provides the bridge from the developer's environment to the IBM API Connect runtime services.
- **Reading input from the command line**
  If a developer toolkit command takes a file as an input parameter, you can direct the command to read the input directly from the command line rather than supplying a separate file; this can be useful when writing scripts to automate command line operations, for example.
- **Scripting with the toolkit commands**
  The IBM API Connect developer toolkit provides commands for cloud administration and API development and management.
- **Working with OpenAPI extensions**
  Use the developer toolkit CLI **extensions** commands to manage OpenAPI extensions in your Catalogs or Spaces.
- **Using the toolkit CLI to execute API tests**
  The IBM API Connect developer toolkit provides CLI commands for automated API behavior testing.

Overview of the command-line tool

The IBM® API Connect developer toolkit provides commands for cloud administration and API development and management.

Command syntax

In general, commands have the following syntax:

apic *command*:*sub-command* [*argument*] [*options*]

where

- *command* is the command, usually the thing on which you are acting (for example, product, app, API, Catalogs, and so on).
- *sub-command* is the action to perform.
- *argument* is the argument, where applicable (for example,**catalog**).
- *options* are any number of command-line options, which have the form **--*option* [*value*]**. Options also have a short form with a single dash instead of a double dash.

For example, **apic apps:publish --server mgmnthost.com**.
For some commands, either the command or sub-command portion is optional. For example:

- **apic products:publish** is equivalent to **apic publish**.
- **apic products:list** is equivalent to **apic products**.

The **create** command has a slightly different syntax:

apic create:*type* [*options*]

Use the **-h** or **--help** option to view command help.
Note: The language in which the CLI help text, and other command response text, is displayed is determined by the locale setting on your local machine.

Viewing command line tool help

Display general command-line help information by entering the following command: **apic --help** or **apic -h**. Display help information for a specific **apic** command by entering the following command: **apic *command_name* --help** or **apic *command_name* -h**.

Viewing version information

Display the version of the command-line tool by entering the command: **apic --version**.

Setting the mode

The API Connect toolkit CLI runs commands on either the provider organization or on the consumer organization. When you run the command, you use the different mode options to identify the instance on which you want to run the command. The following list provides a summary of the modes that are available:

apim
: This mode applies to the administrative instances of the CLI. When you run commands in this mode, it uses the overall API Manager as its scope. This mode is the default mode.
An example of running a command in the apim mode:

```
apic extensions:list-all --mode apim --scope catalog --server server1 --catalog catalog1 --org myOrg --configured-gateway-service service1
```

portaladmin
: This mode applies to the developer portal instances of the CLI. This mode supports commands that you can use to replicate all or part of your Developer Portal environment.
An example of running a command in the portaladmin mode:

```
apic --mode portaladmin custom-theme:create-export --catalog catalog1 --org myOrg --server server1 --format json
```

consumer
: This mode applies to the consumer instances of the CLI. This command uses the consumer organizations that you have permission to access as its scope. You must specify this mode or set it as the default value for the command to use it.
An example of running a command in the consumer mode:

```
apic catalogs:list --mode consumer --scope catalog --server server1 --catalog catalog1 --org myOrg
```

To avoid having to supply the parameter on every consumer CLI command, you can set the **mode** configuration variable, as described in the next section.

Using configuration variables

You can set the values of commonly-used properties in configuration variables. In general, it's easier and more consistent to set configuration variables instead of specifying them using command-line options.
Note:
You can set a configuration variable locally (the default) to affect only the current LoopBack project, or globally (with command-line option **-g**), to affect all projects. The local value supersedes the global value. You can set local configuration variables only for LoopBack projects. When you set configuration variables for OpenAPI projects, they are always global.

The values of local configuration variables are stored in the *project-root*/.apiconnect/config file, where *project-root* is the project root directory. The values of global configuration variables are stored in the *user-home-dir*/.apiconnect/config file, where *user-home-dir* is the user's home directory.

Use the following commands to work with configuration variables:

- **apic config:get *varname*** - Get a configuration variable. Use **apic config** to display the values of all local configuration variables or **apic config -g** to display the values of all global configuration variables.
- **apic config:set *varname*** - Set or update the specified configuration variable.
- **apic config:delete *varname*** - Delete the specified configuration variable.
- **apic config:clear** - Delete all configuration variables.

You set configuration property values by using the **apic config:set** command. By setting configuration properties (for example **catalog** and **app**), you do not need to supply values for these options when you enter a command.

Additionally, you can use **apic properties** commands to work with configuration properties:

- **apic properties:clear** - Clear the configuration properties.
- **apic properties:create** - Augment the configuration properties with additional name/value pairs.
- **apic properties:delete** - Delete the configuration property.
- **apic properties:get** - Get the configuration property.
- **apic properties:list** - List the configuration properties.
- **apic properties:update** - Update the configuration property.

Note:
If you have an environment variable of the same name as a CLI configuration property then, by default, its value will override the value of the corresponding CLI configuration property for any CLI command at that scope.

For example, if you have defined an environment variable called **SPACE** then, by default, that value will be assumed for the value of the **--space** parameter in the following command, regardless of any **space** configuration property setting:

```
apic products:publish my_product.yaml --scope space
```

To prevent environment variables overriding CLI configuration properties, define an environment variable called **APIC_LOAD_FROM_ENV**, set to the value **false**.

The following table describes the configuration variables:

Table 1. Configuration variables

Variable name	Description	Use instead of (or override with) these flags...

Variable name	Description	Use instead of (or override with) these flags...
catalog	Default Catalog name for all commands that manage aspects of a Catalog. The Catalog value can be specified as either: • The full Catalog URI that includes server name and organization name: ***mgmt-server*/api/catalogs/*org-name*/*catalog-name***. In this case, you do not need to specify **--catalog**, **--organization**, or **--server** when you make CLI calls, since their values are included in the full Catalog URI. • The Catalog name, for example: **sandbox**. In this case, you still need to specify **--organization** and **--server** when you make CLI calls. Note: The Catalog name **apic-dev** is reserved for local testing.	• If Catalog URI used in variable assignment: **--catalog, --organization, --server** • If Catalog name used in variable assignment: **--catalog**
cloud	Default management server host name for cloud administration commands. Form: ***mgmt-server*/api/**.	**--server**
consumer	Default URI of an API consumer. Form: ***mgmt-server*/api/consumer-orgs/*org-name*/*catalog-name*/*consumer-org-name***, where *mgmt-server* is the management server, *org-name* is the organization name, *catalog-name* is the Catalog name, and *consumer-org-name* is the consumer organization name.	**--server, --organization, --catalog, --consumer**
mode	The default value of the **--mode** parameter for CLI commands. Set the value to **apim** or **consumer** depending on whether you want to run commands on a provider organization or a consumer organization. If you do not set this variable, and do not supply a **--mode** parameter on a command, the value **apim** is assumed.	--mode
org	Default org name for all commands that manage organizations. Form: ***mgmt-server*/api/orgs/*org-name***, where *mgmt-server* is the management server, *org-name* is the organization name. The org value can be specified as either: • The full org URI that includes the server name: ***mgmt-server*/api/orgs/*org-name***. In this case, you do not need to specify **--server** or **--organization** when you make CLI calls, since their values are included in the full org URI. • The org name, for example: **providerorg1**. In this case, you still need to specify **--server** when you make CLI calls.	• If org URI used in variable assignment: **--organization, --server** • If org name used in variable assignment: **--organization**
space	Default Space URI for all commands that manage aspects of a Space. Form: ***mgmt-server*/api/spaces/*org-name*/*catalog-name*/*space-name***, where *mgmt-server* is the management server, *org-name* is the organization name, *catalog-name* is the Catalog name, and *space-name* is the Space name. You can append the port number to the server name if it is not the default value of 443.	**--server, --organization, --catalog, --space**

To set configuration properties, enter the following command:

```
apic config:set name=value
```

where *name* is the name of the configuration property and *value* the value to assign to it.
For example:

```
apic config:set catalog=sandbox
```

Scripting commands

It's often helpful to automate a series of **apic** commands In a shell script. Since the **apic** tool first requires you to interactively accept the license, you must first use the following command:

```
apic --accept-license
```

Once you do that, your scripts can run non-interactively.
To disable collection of usage analytics, enter this command:

```
apic --live-help
```

Related information

- Command-line tool reference for the developer toolkit

Logging in to a management server

You log in to a management server from the command line by using the **apic login** command. The parameters that you supply determine the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.

Attention: If you want to log in with an OIDC user registry or if you are an IBM Cloud Pak for Integration (CP4I) user, see Logging in to a management server with an OIDC registry.

1. Clear the credentials from any previous login by running the following command:

   ```
   apic client-creds:clear
   ```

   Clearing the credentials ensures that you do not inadvertently log in with the wrong set of credentials (for example, from a different product release or environment).

2. Set the credentials that you want to use now by running the following command:

```
apic client-creds:set path_to_credentials/credential.json
```

Where ***path_to_credentials*** is the location of the credential.json file that you want to use. For example:

```
apic client-creds:set /Users/local_user/credential.json
```

The parameters for the **apic login** command are as follows:

mgmt_endpoint_url
The URL depends on the type of organization that you are logging in with:

- Cloud admin organization or Provider organization, use one of the following URLs:
  - Platform API endpoint URL (note that if you want to run commands that relate to API governance, you must use the platform API endpoint URL to log in).
  - Management API manager URL.
- Consumer organizations, use the consumer API endpoint URL.

These endpoint URLs are configured during the installation of API Connect. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in Viewing platform and UI endpoints, ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

user_id
The user ID you want to log in with. Depending on the tasks that you want to perform, this user ID might be any of the following:

- A user ID that is a member of the cloud administration organization. This is an ID that you could also use to log in to the Cloud Manager user interface.
- A user ID that is a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
- A user ID that is a member of a consumer organization. This is an ID that you could also use to log in to the Developer Portal.

password
The password associated with the supplied user ID.

realm
The *realm* parameter specifies the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.
The format of the *realm* depends on the type of user, as follows:

- Member of the cloud administration organization:

  admin/*identity_provider*

  To determine the identity provider, see How to determine the identity provider.

- Member of a provider organization:

  provider/*identity_provider*

  To determine the identity provider, see How to determine the identity provider.

- Member of a consumer organization:

  consumer:*provider_org*:*catalog*/*identity_provider*

  where *provider_org* is the name of your provider organization, and *catalog* is the name of the Catalog in that provider organization.
  To determine the identity provider, see How to determine the identity provider.

  Important:
  - If you have installed toolkit credentials, as detailed in Installing the toolkit, then at any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
    To revert to the default pre-supplied toolkit credentials for all login operations from the toolkit CLI, use the following command:

    ```
    apic client-creds:clear
    ```

  - If you log in to the CLI as a member of a consumer organization, you must supply the **--mode=consumer** parameter to the **apic login** command, and to all consumer commands. To avoid having to type the parameter every time, you can set the **mode** configuration variable, by entering the following command:

    ```
    apic config:set mode=consumer
    ```

You can also use the command interactively; enter **apic login** and you will be prompted for the values. For example:

```
apic login
Enter your API Connect credentials
Server? platform-api.myserver.com
Realm? provider/default-idp-2
Username? myuser
Password?
Logged into myserver.com successfully
```

Note: If you see a message stating that credentials cannot be found, download new credentials as explained in Downloading the toolkit.

How to determine the identity provider

If you want to log in as a member of the cloud administration organization, or as a member of a provider organization, you can help determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope scope --server mgmt_endpoint_url --fields title,realm
```

where *scope* has the value **admin** or **provider** depending on whether you want to log in as a member of the cloud administration organization, or as a member of a provider organization. The output lists the names and titles of all identity providers, for example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time.
The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**, and the default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
By default, API Connect creates a local user registry for user login for every context. The identity providers associated with these default registries are as follows:

Registry	Identity provider name
Cloud Manager Local User Registry (for login as a member of the cloud administration organization)	default-idp-1
API Manager Local User Registry (for login as a member of a provider organization)	default-idp-2
Sandbox Catalog User Registry (for login as a member of a consumer organization)	sandbox-idp

If you want to log in as a member of a consumer organization, see Logging in as a consumer to the Developer Portal by using the CLI for full details.

Logging out

To log out of a management server, use the following command:

```
apic logout --server mgmt_endpoint_url
```

Logging in to a management server with an OIDC registry

Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.

Attention: Logging in with an OIDC registry is supported for the developer toolkit (used with API Manager) and the Developer Portal admin toolkit, but is not supported for members of consumer organizations. If you are using IBM Cloud Pak for Integration (CP4I), review this topic for login instructions. If you want to log in using a non-OIDC registry, see Logging in to a management server.
To log in, complete the following steps:

1. Clear the credentials from any previous login by running the following command:

   ```
   apic client-creds:clear
   ```

   Clearing the credentials ensures that you do not inadvertently log in with the wrong set of credentials (for example, from a different product release or environment).

2. Set the credentials that you want to use now by running the following command:

   ```
   apic client-creds:set path_to_credentials/credential.json
   ```

   where ***path_to_credentials*** is the location of the credential.json file that you want to use. For example:

   ```
   apic client-creds:set /Users/local_user/credential.json
   ```

3. Log in by running the following command:

   ```
   apic login --server mgmt_endpoint_url --sso
   ```

   where***mgmt_endpoint_url*** is the endpoint URL. When you log in with a Cloud admin or Provider organization, specify one of the following URLs:
   - platform API endpoint URL
   - management API manager URL

   These endpoint URLs are configured during the installation of API Connect. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in Viewing platform and UI endpoints, ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

   CP4I: If you are using API Connect as a component of IBM Cloud Pak for Integration (CP4I), your administrator can provide the correct URL.
4. When the toolkit prompts for the context, type **admin** API Connect (administrators) or **provider** (everyone else):

   ```
   Context? provider
   ```

5. The server responds with the following message:

   ```
   Please copy and paste the url https://mgmt_endpoint_url/auth/manager/sign-in/?from=TOOLKIT to a browser to start the
   authentication process.
   Do you want to open the url in default browser? [y/n]: y
   ```

   Take one of the following actions:

   - If you want to use your default browser to log in to API Manager, type **y** and press Enter.
     The API Manager sign-in page opens in a new browser tab.

   - If you don't use to use your default browser, type **n** and press Enter.
     - Copy the URL from the command window.
     - Open a browser, paste the URL, and press Enter.

     The API Manager sign-in page displays.

6. On the API Manager sign-in page, select the OIDC registry and then log in to API Connect.
   CP4I: Select the Common Services User Registry.

After you log in, API Connect displays the "You are authenticated!" message and provides a temporary token. Copy the token.

7. Return to the command window. Paste the token at the **`API Key?`** prompt and press Enter.

When the token is validated and you are successfully logged in to the toolkit, the following message displays:

```
Warning: Using default toolkit credentials.
Logged into mgmt_endpoint_url successfully
```

Note: If you see a message stating that credentials cannot be found, download new credentials as explained in Downloading the toolkit.

Logging out

To log out of a management server, use the following command:

```
apic logout --server mgmt_endpoint_url
```

Cloud administration commands

A summary of the cloud administration commands in the IBM® API Connect developer toolkit.

Authenticating

Use the **`apic login`** command to authenticate to an API Manager service, and the **`apic logout`** command to remove your local authentication credentials.
Note: When you authenticate successfully, your credentials are stored, in plain text, in the file Linux .netrc or Windows _netrc. You should therefore set the file permissions in such a way that your credentials are not accessible by others.
For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Configuring the command-line tool to use TLS certificates

API Manager uses TLS profiles to secure data transmission. For information on how to create a TLS profile in API Manager, see TLS profiles.

To configure the toolkit command-line tool to use certificates to communicate with an API Manager that has TLS profiles enabled, follow these steps:

For more information about the NODE_EXTRA_CA_CERTS environment variable, see Node.js documentation.

Note: When using any CLI command that applies directly to the configuration of your IBM API Connect cloud, you must supply the parameter setting **`--org admin`** for a command that requires an organization name as a parameter.

Command summary

The following tables summarize **`apic`** commands for cloud administration.

Table 1. Summary commands for cloud administrators

Command	Description	Sub-commands
`apic analytics-services`	Analytics Service commands	• **`apic analytics-services`** - Analytics Service collection operations. • **`apic analytics-services:clear`** - Clear the Analytics Services. • **`apic analytics-services:create`** - Create a Analytics Service. • **`apic analytics-services:delete`** - Delete the Analytics Service by name or ID. • **`apic analytics-services:get`** - Get the Analytics Service by name or ID. • **`apic analytics-services:list`** - List the Analytics Services. • **`apic analytics-services:update`** - Update the Analytics Service by name or ID.
`apic associates`	Associates commands	• **`apic associates`** - Associate collection operations. • **`apic associates:get`** - Get the Associate by name or ID. • **`apic associates:list`** - List the Associates.
`apic availability-zones`	Availability Zone commands	• **`apic availability-zones`** - Availability Zone collection operations. • **`apic availability-zones:clear`** - Clear the Availability Zones. • **`apic availability-zones:create`** - Create a Availability Zone. • **`apic availability-zones:delete`** - Delete the Availability Zone by name or ID. • **`apic availability-zones:get`** - Get the Availability Zone by name or ID. • **`apic availability-zones:list`** - List the Availability Zones. • **`apic availability-zones:update`** - Update the Availability Zone by name or ID.
`apic cloud-settings`	Cloud settings commands	• **`apic cloud-settings:get`** - Get the Cloud Setting. • **`apic cloud-settings:mail-server-configured`** - indicates whether a mail server has been configured. • **`apic cloud-settings:topology`** - Returns summary details of the configuration of your cloud topology. • **`apic cloud-settings:update`** - Update the Cloud Setting.

Command	Description	Sub-commands
`apic configured-gateway-services`	Commands for Configured Gateway Services in a Catalog or Space.	• `apic configured-gateway-services` - Configured Gateway Services operations. • `apic configured-gateway-services:clear` - Delete all Configured Gateway Services from a Catalog or Space. • `apic configured-gateway-services:create` - Configure a Gateway Service in a Catalog or Space. • `apic configured-gateway-services:delete` - Delete a Configured Gateway Service from a Catalog or Space. • `apic configured-gateway-services:get` - Obtain the details of a Configured Gateway Service in a Catalog or Space. • `apic configured-gateway-services:list` - List the Configured Gateway Services in a Catalog or Space.
`apic credentials`	Credential commands	• `apic credentials` - Application Credential collection operations. • `apic credentials:clear` - Clear the Application Credentials. • `apic credentials:create` - Create a Application Credential. • `apic credentials:delete` - Delete the Application Credential by name or ID. • `apic credentials:get` - Get the Application Credential by name or ID. • `apic credentials:list` - List the Application Credentials. • `apic credentials:reset` - Reset the client id and client secret. • `apic credentials:reset-client-secret` - Reset the client secret. • `apic credentials:update` - Update the Application Credential by name or ID. • `apic credentials:verify-client-secret` - Verify the client secret.
`apic extensions`	Extension commands	• `apic extensions` - Extension collection operations. • `apic extensions:document` - Get the document for an extension by id, or by name and version. • `apic extensions:get` - Get an extension by id, or by name and version. • `apic extensions:list` - List all versions of an extension given the name. • `apic extensions:list-all` - List all versions of all extensions.
`apic gateway-services`	Gateway service commands	• `apic gateway-services` - Gateway Service collection operations. • `apic gateway-services:clear` - Clear the Gateway Services. • `apic gateway-services:create` - Create a Gateway Service. • `apic gateway-services:delete` - Delete the Gateway Service by name or ID. • `apic gateway-services:get` - Get the Gateway Service by name or ID. • `apic gateway-services:list` - List the Gateway Services. • `apic gateway-services:reset-oauth-secret` - Reset the OAuth cryptographic • `apic gateway-services:update` - Update the Gateway Service by name or ID.
`apic integrations`	Integrations commands	• `apic integrations` - Integration collection operations. • `apic integrations:clear` - Clear the Integrations. • `apic integrations:clear-all` - Clear all of the Integrations in all of the collections. • `apic integrations:create` - Create a Integration. • `apic integrations:delete` - Delete the Integration by name or ID. • `apic integrations:get` - Get the Integration by name or ID. • `apic integrations:list` - List the Integrations. • `apic integrations:list-all` - List all Integrations in all collections. • `apic integrations:update` - Update the Integration by name or ID.
`apic keystores`	Keystores commands	• `apic keystores` - Keystore collection operations. • `apic keystores:clear` - Clear the Keystores. • `apic keystores:create` - Create a Keystore. • `apic keystores:delete` - Delete the Keystore by name or ID. • `apic keystores:get` - Get the Keystore by name or ID. • `apic keystores:list` - List the Keystores. • `apic keystores:update` - Update the Keystore by name or ID.
`apic mail-servers`	Mail server commands	• `apic mail-servers` - Mail Server collection operations. • `apic mail-servers:clear` - Clear the Mail Servers. • `apic mail-servers:create` - Create a Mail Server. • `apic mail-servers:delete` - Delete the Mail Server by name or ID. • `apic mail-servers:get` - Get the Mail Server by name or ID. • `apic mail-servers:list` - List the Mail Servers. • `apic mail-servers:test-connection` - Test a mail server connection. • `apic mail-servers:update` - Update the Mail Server by name or ID.
`apic notification-templates`	Notification template commands	• `apic notification-templates` - Notification Template collection operations. • `apic notification-templates:get` - Get the Notification Template by name or ID. • `apic notification-templates:list` - List the Notification Templates. • `apic notification-templates:list-all` - List all Notification Templates in all collections. • `apic notification-templates:update` - Update the Notification Template by name or ID.

Command	Description	Sub-commands
apic permissions	Permissions commands	• **apic permissions** - Permission collection operations. • **apic permissions:get** - Get the Permission by name or ID. • **apic permissions:list** - List the Permissions. • **apic permissions:list-all** - List all Permissions in all collections.
apic portal-services	Portal services commands	• **apic portal-services** - Portal Service collection operations. • **apic portal-services:clear** - Clear the Portal Services. • **apic portal-services:create** - Create a Portal Service. • **apic portal-services:delete** - Delete the Portal Service by name or ID. • **apic portal-services:get** - Get the Portal Service by name or ID. • **apic portal-services:list** - List the Portal Services. • **apic portal-services:update** - Update the Portal Service by name or ID.
apic services	Services commands	• **apic services** - Service collection operations. • **apic services:clear** - Clear the Services. • **apic services:clear-all** - Clear all Services in all collections. • **apic services:create** - Create a Service. • **apic services:delete** - Delete a Service. • **apic services:get** - Get the Service by name and version. • **apic services:list** - List the Services. • **apic services:list-all** - List all Services in all collections. • **apic services:update** - Update the Service by name and version.
apic space-settings	Space settings commands	• **apic space-settings:get** - Get the Space Setting. • **apic space-settings:update** - Update the Space Setting.
apic spaces	Space commands	• **apic spaces** - Space collection operations. • **apic spaces:clear** - Clear the Spaces. • **apic spaces:create** - Create a Space. • **apic spaces:delete** - Delete the Space by name or ID. • **apic spaces:get** - Get the Space by name or ID. • **apic spaces:list** - List the Spaces. • **apic spaces:transfer-owner** - Transfer owner to a new member. • **apic spaces:update** - Update the Space by name or ID.
apic tls-client-profiles	TLS client profile commands	• **apic tls-client-profiles** - TLS Client Profile collection operations. • **apic tls-client-profiles:clear** - Clear the TLS Client Profiles. • **apic tls-client-profiles:clear-all** - Clear all of the TLS Client Profiles in the collection. • **apic tls-client-profiles:create** - Create a TLS Client Profile. • **apic tls-client-profiles:delete** - Delete the TLS Client Profile by name or ID. • **apic tls-client-profiles:get** - Get the TLS Client Profile by name or ID. • **apic tls-client-profiles:list** - List the TLS Client Profiles. • **apic tls-client-profiles:list-all** - Lists all of the TLS Client Profiles in a collection. • **apic tls-client-profiles:update** - Update the TLS Client Profile by name or ID.
apic tls-server-profiles	TLS server profile commands	• **apic tls-server-profiles** - TLS Server Profile collection operations. • **apic tls-server-profiles:clear** - Clear the TLS Server Profiles. • **apic tls-server-profiles:clear-all** - Clear all of the TLS Server Profiles in the collection. • **apic tls-server-profiles:create** - Create a TLS Server Profile. • **apic tls-server-profiles:delete** - Delete the TLS Server Profile by name or ID. • **apic tls-server-profiles:get** - Get the TLS Server Profile by name or ID. • **apic tls-server-profiles:list** - List the TLS Server Profiles. • **apic tls-server-profiles:list-all** - List all of the TLS Server Profiles in the collection. • **apic tls-server-profiles:update** - Update the TLS Server Profile by name or ID.
apic truststores	Truststore commands	• **apic truststores** - Truststore collection operations. • **apic truststores:clear** - Clear the Truststores. • **apic truststores:create** - Create a Truststore. • **apic truststores:delete** - Delete the Truststore by name or ID. • **apic truststores:get** - Get the Truststore by name or ID. • **apic truststores:list** - List the Truststores. • **apic truststores:update** - Update the Truststore by name or ID.

Command	Description	Sub-commands
`apic user-registries`	User registry commands	• `apic user-registries` - User Registry collection operations. • `apic user-registries:clear` - Clear the User Registries. • `apic user-registries:create` - Create a User Registry. • `apic user-registries:delete` - Delete the User Registry by name or ID. • `apic user-registries:execute` - Execute a User Registry operation. • `apic user-registries:get` - Get the User Registry by name or ID. • `apic user-registries:list` - List the User Registries. • `apic user-registries:search` - search for users in a user registry. • `apic user-registries:test-connection` - Test a User Registry connection. • `apic user-registries:update` - Update the User Registry by name or ID.
`apic user-registry-settings`	User registry settings commands	• `apic user-registry-settings:get` - Get the User Registry Setting. • `apic user-registry-settings:update` - Update the User Registry Setting.
`apic users`	Users commands	• `apic users` - User collection operations. • `apic users:clear` - Clear the Users. • `apic users:create` - Create a User. • `apic users:delete` - Delete the User by name or ID. • `apic users:get` - Get the User by name or ID. • `apic users:list` - List the Users. • `apic users:request-password-reset` - send a password reset link. • `apic users:search-provider` - Search for provider users from an organization. • `apic users:update` - Update the User by name or ID.
`apic webhooks`	Webhooks commands	• `apic webhooks` - Webhooks collection operations. • `apic webhooks:get` - Get the Webhooks by name or ID. • `apic webhooks:list` - List the Webhooks. • `apic webhooks:update` - Update the Webhooks by name or ID.

API development and management commands

A summary of the core commands in the IBM® API Connect developer toolkit.

Authenticating

Use the `apic login` command to authenticate to an API Manager service, and the `apic logout` command to remove your local authentication credentials.
Note: When you authenticate successfully, your credentials are stored, in plain text, in the file Linux .netrc or Windows _netrc. Therefore, you should set the file permissions in such a way that your credentials are not accessible by others.
For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Configuring the command-line tool to use TLS certificates

API Manager uses TLS profiles to secure data transmission. For information on how to create a TLS profile in API Manager, see TLS profiles.

To configure the toolkit command-line tool to use certificates to communicate with an API Manager that has TLS profiles that are enabled, follow these steps:

For more information about the NODE_EXTRA_CA_CERTS environment variable, see Node.js documentation.

Creating and managing local files

You create and work with API and Product definition YAML files locally before you stage them to API Manager.

To create a local API definition file, use the `apic create:api` command. To create a local Product definition file, use the `apic create:product` command.

Use the `apic apis` and `apic products` commands to list API Manager artifacts of the specified type.

To validate the syntactical correctness of a local API or Product definition file, use the `apic validate` command.

To create a draft API in API Manager from a local API or Product definition file, use the `apic draft-apis:create` and `apic draft-products:create` commands, respectively.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before an API is validated, created in draft, staged, or published. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Working with Catalogs and Spaces

To create a Catalog, use the `apic catalog:create` command. To view information on a Catalog, use the `apic catalog:get` command; to list all Catalogs that are contained in organizations that the currently authenticated user is a member of, use the `apic catalogs` command.

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see Using syndication in IBM API Connect.

To enable Spaces for a Catalog, use the following command:

```
apic catalogs:set catalog_name --spaces enabled
```

Use the toolkit `apic spaces` commands to create and manage Spaces:

- `apic spaces` - List Spaces contained in a Catalog.
- `apic:spaces create` - Create a Space in a Catalog.
- `apic:spaces get` - Get information on a Space in a Catalog.
- `apic:spaces set` - Set information on a Space in a Catalog.
- `apic:spaces delete` - Delete a Space in a Catalog.

Command summary

The following tables summarize `apic` commands for API development and management.

Table 1. Summary of general-purpose commands

Command	Description	Subcommands
`apic config`	List and manage configuration variables. For more information, see Using configuration variables. With no subcommand, lists values of defined configuration variables.	• `apic config` - Manage configuration variables • `apic config:clear` - Delete all configuration variables • `apic config:delete` - Delete a configuration variable • `apic config:get` - Get a configuration variable • `apic config:list` - List the application and global configuration variables • `apic config:set` - Set or update configuration variables
`apic create`	Create a draft API or Product definition YAML file.	• `create:api` - Create a draft API OpenAPI definition YAML file • `create:product` - Create a Product definition YAML file
`apic extensions`	Manage OpenAPI extensions in a Catalog. With no subcommand, lists the extensions in the production Catalog.	• `apic extensions` - Extension collection operations. • `apic extensions:clear` - Delete all versions of an extension given the name. • `apic extensions:clear-all` - Delete all versions of all extensions. • `apic extensions:clone` - Download all versions of all extensions to your local drive. • `apic extensions:create` - Create an extension. • `apic extensions:delete` - Delete an extension by ID, or by name and version. • `apic extensions:document` - Get the document for an extension by ID, or by name and version. • `apic extensions:get` - Get an extension by ID, or by name and version. • `apic extensions:list` - List all versions of an extension given the name. • `apic extensions:list-all` - List all versions of all extensions. • `apic extensions:update` - Update an extension by ID, or by name and version.

Command	Description	Subcommands
apic lb4	Create LoopBack® project and project artifacts. With no subcommand, creates a new LoopBack project. Note: To use the **apic lb4** command, you need to add a double dash, **--**, after the **lb4** subcommand to tell **apic** that the options behind the **--** are for the subcommand belonging to **lb4**. The second **--** is to signify the end of the options. For example, **$ apic lb4 controller -- --help** Note: You can use **$ apic lb4 --help** to show a list of commands that are available, and you can use **$ apic lb4 *subcommand* -- --help** to show the usage of a subcommand.	• **app** - Create a new LoopBack project (default) • **controller** - Add a controller to a LoopBack 4 application • **datasource** - Add a datasource to a LoopBack 4 application • **discover** - Discover models from relational databases • **example** - Download one of LoopBack 4 example projects • **extension** - Create a LoopBack 4 extension • **import-lb3-models** - Import one or more LoopBack 3 models to a LoopBack 4 application • **interceptor** - Generate interceptors • **model** - Add a new model to a LoopBack 4 application • **observer** - Generate life cycle observers for application start and stop • **openapi** - Generate controllers and models from OpenAPI specs • **relation** - Add a relation between two models in a LoopBack 4 application • **repository** - Add a new repository for a selected model to a LoopBack 4 application • **rest-crud** - Generate rest configs for model endpoints • **service** - Add a new remote or local service to a LoopBack 4 application • **update** - Check or update project dependencies of LoopBack modules
apic login	Log in to API Manager.	None. Specify server and credentials with the required flags: • **-p, --password** *password* • **-r, --realm** *realm*. Determines the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **-u, --username** *user_name* For full details on how to log in to your management server from the CLI, see Logging in to the management server.
apic logout	Log out from API Manager.	None. Specify server with the required flag: • **-s, --server** *mgmt_service*. You can append the port number to the server name if it is not the default value of 443.
apic validate	Validate API or Product definition YAML file.	None

Table 2. Summary of commands to manage APIs, Products, and Catalogs

Command	Description	Subcommands
apic apis	List and manage APIs that are staged or published to Catalog or Space. Default subcommand is **list-all**.	• **apic apis** - API collection operations • **apic apis:get** - Get the OpenAPI definition YAML file for an API by name and version, or by ID • **apic apis:list** - List an API by name • **apic apis:list-all** - List all APIs in a Catalog or Space • **apic apis:update** - Update an API by name
apic apps	List and manage developer applications that are registered in a consumer organization. Default subcommand is **list**.	• **apic apps** - Application collection operations • **apic apps:clear** - Clear all applications • **apic apps:create** - Create an application • **apic apps:delete** - Delete an application by name or ID • **apic apps:get** - Get an application object by name • **apic apps:list** - List all the applications in a consumer organization • **apic apps:update** - Update an application by name or ID
apic catalogs	List and manage Catalogs in a provider organization. Default subcommand is **list**.	• **apic catalogs:clear** - Clear all Catalogs from provider organization • **apic catalogs:create** - Create a Catalog • **apic catalogs:delete** - Delete a Catalog by name or ID • **apic catalogs:get** - Get a Catalog object by name or ID • **apic catalogs:list** - List all the Catalogs in a provider organization • **apic catalogs:transfer-owner** - Transfer the ownership of a Catalog to another user • **apic catalogs:update** - Update a Catalog by name or ID
apic catalog-settings	Manage the configuration settings for a Catalog	• **apic catalog-settings:get** - Get the Catalog settings. • **apic catalog-settings:update** - Update the Catalog settings.

Command	Description	Subcommands
apic drafts	List and manage the draft API and Product definitions in a provider organization. Default subcommand is **list**.	• **apic drafts** - Draft collection operations • **apic drafts:clear** - Delete all draft APIs and Products in a provider organization • **apic drafts:list** - List the draft APIs and Products in a provider organization
apic draft-apis	List and manage the draft API definitions in a provider organization. Default subcommand is **list-all**.	• **apic draft-apis** - Draft API collection operations • **apic draft-apis:clear** - Delete all versions of a draft API by name • **apic draft-apis:clear-all** - Delete all draft APIs in a provider organization • **apic draft-apis:clone** - Clone all draft APIs in a provider organization • **apic draft-apis:create** - Create a draft API • **apic draft-apis:delete** - Delete a Draft API by name and version • **apic draft-apis:document** - Get the Draft API document by name and version • **apic draft-apis:get** - Get the OpenAPI definition YAML file for an API by name and version • **apic draft-apis:list** - List all versions of a draft API by name • **apic draft-apis:list-all** - List all draft APIs in a provider organization • **apic draft-apis:update** - Update a draft API by name and version, supplying the revised OpenAPI definition file • **apic draft-apis:update-wsdl** - Update a draft SOAP API by name and version, supplying the revised WSDL definition file in a .wsdl or .zip format Note: There must be a match of the service names in the existing WSDL with the revised WSDL. If a match is found, the WSDL service is converted into a YAML file that is used to update the API. If no match is found, an error message is displayed. • **apic draft-apis:validate** - Validates a draft API • **apic draft-apis:wsdl** - Get the Draft API WSDL document by name and version
apic draft-products	List and manage the draft Product definitions in a provider organization. Default subcommand is **list-all**.	• **apic draft-products** - Draft Product collection operations • **apic draft-products:clear** - Delete all versions of a draft Product by name • **apic draft-products:clear-all** - Delete all draft Products in a provider organization • **apic draft-products:create** - Create a draft Product • **apic draft-products:delete** - Delete a draft Product by name and version • **apic draft-products:get** - Get the Draft Product by name and version • **apic draft-products:list** - List the Draft Products • **apic draft-products:list-all** - List all draft Products in a provider organization • **apic draft-products:publish-all** - Publishes the Draft Product • **apic draft-products:update** - Update a draft Product by name and version, supplying the revised definition file • **apic draft-products:validate** - Validates a draft Product
apic members	List and manage the members of a provider organization, consumer organization, Catalog, or Space. Default subcommand is **list**.	• **apic members** - Member operations • **apic members:clear** - Delete all members • **apic members:create** - Create a member • **apic members:delete** - Delete a member by name or ID • **apic members:get** - Get a member object by name or ID • **apic members:list** - List all members • **apic members:update** - Update the member by name or ID
apic member-invitations	List and manage member invitations. A member invitation is created when a user is invited to be a member of a provider organization, consumer organization, Catalog, or Space. Default subcommand is **list**.	• **apic member-invitations** - Member invitation collection operations. • **apic member-invitations:clear** - Delete all member invitations. • **apic member-invitations:create** - Create a member invitation. • **apic member-invitations:delete** - Delete a member invitation by name or ID. • **apic member-invitations:get** - Get a member invitation object by name or ID. • **apic member-invitations:list** - List all member invitations. • **apic member-invitations:update** - Update a member invitation by name or ID.
apic orgs	List and manage provider organizations, and the admin organization. Default subcommand is **list**.	• **apic orgs** - Organization collection operations • **apic orgs:clear** - Delete all organizations • **apic orgs:create** - Create an organization • **apic orgs:delete** - Delete an organization by name or ID • **apic orgs:get** - Get an organization object by name or ID • **apic orgs:list** - List all organizations • **apic orgs:transfer-owner** - Transfer ownership of an organization • **apic orgs:update** - Update an organization by name or ID
apic org-settings	Manage settings for provider organizations, and the admin organization.	• **apic org-settings:get** - Get the settings object for an organization • **apic org-settings:update** - Update the settings for an organization
apic policies	List and manage policies in a Catalog. Default subcommand is **list**.	• **apic policies** - Policy collection operations • **apic policies:clear** - Clear the Policies • **apic policies:clear-all** - Clear all Policies in all collections • **apic policies:create** - Create a Policy • **apic policies:delete** - Delete a Policy • **apic policies:get** - Get the Policy by name and version • **apic policies:list** - List the Policies • **apic policies:list-all** - List all Policies in all collections • **apic policies:update** - Update the Policy by name and version

Command	Description	Subcommands
`apic products`	List and manage Products that are staged or published to Catalog or Space. Default subcommand is `list-all`.	• `apic products` - Product collection operations • `apic products:clear` - Delete all versions of a Product by name • `apic products:clear-all` - Delete all Products • `apic products:delete` - Delete a Product by name and version • `apic products:execute-migration-target` - Products execute migration target operations • `apic products:get` - Get a Product object by name and version • `apic products:list` - List all versions of a Product by name • `apic products:list-all` - List all Products • `apic products:publish` - Publish a Product to a Catalog or Space, supplying the Product definition YAML file • `apic products:replace` - Replace a Product with another Product • `apic products:set-migration-target` - Set the target Product for migrating subscriptions from a Product • `apic products:supersede` - Supersede a Product with another Product • `apic products:update` - Update a Product by name and version, supplying the revised Product definition YAML file
`apic identity-providers`	View information about identity providers.	• `apic identity-providers` - Identity provider operations • `apic identity-providers:list` - List the identity providers.
`apic spaces`	List and manage Spaces contained in a Catalog. Default subcommand is `list`.	• `apic spaces` - Space collection operations • `apic spaces:clear` - Delete all Spaces from a Catalog • `apic spaces:create` - Create a Space in a Catalog • `apic spaces:delete` - Delete a Space from a Catalog, by name or ID • `apic spaces:get` - Get a Space object by name or ID • `apic spaces:list` - List all the Spaces in a Catalog • `apic spaces:transfer-owner` - Transfer the ownership of a Space to another user • `apic spaces:update` - Update a Space by name or ID
`apic subscriptions`	List and manage subscriptions in a Product or a Catalog. Default subcommand is `list`.	• `apic subscriptions` - Subscription collection operations • `apic subscriptions:clear` - Clear the Subscriptions • `apic subscriptions:create` - Create a Subscription • `apic subscriptions:delete` - Delete the Subscription by name or ID • `apic subscriptions:get` - Get the Subscription by name or ID • `apic subscriptions:list` - List the Subscriptions • `apic subscriptions:update` - Update the Subscription by name or ID

Table 3. Summary of other commands for API developers and managers

Command	Description	Subcommands
`apic consumer-orgs`	Manage consumer organizations	• `apic consumer-orgs` - Consumer Organization collection operations. • `apic consumer-orgs:clear` - Clear the Consumer Organizations. • `apic consumer-orgs:create` - Create a Consumer Organization. • `apic consumer-orgs:delete` - Delete the Consumer Organization by name or ID. • `apic consumer-orgs:get` - Get the Consumer Organization by name or ID. • `apic consumer-orgs:list` - List the Consumer Organizations. • `apic consumer-orgs:transfer-owner` - Transfer owner to a new member. • `apic consumer-orgs:update` - Update the Consumer Organization by name or ID.
`apic consumer-org-settings`	Manage consumer organization settings	• `apic consumer-org-settings:delete` - Delete the Consumer Organization Setting. • `apic consumer-org-settings:get` - Get the Consumer Organization Setting. • `apic consumer-org-settings:update` - Update the Consumer Organization Setting.
`apic groups`	Manage groups	• `apic groups` - Group collection operations. • `apic groups:clear` - Clear the Groups. • `apic groups:create` - Create a Group. • `apic groups:delete` - Delete the Group by name or ID. • `apic groups:get` - Get the Group by name or ID. • `apic groups:list` - List the Groups. • `apic groups:update` - Update the Group by name or ID.
`apic invitations`	Manage invitations. An invitation is created when a user is invited to be the owner of a provider organization, consumer organization, Catalog, or Space.	• `apic invitations` - Invitation collection operations. • `apic invitations:clear` - Delete all invitations. • `apic invitations:create` - Create an invitation. • `apic invitations:delete` - Delete an invitation by name or ID. • `apic invitations:get` - Get the details of an invitation by name or ID. • `apic invitations:list` - List all invitations. • `apic invitations:update` - Update an invitation by name or ID.

Command	Description	Subcommands
`apic member-invitations`	Manage member invitations. A member invitation is created when a user is invited to be a member of a provider organization, consumer organization, Catalog, or Space.	• `apic member-invitations` - Member invitation collection operations. • `apic member-invitations:clear` - Delete all member invitations. • `apic member-invitations:create` - Create a member invitation. • `apic member-invitations:delete` - Delete a member invitation by name or ID. • `apic member-invitations:get` - Get the details of a member invitation by name or ID. • `apic member-invitations:list` - List all member invitations. • `apic member-invitations:update` - Update a member invitation by name or ID.
`apic members`		• `apic members` - Member collection operations. • `apic members:clear` - Clear the Members. • `apic members:create` - Create a Member. • `apic members:delete` - Delete the Member by name or ID. • `apic members:get` - Get the Member by name or ID. • `apic members:list` - List the Members. • `apic members:update` - Update the Member by name or ID.
`apic registrations`		• `apic registrations` - Registration collection operations. • `apic registrations:clear` - Clear the Registrations. • `apic registrations:create` - Create a Registration. • `apic registrations:delete` - Delete the Registration by name or ID. • `apic registrations:get` - Get the Registration by name or ID. • `apic registrations:list` - List the Registrations. • `apic registrations:update` - Update the Registration by name or ID.
`apic role-defaults`		• `apic role-defaults` - Role Default collection operations. • `apic role-defaults:clear` - Clear the Role Defaults. • `apic role-defaults:create` - Create a Role Default. • `apic role-defaults:delete` - Delete the Role Default by name or ID. • `apic role-defaults:get` - Get the Role Default by name or ID. • `apic role-defaults:list` - List the Role Defaults. • `apic role-defaults:list-all` - List all Role Defaults in all collections. • `apic role-defaults:update` - Update the Role Default by name or ID.
`apic roles`		• `apic roles` - Role collection operations. • `apic roles:clear` - Clear the Roles. • `apic roles:create` - Create a Role. • `apic roles:delete` - Delete the Role by name or ID. • `apic roles:get` - Get the Role by name or ID. • `apic roles:list` - List the Roles. • `apic roles:update` - Update the Role by name or ID.
`apic tasks`		• `apic tasks` - Task collection operations. • `apic tasks:clear` - Clear the Tasks. • `apic tasks:create` - Create a Task. • `apic tasks:delete` - Delete the Task by name or ID. • `apic tasks:get` - Get the Task by name or ID. • `apic tasks:list` - List the Tasks. • `apic tasks:update` - Update the Task by name or ID.
`apic user-registries`		• `apic user-registries` - User Registry collection operations. • `apic user-registries:clear` - Clear the User Registries. • `apic user-registries:create` - Create a User Registry. • `apic user-registries:delete` - Delete the User Registry by name or ID. • `apic user-registries:execute` - Execute a User Registry operation. • `apic user-registries:get` - Get the User Registry by name or ID. • `apic user-registries:list` - List the User Registries. • `apic user-registries:search` - search for users in a user registry. • `apic user-registries:test-connection` - Test a User Registry connection. • `apic user-registries:update` - Update the User Registry by name or ID.
`apic user-registry-settings`		• `apic user-registry-settings:delete` - Delete the User Registry Setting. • `apic user-registry-settings:get` - Get the User Registry Setting. • `apic user-registry-settings:update` - Update the User Registry Setting.

Command	Description	Subcommands
`apic users`		• `apic users` - User collection operations. • `apic users:clear` - Clear the Users. • `apic users:create` - Create a User. • `apic users:delete` - Delete the User by name or ID. • `apic users:get` - Get the User by name or ID. • `apic users:list` - List the Users. • `apic users:request-password-reset` - send a password reset link. • `apic users:search-provider` - Search for provider users from an organization. • `apic users:update` - Update the User by name or ID.
`apic test`	Test your APIs	• `apic test {yaml-files}` - Define the tests. • `apic test {yaml-files} --insecureSkipVerify` - Test the APIs with certificate checks disabled. • `apic test {yaml-files} --certPath={location of certs folder}` - Specifies the location of the CA certificate if it is not available in the system keystore. • `api test {yaml-files} --mTLS --certPath={location of certs folder}` - Test the APIs with `mTLS` enabled. • `api test {yaml-files} --config-file={location of config file}` - Define the tests by passing the external configuration.

Creating APIs and applications

You can develop API proxies and API implementations by using the developer toolkit. In the documentation, *API* refers to the API proxy and *application* refers to the API implementation.

LoopBack® is a high-performance Node.js interaction-tier framework for APIs and micro-services. The LoopBack framework can be downloaded and installed using the **CLI + LoopBack + Designer** option for downloading the toolkit. See Installing the toolkit. To create a new LoopBack project, use the command `apic lb4`.
Note: IBM® API Connect is packaged with, and supports, LoopBack version 4. For more information on how to migrate your LoopBack 3 applications to LoopBack 4, see LoopBack 4 Migration Guide.
You can use the developer toolkit or LoopBack to create language-independent APIs by using OpenAPI to proxy to an existing backend implementation or to augment applications that are developed in other languages or frameworks such as Express®, Java™, Swift, Go, and others.

Creating development artifact definitions

Use the `apic create` command to create development artifacts, by using the following commands:

Command	Description
`apic create:api`	Create an OpenAPI definition.
`apic create:api --wsdl` *`filename`*	Create a SOAP API definition from a WSDL definition file, or a .zip file that contains the WSDL definition files for a service. The name and version of the generated API are obtained from the WSDL file. If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.
`apic create:product`	Create an API Product definition.

Note: You can create an API or Product from an OpenAPI template file by using the `--template` *`template-name`* option.
You can also create Product and API definitions non-interactively by providing the `--title` option. This option sets several values that you can also customize with additional options; for example:

```
apic create:api --title Routes
apic create:product --title "Climb On"
```

You can also create the API and Product definitions at the same time:

```
apic create:api --title Routes --product "Climb On"
apic create:api --wsdl globalweather.wsdl --product "Weather Forecasting"
```

Alternatively, you can create APIs and then reference them when you create a new Product; for example:

```
apic create:api --title Routes
apic create:api --title Ascents
apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
```

Validating development artifact definitions

After you edit development artifacts or before you publish artifacts, best practice is to validate them; for example:

```
apic validate routes.yaml                    # Validate an API
apic validate climb-on.yaml                  # Validate the Product and its APIs
apic validate climb-on.yaml --product-only   # Validate the Product only (do not validate the referenced APIs)
```

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file,the `$ref` field is replaced with the contents of the target file before the draft API is created with the **apic drafts:validate** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Developing LoopBack applications

After you've created a LoopBack application with the **apic lb4 app** command, you can add additional functionality to the application with the commands listed in the following table. Run these commands from the project root directory of the application. APIs created with LoopBack can be imported into API Manager.

Command	Description	Subcommands
apic lb4	Create LoopBack project and project artifacts. With no subcommand, creates a new LoopBack project. Note: To use the **apic lb4** command, you need to add a double dash, **--**, after the **lb4** subcommand to tell **apic** that the options behind the **--** are for the subcommand belonging to **lb4**. The second **--** is to signify the end of the options. For example, **$ apic lb4 controller -- --help**	• **app** - Create a new LoopBack project (default) • **controller** - Add a controller to a LoopBack 4 application • **datasource** - Add a datasource to a LoopBack 4 application • **discover** - Discover models from relational databases • **example** - Download one of LoopBack 4 example projects • **extension** - Create a LoopBack 4 extension • **import-lb3-models** - Import one or more LoopBack 3 models to a LoopBack 4 application • **interceptor** - Generate interceptors • **model** - Add a new model to a LoopBack 4 application • **observer** - Generate life cycle observers for application start and stop • **openapi** - Generate controllers and models from OpenAPI specs • **relation** - Add a relation between two models in a LoopBack 4 application • **repository** - Add a new repository for a selected model to a LoopBack 4 application • **rest-crud** - Generate rest configs for model endpoints • **service** - Add a new remote or local service to a LoopBack 4 application • **update** - Check or update project dependencies of LoopBack modules

Publishing APIs and applications

To publish APIs and applications by using the developer toolkit of IBM® API Connect, you set configuration variables to define where you want to publish, log in to the target cloud platform, and then use the appropriate publishing commands.

See the following sections for more information:

- Setting configuration variables
- Logging in to API Connect
- Publishing APIs

Setting configuration variables

The **apic config** command provides global and project-based configuration variables that specify the target Catalog for publishing APIs and applications. The values of these variables are stored in **~/.apiconnect/config** (for global variables) and ***project-dir*/.apiconnect** (for project variables). For a full list of configuration variables, see Overview of the command-line tool.

Set the **catalog** configuration variable to the URI of an API Connect Catalog to define a default Catalog target for all commands managing Catalogs. The **catalog** URI has the form:

https://*mgmt_endpoint_url*/api/catalogs/*org_name*/*catalog_name*

where *mgmt_endpoint_url* is the platform API endpoint URL, *org_name* is the provider organization name, and *catalog_name* is the Catalog name. The *mgmt_endpoint_url* portion sets the default value of the **--server** option, the *org_name* portion sets the default value of the **--org** option, and the *catalog_name* portion sets the default value of the **--catalog** option; you can override any of these values by including the corresponding option in a command.

Set the **space** configuration variable to the URI of an API Connect Space, to define a default Space target for all commands that manage Spaces. The **space** URI has the form:

https://*mgmt_endpoint_url*/api/spaces/*org_name*/*catalog_name*/*space_name*

where *mgmt_endpoint_url* is the platform API endpoint URL, *org_name* is the provider organization name, *catalog_name* is the Catalog name, and *space_name* is the name of the Space. The *mgmt_endpoint_url* portion sets the default value of the **--server** option, the *org_name* portion sets the default value of the **--org** option, the *catalog_name* portion sets the default value of the **--catalog** option, and the *space_name* sets the default value of the **--space** option; you can override any of these values by including the corresponding option in a command.

Although setting these configuration variables is not required, doing so simplifies commands that interact with API Connect clouds by providing default values for frequently used command-line options.

Here is an example of publishing with and without the **catalog** configuration variable set.

Without the configuration variable set:

```
apic products publish climb-on.yaml --server mgmnthost.com --org climbon --catalog sandbox
```

With the configuration variable set:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
catalog: https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic products publish climb-on.yaml
```

You can override default values provided by the **catalog** configuration variable by providing one of the standard options with a different value. For example, use the **--catalog** option with the **apic products publish** command to specify the **qa** Catalog:

```
apic products publish climb-on.yaml --catalog qa
```

Don't forget about global configuration variables. If you use the same Catalog as the default target for multiple projects, set the value globally:

```
apic config:set --global catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
```

Note:
If you have an environment variable of the same name as a CLI configuration property then, by default, its value will override the value of the corresponding CLI configuration property for any CLI command at that scope.

For example, if you have defined an environment variable called **SPACE** then, by default, that value will be assumed for the value of the **--space** parameter in the following command, regardless of any **space** configuration property setting:

```
apic products:publish my_product.yaml --scope space
```

To prevent environment variables overriding CLI configuration properties, define an environment variable called **APIC_LOAD_FROM_ENV**, set to the value **false**.

Logging in to API Connect

Use the **apic login** and **apic logout** commands to manage your authentication. For details, see Logging in to a management server.

Publishing APIs

Publishing APIs to API Catalogs in API Connect clouds enables you to socialize the APIs by using the developer portal and secure them by using the Gateway.

An *API Product* (or simply *Product*) is used to compose APIs for publishing. API Product managers can use it to bundle one or more APIs together, control the visibility of the Product in the developer portal (for example, only allow partners x, y, and z to view and subscribe to the Product), and define Plans to provide consumption options. The Products that reference the APIs and define the consumption Plans are also the primary unit of lifecycle management for APIs.

Use the **apic products publish** command (equivalent to **apic products:publish**) to publish API Products to an API Connect cloud. The following example demonstrates how to create APIs composed by a Product, and publishing the Product and its APIs to a Catalog:

```
apic create:api --title Routes
apic create:api --title Ascents
apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/default-idp-2
apic products publish climb-on.yaml
```

For full details on how to log in to your management server from the CLI, see Logging in to a management server.

Add the **--stage** option to **apic publish** to stage the Product into a Catalog instead of publishing it. Products in a Catalog can be in the following states: staged, published, deprecated, or retired. For example:

```
apic products publish --stage climb-on.yaml
```

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see Using syndication in IBM API Connect.

If default configuration values have been set for the Space, Catalog, organization and management server, the following publish command could be used:

```
apic products publish --scope space product.yaml
```

where *product* is the name of the product that you want to publish.
Note: If the OpenAPI file that defines your API uses a **$ref** field to reference a fragment of OpenAPI code that is defined in a separate file, the **$ref** field is replaced with the contents of the target file before the Product that contains the API is staged or published with the **apic publish** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Managing API Products

Use the **apic products** and **apic apis** commands to manage Products and APIs that have been published to IBM® API Connect Catalogs. Use the **--scope space** option to manage Products and APIs that have been published to Spaces within Catalogs.

Product management command summary

The following table summarizes the commands available for managing API Products. Usage examples follow.

Example command	Description
`apic config:set catalog=https://platform-api.myserver.com/api/catalogs/myorg/sandbox`	Set the default Catalog.
`apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/my-identity-provider`	Login into the management server. For full details on how to log in to your management server from the CLI, see Logging in to the management server.
`apic create:api --title Routes --product "ClimbOn"`	Create the Product and API.
`apic products:publish climbon.yaml`	Publish the Product to the default catalog. Add --stage argument to stage the Product.
`apic products:list-all --scope catalog`	List the Products in the default catalog.
`apic products:get climbon:1.0.0 --output -`	Display the Product's properties. Omit the output argument to download to a file.
`apic apis:list-all --scope catalog`	List the APIs in the Catalog.
`apic apis:get routes:1.0.0 --output -`	Get the API properties. Omit the output argument to download to a file.
`apic products:replace climbon:1.0.0 mapfile.txt`	Replace the Product indicated on the command line with the staged or published Product designated in the mapfile. This retires the replaced Product.
`apic products:supersede climbon:1.0.0 mapfile.txt`	Supersede the Product indicated on the command line with the staged or published Product designated in the mapfile. This deprecates the superseded Product.
`apic products:delete climbon:1.0.0`	Delete the Product from the Catalog. The Product must be either retired or deprecated.

Using the `products` and `apis` commands through a full lifecycle

This example shows a complex lifecycle where a new version of a Product and API replaces the original version at run time.

Note: If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file, the **`$ref`** field is replaced with the contents of the target file before the Product that contains the API is staged or published with the **apic publish** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Set the default Catalog and login to the mgmnthost.com API Connect cloud

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic login --username some-user --password some-password --server platform-api.myserver.com --realm my-identity-provider
```

For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Create and publish an initial version

```
apic create:api --title Routes --version 1.0.0 --filename routes100.yaml
apic create:product --title "Climb On" --version 1.0.0 --apis routes100.yaml --filename climbon100.yaml
apic products:publish climbon100.yaml
```

Create a new version to fix a bug in the API, stage it to the Catalog

```
apic create:api --title Routes --version 1.0.1 --filename routes101.yaml
apic create:product --title "Climb On" --version 1.0.1 --apis routes101.yaml --filename climbon101.yaml
apic products:publish --stage climbon101.yaml
```

Inspect the Catalog

```
apic products:list-all --scope catalog
```

This produces a list of all Products in the catalog. Copy the ID of the `climbon:1.0.1` Product. The ID resembles the following example.

```
https:/server/api/catalogs/3eca6046-3c27-4ad/ab8772bf-0f65-45/products/8f854623-bda1-4f9
```

Create a mapping file

For example, if you are replacing a Product, the mapping file specifies the Product that you want to replace, and the mapping of the Plans from the source Product to the target Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then `product_url` property specifies the URL of `climbon:1.0.0`. This file takes the following form:

```
product_url: https:/server/api/catalogs/{id}/products/{id}
plans:
- source: {source_plan_name_1}
  target: {target_plan_name_1}
- source: {source_plan_name_2}
  target: {target_plan_name_2}
            .
            .
            .
```

Note:

- The source and target Plan names can be the same or different.
- Every Plan in the Product you are replacing must be mapped to a Plan in the replacement Product.

"Hot-replace" version 1.0.0 with 1.0.1

```
apic products:replace climbon:1.0.1 PRODUCT_PLAN_MAPPING_FILE
```

After it is replaced in this way, a Product is retired. It is no longer active.

Note: The Product specified on the command line is the replacement Product. For example, if you are replacing **climbon:1.0.0** with **climbon:1.0.1** then the Product specified on the command line is **climbon:1.0.1**.

Supersede version 1.0.0 with 1.0.1

Rather than hot-replacing an existing Product with a new one (usually an updated version), you can supersede the existing Product with a new one. When you replace a Product, all external application subscriptions to that Product are automatically moved to the new Product. When you supersede a Product, the subscriptions are not automatically moved to the new Product, some action must be taken to subscribe external applications to the superseding Product.
The command to supersede a Product uses the same mapping file as the command to replace a Product. The name of the superseding Product is given on the command line.

```
apic products:supersede climbon:1.0.1 PRODUCT_PLAN_MAPPING_FILE
```

Once superseded, a Product is marked deprecated, meaning that no further subscriptions to the Product are allowed, although it is still active and existing subscriptions still work.
Note: The Product specified on the command line is the superseding Product. For example, if you are replacing **climbon:1.0.0** with **climbon:1.0.1** then the Product specified on the command line is **climbon:1.0.1**. The mapping file specifies the URL of the Product you are superseding.

Set a migration target

It is possible to set a migration target for the existing Product. This helps migration.
Use a command like the following to set the migration target.

```
apic products:set-migration-target climbon:1.0.0 PRODUCT_PLAN_MAPPING_FILE
```

Note: The Product specified on the command line is the Product from which you want to migrate subscriptions. The mapping file specifies the target Product for the subscriptions.
Once a migration target is set, external application developers will be able to migrate their application subscriptions through the Developer Portal with ease. It is also possible to execute a subscription migration using the following command.

```
apic products:execute-migration-target climbon:1.0.0
```

Delete a Product

When the replaced or superseded Product is no longer needed, it can be deleted.

```
apic products:delete climbon:1.0.0
```

Additional Product and API operations

In addition to the lifecycle management capabilities, you can download Products and APIs in a catalog or space using the **clone** sub-command:

Command	Description
apic products:clone	Download all Products and their APIs from the catalog or space.
apic apis:clone	Download all APIs from the catalog or space.

It can also be useful to clear all Products and their APIs from a Catalog, particularly for a development Catalog (you must provide the name of the Catalog as the value of the **--confirm** parameter):

```
apic products:clear --confirm catalog_name
```

where *catalog_name* is the name of the Catalog.
You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see Using syndication in IBM API Connect.

To manage the Products and APIs that have been published to a Space, include the **--scope space** option with the **apic products** and **apic apis** commands. For example, to list the Products that are contained in a Space called *flights*, use the following command:

```
apic products --scope space --space flights --catalog production --org climbonorg --server platform-api.myserver.com
```

Changing the lifecycle state of a Product in a Catalog or Space

To directly change the lifecycle state of a Product that has previously been staged or published to a Catalog or Space, complete the following steps:

- Enter the following command (the terminating hyphen character means that the command takes input from the command line):

  ```
  apic products:update product_name:version --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space] -
  ```

  where:
  - *product_name* is the name of the Product whose lifecycle state you want to change.
  - *version* is the version of that Product.
  - *mgmt_endpoint_url* is the platform API endpoint URL.
  - *organization* is the name of the provider organization in which the Product was previously staged or published.
  - *scope* has one of the following values:
    - **catalog** if the Catalog does not have Spaces enabled.
    - **space** if the Catalog has Spaces enabled. If you specify **space** for the **--scope** parameter you must also supply the **--space** parameter.
  - *catalog* is the name of the Catalog in which the Product was previously staged or published.
  - (optional) *space* is the name of the Space. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command.

  The command returns:

  ```
  Reading PRODUCT_FILE arg from stdin
  ```

- Enter the following data, followed by a new line:

  ```
  state: new_state
  ```

  where *new_state* is the state that you want to change the Product to, and must have one of the following values.
  - staged

    - published
    - deprecated
    - retired
    - archived
- Press `CTRL D` to terminate the input. If the command is successful, the lifecycle state change is confirmed.
  For example:

```
apic products:update finance:1.0.0 --server https://myserver.com --org development --scope catalog --catalog sandbox -
Reading PRODUCT_FILE arg from stdin
state: published
finance:1.0.0    [state: published]   https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-
9e82-427a-abe6-be5b126210f7/products/0f0af980-f505-4f36-b09c-d7b1c9c1a2f2
```

Note:
The command will not succeed if the lifecycle state change you are attempting is not permitted.

For example, the following lifecycle state changes are permitted:

- staged to published
- deprecated to retired

The following lifecycle state changes are not permitted:

- published to staged
- retired to published

For full details, see The Product lifecycle.

To list all Products in a Catalog or Space, together with their lifecycle states, use the following command:

```
apic products:list-all --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space]
```

For example:

```
apic products:list-all --server https://myserver.com --org development --scope catalog --catalog sandbox
graphql-services:1.0.0    [state: staged]      https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-
9e82-427a-abe6-be5b126210f7/products/7652d568-b396-4bfa-bf71-2f18cea63737
finance:1.0.0             [state: published]   https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-
9e82-427a-abe6-be5b126210f7/products/0f0af980-f505-4f36-b09c-d7b1c9c1a2f2
```

To find out the lifecycle state of a specific Product, use the following command:

```
apic products:get product_name:version --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space
space] --fields state --output -
```

For example:

```
apic products:get finance:1.0.0 --server https://myserver.com --org development --scope catalog --catalog sandbox --fields
state --output -
state: published
```

Example scripts

A set of example toolkit scripts that demonstrate how to create and manage organizations, users, apps, Products and APIs are available at https://github.com/ibm-apiconnect/example-toolkit-scripts.

Working with Drafts

Co-locate your APIs and applications in your local source code control systems to support typical development activities such as commits, branching, merges, continuous integration, and so on. The developer toolkit provides the bridge from the developer's environment to the IBM® API Connect runtime services.

API Connect provides an online development capability called *Drafts* where you can define API and Product definitions. The **apic drafts** commands enable synchronization of Product and API artifacts between local source code control systems and drafts.

You can use **drafts** to clear and list your drafts. For example:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox    # set the default Catalog
apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/myldap  # login
into the management server

apic create:api --title routes --product ClimbOn
apic drafts                                          # list what is in drafts
apic drafts:clear --confirm drafts                   # clear drafts collection
apic drafts:list                                     # list the available drafts
```

For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Reading input from the command line

If a developer toolkit command takes a file as an input parameter, you can direct the command to read the input directly from the command line rather than supplying a separate file; this can be useful when writing scripts to automate command line operations, for example.

Reading input from a file

Many developer toolkit commands that create or update new objects in API Connect take a file as an input parameter. For example:

- Register a new gateway service:

  ```
  apic gateway-services:create [flags] GATEWAY_SERVICE_FILE
  ```

- Update a provider organization:

  ```
  apic orgs:update [flags] ORG_FILE
  ```

- Create a new Catalog:

  ```
  apic catalogs:create [flags] CATALOG_FILE
  ```

- Create a new consumer organization:

  ```
  apic consumer-orgs:create [flags] CONSUMER_ORG_FILE
  ```

- Register a new developer application:

  ```
  apic apps:create [flags] APP_FILE
  ```

- Create a new email server:

  ```
  apic mail-servers:create [flags] MAIL_SERVER_FILE
  ```

- Update the list of applications that subscribe to a Product:

  ```
  apic subscriptions:update [flags] SUBSCRIPTION_FILE
  ```

You can format the input file as a YAML file (the default) or as a JSON file. To use a JSON file as input, include the `--format json` parameter.

Reading input from the command line

As an alternative to supplying an explicit file name to the command, you can supply a hyphen (-) in place of the file name parameter; the command will then read the file content directly from the command line as shown in the following examples.

- Register a new DataPower® Gateway (v5 compatible) gateway service:

  ```
  apic gateway-services:create --server platform-api.myserver.com --org admin --availability-zone availability-zone-default
  -
  Reading GATEWAY_SERVICE_FILE arg from stdin
  name: dpgw-service
  title: DataPower gateway service, compatible with v5
  gateway_service_type: datapower-gateway
  endpoint: 'https://mygwhost.com:3000'
  api_endpoint_base: 'https://mygwhost.com:9443'
  sni:
    - host: '*'
      tls_server_profile_url: https://platform-api.myserver.com/api/orgs/75203636-f038-4287-a732-24af4bf7059d/tls-server-
  profiles/3c0a0e93-6aa4-4288-b09c-eccf4901b104
  visibility:
    type: public
  ```

  Note: You can obtain the `tls_server_profile_url` property value for a TLS server profile by using the following command, which lists the URLs for all TLS server profiles:

  ```
  apic tls-server-profiles --org organization_name --server mgmt_endpoint_url
  ```

- Create a new provider organization:

  ```
  apic orgs:create --server platform-api.myserver.com -
  Reading ORG_FILE arg from stdin
  name: development
  title: Development organization
  owner_url: https://platform-api.myserver.com/api/user-registries/1bbbd414-22f1-47cf-8eac-2050530d29a7/c082d755-866e-4394-
  959f-fbb264c6c3a1/users/2db491c7-2d0f-4f60-a8ae-f38d07481f21
  ```

  Note: You can obtain the `owner_url` property value by using the following command, which returns the `url` property for a specific user:

  ```
  apic users:get username --user-registry user_registry_name --server mgmt_endpoint_url --org organization_name --fields url
  --output -
  ```

- Create a new Catalog:

  ```
  apic catalogs:create --server platform-api.myserver.com --org myorg -
  Reading CATALOG_FILE arg from stdin
  name: production
  title: Production Catalog
  summary: Catalog containing APIs in production use
  ```

- Create a new consumer organization:

  ```
  apic consumer-orgs:create --server platform-api.myserver.com --catalog sandbox --org myorg -
  Reading CONSUMER_ORG_FILE arg from stdin
  name: finance-apps
  title: Developers of finance applications
  owner_url: https://platform-api.myserver.com/api/user-registries/a1fb8159-fda1-410f-93ab-a0ea5fd04535/70ce7ec3-e83f-4c87-
  9f3c-4662ad108bbc/users/fddd5df5-c178-4a34-ab92-0a48344d5c9b
  ```

Note: You can obtain the `owner_url` property value by using the following command, which returns the `url` property for a specific user:

```
apic users:get username --user-registry user_registry_name --server mgmt_endpoint_url --org organization_name --fields url
--output -
```

- Register a new developer application:

```
apic apps:create --server consumer-api.myserver.com --org my-consumer-org --mode consumer -
Reading APP_FILE arg from stdin
name: finance
title: Finance application
summary: Mobile app for personal finance management
```

- Create a new email server:

```
apic mail-servers:create --org admin --server platform-api.myserver.com  -
Reading MAIL_SERVER_FILE arg from stdin
title: My email server
name: my-email-server
host: smtp.myemail.com
port: 20
credentials:
  username: me@myemail.com
  password: password
```

- Create a new subscription to subscribe an application to a Product:

```
apic subscriptions:create --app myapp --catalog sandbox --org myorg --server platform-api.myserver.com --consumer-org my-
consumer-org -
Reading SUBSCRIPTION_FILE arg from stdin
product_url: https://platform-api.myserver.com/api/catalogs/960733c1-d7f7-4b90-9bc7-69dbfbe4ce31/ca34537d-adf4-4320-8495-
a7feaa62d679/products/638015c6-a8b0-452e-841f-2ac441ab6962
plan: default-plan
```

Note: You can obtain the `product_url` property value for a Product by using the following command, which lists the URLs for all versions of a Product given the Product name:

```
apic products:list product_name --scope catalog --catalog catalog_name --org provider_org_name --server mgmt_endpoint_url
```

Scripting with the toolkit commands

The IBM® API Connect developer toolkit provides commands for cloud administration and API development and management.

Scripting commands

It's often helpful to automate a series of `apic` commands In a shell script. Since the `apic` tool first requires you to interactively accept the license, you must first use the following command:

```
apic --accept-license
```

Once you do that, your scripts can run non-interactively.
Toolkit command scripts allow you to automate many of the tasks required to set up and maintain your API products. A set of example scripts are available at **https://github.com/ibm-apiconnect/example-toolkit-scripts**.

These scripts demonstrate how to perform the following tasks.

- Create a Provider Organization
- Configure a catalog to use one or more gateways
- Create draft APIs and Products
- Publish Products
- Replace an existing published product with a new version
- Delete a product
- Create a Consumer Organization
- Create a new consumer app
- Subscribe the new app to an existing published product
- Stage a new product version
- Supercede the existing published product with the new one
- Migrate existing subscriptions from the old product to the new product

Working with OpenAPI extensions

Use the developer toolkit CLI **extensions** commands to manage OpenAPI extensions in your Catalogs or Spaces.

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API, depending on the version of IBM® API Connect you are using. An extension is imported into a Catalog, or as Space ion a Catalog, then added to the API schema.

The commands described here are for importing OpenAPI extensions into a Catalog or Space, and viewing and managing them. After you have imported an OpenAPI extension, you can reference it in your API definitions; for details, see Referring to an extension in an API definition.

Note: If Spaces are enabled in a Catalog, an OpenAPI extension that you import into one Space is imported into **all** Spaces; you cannot import an OpenAPI extension into an individual Space in the Catalog. Any subsequent updates are also applied to all Spaces.

Command name	Action	Syntax
extensions clear	The **extensions:clear** command deletes all versions of an extension given the extension name. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **`catalog`** The command is to be applied to Catalog **`space`** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **`space`** and supply the **`--space`** parameter. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **`--space`** parameter is required if the Catalog has Spaces enabled, in which case you must also include **`--scope`** **`space`** in the command. --configured-gateway-service <*service_name*> Specifies the name of the gateway service. --confirm <*catalog_name*> Confirms the clear of the extension. <*extension_name*> Specifies the name of the existing extension. Note: This is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --server or -s <*management_server_endpoint*> Specifies the server endpoint.	**`apic extensions:clear --scope catalog|space --catalog_|_-c catalog_name extension_name --server_|_-s management_server_endpoint --configured-gateway-service gw_service_name --confirm catalog_name --org_|_-o org_name [--space space]`** Example: **`apic extensions:clear --scope catalog --catalog catalog1 extension1 --server endpoint1 --configured-gateway-service gw_service1 --confirm catalog1 --org my_org`** This example deletes all versions of the **`extension1`** extension that are in **`catalog1`** of the **`my_org`** organization, and are paired with **`endpoint1`**.

Command name	Action	Syntax
extensions clear-all	The **extensions:clear-all** command deletes all of the extensions in the specified Catalog or Space. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --configured-gateway-service <*service_name*> Specifies the name of the gateway service. --confirm <*catalog_name*> Confirms the clear of the extension. --org or -o <*organization_name*> Specifies a single organization with the organization name. --server or -s <*management_server_endpoint*> Specifies the server endpoint.	**apic extensions:clear-all** **--scope** **catalog|space** **--catalog | -c** ***catalog_name*** **--server | -s** ***mgt_server_endpoint*** **--configured-gateway-service** ***gw_service_name*** **--confirm** ***catalog_name*** **--org | -o** ***org_name*** **[--space** ***space*****]** Example: **apic extensions:clear-all --scope catalog** **--catalog catalog1 --server endpoint1** **--configured-gateway-service gw_service1** **--confirm catalog1 --org my_org** This example deletes all the extensions that are in **catalog1** of the **my_org** organization, and are paired with **endpoint1**.
extensions clone	The **extensions:clone** command creates a local definition file for each extension. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --org or -o <*organization_name*> Specifies a single organization with the organization name. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:clone** **--scope** **catalog|space** **--catalog | -c** ***catalog_name*** **--org | -o** ***org_name*** **[--space** ***space*****]** **--server | -s** ***mgt_server_endpoint*** **--configured-gateway-service** ***gw_service_name*** Example: **apic extensions:clone --scope catalog** **--catalog catalog1 --org my_org --server endpoint1** **--configured-gateway-service gw_service_1** This example clones the extensions that are in **catalog1** of the **my_org** organization, and are paired with **endpoint1**.

Command name	Action	Syntax
extensions create	The **extensions:create** command creates an extension in a Catalog or Space, given an extension definition file. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. <*extension_file*> Specifies the name of the extension file that contains the new information for your extension. Note: This is the OpenAPI file name, not the name of the extension. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:create** --scope **catalog|space** *extension_file* --server | -s *mgt_server_endpoint* --catalog | -c *catalog_name* **[--space** *space***]** --org | -o *org_name* --configured-gateway-service *gw_service_name* Example: **apic extensions:create --scope catalog filename.yaml --server endpoint1 --catalog catalog1 --org my_org --configured-gateway-service gw_service_1** This example creates an extension in **catalog1** of the **my_org** organization, paired with **endpoint1**, using the **filename.yaml** OpenAPI extension definition file.
extensions delete	The **extensions:delete** command deletes a specific version of an extension. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. <*extension_name*>:<*version_number*> Specifies the name and version number of the extension. Note: *extension_name* is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:delete** --scope **catalog|space** *extension_name*:*version_number* --catalog | -c *catalog_name* --org | -o *org_name* **[--space** *space***]** --server | -s *mgt_server_endpoint* **--configured-gateway-service** *gw_service_name* Example: **apic extensions:delete --scope catalog myextension:1.0.0 --catalog catalog1 --org orgmain --server endpoint1 --configured-gateway-service gw_service_1** This example deletes **myextension** version **1.0.0** that is in **catalog1** of the **orgmain** organization, and is paired with **endpoint1**.

Command name	Action	Syntax
extensions get	The **extensions:get** command retrieves the definition file for a specific version of an extension. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. <*extension_name*>:<*version_number*> Specifies the name and version number of the extension. Note: *extension_name* is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:get** [--scope](#) **catalog|space** ***extension_name*:*version_number*** [--catalog | -c](#) ***catalog_name*** [--org | -o](#) ***org_name*** **[--space *space*]** [--server | -s](#) ***mgt_server_endpoint*** **--configured-gateway-service *gw_service_name*** Example: **apic extensions:get --scope catalog myextension:1.0.0 --catalog catalog1 --org orgmain --server endpoint1 --configured-gateway-service gw_service_1** This example gets **myextension** version **1.0.0** that is in **catalog1** of the **orgmain** organization, and is paired with **endpoint1**.
extensions list	The **extensions:list** command lists all versions of an extension given the extension name. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. <*extension_name*> Specifies the name of the existing extension. Note: This is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:list** [--scope](#) **catalog|space** ***extension_name*** [--catalog | -c](#) ***catalog_name*** [--org | -o](#) ***org_name*** **[--space *space*]** [--server | -s](#) ***mgt_server_endpoint*** **--configured-gateway-service *gw_service_name*** Example: **apic extensions:list --scope catalog my_extension --catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service_1** This example lists all versions of the extension **my_extension** that are paired with **endpoint1**, are in **catalog1**, and in the **my_org** organization.

Command name	Action	Syntax

extensions list-all	The **extensions:list-all** command lists all of the extensions that are available in a Catalog or Space. This is the default command if you enter only `apic extensions`.
	
	The parameters are as follows:
	
	--scope
	Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available:
	
	`catalog`
	The command is to be applied to Catalog
	`org`
	Sets the scope to the organization.
	`space`
	The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to `space` and supply the `--space` parameter.
	
	--server or -s <*management_server_endpoint*>
	Specifies the server endpoint.
	--catalog or -c <*catalog_name*>
	Specifies a single Catalog with the Catalog name.
	--space
	Specifies the name of a Space in a Catalog. The `--space` parameter is required if the Catalog has Spaces enabled, in which case you must also include `--scope`
	`space` in the command.
	--org or -o <*organization_name*>
	Specifies a single organization with the organization name.
	--configured-gateway-service <*service_name*>
	Specifies the name of the gateway service.
		`apic extensions:list-all --scope catalog|space`
		`--catalog | -c catalog_name`
		`--org | -o org_name`
		`[--space space]`
		`--server | -s mgt_server_endpoint`
		`--configured-gateway-service gw_service_name`
		
		Example:
		
		`apic extensions:list-all --scope catalog`
		`--catalog catalog1 --org my_org --server endpoint1`
		`--configured-gateway-service gw_service1`
		
		This example lists the extensions that are paired with `endpoint1`, are in `catalog1`, and in the `my_org` organization.

extensions update	The **extensions:update** command replaces the information of an existing version of an extension with the information in an external file.
	
	The parameters are as follows:
	
	--scope
	Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:
	
	`catalog`
	The command is to be applied to Catalog
	`space`
	The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to `space` and supply the `--space` parameter.
	
	--server or -s <*management_server_endpoint*>
	Specifies the server endpoint.
	--catalog or -c <*catalog_name*>
	Specifies a single Catalog with the Catalog name.
	--space
	Specifies the name of a Space in a Catalog. The `--space` parameter is required if the Catalog has Spaces enabled, in which case you must also include `--scope`
	`space` in the command.
	--org or -o <*organization_name*>
	Specifies a single organization with the organization name.
	--configured-gateway-service <*service_name*>
	Specifies the name of the gateway service.
	<*extension_name*>:<*version_number*>
	Specifies the name and version number of the extension.
	Note: *extension_name* is the extension name, not the file name.
	<*extension_file*>
	Specifies the name of the extension file that contains the new information for your extension.
	Note: This is the OpenAPI file name, not the name of the extension.
		`apic extensions:update --scope catalog|space`
		`extension_name:version_number`
		`extension_file`
		`--catalog | -c catalog_name`
		`--org | -o org_name`
		`[--space space]`
		`--server | -s mgt_server_endpoint`
		`--configured-gateway-service gw_service_name`
		
		Example:
		
		`apic extensions:update`
		`--scope catalog extension1:1.0.0 extension2.yaml`
		`--catalog catalog1 --org my_org --server endpoint1`
		`--configured-gateway-service gw_service1`
		
		This example updates `extension1` version `1.0.0` that is paired with `endpoint1`, in `catalog1`, and in the `my_org` organization, from the file `extension2.yaml`.

Using the toolkit CLI to execute API tests

The IBM® API Connect developer toolkit provides CLI commands for automated API behavior testing.

About this task

Use CLI commands to execute API tests.
Note: In order to execute an API for testing purpose, you must make it online. To make the API online and auto-publish your API document, set the **Auto-publish** toggle on the Preferences page to **On** position. For more information, see Activating an API.

Procedure

1. Install the toolkit: Setting up the API Connect toolkit.
2. Open Terminal.
3. Create a YAML file to define your tests. For more information, see API development and management commands.
4. Run the CLI with the following syntax to execute the tests:

   ```
   apic test yaml-files
   ```

   Where, ***yaml-files*** specifies the location of the YAML file. For example, `apic test test1.yaml`
   Note: Cert files must be named in the following format:
   - `tls.crt` - public key
   - `tls.key`- private key
   - `ca.crt`- CA certificate

   For more information about how the test is defined as a YAML file, see Test definition syntax.
   For more information about the assigning variables on a YAML configuration file, see Variable assignment in YAML configuration.

- **Test definition syntax**
  Information about how the test is defined as a YAML file.
- **Variable assignment in YAML configuration**
  You can define variables within a YAML configuration file using the CLI tool. These variables are used to configure various aspects of the tool.

Test definition syntax

Information about how the test is defined as a YAML file.

The test is defined as a YAML file with the following sections:

- `config` - Displays the default values for the variables that are specified in the file.
- `steps` - Displays the flow for the test case and runs through the list of steps in order. Each step has a common set of parameters.

The `type` attribute in the test definition YAML file describes the type of `steps`.

```
steps:
  - type: request
    method: get
    url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/bank/branches
    var: branches
    mode: json
  - type: assert-is
    expression: branches
    value: array
  - type: assert-exists
    expression: branches.[1]
    stoponfail: true
  - type: assert-is
    expression: branches.[0].type
    value: string
    stoponfail: true
  - type: assert-is
    expression: branches.[0].address.city
    value: string
    stoponfail: true
  - type: assert-compares
    expression1: branches.[0].type
    expression2: branches.[7].type
  - type: request
    method: get
    url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/orders/order/AB1234
    var: payload
    mode: json
  - type: assert-equals
    expression: payload_response_statusCode
    value: 200
    ifexists: false
    stoponfail: false
  - type: assert-equals
    expression: payload_response_header_Content-Type
    value: application/json
  - type: assert-in
    expression: payload_response_header_Content-Type
    values:
      - application/json
      - application/swagger+yaml
  - type: assert-contains
    expression: payload_response_header_Content-Type
    value: app
  - type: assert-matches
    expression: payload_response_header_Content-Type
    value: ^[a-z]+/json
  - type: assert-exists
    expression: "payload"
```

```
    stoponfail: false
  - type: assert-is
    expression: "payload.tracking_reference"
    value: "string"
    ifexists: "false"
    stoponfail: false
  - type: assert-exists
    expression: payload.shipped_at
    stoponfail: false
  - type: assert-exists
    expression: payload.status
    stoponfail: false
  - type: assert-exists
    expression: payload.created_at
    stoponfail: false
```

The following table summarizes the set of parameters supported by the **type** attribute.

Table 1. Summary of the parameters supported by the **type** attribute

Parameters	Description	Sub-attributes

request	Make an HTTP request.	• **method** - defines the HTTP method to use.
		• **url** - defines the URL to make the request to.
		• **params** - defines the key value mapping of parameters to send.
		• **headers** - defines the key value mapping of headers to send.
		• **var** - defines the name of the variable to store the response in.
		• **mode** - defines what type of data to expect and how to parse it (supported: json).
		
		For example,
		
		`- type: request`
		`method: get`
		`url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/bank/branches`
		`var: branches`
		`mode: json`

assert-is	Assert that the type of variable from the response is **value**.	• **expression** - defines the variable to test.
		• **value** - defines the **type** we expect in response.
		
		For example,
		
		`- type: assert-is`
		`expression: branches`
		`value: array`

assert-exists	Assert that a particular variable specified in **expression** exists.	• **expression** - defines the variable to test.
		• **stoponfail** - If one of the test fails, the **stoponfail**attribute stops the execution of the remaining tests. For this, **stoponfail** must be set to **true**.
		
		For example,
		
		`- type: assert-exists`
		`expression: branches.[1]`
		`stoponfail: true`

assert-equals	Assert that a variable is equal to **value**.	• **expression** - defines the variable to test.
		• **value** - defines the **value** to compare against .
		
		For example,
		
		`- type: assert-equals`
		`expression: payload_response_header_Content-Type`
		`value: application/json`

assert-greater	Assert that the variable is greater than **value**.	• **expression** - defines the variable to test.
		• **value** - defines the **value** to compare against.
		
		For example,
		
		`- type: assert-greater`
		`expression: payload_temperature`
		`value: application/json`

assert-less	Assert that the variable is lesser than **value**.	• **expression** - defines the variable to test.
		• **value** - defines the **value** to compare against.
		
		For example,
		
		`- type: assert-less`
		`expression: payload_temperature`
		`value: application/json`

assert-in	Assert that the element identified by a given expression matches at least one item from a given list.	• **expression** - defines the variable to test.
		• **value** - defines an array of values to compare against.
		
		For example,
		
		`- type: assert-in`
		`expression: payload_response_status`
		`value: application/json`

Parameters	Description	Sub-attributes

`assert-matches`	Assert that the value of the element identified by a given expression matches a specified format.	• `expression` - defines the variable to test.
		• `value` - defines the regex value to compare against.
		
		For example,
		
		`- type: assert-matches`
		`expression: payload_response_header_Content-Type`
		`value: ^[a-z]+/json`

`assert-compares`	Assert that two elements are equivalent in some way.	• `expression1` - defines the path to the first element for comparison.
		• `expression2` - defines the path to the second element for comparison.
		
		For example,
		
		`- type: assert-compares`
		`expression1: branches.[0].type`
		`expression2: branches.[7].type`

`assert-contains`	Assert that the value of the element identified by a given expression contains a specific substring.	• `expression` - defines the variable to test.
		• `value` - defines the substring to compare against.
		
		For example,
		
		`- type: assert-contains`
		`expression: payload_response_header_Content-Type`
		`value: app`

`each`	Loop over the array referenced in the expression carrying out the sub-steps for each item found.	`expression` - defines the variable to test.
		
		For example,
		
		`- type: each`
		`expression: "analytics.events"`

For more information about assigning variables on a YAML configuration file, see Variable assignment in YAML configuration.

Variable assignment in YAML configuration

You can define variables within a YAML configuration file using the CLI tool. These variables are used to configure various aspects of the tool.

You can configure a YAML file in three ways:

- Using the same YAML file.
- Using environmental variables
- Using the external configuration YAML files.

Note: Variables must be enclosed in double curly braces. For example, `"{{configs.base_url}}"` or `"{{paths.basePath}}"`. These placeholders, in the format of `"{{...}}"`, will be replaced with their corresponding values from the source YAML file, environmental variables, or the external configuration file depending on the precedence hierarchy.
The precedence hierarchy for variable assignment is as follows:

1. External configuration YAML file (highest precedence)
2. Environmental variables
3. Configuration set in the same YAML file (lowest precedence)

If you configure a YAML file using all the three methods, the variables assigned using the external configuration YAML file is given priority.

1. Configuration set in the same YAML file

You can assign values to variables from within the same YAML file. For this, you must structure your YAML file in the following manner:

```
configs:
   basePath: ...paths:
       - basePath: ...
```

Here, the `configs` key is used to define variables such as `basePath` and `paths`. These variables can be utilized throughout the YAML file to configure the tool.

2. Environmental variables

You can override the values of variables configured in the YAML file using environmental variables. When an environment variable shares the same name as a variable defined in the YAML file, the value of the YAML variable is replaced by the corresponding environment variable. This provides a way to customize configurations externally.

For example, if a variable named `base_url` is defined in the YAML file as `"{{configs.base_url}}"`, and its value is replaced by an environment variable named `base_url`. The value of `base_url` in the YAML file is overridden by the value of the `base_url` environment variable.

3. External configuration YAML file

The CLI tool supports the highest level of configuration precedence through external configuration files. To use an external configuration file, you must specify its file path using the `--config-file` or `-c` flag when running the CLI tool. Any variables defined in the external configuration file will supersede those defined within the main YAML file or through the environmental variables.

For example, consider an external configuration file named `config.yaml` with the following content:

```
external_config:
   base_url: https://example.comapi_key: your-api-key
```

When you run the CLI tool with the `--config-file=config.yaml` flag, variables defined in the`config.yaml` file will replace the corresponding variables in the main YAML file or the environmental variables.

For more information about how the test is defined as a YAML file, see Test definition syntax.

Managing platform REST API keys

Create API keys associated with your user account, and then use them to authenticate when you call the platform REST APIs provided by API Connect.

About this task

The API Connect platform REST APIs require authentication for use. To call an API interactively, you can log into the toolkit CLI with an option to generate the API key. To call an API programmatically, you can generate an API key and then exchange it for an API Connect access token. This requirement applies only to the APIs that are provided by API Connect. You do not need the API key for calling APIs that you imported or created. The API key is intended for use with the IBMid and might not work with other user registries.

Procedure

1. Create an API key:
   a. Log in to API Connect.
   b. On the address bar, add `/apikeys` to the end of the URL (after the organization name).
      For example:

      ```
      https://manager.example.com/manager/myorg/apikeys
      ```

   c. On the API Keys page, click Add.
   d. In the "Create API Connect API Key" box, provide a title for the key (unique within your user account) and an optional description; then click Create.
2. Manage API Keys:
   a. Log in to API Connect.
   b. On the address bar, add `/apikeys` to the end of the URL.

Searching for items in API Manager

Use the search feature in IBM® API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.

Search is available from any page in API Manager and can be accessed by typing in the search field in the page banner, or by clicking Search in the navigation list.

Using Search

The Search feature is available on all pages of the API Manager. To start searching, just type a string into the Search field and press Enter. Whenever you press Enter in the Search field, the Search page displays with results and additional options. If you press Enter in an empty Search field, or click Search in the navigation list, then the Search page displays a list all items. If you type a string before pressing Enter, the page displays the results from the corresponding search.

Search results include all items that contain the search string in a text field. For example, suppose you searched for "Crafted". The results might look like the following image, with items that don't match the search string exactly, but do include the string in a text field such as a title or a name.

By default, the search returns all types of items that contain the string. Sort results on a particular column by clicking the column header.

When you find an item you want to work with, click the . . . actions menu next to the item's "Modified" date to see what you can do. The list of possible actions depends on the item's type.

You can limit the search results by selecting an item type from the list that displays before the results. Click More to view additional types. If you select a type from the More menu, it replaces a type in the list.

If you want to refine the search further, click Options. On the Options panel, click Catalogs to Search and select which catalogs to search (the default is all catalogs). You can select up to 5 catalogs for a limited search.

You can also choose whether only exact matches (the complete string) are included in results, or items containing similar strings are also included.

Working with API definitions

An API definition specifies the complete configuration for an API. You can create and configure your APIs either by using either the API Designer UI application, or by using the browser based API Manager UI.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
If you are working with APIs that conform to the OpenAPI Specification, note that API Connect uses the following terms:

- OpenAPI Specification:
  The OpenAPI Specification defines a standard, language-agnostic interface to RESTful APIs. API Connect supports version 2 and version 3 of the OpenAPI Specification.
- OpenAPI document:
  One or more files that describe an API conforming to the OpenAPI Specification.
- OpenAPI definition:
  The description of an API that conforms to the OpenAPI Specification. In API Connect, you can create the API definition by filling in settings and properties, or by importing an OpenAPI document that contains an API definition that you want to work with.

The following topics provide full details for creating and configuring your APIs.

- **Creating an API definition**
  You can create API definitions by using the API Designer or the command line interface in IBM® API Connect.
- **Editing an OpenAPI 2.0 API definition**
  IBM API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 2.0 specification.
- **Editing an OpenAPI 3.0 API definition**
  IBM API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 3.0 specification.
- **LDAP authentication**
  The Lightweight Directory Access Protocol (LDAP) is an internet protocol for accessing and maintaining distributed directory information services over a network. If you rely on LDAP to authenticate users for web applications, take a minute to review the contents of this topic before beginning.
- **Authentication URL user registry**
  You can use an Authentication URL user registry to specify a REST authentication service to manage user authentication, and to optionally provide additional metadata to be embedded in the token.
- **Activating an API**
  After you have created an API definition you can activate it to auto-publish your API document and make it available for testing.
- **Testing an API**
  Select a test tool and verify that your API works as you intended.
- **Staging an API**
  The graphical wizard provides an option that adds the API to a Product and stages the Product in a Catalog. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.
- **Publishing an API**
  The user interface provides an option that adds an API to a Product and publishes the Product in a Catalog. Publishing a draft Product makes the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.
- **Creating a new version of an API definition**
  You can create multiple versions of an API definition and edit the versions independently by using IBM API Connect.
- **Updating an API definition from a file**
  You can update an API by uploading a .yaml or .json file that contains the OpenAPI definition for the revised API.
- **Updating a SOAP API**
  You can update the configuration of an existing SOAP API either by uploading a WSDL file, or by uploading a .zip archive that contains a primary WSDL file together with other WSDL or XSD files that it references.
- **Renaming an API definition**
  By renaming an API definition, you change the `name` property that, together with the version, is used to uniquely identify the API definition in API Connect. The `name` property is initially generated automatically when you first create the API definition, based on the title, but you can later change it if desired.
- **Changing an API rate limit**
  When you activate an API to make it available for testing, as described in Activating an API, no rate limit is applied to restrict calls to the API. However, if desired, you can apply a rate limit to the API, or modify a previously applied rate limit. The rate limit defines the maximum number of calls allowed in a specified time period.
- **Adding an OpenAPI extension to an API**
  You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An OpenAPI extension is imported into a Catalog, or to a Space within a Catalog, then added to the API schema.
- **Downloading an API definition**
  You can download the details of your API definitions so that you can store them for later recovery.
- **Deleting an API definition**
  You can delete an API definition that is no longer required.
- **Using an options file when importing a WSDL service**
  When you create an API definition, or add a target WSDL service to an API definition, by importing a .zip file, you can specify additional directives by including an options file in the .zip file.
- **Variable references in API Connect**
  In API Connect you can reference different variables in your API definition.
- **API properties**
  Properties are used by the gateway to control behavior of certain policies. Typically, you provide properties, but the policy can also provide properties settings.
- **API policies and logic constructs**
  Policies and logic constructs are pieces of configuration that control a specific aspect of processing in the Gateway server during the handling of an API invocation at run time.
- **Tags in API Connect**
  There are a number of forms of tagging in IBM API Connect.

Creating an API definition

You can create API definitions by using the API Designer or the command line interface in IBM® API Connect.

Before you begin

An API is a set of functions that provide some business or technical capability and can be called by applications by using a defined protocol. Applications are typically mobile or web applications, and they use the HTTP protocol. An API definition is composed of paths, and can be one of the following types:

REST API definition
: A REST API is a defined set of interactions that uses the HTTP protocol, typically by using JSON or XML as the data format that is exchanged. For example, a data request might use an HTTP GET method, and a data record might use an HTTP POST method. The choice of data format depends on the type of application that is calling the API. JSON is commonly used for web pages or mobile applications that present a user interface (by using JavaScript or HTML), whereas XML is often used for machine-to-machine scenarios.

  You can create REST APIs by using LoopBack® functions to create models and data sources. These are then used by your REST API definition and exposed to your users.

  Alternatively, you can expose and secure your existing APIs by using a Proxy or Invoke policy.

  In either case, you can configure your API definition either by using the API Designer, or by writing an OpenAPI definition file and publishing it using either API Designer or the command line interface.

SOAP API
: You can create SOAP API definitions that are based on an existing Web Services Description Language (WSDL) file. You can use this facility to benefit from the capabilities that are provided by API Connect, which include analytics and mapping between variables. You can also expose the API by using the Developer Portal for any existing SOAP services in your organization, including any SOAP services that are part of a service-oriented architecture (SOA) or Enterprise Service Bus (ESB) infrastructure.

  You can create SOAP API definitions through either the command line interface, or through API Designer.

About this task

You can create definitions for REST APIs or SOAP APIs.

- In the API Designer, you can add a REST API definition either by composing the API definition, and its operations, from scratch, or by importing an OpenAPI definition file. You can also use the tooling to quickly create a proxy API that calls an existing endpoint.
- If you have an existing SOAP service that you want to expose more widely, you can add a SOAP API to IBM® API Connect. You can use the Developer Portal to publicize the SOAP service to the developers. If a developer wants to use the SOAP API, you can use API Connect to manage their sign-up and access to the service, and track the usage of that API.

Procedure

1. Quickly create an API definition by using one of the following wizards:
   - Creating a REST proxy API from a target service
   - Creating a REST proxy API from an existing OpenAPI service
   - Creating a new REST OpenAPI definition
   - Creating a REST proxy API from an existing WSDL service
   - Adding a REST API by importing an OpenAPI definition file
   - Creating a SOAP proxy API from an existing WSDL service
2. After you create your API definition, you can define it in more detail by following the instructions in Editing an OpenAPI 2.0 API definition.

- **Creating a REST proxy API from a target service**
  If you have an existing REST service that you want to expose through an IBM API Connect API definition, you can create a proxy API and specify the target endpoint by using the API Designer.
- **Creating a REST proxy API from an existing OpenAPI service**
  If you have an existing OpenAPI described target service that you want to expose through an IBM API Connect API definition, you can create a proxy API and specify the target endpoint.
- **Creating a REST proxy API from an existing WSDL service**
  If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect REST proxy API that calls that SOAP service.
- **Creating a SOAP proxy API from an existing WSDL service**
  If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect SOAP proxy API that calls that SOAP service.
- **Creating a new REST OpenAPI definition**
  You can create and edit draft REST API definitions by using the API Designer or the API Designer user interface in IBM API Connect.
- **Adding a REST API by importing an OpenAPI definition file**
  You can use an OpenAPI definition file to import a REST API into IBM API Connect.
- **Adding a SOAP API by importing a zip file**
  You can use an OpenAPI definition file to import a SOAP API into IBM API Connect.
- **Creating a GraphQL proxy API**
  GraphQL is a query language for APIs that gives an application client greater control over what data it retrieves in an API request when compared with a REST API request. IBM API Connect enables you to create a GraphQL API proxy definition that proxies a backend GraphQL server, and to define rate limiting controls that reflect the amount of data that is returned from the server by a request to the GraphQL API.
- **Importing an API from the CP4I asset repository**
  If you are using IBM API Connect with IBM Cloud Pak for Integration (CP4I), you can import an API definition from the CP4I asset repository.

Related concepts

- Using the developer toolkit command-line tool

Creating a REST proxy API from a target service

If you have an existing REST service that you want to expose through an IBM® API Connect API definition, you can create a proxy API and specify the target endpoint by using the API Designer.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Create proxy REST APIs in minutes by using the API Designer tool to create an API from target service. This procedure creates a REST proxy that routes all traffic to a target REST API or service endpoint.

Procedure

To compose a proxy API from a target service, complete the following steps.

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select From target service.
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see apic draft-apis.
   - The Version corresponds to the value of the **info.version** property of the API's OpenAPI definition. The **version.release.modification** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
5. Specify the existing REST API endpoint that you want to call in the Target Service URL field.
6. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **X-IBM-Client-Id** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.

     For information about security options in IBM API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **cors** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **cors** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **request.attributes.isCORSPreflight** flag is set to **true**.
     - For all preflight requests, the **security** and **client-identification** preflow policies are always skipped, whether CORS is enabled or not enabled.
7. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
8. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a proxy API from an existing target service.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Creating a REST proxy API from an existing OpenAPI service

If you have an existing OpenAPI described target service that you want to expose through an IBM® API Connect API definition, you can create a proxy API and specify the target endpoint.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Create proxy REST APIs in minutes by using the API Designer tool to create an API from existing OpenAPI service. This procedure creates a REST proxy that routes all traffic to a target REST API or service endpoint.

Procedure

To compose a proxy API from an existing OpenAPI service, complete the following steps.

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select From existing OpenAPI service, and click Next.
4. To upload the service information from an OpenAPI file, you can either drag and drop your file, or browse and select the file that you want to use. Valid file types are YAML, YML, etc.
   - Click Browse and browse for the OpenAPI file.
   - Drag and drop the file into the active area.

   After you upload the file, the OpenAPI specification is evaluated and a message displays whether it is valid.
5. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see apic draft-apis.
   - The Version corresponds to the value of the **info.version** property of the API's OpenAPI definition. The **version.release.modification** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
6. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **X-IBM-Client-Id** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.

     For information about security options in IBM API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **cors** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **cors** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **request.attributes.isCORSPreflight** flag is set to **true**.
     - For all preflight requests, the **security** and **client-identification** preflow policies are always skipped, whether CORS is enabled or not enabled.
7. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the **Product:Manage** and **Subscription:Manage** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
8. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

   If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

9. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a proxy API from an existing OpenAPI service.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Creating a REST proxy API from an existing WSDL service

If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect REST proxy API that calls that SOAP service.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

If the WSDL file is a stand-alone file with no external dependencies, you can load the .wsdl file from a directory to create the REST API definition.

If the WSDL file references other WSDL files or references XSD files containing XML schema definitions, you must create a .zip archive of the WSDL file and its dependent documents, and then load the .zip file from a directory to add the REST API definition.

Procedure

To add a REST API definition by loading a WSDL file, complete the following steps:

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. On the Add API pane, select From existing WSDL service (REST Proxy). Click Next.
   The Create API from Existing WSDL Service (REST Proxy) window opens.
4. To upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, you can either drag and drop your file, or browse and select the file that you want to use.
   After you upload the file, the WSDL is evaluated and a message displays whether the WSDL is valid.

   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.

5. Click Next. At the Select Service panel, select a WSDL service from the imported file.
6. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see apic draft-apis.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
7. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.

     For information about security options in IBM® API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:

- Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
- Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.

- You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
- To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

9. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

   If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

10. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a REST API definition by using an existing WSDL file.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

You can also manage the Product lifecycle, and control who can see and subscribe to your Product, by opening the Sandbox Catalog associated with your API in the Manage page of the API Designer UI.

Creating a SOAP proxy API from an existing WSDL service

If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect SOAP proxy API that calls that SOAP service.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Note: By default, the SOAP proxy API that is created will have the basepath set to the WSDL service name. You can edit the SOAP proxy API to change this basepath.
You can add a SOAP API to expose an existing SOAP service by supplying the WSDL file that defines that existing service in one of the following ways:

- If the WSDL file is a stand-alone file with no external dependencies, you can load the .wsdl file from a directory to create the SOAP API definition.
- You can provide one or more WSDL files in a single .zip file that contains the WSDL files and any necessary schemas.
  If the WSDL file references other WSDL files or references XSD files containing XML schema definitions, you must create a .zip archive of the WSDL file and its dependent documents, and then load the .zip file from a directory to add the SOAP API definition.

- If you are using API Designer with existing APIs that were created from a WSDL or WSDL.zip file in Version 5 API Designer, make sure that the following requirements are met:
  - The WSDL or WSDL.zip file must be stored in the same directory as the API's YAML file.
  - In the API's YAML file, the **`x-ibm-configuration`** --> **`wsdl-definition`** --> **`wsdl`** property must point directly to the WSDL or WSDL.zip file with no path specified (the files are located in the same directory).

The service must support Web Services Basic Profile Version 1.1 - Second Edition.

Procedure

To add a SOAP API definition by loading a WSDL file, complete the following steps:

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. Select From existing WSDL service (SOAP Proxy). Click Next.
   The Create API from Existing WSDL Service (SOAP Proxy) window opens.
4. To upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, you can either drag and drop your file, or browse and select the file that you want to use.
   After you upload the file, the WSDL is evaluated and a message displays whether the WSDL is valid.

   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.

5. Click Next. At the Select Service panel, select a WSDL service from the imported file.
6. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see apic draft-apis.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
7. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.

     For information about security options in IBM® API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
9. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

   If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

10. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a SOAP API definition by using an existing WSDL file.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

You can also manage the Product lifecycle, and control who can see and subscribe to your Product, by opening the Sandbox Catalog associated with your API in the Manage page of the API Designer UI.

Creating a new REST OpenAPI definition

You can create and edit draft REST API definitions by using the API Designer or the API Designer user interface in IBM® API Connect.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

To create a new REST OpenAPI definition, complete the following steps.

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select New OpenAPI .
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see apic draft-apis.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
5. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.

     For information about security options in IBM API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
6. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
7. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You successfully created a REST API definition. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Adding a REST API by importing an OpenAPI definition file

You can use an OpenAPI definition file to import a REST API into IBM® API Connect.

Before you begin

Your file must conform to version 2.0 or version 3.0 of the OpenAPI specification. The format of the file can be JSON or YAML.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Api-Drafts:Edit`, `Settings:View`, and `App:View` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

If you are using the API Designer UI and you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, use the import mechanism described here rather than copying the file into your local API Designer directory; the import operation adds API Connect specific sections that are required by API Designer.

Procedure

To add a REST API by importing an OpenAPI file, complete the following steps:

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. In the Import section, select Existing OpenAPI, then click Next.
4. Choose one of the following methods for importing the file:
   - Drag and drop a file
     Open another window, select a file. Drag the file to the Select a file box, and release the file.
   - Browse for a file
     Click the Select a file box. Locate the file and select it.
   - Specify the URL of a file
     In the Or specify a file URL field, type or paste a URL for the file. Optionally add a User name and Password if they are required for accessing the file.

   The following file types are supported if they contain a valid OpenAPI definition: .json, .yml, and .yaml.
5. Click Next to import the selected file.
   The wizard checks the validity of the YAML, and displays a message indicating successful validation.

   Notes:
   - If you are using the API Manager UI, the import operation fails if the file defines an API that has the same name and version as an existing API definition. However, if you are using the API Designer UI, API definitions are uniquely identified by the file name in your local file system; therefore, if you import two different files that define the same API name and version, two API definitions with the same name and version are created in API Connect, with no error.
   - Any validation error messages are displayed in English only, and are not translated.
6. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the

API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
    - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
  - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
  - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
7. Click Next. The Import API Summary panel indicates that the YAML file is loaded and valid.
   If you selected Activate API, the wizard populates an API Endpoint URL, and displays a Client ID and Client Secret that you can use.
8. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

When the API definition has been imported, it is shown in the list of API definitions in the Develop page. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Adding a SOAP API by importing a zip file

You can use an OpenAPI definition file to import a SOAP API into IBM® API Connect.

Before you begin

The format of the file must be .zip, and the file must contain the WSDL definition and the YAML file that defines the API. The YAML file must conform to version 2.0 of the OpenAPI specification.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "**`(?`**" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

If you are using the API Designer UI and you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, use the import mechanism that is described here rather than copying the file into your local API Designer directory; the import operation adds API Connect specific sections that are required by API Designer.

For more information on how to create a .zip file, see Downloading an API definition.

Procedure

To add a SOAP API by importing a .zip file, complete the following steps:

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.

3. In the Import section, select Existing OpenAPI, then click Next.
4. To import a file from your local file system, you can either drag and drop the file or click the link to select the file from your local file system.
   The wizard checks the validity of the WSDL and YAML, and displays a message that indicates a successful validation.
   Note:
   - If you are using the API Manager UI, the import operation fails if the file defines an API that has the same name and version as an existing API definition. However, if you are using the API Designer UI, API definitions are uniquely identified by the file name in your local file system; therefore, if you import two different files that define the same API name and version, two API definitions with the same name and version are created in API Connect, with no error.
   - Any validation error messages are displayed in English only, and are not translated.
5. Click Next.
6. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
7. Click Next. The Import API Summary panel indicates that the file is loaded and valid.
   If you selected Activate API, the wizard populates an API Endpoint URL, and displays a Client ID and Client Secret that you can use.
8. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

When the API definition has been imported, it is shown in the list of API definitions in the Develop page. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

API Gateway only

Creating a GraphQL proxy API

GraphQL is a query language for APIs that gives an application client greater control over what data it retrieves in an API request when compared with a REST API request. IBM® API Connect enables you to create a GraphQL API proxy definition that proxies a backend GraphQL server, and to define rate limiting controls that reflect the amount of data that is returned from the server by a request to the GraphQL API.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

GraphQL provides the following particular advantages over REST APIs:

- The application client can request only the data that it needs. For example, when retrieving bank account records, request only the account number and current balance for each account, but not the customer name and address details. With a REST API request, either the backend REST service must provide separate endpoints for different data subsets, or the application client must retrieve the complete records and then discard the unwanted data.
- The application client can retrieve multiple related resources in a single request. For example, a customer's bank account record might include an array that references other finance products that the customer holds. If an application client wants to retrieve the bank account details for a specific customer, and details of the other finance products for that customer, then with a REST API the client would first retrieve the bank account details, then make separate requests for each of the other products. A GraphQL API can be designed to allow the client to retrieve all this information in a single request.

However, this flexibility presents rate limiting challenges, because two seemingly very similar requests might return vastly different amounts of data, and what might have required multiple REST API requests, each counting towards the rate limit, might require only a single GraphQL API request. It is important therefore that rate limiting controls are imposed that reflect the amount of data that is retrieved. API Connect extends the GraphQL standard by providing, in a GraphQL API definition, the ability to configure a range of settings that are used to calculate the complexity of a GraphQL request and an associated cost that counts towards the rate limit.

Procedure

To create a GraphQL API proxy definition, complete the following steps:

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. Select From existing GraphQL service (GraphQL proxy).
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see apic draft-apis.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
5. In the GraphQL Server section, specify the following values:
   - GraphQL server URL: this is the URL that is used for requests to the backend GraphQL API. The GraphQL schema is imported automatically from the specified URL.
   - Schema name: the name that you enter here is used to identify the schema definition that is created from the imported GraphQL schema. The field is pre-populated with host name segment of the value entered in the GraphQL server URL field, but you can change it.
6. Click Next. If there are any warnings indicated relating to the imported schema, you can review them now by clicking View.
   You can deal with these warnings as appropriate after you have created your GraphQL proxy API.
7. In the Operations and Paths section, select the operations and paths that you want to include.
   The operation path of **`/graphql`** is already selected and you cannot change this setting; this is the path for application client requests to API Connect that invoke the GraphQL API.

   For details of the mechanisms supported for sending a request to the **`/graphql/cost`** endpoint, see Request mechanisms supported by GraphQL endpoints.

   You can also select the operation path of graphql/cost; this path enables application clients to obtain details of the cost of a request to the GraphQL API before making the actual request. In a production environment, in particular, you should consider carefully the resource implications of making this path available. For full details regarding the enablement of the cost endpoint, see Enabling the cost endpoint for a GraphQL API.

   To form the full API paths, these path segments are appended to the **`basepath`** that you specified in step 4.

   To allow application clients to send introspection requests for this GraphQL proxy API, select Support default introspection. For full details, see Supporting introspection for a GraphQL API.

   To allow users to test the GraphQL proxy API from a GraphiQL editor, select Enable GraphiQL editor. For full details, see Enabling the GraphiQL editor for a GraphQL API.

   Note: The graphql/cost, Support default introspection, and Enable GraphiQL editor options each automatically generate policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required.
8. Optionally, you can replace the GraphQL schema that was imported from the GraphQL server URL by uploading a schema from your local file system. Click Replace; you can then either drag and drop your file, or click where indicated to select the file from your local file system. Click Upload when done.
   Note:
   - The schema must be written in the GraphQL Schema Definition Language (SDL). For more information, see Type language in the GraphQL documentation at https://graphql.org/.
   - If you upload a schema from a local file having previously uploaded a schema from a URL, the schema URL setting that is stored in the OpenAPI source for the API, and subsequently displayed in the user interface, retains the previously specified URL value rather than indicating a file location.
9. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. For information about security options in IBM API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
10. Optional: Select Activate API if you want to immediately use the API for further development and testing.
    Note:
    - When you select the Activate API option, API Connect automatically completes the following actions:
      - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
      - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
    - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and

configuring catalogs.
    - To use the Activate API option, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
11. Click Next to create your API definition.
    The Summary panel displays messages as the definition is created, and the selected security options are enforced.

    If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

12. Click Next to create your API definition.
    The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

13. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

What to do next

Use the GraphQL schema editor to review, and deal with, any warnings associated with the schema, and to configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit; for details, see Using the GraphQL schema editor.

- **Using the GraphQL schema editor**
  The GraphQL schema editor allows you to a configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit.
- **Supporting introspection for a GraphQL API**
  If you select the Support default introspection option when creating a GraphQL proxy API, client applications can send GraphQL introspection requests to the API.
- **Enabling the GraphiQL editor for a GraphQL API**
  If you select the Enable GraphiQL editor option when creating a GraphQL proxy API, users can test the API by using a GraphiQL editor in a web browser; API Connect responds to the initial GraphiQL editor request with an HTML page that enables testing from the GraphiQL editor.
- **Enabling the cost endpoint for a GraphQL API**
  If you enable the `/graphql/cost` endpoint when creating a GraphQL proxy API, a calling application can obtain details of the cost of executing a request on the backend GraphQL server before making the actual backend request.
- **Securing a GraphQL API by using a client ID**
  If you select the Secure using Client ID option when creating a GraphQL proxy API, API Connect automatically adds Rate limit policies to the API assembly.
- **Request mechanisms supported by GraphQL endpoints**
  API Connect supports various mechanisms for sending requests to GraphQL proxy API endpoints.
- **GraphQL custom schema directives and scalar types**
  The API Connect DataPower API Gateway extends the GraphQL specification by providing additional schema directives and custom scalar types.
- **@remove directive**
  The `@remove` GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context.
- **GraphQL limitations**
  This page details the limitations in the API Connect GraphQL implementation for the current release.

API Gateway only

Using the GraphQL schema editor

The GraphQL schema editor allows you to a configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit.

Introduction

When the GraphQL schema editor opens, all the types defined in the GraphQL schema are listed. You can expand a type to display all the fields that are defined for that type.

For each type, you can specify the following setting:

Type weight
: The weighting factor that you want to apply to the type for use when calculating the type cost for a request to the GraphQL API. In general, the weighting factor for a type will reflect the resource implications for a request that retrieves values of that type; for example:

  - A complex object might be weighted more heavily than a String.
  - Values of one type might be retrieved from a different backend database to values of another type, and accessing one database requires more CPU resource, so types associated with this database are weighted more heavily.

For each field, you can specify the following settings:

Field weight
: The weighting factor that you want to apply to the field for use when calculating the field cost of a request to the GraphQL API.

Assumed size
: The size limit that the backend server imposes on the number of values of this field that are returned, in a list, for each separate retrieval of the field in an API request. If an assumed size has been defined for this field in the imported GraphQL schema, its value is displayed. You an enter a value, or change the current value, and the schema definition stored in API Connect is updated accordingly. You must ensure that the specified value corresponds with the implementation or configuration on the backend server so that API Connect can apply rate limiting correctly. The assumed size is intended to be configured for fields that return lists of values, to tell the cost analysis how many values to expect.

Slicing arguments
: A comma separated list of the arguments that are used by the backend server to limit the number of values of this field that are returned, in a list, for each separate retrieval of the field in an API request. These must correspond with the implementation or configuration on the backend server. For example, there might be slicing arguments of **`first`** and **`last`** that are used to specify a range of objects to be returned by an API request.

Sized fields
: In some cases, a field with a configured Assumed size or Slicing arguments setting returns an object, a field of which returns the values whose number is to be sized. This is common in the connections pattern for pagination, where fields with slicing arguments **`first`** or **`last`** return a **`connections`** object, that contains the sized list in an **`edges`** field. The Sized fields option allows the cost analysis to consider these indirect relationships between assumed sizes or slicing arguments and the sized list of values. Supply a comma separated list of field names.

You access the GraphQL schema editor in either of the following ways:

- Immediately after creating a new GraphQL proxy API , by clicking Edit API, then clicking the GraphQL Schema tab. For GraphQL proxy API creation details, see Creating a GraphQL proxy API.
- By modifying the configuration of an existing API; complete the following steps:
  1. In the navigation pane, click Develop, then select the APIs tab.
  2. Alongside the GraphQL API definition that you want to work with, click the options icon and then click Edit API.
  3. Click the GraphQL Schema tab.

Modifying a setting for a single type or field

For a numerical setting, click the setting alongside the required type or field, then enter the required value, or use the stepper control. For a setting that has a textual value, enter the value directly. You might first want to filter the display to show only a relevant subset of types and fields; see Filtering the display.

Modifying settings for multiple types and fields

To modify settings for multiple types and fields in a single operation, complete the following steps:

1. Select the check boxes alongside the types and fields whose settings you want to modify.
2. Click Apply analysis configuration.
3. On the Type tab, specify the settings that you want to apply to the selected types.
4. On the Field tab, specify the settings that you want to apply to the selected fields.
5. Click Apply to apply the settings to the selected types and fields.
6. When you have made all the required modifications to the selected types and fields, click Done; this actions clears all check box settings.

To to restore any type or field settings to the initial default settings after having applied an analysis configuration, select the check boxes alongside the required types and fields, then click Remove analysis configuration.

You might first want to filter the display to show only a relevant subset of types and fields; see Filtering the display.

Filtering the display

To display only those type and fields that contain a specified string, enter the required filter string in the Search schema field, then press Enter.

If a type matches the filter, the type and all its fields are displayed. If a field matches the filter but not its parent type, the parent type is displayed together with all matching fields. You can enter multiple filter strings; the items displayed are those that contain all strings.

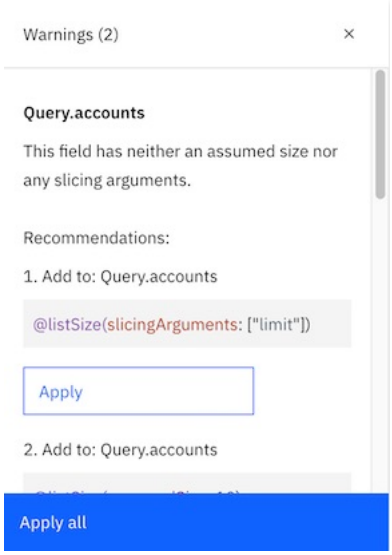
You can now use the operations described in Modifying a setting for a single type or field and Modifying settings for multiple types and fields to update the settings for the displayed types and fields.

To remove a specific filter string from the search, click the Close icon for that filter string. To restore the full type and field display by removing all filter strings, click the Clear icon at the end of the search field.

GraphQL schema warnings

Where applicable, API Connect will recommend updates to the analysis configuration to protect the backend server from excessive resource utilization, and to ensure correct cost estimation for requests. These recommendations are displayed as warnings in the GraphQL schema editor.

If a type contains one or more fields with warnings, this is indicated by a warning count icon 2 alongside the type. You can click the warning count icon to see the warnings for that type; the Warnings window opens at the relevant warnings, for example:



To see the fields that have warnings, expand the type; a warning icon is displayed alongside fields with warnings. To see the details of a warning for a field, click the warning icon alongside the field

If you click Accept under any warning in the Warnings window, the recommended update is applied to the schema automatically.

To apply the suggested updates for all warnings in a single operation, click Apply all in the Warnings window, then click Apply to confirm.

You can filter the display to include only items with warnings; click the Menu icon, then select Show warnings only.

Applying @remove directives to types and fields in the GraphQL schema

The **`@remove`** GraphQL schema directive specifies conditions for removing items from validation or introspection for each transaction based on values in the API context. For example, you can prevent specific Plans from using certain types or fields.

For more details on the **`@remove`** directive, including examples, see rapic_graphql_extensions.html#reference_wrt_bk1__5mb__at_remove.

To apply an **`@remove`** directive to an item in your GraphQL schema, complete the following steps:

1. Click the settings icon in the Show/hide column alongside the required item. The Show/hide settings window opens.
2. To remove the item depending on a boolean condition, enter the boolean expression in the Custom expression field; the following directive will be added to the item in the schema:

   `@remove(if: [`*`expression`*`])`

   To remove the item unconditionally, change the Show in schema slider control to Hide in schema; the following directive will be added to the item in the schema:

   `@remove(if: ["true"])`
3. Click Next. A summary window opens. If the removal is permitted, any related items that will also have the **`@remove`** directive applied are listed; for example, if you apply an **`@remove`** directive to a type, and that type is referenced as the data type of a field on another type, the **`@remove`** directive is also applied to that field. If the removal is not permitted, an explanation is displayed.
4. If the removal is permitted, click Done to apply the **`@remove`** directive. If the removal is not permitted, either click Cancel to close the window or click Back and amend your settings.
5. To see the updates to the GraphQL JSON schema, click View source.

You can use the settings icon to modify or delete previously applied **`@remove`** directives. To remove a conditional **`@remove`** directive, delete the expression from the Custom expression field. To remove an unconditional **`@remove`** directive, change the Hide in schema slider control to Show in schema.

Viewing the GraphQL schema

To view the GraphQL JSON schema that was previously uploaded, click View source. Note that the schema includes **`directive`** statements and attribute values, added by API Connect, that reflect the configuration settings.

Replacing the GraphQL schema

To replace the GraphQL schema, complete the following steps:

1. Click Replace.
2. Specify the replacement schema:
   - To replace the schema by introspecting a URL, complete the following steps:
     - Select Introspect from URL.
     - Enter the URL in the GraphQL server URL field, then click Introspect.

     Note: If you replace the schema from a URL that is different to the one specified as the backend GraphQL server, in the GraphQL server URL field, when the GraphQL proxy API was created, the schema itself is replaced but the backend URL remains unchanged. You must correspondingly modify the URL setting on the **`invoke`** policy in the API assembly of your GraphQL proxy API.
   - To replace the schema by uploading a file, complete the following steps:
     - Select Upload schema definition language (SDL) file.

- Either drag and drop the file or click the link to select the file from your local file system.

Note:

- The schema must be written in the GraphQL Schema Definition Language (SDL). For more information, see Type language in the GraphQL documentation at https://graphql.org/.
- If you upload a schema from a local file having previously uploaded a schema from a URL, the schema URL setting that is stored in the OpenAPI source for the API, and subsequently displayed in the user interface, retains the previously specified URL value rather than indicating a file location.

All the changes between the replacement schema and the current schema are listed.

3. Update the schema as required:
   - To have all new types and fields shown by default, select New schema for the Update schema defaults giving preference to setting. You can then choose to hide specific items by selecting Hide in the Action column alongside an item. Hiding an item causes an `@remove` directive to be added to the item in the schema source, as detailed in Applying @remove directives to types and fields in the GraphQL schema.
   - To have all new types and fields hidden by default, select Old schema for the Update schema defaults giving preference to setting. You can then choose to show specific items by selecting Show in the Action column alongside an item.

   Note: If the current schema contains items that are not in the replacement schema, these items are deleted. Such deletions are shown in the change listing with the Accept setting displayed in the Action column; you cannot change this setting.
4. Click Next. A change summary page is displayed. If any removals are not permitted, an explanation is displayed, and you cannot complete the schema replacement; either click Cancel to close the window or click Back and amend your settings..
5. Click Submit to complete the schema replacement.

Downloading the GraphQL schema

To download the GraphQL schema to a local file, click the Download. Note that the downloaded schema includes all additional settings that reflect your configuration updates.

- GraphQL custom schema directives and scalar types

API Gateway only

Supporting introspection for a GraphQL API

If you select the Support default introspection option when creating a GraphQL proxy API, client applications can send GraphQL introspection requests to the API.

Introspection allows client applications to request details of all the types and fields that are defined in a GraphQL schema. When you create a GraphQL proxy API, introspection requests sent to that API from client applications are handled by the gateway. The response reflects any modifications you have made to the schema by using the GraphQL schema editor.

When you select the Support default introspection option, API Connect creates the introspection endpoint. A GraphiQL editor always attempts to introspect a GraphQL endpoint, so disabling this option significantly reduces the test capability for GraphiQL editor users. This option also automatically generates policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required; see the API assembly policies for introspection support section for details. Disabling this option also limits the capability of the Developer Portal to test the GraphQL proxy API.

On the other hand, providing introspection support can have resource implications, and you might choose to communicate the schema information in another way. However, note that the GraphiQL editor does not allow custom introspection queries to populate the document explorer. For more information on introspection, see Introspection in the GraphQL documentation at https://graphql.org/.

API assembly policies for introspection support

This section details the API assembly policy configuration that is generated automatically if the Support default introspection option is selected when a GraphQL proxy API is created. If the option is not selected at creation time, and you later decide that you want to enable it, you must add it manually to the API assembly.

A `case` is added to a `switch` policy with the following condition:

```
($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'standard-introspection')
```

If the condition is true, the following policies are executed in sequence, with property settings as indicated:

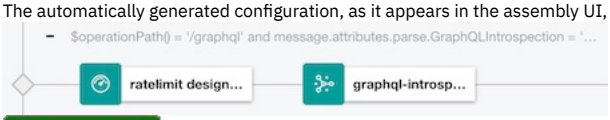
Rate limit

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

GraphQL introspect

Property	Value
Input	message
Output	No value, defaults to input

The automatically generated configuration, as it appears in the assembly UI, is as follows:



API Gateway only

Enabling the GraphiQL editor for a GraphQL API

If you select the Enable GraphiQL editor option when creating a GraphQL proxy API, users can test the API by using a GraphiQL editor in a web browser; API Connect responds to the initial GraphiQL editor request with an HTML page that enables testing from the GraphiQL editor.

Disabling the Enable GraphiQL editor option reduces gateway traffic and latency and, furthermore, the Developer Portal provides equivalent test capability regardless of whether or not you enable the option.

This option automatically adds the following property setting to the OpenAPI source for the GraphQL proxy API:

```
html-page: 'store:///graphiql.html'
```

If you disable the Enable GraphiQL editor during API creation and later decide that it is required, you can either manually add this property setting, or you can select Enable GraphiQL editor on the API Setup page of the Design tab of the API..
Note:

- The `html-page` property should be used **only** with a GraphQL proxy API.
- `store:///graphiql.html` is the only value allowed for the `html-page` property.
- If you add the `html-page` property but the Support standard introspection property was not enabled during API creation, the GraphiQL HTML page will not show any documentation regarding the GraphQL backend server, perform query validation, or perform smart lookup. For details on how to manually create the required assembly policy configuration, see Supporting introspection for a GraphQL API.

API Gateway only

Enabling the cost endpoint for a GraphQL API

If you enable the `/graphql/cost` endpoint when creating a GraphQL proxy API, a calling application can obtain details of the cost of executing a request on the backend GraphQL server before making the actual backend request.

The "cost" does not relate purely to monetary cost but can take into account factors such as computational time, memory consumption, and other such factors, in addition to the actual financial costs associated with, say, using third-party systems to retrieve data.

In a production environment, in particular, you should consider carefully the resource implications of making this path available. Note, however, that enabling the `/graphql/cost` endpoint automatically generates policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required; see the API assembly policies for the cost endpoint section for details.

API assembly policies for the cost endpoint

This section details the API assembly policy configuration that is generated automatically if the `/graphql/cost` operation path is selected when a GraphQL proxy API is created. If the path is not selected at creation time, and you later decide that you want to enable it, you must add it manually to the API assembly.

A `case` is added to a `switch` policy with the following condition:

```
($operationPath() = '/graphql/cost' and message.attributes.parse.GraphQLIntrospection = 'not-introspection')
```

If the condition is true, the following policies are executed in sequence, with property settings as indicated:

Rate limit

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

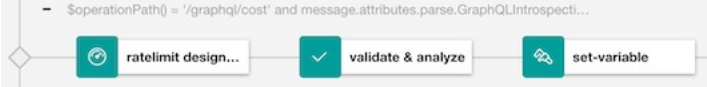
Validate

Property	Value
Input	message
Output	No value, defaults to input
Validate against	GraphQL

Set Variable

Property	Value
Action	Set
Set	message.body
Type	any
Value	$(message.attributes.graphql)

The automatically generated configuration, as it appears in the assembly UI, is as follows:



API Gateway only

Securing a GraphQL API by using a client ID

If you select the Secure using Client ID option when creating a GraphQL proxy API, API Connect automatically adds Rate limit policies to the API assembly.

This section details the Rate limit policy configuration that is generated automatically. If the Secure using Client ID option is not selected at creation time, and you later decide that you want to enable it, you must add the appropriate Rate limit policies manually to the API assembly.

The automatically generated Rate limit policies are added to the **switch** cases in the assembly as follows:

- **switch** case:

  ```
  ($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'not-introspection' and
  message.attributes.graphql.operationType = 'subscription')
  ```

  A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Count Limit Name	graphql-subscription-type-cost
Operation	Increment
Count Limit Name	graphql-subscription-field-cost
Operation	Increment

  The policy as it appears in the assembly UI is as follows:

  This Rate limit policy limits the number of HTML web browser requests for a GraphiQL editor sent to the **/graphql** endpoint.

- **switch** case:

  ```
  ($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'not-introspection' and
  message.attributes.graphql.operationType != 'subscription')
  ```

  Two Rate limit policies with the following property settings:

  - Policy 1:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-type-cost
Operation	Consume
Rate Limit Name	graphql-field-cost
Operation	Consume
Rate Limit Name	graphql-input-type-cost
Operation	Consume

    This Rate limit policy limits calls to the GraphQL proxy API by calculating the expected cost of the query, and then correspondingly reducing the available cost balance that remains of the total configured cost limit. The expected cost is calculating by applying the weighting factors that have been attached to the types and fields in the GraphQL schema; for more information, see Using the GraphQL schema editor.

    The expected cost is calculated by the Validate policy that precedes the Rate limit policy and placed in the API context to be made available to the Rate limit policy. For details on the Validate policy, see Validate.

    The details of the cost calculations to which the referenced rate limits are applied are as follows:

    - **graphql-field-cost**: The weighted sum of fields being selected in a query. Fields that return values of scalar or enum types have a weight of 0.0 and therefore don't affect field cost.
      For example, consider the following query, where it is assumed that the value **max** in the **filter** argument of field **Query.offices** constrains the number of **Office** objects being returned:

      ```
      query {
        offices (filter: {location: "NY", max: 3}) {
          address {
            street
          }
        }
      }
      ```

      The **Address.street** field is of type **String** and therefore has a weight of 0.0. Non scalar and non enum field weights that are not changed in the GraphQL schema editor assume a default value of 1.0. If the **Office.address** field weight has been set to 3.0, the total field cost is 10.0, calculated as follows:

Field	Weight	Field cost
Query.offices	1.0	1 x 1.0 = 1.0
Office.address	2.0	3 x 3.0 = 9.0
Address.street	0.0	0.0
	Total cost:	1.0 + 9.0 + 0.0 = 10.0

    - **graphql-type-cost**:
      The weighted sum of types being returned by a query. Scalar or enum types have a weight of 0.0 and therefore don't affect type cost.

      Considering the previous example, and assuming that all types have a default weight of 1.0, the total type cost is 7 (1 x **Query** type + 3 x **Office** types + 3 x **Address** types.

    - **graphql-input-type-cost**:
      The weighted sum of input types being sent in a query. Scalar or enum input types have a weight of 0.0 and therefore don't affect input type cost.

Considering the previous example, the input type cost is 1.0, because one **`FilterInput`** type is sent in the **`filter`** argument. **`FilterInput.location`** is a **`String`** type and **`FilterInput.max`** is an **`Int`** type, so they are not included as they are scalars.

- Policy 2:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-type-cost
Operation	Replenish
Rate Limit Name	graphql-field-cost
Operation	Replenish

This Rate limit policy limits calls to the GraphQL proxy API by calculating the actual cost of the query, and then correspondingly reducing the available cost balance that remains of the total configured cost limit. The actual cost is calculating by applying the weighting factors that have been attached to the types and fields in the GraphQL schema; for more information, see Using the GraphQL schema editor.

Note that if the actual cost is less than the expected cost, this Rate limit policy will appropriately restore some of the available cost balance that had been removed by Policy 1, thereby overriding the original actual cost limitation. The actual cost might be less than the expected cost if, for example, the query requested more data than was available in a backend database. You can delete one or other of these Rate limit policies from the assembly if desired.
Note: Such unused cost is **not** restored if there are GraphQL response errors. The purpose of this restriction is to prevent malicious requests that cause large amounts of erroneous backend processing while only using a small amount of cost.
The actual cost is calculated by the Validate policy that precedes the Rate limit policy and placed in the API context to be made available to the Rate limit policy. For details on the Validate policy, see Validate.

The policies as they appear in the assembly UI are as follows:

- **`switch`** case:

```
($operationPath() = '/graphql/cost' and message.attributes.parse.GraphQLIntrospection = 'not-introspection')
```

A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

The policy as it appears in the assembly UI is as follows:

This Rate limit policy limits the requests sent to the **`/graphql/cost`** endpoint for retrieving the cost of a GraphQL query.

- **`switch`** case:

```
($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'standard-introspection')
```

A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

The policy as it appears in the assembly UI is as follows:

This Rate limit policy limits standard introspection requests sent to the **`/graphql`** endpoint.

The rate limits that are referred to by the Rate Limit Name settings in these policies are predefined in Plans that are created in Products that contain one or more GraphQL proxy APIs. You can configure the actual rate limiting values there; for more information, see Editing a draft Product.

For more information on the Rate Limit policy, see Rate Limit.

API Gateway only

Request mechanisms supported by GraphQL endpoints

API Connect supports various mechanisms for sending requests to GraphQL proxy API endpoints.

You can use any of the following mechanisms for sending requests to the **`/graphql`** and **`/graphql/cost`** endpoints on a GraphQL proxy API:

- **GET**: the GraphQL query must be specified in a URL query parameter called **query**.
  For example:

  ```
  https://hostname/basepath/graphql?query={accounts(limit:100){name{first,last}}}
  ```

  The following example includes the **variables** and **operationName** properties, with URL encoding:

  ```
  https://hostname/basepath/graphql?
  query=query%20fetchAccounts%20($limit:%20Int)%20{accounts(limit:%20$limit)%20{name{first,last}}}&variables=
  {"limit":100}&operationName=fetchAccounts
  ```

- **POST** with a JSON-encoded body: the **Content-Type** header must be set to **application/json**, and the GraphQL query must be sent in the **query** key of the JSON object.
  For example:

  ```
  {
    "query": "query fetchAccounts ($limit: Int) {accounts(limit: $limit) {name{first,last}}}",
    "variables": {"limit": 100},
    "operationName": "fetchAccounts"
  }
  ```

  The **variables** and **operationName** are optional. For more information, see POST request in the GraphQL documentation at https://graphql.org/..

- **POST** with graphql content: the **Content-Type** header must be set to **application/graphql**; the entire body of the **POST** is treated as the GraphQL query

Note: For a request sent to the **/graphql** endpoint, the GraphQL proxy API always sends the request to the backend GraphQL server as a **POST** with a JSON-encoded body, so the backend GraphQL server must support this mechanism otherwise the call fails.

GraphQL custom schema directives and scalar types

The API Connect DataPower® API Gateway extends the GraphQL specification by providing additional schema directives and custom scalar types.

Custom schema directives

@cost
: The **@cost** directive associates weight values with types or fields. Types are used to calculate type cost of a request to the GraphQL API. Fields are used to calculate field cost of a request to the GraphQL API. For more information, see The Cost Directive.

@listSize
: The **@listSize** directive applies slicing arguments to fields. For more information, see The List Size directive.

@remove
: The **@remove** GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context. For more information, see @remove directive

@scalarParam
: The **@scalarParam** directive allows further customization of custom scalar types. For more information, see @scalarParam directive.

Custom scalar types

Date
: The **Date** custom scalar type is used to define custom scalars that specify dates. For more information, see Date Custom Scalar.

DateTime
: The **DateTime** custom scalar type is used to define custom scalars that specify date and time. For more information, see DateTime Custom Scalar.

JSON
: The **JSON** custom scalar type is used to specify JSON payloads. For more information, see JSON Custom Scalar.

Long
: The **Long** custom scalar type enables the use of integers larger than those allowed by **Int**. For more information, see Long Custom Scalar.

Related reference

- Using the GraphQL schema editor

@remove directive

The **@remove** GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context.

For example, you can prevent specific Plans from using certain types or fields. For more information on the API context, see API Connect context variables.

Note: The **@remove** directive dynamically modifies the schema so that queries that do not conform to the schema, after any **@remove** directives have been evaluated, would be rejected by a **validate** policy.

Syntax

```
@remove(if: [String]) on SCALAR | OBJECT | FIELD_DEFINITION | ARGUMENT_DEFINITION | INTERFACE | UNION | ENUM | ENUM_VALUE | IN
```

Arguments

Argument name	Type	Description
if	List of strings	JSONata condition that specifies the criteria for removal of a type or field from validation or introspection.

Limitations and propagation rules

For limitations and propagation rules, see Limitations and propagation rules for the GraphQL `@remove` directive.

Example 1

Remove the `creditCard` type if the current API plan is `bronze`.

```
type creditCard @remove(if: ["plan.name in [\"bronze\"]"])
```

Example 2

Remove the `creditCard` type if the current API plan is not `gold`, and remove the field `card1` if the API plan is `bronze`.

```
type creditCard @remove(if: ["$not(plan.name = \"gold\")"]){
   field1: String
}
type User {
  card1: creditCard @remove(if: ["plan.name = 'bronze'", "$not(plan.name = \gold\")"])
}
```

API Gateway only

GraphQL limitations

This page details the limitations in the API Connect GraphQL implementation for the current release.

- Specialized handling of custom scalars is not supported, except for validation of the `Long` custom scalar type. Input values provided for all other custom scalar types are passed through.
- The following actions and functions cannot read or write to parsed GraphQL queries. Some of these policies might read and write a serialized form of the GraphQL query.
  - Assembly GatewayScript policy
  - Assembly Map policy
  - Assembly Redaction policy
  - Assembly Set Variable policy
  - Assembly XSLT policy
  - `setVar()` function
- When reading parsed GraphQL queries, the Assembly Switch policy cannot use wildcards or read arguments.
- GraphQL schemas cannot be serialized.
- GraphQL messages received with `Content-Type: application/graphql` or `Content-Type: application/json` will send that same content type to the backend. This behavior cannot be overridden.
- All GraphQL schemas are checked for unbounded lists, including those that are not referenced in the assembly. This behavior can cause validation errors that prevent the GraphQL API from being published.
- The GraphQL schema editor generates warnings for fields that contain unbound lists of values if either of the following conditions is true.
  - The values in the list are of composite type. However, the warning is not valid if the composite type in the list has a defined type weight of 0.0 and all its sub-fields also have weights of 0.0 (both the fields and the types of the values they return).
  - The values in the list are of scalar type, for which a weight other than 0.0 was defined.
- Extending schemas is not supported.
- GraphQL APIs can be tested from the Developer Portal user interface. However, not all authentication methods are supported. You must use one of the following authentication methods:
  - Unsecured
  - Client ID, passed in the header
  - Client ID and secret, passed in the header

  Also, `cost` metrics are not supported, and rate limits specific to GraphQL are not listed in Product plans.

Importing an API from the CP4I asset repository

If you are using IBM® API Connect with IBM Cloud Pak for Integration (CP4I), you can import an API definition from the CP4I asset repository.

About this task

To complete this task you must be assigned a role that has the `Api-Drafts:Edit` permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. In the Import section, select From asset repository, then click Next.
4. Click Launch the asset repository.
5. From the asset repository listing, click the name of the API that you want to import.
   An API explorer window opens, enabling you to examine the details of the API.
6. Click Create from asset.
   The validity of the API definition is checked, and a message is displayed indicating successful validation.
7. Click Next.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:

- Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
- Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.

- You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
- To use the Activate API option, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

9. Click Next.
   The Summary panel displays messages as the API definition is created.
10. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Editing an OpenAPI 2.0 API definition

IBM® API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 2.0 specification.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

You can open an API for editing in either of the following ways:

- During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
- To open an existing API for editing, complete the following steps:
  1. In the navigation pane, click Develop, then select the APIs tab.
  2. Click the title of the API version that you want to work with.

- **Specifying API metadata**
  API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.
- **Specifying the host for an API**
  You specify a host for an API if you want external developers on the portal to access your APIs by using a host address that is not the same as the API endpoints that are defined for the gateway services where your API will run.
- **Specifying the basepath for an API**
  The base path is the initial URL segment of the API, and does not include the host name or any additional segments for paths or operations. It is shared by all operations in the API.
- **Specifying the schemes for an API**
  Schemes define which transfer protocols you want your API to use. If your API is enforced by an API Connect gateway, only the HTTPS protocol is supported.
- **Specifying the MIME types that an API consumes**
  You can specify which types of media your API will accept when calls are made to it. The API Connect gateway supports XML and JSON.
- **Specifying the MIME types that an API produces**
  You can specify which types of media your API will return when calls are made to it. The API Connect gateway supports XML and JSON.
- **Enforcing security requirements on an API**
  To enforce security requirements on an API, you apply previously created security schemes that specify various aspects of API security configuration.
- **Specifying external documentation for an API**
  You can reference an external resource for extended documentation for an API.
- **Adding tags to an API**
  You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Defining Paths for an API**
  A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.
- **Defining schema definitions for an API**
  Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.
- **Defining parameters for an API**
  Parameters can specify variable elements of a URL path, query parameters, headers, or a request body.
- **Defining responses for an API**
  Responses define the HTTP status code and data returned in a response body and headers. Responses defined for an API can be used across operations.
- **Specifying gateway and portal settings**
  Define general configuration settings for your API.
- **Defining target services for an API**
  A target service defines a web service that you want to use in your API definition.
- **Setting API properties**
  In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.

- **Configuring application authentication for an API**
  Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.
- **Configuring activity logging**
  You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.
- **Configuring v5 compatibility options**
  You can configure settings to ensure compatibility with API Connect Version 5.0 compatible APIs that are converted for use with the DataPower API Gateway.
- **Including elements in your API assembly**
  An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.
- **Specifying the gateway type for an API definition**
  An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). A default gateway type is set when you create an API definition, but you can edit the API configuration to specify a different gateway type.
- **Converting an API definition for deployment to the DataPower API Gateway**
  IBM API Connect provides two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway. If you have an API definition that was developed for the DataPower Gateway (v5 compatible) and you want to port it to the DataPower API Gateway, you must make changes to convert it before deployment.
- **Modifying a GraphQL schema**
  For a GraphQL API, an editor is provided for modifying the associated GraphQL schema.
- **Validating the OpenAPI YAML source**
  How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.
- **Validating an API document by using API governance**
  How to use API governance rulesets to validate and enforce organizational governance policies and best practices. You can validate APIs from the API Manager UI, the API Designer UI, or the toolkit CLI.

Specifying API metadata

API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click Info.
3. Provide the following information:
   - Title (required): The title of the API.
   - Name: The name was generated automatically when the API was created and cannot be changed. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see apic draft-apis.
   - Version: The API version is specified when the API is initially created and cannot be changed thereafter. You can, however, create a new version of an existing API; see Creating a new version of an API definition.
   - Description: An optional description of the API. You can use CommonMark syntax for rich text representation.
   - Terms of Service: A URL to the Terms of Service for the API.
   - Contact Name: The identifying name of the contact person/organization.
   - Contact Url: A URL pointing to the contact information.
   - Contact Email: The email address of the contact person/organization.
   - License Name: The license name used for the API.
   - License Url: A URL to the license used for the API.
4. Click Save when done.

Specifying the host for an API

You specify a host for an API if you want external developers on the portal to access your APIs by using a host address that is not the same as the API endpoints that are defined for the gateway services where your API will run.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click Host.

3. Enter the required host name.
   Note: To enable this capability, you must additionally configure API vanity endpoints in the Catalog Settings for the Catalog to which the API is published. For information on configuring vanity endpoints, see Creating and configuring Catalogs
4. Click Save when done.

Specifying the basepath for an API

The base path is the initial URL segment of the API, and does not include the host name or any additional segments for paths or operations. It is shared by all operations in the API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click Base Path.
3. Enter the required base path, preceded by a forward slash character (/).
4. Click Save when done.

Specifying the schemes for an API

Schemes define which transfer protocols you want your API to use. If your API is enforced by an API Connect gateway, only the HTTPS protocol is supported.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section then, if there are already one or more schemes defined, expand Schemes List.
3. To specify a new scheme, click the add icon ⊕ alongside Schemes List. To modify an existing scheme, click the scheme entry in the navigation pane.
4. Select the required scheme from the list provided, then click Create.
5. Click Save when done.

Specifying the MIME types that an API consumes

You can specify which types of media your API will accept when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section then, if there are already one or more consumes MIME types defined, expand Consumes.
3. To specify a new MIME type, click the add icon ⊕ alongside Consumes. To modify an existing MIME type, click the MIME type entry in the navigation pane.
4. Enter the required value in the Mime Type field; for example, **`application/json`** or **`application/xml`**. Then click Create.
5. Click Save when done.

Specifying the MIME types that an API produces

You can specify which types of media your API will return when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section then, if there are already one or more produces MIME types defined, expand Produces.
3. To specify a new MIME type, click the add icon ⊕ alongside Produces. To modify an existing MIME type, click the MIME type entry in the navigation pane.
4. Enter the required value in the Mime Type field; for example `application/json` or `application/xml`. Then click Create.
5. Click Save when done.

Enforcing security requirements on an API

To enforce security requirements on an API, you apply previously created security schemes that specify various aspects of API security configuration.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme definitions, see Defining security schemes.

The following restrictions exist when you apply security schemes to an API:

- You cannot apply more than two API key security schemes to an API.
- If you apply an API key security scheme for client secret, you must also apply an API key security scheme for client ID.
- If you require the application developer to supply both client ID and client secret, you must apply two separate API key security schemes.
- You can have at most one API key scheme of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
- You can have at most one API key scheme of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
- You cannot apply more than one basic security scheme to an API. If you apply a basic security scheme, you cannot also apply an OAuth security scheme.
- You can apply at most one OAuth security scheme to an API.

A security requirement specifies one or more security schemes whose conditions must all be satisfied for the API to be called successfully. You can define multiple security requirements; in this case, an application can call your API if it satisfies any of the security requirements you have defined.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand General.
3. To create a new security requirement for the API, complete the following steps:
   a. Click the add icon ⊕ alongside Security in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined; see Defining security schemes.
      If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme; for more information, see Defining OAuth2 security schemes.

      If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower® API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

      Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Submit when done.
4. To modify an existing security requirement, complete the following steps:
   a. Click Security in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
   b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.

c. Click Submit when done, then click Save.
d. To delete a security requirement, click the appropriate delete icon , click Delete to confirm, then click Save.
e. To disable security for the API, clear the Require one of the following Security Requirements check box, then click Save.

- **Defining security schemes**
  A security scheme specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.
- **Enabling CORS support for an API**
  You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Defining security schemes

A security scheme specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create security definitions of the following types:

Type	Description
Basic authentication	Use a basic authentication security definition to specify a user registry or an authentication URL to be used to authenticate access to the API.
API key	Use an API key security definition to specify what application credentials are required to call an API.
OAuth2	Use an OAuth2 security definition to specify settings for OAuth token based authentication for your API.

- **Defining basic authentication security schemes**
  A basic authentication security scheme is used when an application that calls the API is required to authenticate through a user registry.
- **Defining API key security schemes**
  An API key security scheme is used to specify the credentials that an application must provide to identify itself when calling the API operations.
- **Defining OAuth2 security schemes**
  An OAuth2 security scheme defines the settings for controlling access to the API operations through the OAuth authorization standard.

Defining basic authentication security schemes

A basic authentication security scheme is used when an application that calls the API is required to authenticate through a user registry.

Before you begin

For authenticating access to the operations of APIs that are enforced on the API Connect gateway, the following user registry types are supported:

- Authentication URL
- LDAP

The following user registry types are **not** supported:

- OpenID Connect (OIDC)
- Local User Registry (LUR)
- A custom user registry

Before you can create a basic authentication security definition in an API, the user registry must exist. To create a user registry, you can use either API Manager or Cloud Manager. When you create a registry in API Manager, it is visible only to your provider organization. When you create a registry in Cloud Manager, you can make it visible to multiple provider organizations.

To create a user registry with API Manager, see Working with user registries.

To create a user registry with Cloud Manager, see User registries overview.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you use basic authentication, you require API users to provide a valid user name and password to access selected operations. The application developer must also provide an HTTP authorization header in requests that are sent to operations that require basic authentication.

When you use an authentication URL, the user credentials that are provided in the authorization header are validated by the endpoint specified in the URL. If the user is authenticated, IBM® API Connect expects an authentication URL to return an HTTP `200 OK` response status code. All other HTTP response status codes result in an authentication failure and access is denied.

For more information about using an LDAP user registry for authentication, see LDAP authentication.

For information about using an Authentication URL, see Authentication URL user registry.

To make use of a basic authentication security scheme, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create a basic authentication security scheme, click the add icon ⊕ alongside Security Schemes, then select basic for the Security Definition Type. To edit an existing basic authentication security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Name field.
5. Select the user registry from the Authenticate using User Registry list.
   The user registries in the list are those that have been enabled in the Sandbox Catalog; for details, see Creating and configuring Catalogs.
6. Optionally, provide a Description for the security scheme. You can use CommonMark syntax for rich text representation.
7. If you are creating a new basic authentication security scheme, click Create.
   The security scheme details are displayed for further editing.
8. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

For more information on LDAP and Authentication URL, see LDAP authentication and Authentication URL user registry.

Defining API key security schemes

An API key security scheme is used to specify the credentials that an application must provide to identify itself when calling the API operations.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can require that, when calling an API operation, an application must provide either a client ID, or a client ID and client secret; you create an API key security scheme to specify a credentials requirement. If you require that an application must provide both a client ID and client secret, you must create two API key security schemes, one for each type of credentials.

To make use of an API key security scheme, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create an API key security scheme, click the add icon ⊕ alongside Security Schemes, then select apiKey for the Security Definition Type. To edit an API key existing security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Security Scheme Name field.
5. Specify the parameter name in the Name field.
   If your API is not enforced by the API Connect gateway, enter the parameter name required by your gateway.

   If your API is enforced by the IBM® API Connect gateway, the required value depends on the gateway type setting for the API, as follows:
   - DataPower® API Gateway: For a key of type client secret, you must include the string "secret", ignoring case, in the value you specify in the Name field; if the value does not contain the string "secret" then the key is assumed to be of type client ID.
   - DataPower Gateway (v5 compatible): the value must be as specified in the following table, depending on where the client credentials are located, and the type of credentials.

   Table 1. Client ID and Client secret parameter name values for the DataPower Gateway (v5 compatible)

Location of credentials	Type of credentials	Parameter name
Header	Client ID	X-IBM-Client-Id
Header	Client secret	X-IBM-Client-Secret
Query	Client ID	client_id
Query	Client secret	client_secret

   When you first create an API, a default API key security definition, of type client ID, is provided.

   For information about including API key parameters in an API call, see Calling an API.
   Note:
   - You cannot apply more than two API key security definitions to an API.
   - If you apply an API key security definition for client secret, you must also apply an API key security definition for client ID.
   - If you require the application developer to supply both client ID and client secret, you must apply two separate API key security definitions.
   - You can have at most one API key definition of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
   - You can have at most one API key definition of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.

- The client ID and client secret headers that are specified in the request when the API is called are **not** added automatically to the message context. If you need these headers in the message context for subsequent processing, include a **`set-variable`** policy in your API assembly that adds the headers to the message content, taking the values specified in the request; you can do this in either of the following ways:
  - In the Assemble tab, add a Set Variable policy to your API assembly that defines the appropriate actions; for example:

    Table 2.

Action	Set	Type	Value
Set	message.headers.X-IBM-Client-Id	string	$(request.headers.X-IBM-Client-Id)
Set	message.headers.X-IBM-Client-Secret	string	$(request.headers.X-IBM-Client-Secret)

    For more information on configuring a Set Variable policy, see Set Variable.
  - In the Source tab, add a **`set-variable`** policy directly to the assembly section in your OpenAPI source; for example:

```
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-IBM-Client-Id
            value: $(request.headers.X-IBM-Client-Id)
            type: string
          - set: message.headers.X-IBM-Client-Secret
            value: $(request.headers.X-IBM-Client-Secret)
            type: string
```

    For more information on defining a **`set-variable`** policy in your OpenAPI source, see set-variable.

  You should position the **`set-variable`** before any policy that needs to access the API key headers; for example, an invoke policy that calls a back-end service that is required to identify the application that made the initial request.

6. Select the Key Type: client_id or client_secret.
   Important: The client_id is not confidential and functions as a "SecurityScheme" only in the meaning of the OpenAPI specification.
   If you use only the client_id (without the client_secret) as your API Key, be aware that the client_id is not considered a confidential value in the API Manager UI; for example, it might be displayed to other authenticated members of the provider organization. The client_id is treated as a public identifier for apps and cannot be kept private.

   If authentication of the identity of the app calling an API is needed, then the API Key should use both a client_id to identify the app, plus a client_secret to authenticate it. The client_secret is designed to be known only to the app and the authorization server, and it should be protected. IBM API Connect protects the client_secret: it is only available when first generated, it can be stored as a one-way hash to prevent retrieval or leaks, and it can be changed and reset without changing the corresponding client_id. When an API Key is not marked as a client_secret, it will not be protected in the API Manager UI.

7. Specify whether the credentials are sent in the request header, or as query parameters, by selecting one of the following Located In options:

   header
   : The credentials are sent in the request header. This is the default setting.

   query
   : The credentials are sent as query parameters. This method is less secure because the client secret could be exposed in a log file.

   The selected option is enforced, and API calls fail if the credentials are included in the wrong location by the caller.

   Note:
   - You must specify the same location for the client ID and client secret, either header or query.
   - If you migrated from API Connect V5, API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. For information about the differences, see Client ID behavior in API key security definitions.
8. Optionally, provide a Description for the security scheme. You can use CommonMark syntax for rich text representation.
9. If you are creating a new API key security scheme, click Create.
   The security scheme details are displayed for further editing.
10. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

- **Client ID behavior in API key security definitions**
  How the Client ID behaves in API key security definitions in IBM API Connect 10 compared to Version 5.

Client ID behavior in API key security definitions

How the Client ID behaves in API key security definitions in IBM® API Connect 10 compared to Version 5.

API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. Refer to the following table to understand the differences in Client ID behavior for different use cases.
Note: Although a client_id in the request body is supported, this data is not used during security requirement processing.

Table 1. Client ID behavior in V5 and V10

Use case	Description of security requirement	V5 behavior	V10 behavior
1	Allows client_id in the query, and the request contains multiple client_ids in the query.	Uses the first client ID in the request.	401 invalid client ID or secret.
2	Allows client_id in the header, and the request contains multiple client_ids in the header.	401 invalid client ID or secret.	401 invalid client ID or secret.
3	Allows client_id in the header, and the request contains multiple client_ids in the query and the header (1 in the query, 1 in the header).	401 client ID in wrong location.	Client ID in query is ignored.

Use case	Description of security requirement	V5 behavior	V10 behavior
4	Allows client_id in the query, and the request contains multiple client_ids in the query and the header.	Client ID in header is ignored.	Client ID in header is ignored.
5	Allows client_id in the query or header, and both the query and header contain multiple client_ids.	Header returns 401 client ID in wrong location. Query uses the first client ID in the request.	401 invalid client ID or secret.
6	Allows client_id in the header, and the request contains a valid client_id in the query, and an invalid client_id in the header.	401 client ID in wrong location.	401 invalid client ID or secret.
7	Allows client_id in the query, and the request contains a valid client_id in the header, and an invalid client_id in the query.	401 invalid client ID or secret.	401 invalid client ID or secret.
8	Allows client_id in the query or header, and both the query and header contain valid client_ids.	200 OK.	403 multiple client IDs.
9	Allows client_id in the query or header, and both the query and header contain invalid client_ids.	401 client ID in wrong location.	401 invalid client ID or secret.
10	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the query is valid.	200 OK.	Uses the valid one 200 OK.
11	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the header is valid.	401 client ID in wrong location.	Uses the valid one 200 OK.
12	Allows client_id in the query or header, and both the query and client_id is missing in the request (no security requirement, but client security is defined in the assembly).	401 invalid client ID or secret.	• When Return V5 Responses compatibility option is off: 401 client ID is missing. • When Return V5 Responses compatibility option is on: 401 invalid client ID or secret. For information about setting compatibility options, see Configuring v5 compatibility options.

Defining OAuth2 security schemes

An OAuth2 security scheme defines the settings for controlling access to the API operations through the OAuth authorization standard.

Before you begin

Before you can create an OAuth2 security scheme, you must:

1. Create an OAuth provider.
   - To use Cloud Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
   - To use API Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
2. Add the OAuth provider to a catalog. If you have not created any catalogs, use the Sandbox Catalog. See the OAuth instructions step in Creating and configuring Catalogs.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an OAuth2 security scheme, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create an OAuth2 security scheme, click the add icon ⊕ alongside Security Schemes, then select oauth2. To edit an existing OAuth2 security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Security Scheme Name field.
5. Provide the following information:
   - Security Scheme Name: An identifying name of your choice.
   - OAuth Provider: Select the OAuth provider to be used.
   - Flow: Select one of the following options:
     - Implicit
     - Resource Owner - Password
     - Application
     - Access Code

     Note: The flow options that are available for selection depend on which options are supported by the selected OAuth provider.
     If you selected Resource owner - JWT as the supported grant type when you created the OAuth provider, you must select Resource owner - Password as the Flow for this security scheme.
   - Description: An optional description of the OAuth2 security scheme. You can use CommonMark syntax for rich text representation.

- The URL endpoints (the applicable endpoints depend on the flow type):
  - Authorization Url
  - Token Url

  Note: The URL endpoint values supplied here are maintained only for informative purposes, no validation or other action is applied to them by API Connect. The OAuth security that is applied depends on the specified OAuth provider.
- Scopes (available if you are editing an existing OAuth2 security scheme):
  - To add a new scope, click Add. To edit an existing scope, click the options icon ⋮ alongside the required scope, then click Edit.
  - Provide the following information:
    - Scope: The scope identifier.
    - Description: An optional description of the scope. You can use CommonMark syntax for rich text representation.
    - If you are creating a new scope, click Create.

6. If you are creating a new OAuth2 security scheme, click Create.
   The security scheme details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Enabling CORS support for an API

You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Before you begin

This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.

About this task

Note:

- CORS support is available only on the DataPower® API Gateway.
- When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
- When CORS is enabled and a preflight request is received, only the following API actions are performed:
  - The **`cors`** preflow policy configures the appropriate response headers.
  - The response headers are set.
- When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
- For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

To enable CORS support for an API, complete the following steps:

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click CORS.
   The CORS page opens.
3. Select Enabled.
4. Optional: Configure a CORS policy.
   Should you create a CORS policy? Review the following considerations:
   - A CORS policy is an optional part of an API definition. If an API definition has no CORS policy but CORS is enabled, then CORS requests will be accepted from all Origins.
     If you want to accept CORS requests from all Origins, then enable CORS but do not add a CORS policy to the API definition.
   - If you create a CORS policy, then CORS requests will only be accepted from Origins that are explicitly listed in the CORS rules contained in the CORS policy. CORS requests from any other Origins will be rejected.
     If you want to accept CORS requests from only a limited number of Origins (and might also want to configure the Access-Control-Allow-Credentials and Access-Control-Expose-Headers response headers), then you should enable CORS and create a CORS policy. Only those Origins explicitly listed in the allow-origin field of the CORS rules in the CORS policy will be accepted; CORS requests from any Origins not listed will be rejected.
   - To configure a new CORS policy, complete the following steps:
     - Alongside Policy, click Add.
     - To include the header **`Access-Control-Allow-Credentials: true`** in a response. select Allow Credentials. The **`Access-Control-Allow-Credentials`** response header tells browsers whether to expose the response to front-end JavaScript code when the request's credentials mode (**`Request.credentials`**) is set to **`include`**.
     - To append one or more of the following values to the **`Access-Control-Expose-Headers`** response header, select Expose headers, and select from the following options:
       - Predefined - The predefined value of the Gateway. This option is selected by default.
       - Backend - The value of **`Access-Control-Expose-Headers`** from the backend response.
       - Custom - A custom string.
     - Click Create.

- Alongside Allowed Origins click Add.
- Enter the origin URL, then click Create. This setting indicates that the response can be shared with requesting code from the specified origin.

- To modify an existing CORS policy, click its entry on the CORS page. You can then modify individual origin URLs, add further origins, and change the Allow Credentials setting.

Example

The following example has three rules:

- Accept an Origin header of `https://example.com`, and return `Access-Control-Allow-Credentials: true` in the CORS response.
- Accept an Origin header of `http://domain.com`. No `Access-Control-Allow-Credentials` header will be returned in the response.
- Accept any of the following Origin headers:
  - `http://example2.com`
  - `http://example3.com`
  - `http://example4.com`

  No `Access-Control-Allow-Credentials` header will be returned in the response.

```
cors:
  enabled: true
  policy:
    -
      allow-origin:
        - 'https://example.com'
      allow-credentials: true
    -
      allow-origin:
        - 'http://domain.com'
    -
      allow-origin:
        - 'http://example2.com'
        - 'http://example3.com'
        - 'http://example4.com'
```

5. Click Save to save your changes.
6. Optional: To implement your own CORS solution using custom OPTIONS operations, complete the following steps:
   a. Add the following headers to your HTTP responses:

   ```
   Access-Control-Allow-Origin: https://<portalhostname>
   Access-Control-Allow-Headers: Origin, X-Requested-With, Content-Type, Accept
   ```

   Where `<portalhostname>` is your Developer Portal host name.
   b. Optional: You can proxy your API through API Connect as an enforced invoke API so that CORS is handled automatically.

Important:

- If you implement your own CORS solution, you **must** disable the CORS option described in step 3
- CORS preflight requests are sent by using the HTTP `OPTIONS` method. Therefore, if you require these requests to be handled by the API Connect gateway then you must enable the `OPTIONS` method for all APIs that will handle preflight requests; see Defining Paths for a REST API.
- `OPTIONS` requests are counted as API calls against any configured rate limit. Note that you can apply rate limits to individual operations; see Defining rate limits for an API operation.

Specifying external documentation for an API

You can reference an external resource for extended documentation for an API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click External Documentation.
3. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
4. Click Save when done.

Adding tags to an API

You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General then, if there already one or more tags defined, expand Tags.
3. To add a new tag, click the add icon ⊕ alongside Tags in the navigation pane. To edit an existing tag, click the tag name in the navigation pane.
4. Provide the following information:
   - Name (required): The name of the tag.
   - Description: An optional description of the tag. You can use CommonMark syntax for rich text representation.
   - External Documentation > URL (available when editing an existing tag): The URL for target documentation that describes this tag.
   - External Documentation > Description (available when editing an existing tag): An optional description of the target documentation.
5. If you are creating a new tag, click Create.
6. Click Save when done.

Defining Paths for an API

A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more Paths defined, expand Paths.
3. To create a new Path, click the add icon ⊕ alongside Paths in the navigation pane. To edit an existing Path, click the Path in the navigation pane.
4. Provide the following information:
   - Path: A relative path to an individual endpoint.
     The path is appended to the base path to construct the full URI to access the APIs. The path must start, but not end, with the / character. A parameter at the end of the path can contain a qualifier to match one or more path levels.

     If you specify just the name of the parameter, then one level of that path is matched. If you want to allow for multiple levels of the path, you can prefix the parameter with one of the following qualifiers:

     - * to indicate 0 or more occurrences
     - + to indicate 1 or more occurrences

     The + and * qualifiers can only be used at the end of the path.

     For example, the path:

     ```
     /petstore/{type}/{*category}
     ```

     matches the following paths, where only one type value is matched, but all (0 or more) categories are matched:

     ```
     /petstore/cats
     /petstore/cats/supplies
     /petstore/cats/supplies/health
     /petstore/cats/supplies/health/medicines
     /petstore/cats/supplies/health/medicines/a/b/c
     ```

   - $ref (available when editing an existing Path): A reference to a Path that is defined elsewhere, either in this OpenAPI definition, or in an external file. A reference enables reuse of a set of operations already defined for a Path in this API, or in a file that is either a complete API definition or an OpenAPI fragment.
     The reference uses JSON pointer notation. For example, a reference to a Path called `/mypath` in this API would have the following format:

     ```
     #/paths/~1mypath
     ```

     The `~1` characters are used to escape the `/` character, which is being used literally in the path name rather than as a special character.
     A reference to a path in an external file called path_fragments.yaml would have the following format:

     ```
     file://path_fragments.yaml/paths/~1mypath
     ```

5. If you are creating a new Path, click Create.
   The Path details are displayed for further editing as described in step 4.
6. Click Save when done.

- **Defining parameters for a path**
  Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

- **Defining operations for a path**
  Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

Defining parameters for a path

Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there already one or more parameters defined, expand Path Parameters.
4. You can either create a new parameter, or edit any existing parameter.
   - To create a parameter, click the add icon ⊕ alongside Path Parameters, then refer to Creating a parameter.
   - To edit an existing parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining operations for a path

Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required path.
3. Click the add icon ⊕ alongside Operations under the Path in the navigation pane.
4. Provide the following information:
   - Verb: Select the operation type from the following options:
     - get
     - post
     - put
     - delete
     - options
     - head
     - patch
     - trace
   - Summary: A summary of what the operation does.
   - Description: A description of the operation behavior.
   - Operation: Unique string used to identify the operation. The id must be unique among all operations described in the API.
   - Deprecated: Declares this operation to be deprecated. Consumers should refrain from using the declared operation.
5. Click Create.
6. Click Save when done.

- **Adding tags to an operation**
  You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Specifying external documentation for an operation**
  You can referencing an external resource for extended documentation for an API operation.
- **Specifying the MIME types that an API operation produces**
  You can specify which types of media your API operation will return when calls are made to it. The API Connect gateway supports XML and JSON.
- **Specifying the MIME types that an API operation consumes**
  You can specify which types of media your API operation will accept when calls are made to it. The API Connect gateway supports XML and JSON.
- **Defining parameters for an operation**
  Responses define the HTTP status code and data returned in a response body and headers.

- **Defining responses for an operation**
  Responses define the HTTP status code and data returned in a response body and headers. A response defined for an operation is one that can returned by executing the operation.
- **Specifying schemes for an operation**
  The schemes settings define which transfer protocols you want your API operation to use.
- **Enforcing security requirements on an operation**
  To enforce security requirements on an API operation, you apply previously created security schemes that specify various aspects of API security configuration.

Adding tags to an operation

You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To add a new operation tag, click the add icon ⊕ alongside the Tags entry for the operation in the navigation pane. To edit an existing tag, expand Tags then click the tag name in the navigation pane.
5. Provide the following information:
   - Name (required): The name of the tag.
6. If you are creating a new operation tag, click Create.
7. Click Save when done.

Specifying external documentation for an operation

You can referencing an external resource for extended documentation for an API operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click External Documentation.
4. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
5. Click Save when done.

Specifying the MIME types that an API operation produces

You can specify which types of media your API operation will return when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To specify a new MIME type, click the add icon ⊕ alongside Produces. To modify an existing MIME type, click the MIME type entry in the navigation pane.
5. Enter the required value in the Mime Type field; for example **`application/json`** or **`application/xml`**. Then click Create.
6. Click Save when done.

Specifying the MIME types that an API operation consumes

You can specify which types of media your API operation will accept when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To specify a new MIME type, click the add icon ⊕ alongside Consumes. To modify an existing MIME type, click the MIME type entry in the navigation pane.
5. Enter the required value in the Mime Type field; for example, **`application/json`** or **`application/xml`**. Then click Create.
6. Click Save when done.

Defining parameters for an operation

Responses define the HTTP status code and data returned in a response body and headers.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. You can either create a new operation parameter, or edit any existing parameter.
   - To create an operation parameter, click the add icon ⊕ alongside Path Parameters, then refer to Creating a parameter.
   - To edit an existing operation parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining responses for an operation

Responses define the HTTP status code and data returned in a response body and headers. A response defined for an operation is one that can returned by executing the operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing responses, expand Responses.

4. You can either create a new response, or edit any existing response.
   - To create a response, click the add icon ⊕ alongside Responses, then refer to Creating a response.
   - To edit an existing response, click the response name in the navigation pane, then refer to Editing a response.

Specifying schemes for an operation

The schemes settings define which transfer protocols you want your API operation to use.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing schemes, expand Schemes List.
4. You can either add a new scheme, or edit any existing scheme.
   - To add a scheme, click the add icon ⊕ alongside Schemes List, select the required transfer protocol, then click Create.
     Note: If your API is enforced by an API Connect gateway, only the HTTPS protocol is supported.
   - To edit an existing scheme, click the scheme in the navigation pane, then change the transfer protocol as required.
5. Click Save when done.

Enforcing security requirements on an operation

To enforce security requirements on an API operation, you apply previously created security schemes that specify various aspects of API security configuration.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security schemes, see Defining security schemes.

A security requirement specifies one or more security scheme definitions whose conditions must all be satisfied for the API operation to be called successfully. You can define multiple security requirements; in this case, an application can call your API operation if it satisfies any of the security requirements you have defined.

Any security requirements that you define for an operation completely override any security requirements defined on the parent API. If you do not define any security requirements for an operation, or you delete all security requirements from an operation, the operation inherits the security requirements defined on the parent API. For more information, see Enforcing security requirements on an API.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To create a new security requirement for the operation, complete the following steps:
   a. Click the add icon ⊕ alongside the Security entry for the operation in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have previously been defined; see Defining security schemes.
      If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme; for more information, see Defining OAuth2 security schemes.

      If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower® API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

      Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the **`X-IBM-Client-Id`** or **`client_id`** must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Save when done.
5. To modify an existing security requirement, complete the following steps:
   a. Click the Security entry for the operation in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.

b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
c. Click Submit when done, then click Save.
d. To delete a security requirement, click the appropriate delete icon, click Delete to confirm, then click Save.
e. To disable security for the operation, clear the Require one of the following Security Requirements check box, then click Save.

Note: These settings completely override any security requirements defined on the parent API; see Enforcing security requirements on an API.

Defining schema definitions for an API

Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
An API created in OpenAPI 2.0 includes a section where API payload definitions are defined. The payload definitions describe the structure of data transmitted in API requests and responses, utilizing a specialized JSON schema variant specific to OpenAPI. Each payload definition corresponds to a schema, which lists the expected data fields. These data fields are represented as properties within the schema and include a set of attributes that describe their type, permissible values, mandatory status, and other characteristics. Although numerous attributes are available, the majority of them are infrequently utilized.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more schemas defined, expand Definitions.
3. You can create a new schema, or edit any existing schema.
   - To create a schema, click the add icon alongside Definitions, then refer to Creating schema definitions.
   - To edit an existing schema, click the schema component name in the navigation pane, then refer to Editing schema definitions.

- **Creating schema definitions**
  Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.
- **Editing schema definitions**
  Schemas provide developers with information about the request that they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Creating schema definitions

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
For details of the areas in your API definition from where you can create a schema, see the following topics:

- Defining schema definitions for an API
- Editing a response

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon.

Procedure

1. To create a schema definition, click the add icon alongside Definitions.
   The Add object wizard for a schema is displayed.
2. Provide the following information:
   - Schema Name: This name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/definitions/`*`Name`*

- Title: The schema title.
- Type: The schema data type; select one of the following:
  - array
  - boolean
  - integer
  - number
  - object
  - string

3. Click Create.
   The schema definitions details are displayed for further editing; see Editing schema definitions.

Editing schema definitions

Schemas provide developers with information about the request that they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
For details of the areas in your API definition from where you can edit a schema, see the following topics:

- Defining schema definitions for an API
- Editing a response

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The table view presents the properties within a schema alongside their essential attributes, such as name, type, description, and required status. The secondary pop-up enables access for viewing and editing the more detailed and less commonly used attributes that are associated with each data field.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

You can configure the following schema definition settings:

- Schema Name: This name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

  `#/definitions/Name`

  To change the name, click the Source icon, change the value in the field, then click Save.
- Optional: Title: The schema title.
- Type: The schema data type; select one of the following:
  -
    - array
    - boolean
    - integer
    - number
    - object
    - string

  Note: If you change the type of an existing schema, any existing settings that are not relevant to the new type are still retained in the OpenAPI source even though they are no longer displayed in the user interface. You should therefore avoid porting a schema from one type to another but instead either create a new schema or modify the OpenAPI source directly; to open the source editor, click the Source icon </> .
- Properties: The schema property. To add a property to the schema, click Add alongside the Properties section heading, complete the details and click Save.
- Additional schema settings dependent on the selected Type of property. To view and edit these schema settings, click the Options menu next to the property you want to view and select Details.
  - boolean: no type specific settings.
  - integer:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Multiple Of: Division of an integer instance by this value must result in an integer.
    - Maximum: An integer instance must be less than or equal to this value.
    - Exclusive Maximum: An integer instance must be strictly less than this value.
    - Minimum: An integer instance must be greater than or equal to this value.
    - Exclusive Minimum: An integer instance must be strictly greater than this value.
  - number:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Multiple Of: Division of a number instance by this value must result in an integer.
    - Maximum: A number instance must be less than or equal to this value.
    - Exclusive Maximum: A number instance must be strictly less than this value.
    - Minimum: A number instance must be greater than or equal to this value.
    - Exclusive Minimum: A number instance must be strictly greater than this value.

    - object:
        - Max Properties: The number of properties in an object instance must be less than or equal to this value.
        - Min Properties: The number of properties in an object instance must be greater than or equal to this value.
        - Required Properties: An array of property names; every property name in the array must be the name of a property in an object instance. To add a required property name, click Add alongside the Required Properties section heading, enter the name, then click Create.
    - string:
        - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
        - Pattern: A regular expression; a string instance must successfully match the expression.
        - Max Length: The maximum allowed number of characters in a string instance.
        - Min Length: The minimum allowed number of characters in a string instance.
        - Enum: An array of string values; a string instance must match one of the array values. To add an enum value, click Add, enter the value, then click Create.
- General settings; select the required options:
    - Required: A property associated with this schema is required.
    - Read Only: A property associated with this schema can be returned in a response but should not be included in a request. For example, properties whose values are system generated identifiers will be defined as Read Only because application clients wouldn't be able to set these.
- Example Value: An example value. Whatever you enter here is displayed as-is in the Developer Portal.
- External Documentation: An external resource for extended documentation; provide the following information:
    - URL (required): The URL for the target documentation.
    - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
- Xml: Metadata that allows for more fine-tuned XML model definitions; provide the following information:
    - Name: Replaces the name of the element or attribute that is used for the described schema property.
    - Namespace: The URL of the namespace definition.
    - Prefix: The prefix to be used for the Name.
    - Attribute: Specifies whether the property definition translates to an attribute instead of an element.
    - Wrapped: For an array definition, Specifies whether the array is wrapped (for example, `<books><book/><book/></books>`) or unwrapped (`<book/> <book/>`).
- Click Save when done.

Example

By defining properties, you can create more complex data structures. For example, you could define an "Address" schema that has the following properties:

PROPERTY NAME	PROPERTY TYPE
street1	string
street2	string
city	string
state	string
zip_code	string

and then define a "BankBranch" schema that has the following properties, one of which is a reference to the Address schema:

PROPERTY NAME	PROPERTY TYPE
address	address
type	string
id	string

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining parameters for an API

Parameters can specify variable elements of a URL path, query parameters, headers, or a request body.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there already one or more parameters defined, expand Parameter Definitions.
3. You can either create a new parameter, or edit any existing parameter.
    - To create a parameter, click the add icon alongside Parameters, then refer to Creating a parameter.
    - To edit an existing parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

- **Creating a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.
- **Editing a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for the API, or for Paths and Path operations in your API definition.

Creating a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.

Before you begin

Launch the parameter creation window. For details of the areas in your API definition from where you can create a parameter, see the following topics:

- Defining parameters for a path
- Defining parameters for an operation
- Defining parameters for an API

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Parameter Name: The name of the parameter.
   - Located In: The location of the parameter. Select one of the following options:
     - query: Parameters that are appended to the URL. For example, ***`url_path`*`?myparam=myvalue`**.
     - header: Custom headers that are expected as part of the request.
     - path: The parameter value is part of the operation's URL, enclosed in {}.
     - body: Parameters that describe the body of POST, PUT and PATCH requests.
   - Description: A description of the parameter.
   - Type: The data type of the parameter.
   - Format: Select the data format; the available options depend on the selected Type.
   - Select the following option as required:
     - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
     - Allow Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
2. Click Create.
   The parameter details are displayed for further editing; see Editing a parameter.

Editing a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for the API, or for Paths and Path operations in your API definition.

Before you begin

Open the details form for a parameter. For details of the areas in your API definition from where you can edit a parameter, see the following topics:

- Defining parameters for a path
- Defining parameters for an operation
- Defining parameters for an API

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
   - Type: The data type of the parameter.
   - Format: Select the data format; the available options depend on the selected Type.
   - Select the following options as required:
     - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
     - Allow Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining responses for an API

Responses define the HTTP status code and data returned in a response body and headers. Responses defined for an API can be used across operations.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there already one or more responses defined, expand Response Definitions.
3. You can either create a new response, or edit any existing response.
   - To create a response, click the add icon ⊕ alongside Response Definitions, then refer to Creating a response.
   - To edit an existing response, click the response name in the navigation pane, then refer to Editing a response.

- **Creating a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.
- **Editing a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Creating a response

Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.

Before you begin

Launch the response creation window. For details of the areas in your API definition from where you can create a response, see the following topics:

- Defining responses for an API
- Defining responses for an operation

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The HTTP status code.
   - Description (required): A description of the response.
2. Click Create.
   The response details are displayed for further editing; see Editing a response.

Editing a response

Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Before you begin

Open the details form for a response. For details of the areas in your API definition from where you can edit a response, see the following topics:

- Defining responses for an API
- Defining responses for an operation

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The HTTP status code.
   - Description (required): A description of the response.
   - Schema: The schema defines the response structure.
     To define a schema for the response, click Create, then refer to Creating schema definitions.

     If the response already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing schema definitions.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Specifying gateway and portal settings

Define general configuration settings for your API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, then click Gateway and portal settings.
3. Provide the following information:
   - Target Services: Define web services that you want to use in your API definition. For details, see Defining target services for an API.
   - Enforced: Select this option to enforce the API by using the DataPower® API Gateway. Clear this option if you are managing the API on a gateway other than the DataPower API Gateway. Although not published to a gateway by API Connect, an unenforced API is still available in the Developer Portal for subscription by application developers.
   - Phase: The phase of the lifecycle that your API is in; select one of the following options:
     - Realized (default) - The API is in the implementation phase.
     - Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
     - Specified - The API has been fully designed and passed an internal milestone but has not yet been implemented.
   - Testable: Select this option to allow the API's operations to be tested using the test tool in the Developer Portal.
     Note: For the test tool to work, an API must be included in a Plan in a Product that is staged in a Catalog.
   - CORS: Enable and configure cross-origin resource sharing (CORS) support for your API. For details, see Enabling CORS support for an API.
   - Properties: Add properties that can be referenced in your API definition. For details, see Setting API properties.
   - Catalog Properties: Define property values that are specific to a particular Catalog. For details, see Defining Catalog specific property values.
   - Gateway: For details, see Specifying the gateway type for an API definition.
   - Application Authentication: Enable application authentication to protect your API with a certificate. For details, see Configuring application authentication for an API.

- Application Authentication Source: If application authentication is enabled, specify how the client certificate is sent to the gateway. For details, see Configuring application authentication for an API.
- Activity Log: Configure your logging preferences for the API activity that is stored in analytics. For details, see Configuring activity logging.
- Compatibility: For details, see Configuring v5 compatibility options.
- Html Page: For a GraphQL API, the HTML page with which the API responds to an initial GraphiQL editor request. Currently, the only option is `store:///graphiql.html`. For more information, see Enabling the GraphiQL editor for a GraphQL API.
- Graphql Schema: For a GraphQL API, the name of the schema definition that references the imported GraphQL schema. For information on uploading a schema during GraphQL API creation, see Creating a GraphQL proxy API. For information on replacing the schema for an existing GraphQL API, see Using the GraphQL schema editor.
- Exxtensions: Extensions added to the API to extend the OpenAPI specification. For details, see Adding an OpenAPI extension to an API.

Defining target services for an API

A target service defines a web service that you want to use in your API definition.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more target services defined, expand Target Services.
3. To define a new API target service, complete the following steps:
   a. Click the add icon alongside Target Services in the navigation pane.
   b. Upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, by either dragging and dropping your file, or browsing and selecting the file that you want to use.
   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.

   The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see Including elements in your API assembly.
4. Select the service that you want to add.
5. Click Save to save your changes.
6. To view the source for an existing target service, click the target service name in the navigation pane.

Results

The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see Including elements in your API assembly.

Setting API properties

In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API properties include property name, value, and, optionally a specific Catalog to which a property value applies. For a list of pre-supplied API properties relating to various policies, see API properties.
Note: Once defined, an API property is read only.
For information on how to reference a property in an API definition, see Variable references in API Connect.

It is also possible to define properties that are specific to a Catalog and can be referenced by any of the APIs in that Catalog; for more information, see Creating and configuring Catalogs. Note that if you define a Catalog property of the same name as an API property, the API property takes precedence over the Catalog property.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more API properties defined, expand Properties.
3. Configure an API property.
   - To define a new API property, complete the following steps:
     - Click the add icon alongside Properties in the navigation pane.
     - Provide the following information:
       - Property Name: Enter a name for the property; this name is used to reference the property. The following character set is supported for the name of an API property: `[A-Za-z0-9_-]+`. Spaces are allowed.
       - Property Value: A default value for the property. Leave blank if the property is to have a null vale by default.
       - Description: An optional description of the property. You can use CommonMark syntax for rich text representation.
       - Select Property Value is Base64 Encoded if you want to hide the property values, or protect user passwords from casual observance.
         Note: If you encode a property value, it is saved in Base64 encoded form; it is **not** encrypted. If you subsequently clear the Encoded check box, the original property value is restored in its unencoded form.
     - Click Create.
   - To modify an existing API property, click the property name in the navigation pane. You can then change any of the configuration settings.
4. Click Save to save your changes.

- **Defining Catalog specific property values**
  For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Defining Catalog specific property values

For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Before you begin

You must have previously created the API property that you now want to define a Catalog specific value for; see Setting API properties.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more Catalog specific property values defined, expand Catalog Properties.
3. Configure a Catalog specific property value.
   - To define a new Catalog specific property value, complete the following steps:
     - Click the add icon alongside Catalog Properties in the navigation pane.
     - Type the Catalog Name exactly as it displays in the **`name`** field for the selected Catalog.
       Tip: For the best result, manually type the catalog's name instead of selecting its title. Using the catalog name is safer than using its title, because the title might not be unique within the provider organization and might be modified later (which breaks the association between the property and the catalog). The catalog's name is always unique within the provider organization and cannot be changed.
     - Click Create. The Catalog properties details for the specified catalog are displayed for further editing.
     - Alongside Property Overrides, click Add.
     - Provide the following information:
       - Property Name to Override: Enter the name of the API property that you want to define a Catalog specific value for. The name **must** match the name of a previously defined API property; see Setting API properties.
       - Property Value: The Catalog specific property value. Leave blank if the property is to have a null value by default.
     - Click Create.
   - To modify an existing Catalog specific property value, click the Catalog name in the navigation pane. You can then change the Catalog name, and add, modify, or delete property override settings.
4. Click Save to save your changes.

Configuring application authentication for an API

Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Enable application authentication, as follows:
   Note: To identify the application, you must enable a security requirement of type **`clientID`**.
   a. Select the Gateway tab, expand Gateway and portal settings, then click Application Authentication.
   b. Select Certificate.
3. Specify how the client certificate is sent to the gateway, as follows:
   a. In the navigation pane, click Application Authentication Source.
      Any existing application authentication source definitions are listed.
   b. Alongside Application Authentication Source, click Add.
   c. Select the required option, header or tls-cert.
      You can separately add one or both of the options.
      When the API is called, an X509 client certificate must be supplied, either in the specified HTTP header, or as a TLS client certificate from TLS mutual authentication. For any Developer Portal application that calls the API, the certificate must be entered in the Developer Portal user interface; for details, see Registering an application.

      The Gateway service to which the API is published can be configured to use TLS mutual authentication to secure API calls made to that Gateway service; for details, see Configuring the initial Gateway service. If you select this option, continue to sub-step d.

      If you are using a load balancer, you must configure the load balancer to use the specified HTTP header to relay the appropriate client certificate to the Gateway service after the load balancer terminates the TLS communication.

   d. If you select the tls-cert option, enable mTLS at the Gateway level.
      This can be done by enabling "Mutual authentication: Required" in the TLS Server Profile configured in the Gateway Service in the Cloud Manager Topology (requires cloud administrator permissions). For information, see Registering a gateway service.

      You can create a Truststore (with the root or intermediate CA certificate) for use with the TLS Server Profile.

      The following example cURL command uses a client-cert during SSL:

      ```
      **curl -X GET 'https://GW-Server:9443/test/sandbox/mtls-testing/callmtls-call' -H 'X-IBM-Client-Id:
      1872xxxxxxxxxxxx' --cert my-leaf-cert.pem --key my-leaf-cert.key -k -v**
      ```

      Note: This feature is intended for the scenario where different applications will be registered with different end certificates in the Developer Portal, which will have the same intermediate or root CA issuer. The certificate will pass Gateway-level mTLS if it matches the issuer available in the Truststore, but will only allow access the to API that matches the correct end certificate.
4. Click Create.
5. Click Save to save your changes.

Configuring activity logging

You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An API event record exists for each API execution event in the Gateway server. By default, the content type for a successful API execution is activity, and payload for an API call the results in an error code. When you compose your API definition, you can change the type of content to log in these API event records. During API execution, the activity data is stored in the **`log`** context variable, which populates the API event record on completion of the API execution; for more information, see API activity logging context variables.

Note:
Activity logging that calls for logging of analytics data upon success doesn't apply for the OAuth provider. The OAuth provider logs analytics data for failure cases, but doesn't log successful cases.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click Activity Log.
3. Select Enabled, then select options for the Success Content and Error Content fields as follows:

Field label	Description

Field label	Description
Success Content	Defines the type of content to be logged when the operation is successful. • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only; only the resource URI is recorded. • header: Logs activity and header; the HTTP headers, in addition to the resource URI are recorded. • payload: Logs activity, header, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is activity.
Error Content	Indicates what content to log when an error occurs. • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only; only the resource URI is recorded. • header: Logs activity and header; the HTTP headers, in addition to the resource URI are recorded. • payload: Logs activity, header, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is payload.
Preserved request header	Click Add to specify customized request headers to preserve for logging to analytics.
Preserved response header	Click Add to specify customized response headers to preserve for logging to analytics.

4. Click Save to save your changes.

Configuring v5 compatibility options

You can configure settings to ensure compatibility with API Connect Version 5.0 compatible APIs that are converted for use with the DataPower API Gateway.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click Compatibility.
3. Select from the following options as required:
   - Return V5 Responses: Return v5-compatible responses, such as OAuth and client security error responses.
   - Copy Id Headers to Message: Copy security headers to the message context for retrieval by the invoke back-end service.
   - Enforce Required Params: Check the request for required parameters during API routing. When enabled, a request that does not provide a required parameter is rejected.
   - Allow Chunked Uploads: Allow the assembly **`invoke`** policy to send documents to the server with **`Transfer-Encoding: chunked`**. This setting applies only to the **`invoke`** 1.5.0 wrapper policy deployed from API Connect using the migration utility. It does not apply to the native API Gateway assembly **`invoke`** policy.
4. Use the YAML source to set the following options as required:

Option	Valid values	Description
`allow-trailing-slash`	**`true / false`**	Specify whether to allow the request URL to end with a / character. The default value is **`false`**.
`get-raw-body-value`	**`true / false`**	Specify whether the GatewayScript **`apim.getvariable()`** API returns the raw body instead of parsing. This setting applies only when the context is other than **`message`**. The default value is **`false`**.
`request-headers`	**`true / false`**	Specify whether to populate v5-compatible headers such as **`X-Client-IP`** and **`X-Global-Transaction-ID`** in the **`request.headers`** context variable. The default value is **`false`**.

5. Click Save to save your changes.

Including elements in your API assembly

An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
In the Policies view of IBM® API Connect, you can add and configure elements in your assembly. You can also directly add elements to the OpenAPI definition of your API.

- **The assembly editor**
  The API Designer of IBM API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

- **Adding elements to your assembly**
  Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.
- **Handling errors in the assembly**
  Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

The assembly editor

The API Designer of IBM® API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can access the Assemble view by clicking the Gateway tab in the API editor, and then click Policies. This tab includes the following options:

- Palette - lists the available elements in the assembly flow.
- Canvas - used to arrange and visualize the elements in the assembly.
- Property sheet - used to configure the elements in the assembly.

The palette

The palette is a list of different elements that you can include in your assembly. To view the palette, click the plus icon ⊕ on the canvas. You can use the Rotate icon ⟳ to rotate the palette as you prefer. To maximize and minimize the palette view, click the Maximize and Minimize icons.

You can release the palette by clicking the Close icon ✕.

The canvas

You can use the canvas to create a graphical representation of the assembly flow. To add an element to the assembly flow from the palette, click the plus icon ⊕ at the appropriate location on the canvas and select the required element from the available list. To delete an element from the canvas, hover over the element and click the Delete icon 🗑.

Note: You must click Save in the Assemble view to save your assembly updates, and to make them appear in the Source view.
API calls are made at the initial, unfilled, circle, and returned at the final, filled, circle. You can insert elements between the two circles to modify the data received from the call, or returned by the response.

You can use the Show catches toggle to show and hide error catches in the palette. A catch is a section of the assembly that is applied when an API call results in the corresponding HTTP status code being returned. Click the catch section to open the property sheet for all your catches.

You can zoom the view of your canvas in and out by clicking the + and - icons. To fit the canvas to the screen size, click the Fit to screen icon ⛶.

The property sheet

When you select an element in the assembly by clicking it, details about the element are displayed in the property sheet. In this pane, you can configure the element's properties. The options available to you in the property sheet are specific to the type of element that you are working with. For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down menu.

You can release the property sheet by clicking the Close icon ✕.

The behavior of an assembly

The assembly runs policies in order and acts on different contexts of the API call. When an API call is made, security and rate limits are enforced before the assembly is executed. During the assembly, the flow can be branched, thrown, and caught according to the policies available. The message context flows through the assembly, being used and altered by various policies. In addition to the message, other contexts can be accessed and created.

Security and rate limiting
: Before the assembly is executed, security and then rate limits are enforced.
First, security definitions and CORS access control are used to authenticate an API call. Any API Key security definitions are used to identify applications that have subscriptions to a Product containing the API. If a security definition does not allow access, the API call is rejected.

: If an application is identified by its client ID or client secret, a rate limit can be enforced based on the Plan or operation called.

The assembly execution sequence
: The assembly is executed in order from the initial, filled, circle to the final, unfilled, circle. However, there is room for branching, when `if` and `operation-switch` logic constructs are used, or for the remaining assembly to be ignored when a `throw` policy is executed.
The message is the context that is acted upon by any policy that isn't otherwise configured. At the beginning of the API call, the message is empty and at the end of the API call, the message is used as the response.

: The request context contains the information that is sent by the API caller and varies with the type of operation called as well as the configuration of that operation. For example, a GET operation can never have a populated `request.body`, and you can configure an operation to have `request.parameters` (query parameters).
The first policy in an assembly acts on the request and produces the first instance of the message. If there are no policies, the request is returned to the caller.

Managing contexts
: Because the message can be overwritten, it is useful to create and reference new contexts where possible so that they are saved and reused during the API call.

  - Use the `map` policy to overwrite the message context when you need to execute a policy that only acts on the message.
  - Use the request context when you want to use the original request made to the API.
  - Use the `map`, `invoke`, and `proxy` policies to create new contexts when you want to save your message.

Note: When you create a new context, unless you are also mapping to the message, the message is overwritten with an empty object.

For example, **invoke** is the first policy in the assembly and its response overwrites the request as the message. The message is then acted upon by a **validate** policy, and a **map** policy then saves the message as a new context, ready for a second **invoke** policy to overwrite the message without losing the first **invoke** policy's output.

You can also access contexts outside of the message or your custom contexts, but these contexts cannot be written to. For a list of contexts, see API Connect context variables.

Branches and catches

Using logic constructs, such as **operation-switch** or **if**, you can execute different sections of the assembly when certain conditions are fulfilled. When the assembly branches, the subsection of the assembly contained by the construct is executed in the same manner as a complete assembly. However, contexts are shared with the complete assembly.

When a catch is triggered, either by an error occurring during the execution of a policy or because a **throw** policy is encountered, the rest of the assembly flow is ignored. All contexts are shared by the catch being executed and when the end of the catch is reached, the API call is completed. There is no way to return from a catch to the rest of the assembly.

Adding elements to your assembly

Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can use the assembly tool in the UI to create assemblies that are used to manipulate requests made to or responses made by any of your API's operations.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

If you want to use the Source view to edit the source of your API definition, see execute OpenAPI extension for more information about how to configure the OpenAPI YAML.

For more information about the use of the assembly tool, see The assembly editor.

Procedure

To add elements to your assembly using the assembly tool, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Use the Policies view to add an element.
   Note: You must specify a version for the policy. To prevent errors due to incompatible versions of a policy between the API and the gateway, API Connect will only publish an API to the gateway if the policy version in the API exactly matches the version present on the gateway.
   a. Select the Gateway tab, then click Policies in the navigation pane.
   b. Click the plus icon ⊕ at the appropriate location on the canvas to view the palette that lists the available elements.
   c. Select the element that you want to add from the palette to the canvas by clicking it.
      Note:
      - Elements are applied in order from the initial, unfilled, circle to the final, filled, circle.
      - Unless an Operation Switch element is used, the whole assembly applies to every operation in the API.
   d. Add and edit the element properties by clicking the element and using the property sheet.
      For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down list. For information about the properties of policy elements, see API policies and logic constructs. For information about the properties of logic constructs, see Logic Constructs.
   e. Specify a version for the policy.
      To add a version, click the Source icon </>, and complete the **version** section of the policy YAML. For example:

```
execute:
  - invoke:
      version: 2.2.0
      title: invoke
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions. For more information about how to configure the policy OpenAPI YAML, see execute OpenAPI extension.

4. Optional: Repeat Steps 3.b to 3.e for any additional elements that you want to add.
5. Click Save to save your changes.

Results

You have added one or more elements to your assembly.

Handling errors in the assembly

Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The catch section of the assembly is used to implement an assembly in the instance that an error is thrown during the assembly execution. For example, the assembly could contain a **`throw`** element, the API caller could fail to authenticate, or a policy could fail to execute correctly. Each error can be handled with a different catch and each catch can handle multiple status errors.

Procedure

To create a catch and include elements in it, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to apply a catch to.
3. Select the Gateway tab, then click Policies in the navigation pane.
4. Set the Show catches toggle in the menu bar of the canvas to the Show position.
5. Click Catches in the canvas, or a Catch icon if one is displayed.
   The property sheet for the API's catches opens.
6. To add a default catch that is executed when an otherwise uncaught error is thrown, click Add default catch.
   Note: If you have a default catch before another catch in precedence, the default catch will activate even when the other catch's error is thrown.
7. To add a new catch, click Add catch.
8. To specify which errors the catch applies to, use the Select errors field and select the appropriate error.
9. Optional: To remove an error case from a catch, clear the corresponding checkbox from the Select errors drop-down. To clear all the error cases from a catch, click the cross corresponding to the total number of error cases in the Select errors field.
10. Optional: To change the precedence of your catches, use the Move up or Move down icons.
    If an error case is handled by multiple catches, the catch at the beginning of the list is applied.
11. To add an element to a catch from the palette, click the plus icon at the appropriate location in the assembly flow. Select an element that you want to apply to the catch by clicking it.
12. Click Save to save your changes.

What to do next

If you added a catch for ConnectionError, SOAPError, or OperationError, you must add the same error to the Stop on error setting for the **`Invoke`** policy in your assembly. Otherwise, if the error occurs during the execution of the **`Invoke`** policy, it is not caught, the policy execution is allowed to complete, and the assembly flow continues. For details on configuring an **`Invoke`** policy, see Invoke.

For details of all the errors that can be returned by the assembly and are available to the catch function, see Error cases supported by assembly catches.

Specifying the gateway type for an API definition

An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). A default gateway type is set when you create an API definition, but you can edit the API configuration to specify a different gateway type.

About this task

Note: This task relates only to an OpenAPI 2.0 API definition. An OpenAPI 3.0 API is supported only on the DataPower API Gateway.
DataPower Gateway (v5 compatible) has been available with IBM® API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You must specify which type of gateway each API uses. APIs can use only one type of gateway.

When you create a new API definition, or import an API definition that has no gateway type configured, the gateway type defaults according to the gateway types of the gateway services that are enabled in your Sandbox Catalog, as indicated in the following table.

Table 1. Default gateway type for a new API definition

Gateway Service enablement in Sandbox Catalog	Default gateway type for new API definition
No gateway services enabled	DataPower API Gateway
At least one gateway service of each type enabled	DataPower API Gateway
One or more gateway services only of type DataPower API Gateway enabled	DataPower API Gateway
One or more gateway services only of type DataPower Gateway (v5 compatible) enabled	DataPower Gateway (v5 compatible)

If you import an API definition that already has a gateway type configured, that gateway type is retained.
Note that when you modify your API definitions to use a specific gateway type, you must ensure that each policy and policy version in the API are supported by the gateway type. DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

For example, DataPower Gateway (v5 compatible) supports version **1.0.0** of the **invoke** policy, but DataPower API Gateway requires version **2.0.0**.

For information on policies, see execute.

For information on policy versions, see the documentation for each individual policy. For example, to review the **invoke** policy, see invoke.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Click the title of the API you want to update.
3. Select the Gateway tab, then click Gateway and portal settings.
4. Select the type:
   - datapower-gateway for the DataPower Gateway (v5 compatible)
   - datapower-api-gateway for the DataPower API Gateway.

   Note: The Gateway Type selection is not applicable if the Enforced option is disabled, because an unenforced API is not managed on an API Connect gateway.
5. Click Save to retain the changes.
6. In the navigation pane, select Policies to ensure that your API uses policies that are supported by the gateway type you selected.

   Policies in an existing API that are not supported by the new gateway type are grayed out and flagged with a red exclamation point: .

   Some policies are supported by only one gateway type. Some policies are supported by both gateway types, but require a different version of the policy for each gateway type.

Related tasks

- Converting an API definition for deployment to the DataPower API Gateway

Converting an API definition for deployment to the DataPower API Gateway

IBM® API Connect provides two gateway types, DataPower® Gateway (v5 compatible) and DataPower API Gateway. If you have an API definition that was developed for the DataPower Gateway (v5 compatible) and you want to port it to the DataPower API Gateway, you must make changes to convert it before deployment.

About this task

Note: This task relates only to an OpenAPI 2.0 API definition. An OpenAPI 3.0 API is supported only on the DataPower API Gateway.
DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

To convert an API for deployment to the DataPower API Gateway, you must, as a minimum, change the gateway type setting on the API definition, and ensure that each policy and policy version in the API are supported by the DataPower API Gateway; DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

In addition, depending on the specific policies in your API assembly, some policies might require modification to adapt them for use with the DataPower API Gateway.

The following procedure provides instructions for converting your API definition:

Procedure

1. Set the gateway type for the API to DataPower API Gateway, and ensure policy type and version compatibility. For details, see Specifying the gateway type for an API definition.
2. Refer to the DataPower API Gateway porting notes for detailed instructions on how to convert your API definition.

Modifying a GraphQL schema

For a GraphQL API, an editor is provided for modifying the associated GraphQL schema.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To open the GraphQL schema editor for a GraphQL API, complete the following steps:

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the GraphQL Schema tab.

What to do next

For full details on how to use the editor, see Using the GraphQL schema editor.

Validating the OpenAPI YAML source

How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.

About this task

When you're configuring an API in the API editor, you can validate the OpenAPI YAML source by clicking Validate > With specifications. If any swagger parser validation errors are found, an error icon is displayed that you can then click to see the individual errors, and where they occur in the YAML. You can then fix the errors, save the updates, and continue to validate the OpenAPI YAML throughout the API configuration process.
Note:

- OpenAPI validation does not show gateway or policy errors that will stop your API from being staged or published. This type of validation occurs only when you try to stage or publish your API. For more information, see Staging an API or Publishing an API.
- You can also validate your API document by using API governance rulesets. For more information, see Validating an API document by using API governance.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To validate the OpenAPI YAML source, complete the following steps.

1. Open the required API for editing, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
2. Click Validate > With specifications from the menu bar in the header.

3. If any swagger parser validation errors are found, an error icon is displayed on the header menu bar, with the number of OpenAPI errors found displayed next to the icon.

   For example,

.
4. You can then click the error icon to see a detailed list of the errors, and their location in the YAML. If you're in Form view, you can click an individual error to navigate directly to the relevant API section in the form.
5. After you fix the error, click Save to save your updates, and then click Validate again.
6. When all of the errors are fixed, the validation returns a success message.

   For example, 
.

Validating an API document by using API governance

How to use API governance rulesets to validate and enforce organizational governance policies and best practices. You can validate APIs from the API Manager UI, the API Designer UI, or the toolkit CLI.

Before you begin

Before you can use API governance rulesets to validate your API documents, the API governance optional add-on must be enabled on your management subsystem by your system administrator. See Enabling API governance on Kubernetes, and Enabling API governance on VMware for more information. If API governance is enabled in your deployment, the API governance resource is displayed on the Resources page in the API Manager.

The API governance service is available to all user roles.

Tip: Before using the API governance service to validate your API document, you should run Validate > With specifications to validate the OpenAPI YAML source. For more information, see Validating the OpenAPI YAML source.

About this task

API governance is an IBM® API Connect service that can be used to validate and enforce organizational governance policies and best practices to your API development process. API governance contains the following types of rulesets:

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization.
- Global rulesets - these are preconfigured IBM and Spectral rulesets that contain the rules that are shared with your provider organization, and cannot be edited. Note that the Spectral ruleset names are prefixed by spectral-, and that their version matches the version of that ruleset that's available in Spectral.

You can create your own provider organization rulesets to validate your Swagger, OpenAPI, and AsyncAPI documents against, or use the global rulesets that are provided by default. For more information about configuring rulesets, see Configuring API governance in the API Manager.

API governance in IBM API Connect is based on the open-source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

You can complete this task by using the API Manager UI, and by using API Designer when the UI is online, and is connected to a cloud instance that has the API governance microservice enabled on it. You can also use the toolkit CLI; for details see Validating an API document by using the toolkit CLI.

The following methods can be used to validate your API documents with rulesets by using the API Manager or the API Designer UIs:

- From within an API
- From within the Rulesets tab

Procedure

- To validate an API document from within the API, complete the following steps.
  1. Open the required API for validating, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
  2. Click Validate > With rulesets from the menu bar in the header.

     
  3. Select the rulesets that you want to validate your API document against, and click Next.
  4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  5. Click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. You can click on an error to take you to the specific section of the API that needs correcting. The API can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
  6. Optional: You can click Download to download the results of the validation into a .csv file.
  7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
  8. Click Done when finished.
- To validate one or more draft API documents from within the Rulesets tab, complete the following steps.
  1. In the API Manager, click Resources.
  2. In the Resources navigation menu, select API governance.
  3. Click Validate.
  4. Select the rulesets that you want to validate your API document against, and click Next.
  5. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  6. Select the APIs that you want to validate, and click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. You can click on an error to take you to the specific section of the API that needs correcting. If no errors are found, a success message is displayed.
  7. Optional: You can click Download to download the results of the validation into a .csv file.
  8. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
  9. Click Done when finished.

Results

Your API document is validated against one or more rulesets.

What to do next

You can use the results of the validation to help you improve your API document. You can also use the results to help you edit the rulesets, and create new rulesets; see Configuring API governance in the API Manager for more information.

- **Validating an API document by using the toolkit CLI**
  How to use the API Connect toolkit CLI to run API governance validation scans on your API documents.

Related information

- The API governance ruleset lifecycle

Validating an API document by using the toolkit CLI

How to use the API Connect toolkit CLI to run API governance validation scans on your API documents.

About

API governance is an IBM® API Connect service that can be used to validate and enforce organizational governance policies and best practices to your API development process. The following information provides details of the toolkit CLI commands for running and managing validation scans on your API documents. You can also validate an API document by using the API Manager and the API Designer UIs. For more information about validation scanning, see Validating an API document by using API governance.

The following methods can be used to validate your API documents with rulesets by using the toolkit CLI:

- Validate a single API document that is stored locally
- Validate one or more draft APIs that are stored on the management server

Validate a single API document that is stored locally

To validate a single API document against one or more rulesets, complete the following steps. The OpenAPI document must be stored locally.

1. Log in to the toolkit as the owner or an admin of your provider organization.
   For example:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Run the **compliance:validate** toolkit command in `governance` mode.

   ```
   apic --mode governance compliance:validate --org <target_org> --server <server_url> --rulesets <ruleset_name_1>,
   <ruleset_name_2> API_FILE
   ```

   where:
   - `<target_org>` is the name of the provider organization that owns the APIs to be validated.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `<ruleset_name_1>,<ruleset_name_2>` is a comma-delimited list specifying the names of the rulesets to be applied to the API. (Specify each ruleset name; do not use the ruleset IDs.)
   - `API_FILE` is the path and filename of the OpenAPI document to be validated.

Validate one or more draft APIs that are stored on the management server

The APIs must be stored as draft APIs in your provider organization; this operation validates all of the draft APIs that are listed in the `COMPLIANCE_REQUEST_FILE`.

1. Create a JSON `COMPLIANCE_REQUEST_FILE` that specifies the location of the draft APIs and the rulesets to use during validation.
   The following example shows a configuration file that specifies two draft APIs, and two rulesets. In the `spectral-oas` ruleset, the `info-contact` rule is disabled and will be ignored during validation.

   ```
   {
     "apiUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/a08898fe-b422-41d3-
   b058-c3280d632e93","https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/26692eab-f43b-
   4af3-985c-2deaa401eb7f"]
     "config" : {
       "rulesets": [
         {
           "rulesetName": "spectral-oas",
           "disabled": ["info-contact"]
         },
         {
           "rulesetName": "spectral-owasp",
           "disabled": []
         }
         ]
    }
   }
   ```

   where:

- **`apiUrls`** is a comma-delimited list of URLs. Each URL specifies the location of the draft APIs in a particular provider organization.
- **`rulesetName`** is a list of rulesets to be applied to the APIs during validation.
  For each ruleset in the list, you can optionally add the **`disabled`** property with a comma-delimited list of rules to ignore during validation.

2. Log in to the toolkit as the owner or an admin of your provider organization. See Step 1 for details.
3. Run the **compliance:validate_all** toolkit command in **`governance mode`**.

```
apic --mode governance compliance:validate_all --org <target_org> --server <server_url> COMPLIANCE_REQUEST_FILE
```

where:

- ***`<target_org>`*** is the name of the provider organization that owns catalog containing the APIs to be validated.
- ***`<server_url>`*** is the management server URL that you use for logging in to the toolkit.
- ***`COMPLIANCE_REQUEST_FILE`*** is the path and filename of the configuration file that lists the APIs and rulesets to be used during the validation (for example, validate-apis.json).

Editing an OpenAPI 3.0 API definition

IBM® API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 3.0 specification.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

You can open an API for editing in either of the following ways:

- During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
- To open an existing API for editing, complete the following steps:
  1. In the navigation pane, click Develop, then select the APIs tab.
  2. Click the title of the API version that you want to work with.

- **OpenAPI 3.0 support in IBM API Connect**
  IBM API Connect supports the OpenAPI 3.0 specification, with some limitations. The current implementation includes complete support for the Berlin Group NextGen PSD2 requirements.
- **Specifying API metadata**
  API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.
- **Defining servers for an API**
  Server definitions in an API provide information for connecting to target servers.
- **Enforcing security requirements on an API**
  To enforce security requirements on an API, you apply previously created security scheme components that define various aspects of API security configuration.
- **Specifying external documentation for an API**
  You can reference an external resource for extended documentation for an API.
- **Adding tags to an API**
  You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Defining Paths for an API**
  A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.
- **Defining components for an API**
  Components are reusable objects relating to various aspects of your API definition. A component has no effect on the API unless it is explicitly referenced from elsewhere in your API definition.
- **Specifying gateway and portal settings**
  Define general configuration settings for your API.
- **Defining target services for an API**
  A target service defines a web service that you want to use in your API definition.
- **Setting API properties**
  In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.
- **Configuring application authentication for an API**
  Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.
- **Configuring activity logging**
  You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.
- **Including elements in your API assembly**
  An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.
- **Validating the OpenAPI YAML source**
  How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.
- **Validating an API document by using API governance**
  How to use API governance rulesets to validate and enforce organizational governance policies and best practices. You can validate APIs from the API Manager UI,

the API Designer UI, or the toolkit CLI.

OpenAPI 3.0 support in IBM API Connect

IBM® API Connect supports the OpenAPI 3.0 specification, with some limitations. The current implementation includes complete support for the Berlin Group NextGen PSD2 requirements.

Overview

A Product can contain any combination of OpenAPI 2.0 and OpenAPI 3.0 APIs. When you publish a Product that contains an OpenAPI 3.0 API, that API is validated to ensure that it is syntactically correct, and that references to configuration resources and policies resolve correctly, in the same way that OpenAPI 2.0 APIs are validated.

You can also validate OpenAPI 3.0 APIs in your local file system by using the **`apic validate`** command provided by the developer toolkit CLI; for details, see Validating the YAML or JSON definition of an API or Product.

If you retrieve an API object by using the developer toolkit CLI or the API Connect REST APIs, there is an **`oai_version`** property that defines which OpenAPI version the API represents.

There is no OpenAPI 3.0 API support with the DataPower® Gateway (v5 compatible); OpenAPI 3.0 API support is provided by the DataPower API Gateway **only**.

Limitations

The limitations to the OpenAPI 3.0 support in IBM API Connect are as follows:

User interface limitations

- Some aspects of the OpenAPI 3.0 specification are not currently supported by the user interface. In such circumstances, use the OpenAPI source directly.
- Validation errors that are identified locally are reflected in the API editor header almost immediately. However, some validation errors can be identified only by the API Manager backend and are not reflected until the API is saved; this means that, on saving an API, some validation errors might appear or disappear.
- The user interface does not currently support referencing a request body component from the request body of an operation. If you want to reference a request body component, add the reference to the request body of the operation directly in the OpenAPI source:

  ```
  requestBody:
    $ref: '#/components/requestBodies/request_body_component_name'
  ```

  The reference **is** confirmed on the details page for the request body in the user interface however.
- If, in the API Designer user interface, you create and activate an API of the same name and version as one that has already been activated from the API Manager user interface, the Edit Rate Limit operation fails.

Limitations for APIs that are enforced by the DataPower API Gateway

To suppress the error message for the following limitations and publish the API, set the **`x-ibm-configuration.compatibility.suppress-limitation-errors`** property to **`true`** as shown in the following example:

```
compatibility:
  suppress-limitation-errors: true
```

Attention: Enabling **`suppress-limitation-errors`** merely disables the error messages so that the API can be published.

- General limitations.
  - The **`servers`** array cannot contain more than one server.
  - The **`url`** entry in the **`servers`** array cannot contain **`variables`**.
  - The **`path`** objects cannot contain server object overrides.
  - There is no support for converting a WSDL defined SOAP service into an OpenAPI 3.0 API.
  - There is no support for callbacks or links, and APIs containing them will not be published.
  - The following constructs of Open API 3.0 are less commonly used, and are not supported:
    - **`allowEmptyValue`**
    - **`allowReserved`**
- Assembly policies.
  - All policies are supported.
  - JSON schema support is limited to Draft 4 and earlier. Therefore, the following policies are limited to those drafts:
    - **`gatewayscript`**
    - **`set-variable`**
    - **`switch`**
    - **`json-to-xml`**
    - **`xml-to-json`**
    - **`parse`**
    - **`xslt`**
    - **`map`**
    - **`validate`**

    For detailed information about the Draft 4 and earlier specifications, see https://json-schema.org/specification-links.html#draft-4.
  - Security.
    - The OpenID Connect (OIDC) security scheme is not supported.
    - The use of cookies in an API key is not supported.

Specifying API metadata

API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand the General section, then click Info.
3. Provide the following information:
   - Title (required): The title of the API.
   - Name: The name was generated automatically when the API was created and cannot be changed. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see apic draft-apis.
   - Version: The API version is specified when the API is initially created and cannot be changed thereafter. You can, however, create a new version of an existing API; see Creating a new version of an API definition.
   - Description: An optional description of the API. You can use CommonMark syntax for rich text representation.
   - Terms of Service: A URL to the Terms of Service for the API.
   - Contact Name: The identifying name of the contact person/organization.
   - Contact URL: A URL pointing to the contact information.
   - Contact Email: The email address of the contact person/organization.
   - License Name: The license name used for the API.
   - License URL: A URL to the license used for the API.
4. Click Save when done.

Defining servers for an API

Server definitions in an API provide information for connecting to target servers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand General then, if there are already one or more servers defined, expand Servers.
3. To create a new server definition, click the add icon ⊕ alongside Servers in the navigation pane. To edit an existing server definition, click the server URL in the navigation pane.
4. Provide the following information:
   - Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

     ```
     /my_basepath
     ```

     For full details on how the server URL is used to determine the full URL endpoint, see Configuring vanity endpoints for a Catalog.
   - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
   - Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
     - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
     - Provide the following information:
       - Server Variable Name (required).
       - Default value (required).
       - An optional rich text description. You can use CommonMark syntax for rich text representation.

- One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
- If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
- If required, use the breadcrumb trail to return to your server definition for further editing.

5. If you are creating a new server definition, click Create.
   The server definition details are displayed for further editing as described in step 4.
6. Click Save when done.

Enforcing security requirements on an API

To enforce security requirements on an API, you apply previously created security scheme components that define various aspects of API security configuration.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme components, see Defining security scheme components.

The following restrictions exist when you apply security schemes to an API:

- You cannot apply more than two API key security schemes to an API.
- If you apply an API key security scheme for client secret, you must also apply an API key security scheme for client ID.
- If you require the application developer to supply both client ID and client secret, you must apply two separate API key security schemes.
- You can have at most one API key scheme of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
- You can have at most one API key scheme of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
- You cannot apply more than one basic security scheme to an API. If you apply a basic security scheme, you cannot also apply an OAuth security scheme.
- You can apply at most one OAuth security scheme to an API.

A security requirement specifies one or more security scheme components whose conditions must all be satisfied for the API to be called successfully. You can define multiple security requirements; in this case, an application can call your API if it satisfies any of the security requirements you have defined.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand General.
3. To create a new security requirement for the API, complete the following steps:
   a. Click the add icon ⊕ alongside Security in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined in security scheme components; see Defining security scheme components.
   If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme component; for more information, see Defining OAuth2 security scheme components.

   If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

   Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the **`X-IBM-Client-Id`** or **`client_id`** must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Submit when done.
4. To modify an existing security requirement, complete the following steps:
   a. Click Security in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
   b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
   c. Click Submit when done, then click Save.
   d. To delete a security requirement, click the appropriate delete icon , click Delete to confirm, then click Save.
   e. To disable security for the API, clear the Require one of the following Security Requirements check box, then click Save.

What to do next

Fore more information on LDAP and Authentication URL, see LDAP authentication and Authentication URL user registry.

- **Enabling CORS support for an API**
  You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Enabling CORS support for an API

You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Before you begin

This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.

About this task

Note:

- CORS support is available only on the DataPower® API Gateway.
- When CORS is enabled, the API Gateway runs the `cors` preflow policy to handle all CORS requests that are made to the API.
- When CORS is enabled and a preflight request is received, only the following API actions are performed:
  - The `cors` preflow policy configures the appropriate response headers.
  - The response headers are set.
- When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.
- For all preflight requests, the `security` and `client-identification` preflow policies are always skipped, whether CORS is enabled or not enabled.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

To enable CORS support for an API, complete the following steps:

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click CORS.
   The CORS page opens.
3. Select Enable CORS.
4. Optional: Configure a CORS policy.
   Should you create a CORS policy? Review the following considerations:
   - A CORS policy is an optional part of an API definition. If an API definition has no CORS policy but CORS is enabled, then CORS requests will be accepted from all Origins.
     If you want to accept CORS requests from all Origins, then enable CORS but do not add a CORS policy to the API definition.
   - If you create a CORS policy, then CORS requests will only be accepted from Origins that are explicitly listed in the CORS rules contained in the CORS policy. CORS requests from any other Origins will be rejected.
     If you want to accept CORS requests from only a limited number of Origins (and might also want to configure the Access-Control-Allow-Credentials and Access-Control-Expose-Headers response headers), then you should enable CORS and create a CORS policy. Only those Origins explicitly listed in the allow-origin field of the CORS rules in the CORS policy will be accepted; CORS requests from any Origins not listed will be rejected.
   - To configure a new CORS policy, complete the following steps:
     - Alongside CORS Policy, click Add.
     - To include the header `Access-Control-Allow-Credentials: true` in a response. select Allow Credentials. The `Access-Control-Allow-Credentials` response header tells browsers whether to expose the response to frontend JavaScript code when the request's credentials mode (`Request.credentials`) is set to `include`.
     - To append one or more of the following values to the `Access-Control-Expose-Headers` response header, select Expose headers, and select from the following options:
       - Predefined - The predefined value of the Gateway. This option is selected by default.
       - Backend - The value of `Access-Control-Expose-Headers` from the backend response.
       - Custom - A custom string.
     - Click Create.
     - Alongside Allowed Origins click Add.
     - Enter the origin URL, then click Create. This setting indicates that the response can be shared with requesting code from the specified origin.
   - To modify an existing CORS policy, click its Allowed Origins entry on the CORS page. You can then modify individual origin URLs, add further origins, and change the Allow Credentials setting.

   Example

   The following example has three rules:
   - Accept an Origin header of `https://example.com`, and return `Access-Control-Allow-Credentials: true` in the CORS response.
   - Accept an Origin header of `http://domain.com`. No `Access-Control-Allow-Credentials` header will be returned in the response.
   - Accept any of the following Origin headers:
     - `http://example2.com`
     - `http://example3.com`
     - `http://example4.com`

     No `Access-Control-Allow-Credentials` header will be returned in the response.

```
cors:
  enabled: true
  policy:
    -
      allow-origin:
        - 'https://example.com'
      allow-credentials: true
    -
      allow-origin:
```

```
          - 'http://domain.com'
      -
        allow-origin:
          - 'http://example2.com'
          - 'http://example3.com'
          - 'http://example4.com'
```

5. Click Save to save your changes.
6. Optional: To implement your own CORS solution using custom OPTIONS operations, complete the following steps:
   a. Add the following headers to your HTTP responses:

      ```
      Access-Control-Allow-Origin: https://<portalhostname>
      Access-Control-Allow-Headers: Origin, X-Requested-With, Content-Type, Accept
      ```

      Where `<portalhostname>` is your Developer Portal host name.
   b. Optional: You can proxy your API through API Connect as an enforced invoke API so that CORS is handled automatically.

Important:

- If you implement your own CORS solution, you **must** disable the CORS option described in step 3
- CORS preflight requests are sent by using the HTTP **`OPTIONS`** method. Therefore, if you require these requests to be handled by the API Connect gateway then you must enable the **`OPTIONS`** method for all APIs that will handle preflight requests; see Defining Paths for a REST API.
- **`OPTIONS`** requests are counted as API calls against any configured rate limit. Note that you can apply rate limits to individual operations; see Defining rate limits for an API operation.

Specifying external documentation for an API

You can reference an external resource for extended documentation for an API.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand the General section, then click External Documentation.
3. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
4. Click Save when done.

Adding tags to an API

You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand the General then, if there already one or more tags defined, expand Tags.
3. To add a new tag, click the add icon ⊕ alongside Tags in the navigation pane. To edit an existing tag, click the tag name in the navigation pane.
4. Provide the following information:
   - Name (required): The name of the tag.
   - Description: An optional description of the tag. You can use CommonMark syntax for rich text representation.
   - External Documentation > URL (available when editing an existing tag): The URL for target documentation that describes this tag.

- External Documentation > Description (available when editing an existing tag): An optional description of the target documentation.

5. If you are creating a new tag, click Create.
   The tag details are displayed for further editing as described in step 4.
6. Click Save when done.

Defining Paths for an API

A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The Path is appended to the server URL to form the full URL. For details on configuring servers, see Defining servers for an API.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. If there are already one or more Paths defined, expand Paths.
3. To create a new Path, click the add icon ⊕ alongside Paths in the navigation pane. To edit an existing Path, click the Path in the navigation pane.
4. Provide the following information:
   - Path: A relative path to an individual endpoint.
     The path is appended to the base path to construct the full URI to access the APIs. The path must start, but not end, with the / character. A parameter at the end of the path can contain a qualifier to match one or more path levels.

     If you specify just the name of the parameter, then one level of that path is matched. If you want to allow for multiple levels of the path, you can prefix the parameter with one of the following qualifiers:

     - * to indicate 0 or more occurrences
     - + to indicate 1 or more occurrences

     The + and * qualifiers can only be used at the end of the path.

     For example, the path:

     ```
     /petstore/{type}/{*category}
     ```

     matches the following paths, where only one type value is matched, but all (0 or more) categories are matched:

     ```
     /petstore/cats
     /petstore/cats/supplies
     /petstore/cats/supplies/health
     /petstore/cats/supplies/health/medicines
     /petstore/cats/supplies/health/medicines/a/b/c
     ```

   - Ref (available when editing an existing Path): A reference to a Path that is defined elsewhere, either in this OpenAPI definition, or in an external file. A reference enables reuse of a set of operations already defined for a Path in this API, or in a file that is either a complete API definition or an OpenAPI fragment.
     The reference uses JSON pointer notation. For example, a reference to a Path called `/mypath` in this API would have the following format:

     ```
     #/paths/~1mypath
     ```

     The `~1` characters are used to escape the `/` character, which is being used literally in the path name rather than as a special character.
     A reference to a path in an external file called path_fragments.yaml would have the following format:

     ```
     file://path_fragments.yaml/paths/~1mypath
     ```

   - Summary: An optional summary, intended to apply to all operations in this path.
   - Description: An optional description, intended to apply to all operations in this path. You can use CommonMark syntax for rich text representation.
5. If you are creating a new Path, click Create.
   The Path details are displayed for further editing as described in step 4.
6. Click Save when done.

- **Defining servers for a Path**
  Server definitions for a Path provide alternative target servers when calling the API at that Path.
- **Defining parameters for a Path**
  Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.
- **Defining operations for a Path**
  Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

Defining servers for a Path

Server definitions for a Path provide alternative target servers when calling the API at that Path.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: It is unlikely that you will need to define servers for a Path because it applies only if the API operations are distributed across different gateway endpoints, and such a configuration is possible only if you are hosting your API operations on your own runtime endpoints outside of API Connect. For an API that is published to the DataPower API Gateway, all API operations are invoked on the same gateway service.
A server defined for a Path overrides any server defined for the parent API. You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there already one or more servers defined for the Path, expand Servers.
4. To create a new server definition for the Path, click the add icon ⊕ alongside Servers under the Path in the navigation pane. To edit an existing server definition, click the server URL under the Path in the navigation pane.
5. Provide the following information:
   - Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

     ```
     /my_basepath
     ```

     For full details on how the server URL is used to determine the full URL endpoint, see Configuring vanity endpoints for a Catalog.
   - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
   - Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
     - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
     - Provide the following information:
       - Server Variable Name (required).
       - Default value (required).
       - An optional rich text description. You can use CommonMark syntax for rich text representation.
       - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
     - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
     - If required, use the breadcrumb trail to return to your server definition for further editing.
6. If you are creating a new server definition, click Create.
   The path details are displayed for further editing as described in 5.
7. Click Save when done.

Defining parameters for a Path

Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to `header`.
- A parameter can have various format styles, the style of a header is always `simple`.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there already one or more parameters defined, expand Parameters.
4. You can either create a new parameter, or edit any existing parameter.
   - To create a parameter, click the add icon alongside Parameters, then refer to Creating a parameter.
   - To edit an existing parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining operations for a Path

Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there are one or more operations, expand Operations.
4. To create an operation, click the add icon alongside Operations under the Path in the navigation pane. To edit an existing operation, click the operation name under the Path in the navigation pane.
5. Provide the following information:
   - Verb: Select the operation type from the following options:
     - get
     - post
     - put
     - delete
     - options
     - head
     - patch
     - trace
   - Summary: A summary of what the operation does.
   - Description: A description of the operation behavior. You can use CommonMark syntax for rich text representation.
   - Operation ID: Unique string used to identify the operation. The id must be unique among all operations described in the API.
   - Deprecated: Declares this operation to be deprecated. Consumers should refrain from using the declared operation.
6. If you are creating a Path operation, click Create.
7. Click Save when done.

- **Adding tags to an operation**
  You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Specifying external documentation for an operation**
  You can referencing an external resource for extended documentation for an API operation.
- **Defining parameters for an operation**
  Operation parameters can, for the URL path associated with that specific operation, define variable elements of the URL path, query parameters, headers, or body parameters.
- **Defining the request body for an operation**
  A request body defines the structure of the body of an API request.
- **Defining responses for an operation**
  Responses define the HTTP status code and data returned in a response body and headers.
- **Enforcing security requirements on an operation**
  To enforce security requirements on an API operation, you apply previously created security scheme components that define various aspects of API security configuration.
- **Defining servers for an operation**
  Server definitions for an API operation provide alternative target servers when calling that operation.

Adding tags to an operation

You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To add a new operation tag, click the add icon ⊕ alongside the Tags entry for the operation in the navigation pane. To edit an existing tag, expand Tags then click the tag name in the navigation pane.
5. Provide the following information:
   - Name (required): The name of the tag.
6. If you are creating a new operation tag, click Create.
   The tag details are displayed for further editing as described in step 5.
7. Click Save when done.

Specifying external documentation for an operation

You can referencing an external resource for extended documentation for an API operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click External Documentation.
4. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
5. Click Save when done.

Defining parameters for an operation

Operation parameters can, for the URL path associated with that specific operation, define variable elements of the URL path, query parameters, headers, or body parameters.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An operation parameter overrides a parameter of the same name defined on the parent Path; see Defining parameters for a Path.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. You can either create a new operation parameter, or edit any existing parameter.
   - To create an operation parameter, click the add icon alongside Parameter, then refer to Creating a parameter.
   - To edit an existing operation parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining the request body for an operation

A request body defines the structure of the body of an API request.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Note: The user interface doesn't currently support referencing a request body component from an operation. However, you can add the reference directly to the OpenAPI YAML source for your API definition, for example:

```
paths:
  /mypath:
    get:
          .
          .
          .
      requestBody:
        $ref: '#/components/requestBodies/my_requestbody_component'
          .
          .
          .
```

For information on request body components, see Defining request body components.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click requestBody.
4. Provide the following information:
   - Description: An optional description of the request body. This could contain examples of use. You can use CommonMark syntax for rich text representation.
   - Content: A content definition describes the content of the request body.
     To define a new content definition for the request body, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.
   - Required: Determines if the request body is required in the request.
5. Click Save when done.

Defining responses for an operation

Responses define the HTTP status code and data returned in a response body and headers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing responses, expand Responses.
4. You can either create a new response, or edit any existing response.
   - To create a response, click the add icon ⊕ alongside Responses, then refer to Creating a response.
   - To edit an existing response, click the response name in the navigation pane, then refer to Editing a response.

Enforcing security requirements on an operation

To enforce security requirements on an API operation, you apply previously created security scheme components that define various aspects of API security configuration.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme components, see Defining security scheme components.

A security requirement specifies one or more security scheme components whose conditions must all be satisfied for the API operation to be called successfully. You can define multiple security requirements; in this case, an application can call your API operation if it satisfies any of the security requirements you have defined.

Any security requirements that you define for an operation completely override any security requirements defined on the parent API. If you do not define any security requirements for an operation, or you delete all security requirements from an operation, the operation inherits the security requirements defined on the parent API. For more information, see Enforcing security requirements on an API.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To create a new security requirement for the operation, complete the following steps:
   a. Click the add icon ⊕ alongside the Security Requirements entry for the operation in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined in security scheme components; see Defining security scheme components.
   If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme component; for more information, see Defining OAuth2 security scheme components.

   If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

   Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the **`X-IBM-Client-Id`** or **`client_id`** must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Submit when done.
5. To modify an existing security requirement, complete the following steps:
   a. Click the Security entry for the operation in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
   b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
   c. Click Submit when done, then click Save.
   d. To delete a security requirement, click the appropriate delete icon , click Delete to confirm, then click Save.
   e. To disable security for the operation, clear the Require one of the following Security Requirements check box, then click Save.

Note: These settings completely override any security requirements defined on the parent API; see Enforcing security requirements on an API.

Defining servers for an operation

Server definitions for an API operation provide alternative target servers when calling that operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A server defined for an operation overrides any server defined for the parent API or Path. You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there already one or more servers defined for the operation, expand Servers.
4. To create a new server definition for the operation, click the add icon ⊕ alongside Servers under the operation in the navigation pane. To edit an existing server definition, click the server URL under the operation in the navigation pane.
5. Provide the following information:
   - Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

     ```
     /my_basepath
     ```

     For full details on how the server URL is used to determine the full URL endpoint, see Configuring vanity endpoints for a Catalog.
   - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
   - Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
     - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
     - Provide the following information:
       - Server Variable Name (required).
       - Default value (required).
       - An optional rich text description. You can use CommonMark syntax for rich text representation.
       - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
     - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
     - If required, use the breadcrumb trail to return to your server definition for further editing.
6. If you are creating a new server definition, click Create.
   The path details are displayed for further editing as described in 5.
7. Click Save when done.

Defining components for an API

Components are reusable objects relating to various aspects of your API definition. A component has no effect on the API unless it is explicitly referenced from elsewhere in your API definition.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The following subtopics detail the various types of API component:

- **Defining schema components**
  Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.
- **Defining response components**
  Response components define reusable response objects that specify the HTTP status code and data returned in a response body and headers.
- **Defining parameter components**
  Parameter components define reusable parameters that can specify variable elements of a URL path, query parameters, headers, or a request body.
- **Defining example components**
  An example component is a reusable example that you can add to an API to make the specification of your API clearer.

- **Defining request body components**
  A request body component is a reusable definition of the structure of the body of an API request.
- **Defining header components**
  A header component defines a reusable custom header that can be sent in an API request or returned in an API response.
- **Defining security scheme components**
  A security scheme component specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.
- **Defining link components**
  A link component is a reusable link definition that can be used to describe how various values returned by one operation can be used as input for other operations. In this way, links provide a known relationship and traversal mechanism between the operations.

Defining schema components

Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

An API created in OpenAPI 3.0 includes a section where API payload definitions are defined. The payload definitions describe the structure of data transmitted in API requests and responses, utilizing a specialized JSON schema variant specific to OpenAPI. Each payload definition corresponds to a schema, which lists the expected data fields. These data fields are represented as properties within the schema and include a set of attributes that describe their type, permissible values, mandatory status, and other characteristics. Although numerous attributes are available, the majority of them are infrequently utilized.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a schema component, you reference it from elsewhere in your API definition. You can reference a schema from the following locations:

- An API Path parameter; see Defining parameters for a Path.
- An API operation parameter; see Defining parameters for an operation.
- The request body of an API operation; see Defining the request body for an operation.
- An API operation response; see Defining responses for an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more schemas components defined, expand Schemas.
3. You can create a new schema component, or edit any existing schema component.
   - To create a schema component, click the add icon alongside Schemas, then refer to Creating a schema component.
   - To edit an existing schema component, click the schema component name in the navigation pane, then refer to Editing a schema component.

- **Creating a schema component**
  Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.
- **Editing a schema component**
  Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Creating a schema component

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
Launch the schema creation window. For details of the areas in your API definition from where you can create a schema, see the following topics:

- Editing a content definition
- Editing a header
- Editing a parameter
- Defining schema components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. To create a schema definition, open the Componentselement and click the add icon ⊕ alongside Schema.
   The Add object wizard for a schema is displayed.
2. Provide the following information:
   -
     - Schema Name: If you are creating a schema component, this name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/schemas/Name`

     - Title: The schema title.
     - Type: The schema data type; select one of the following:
       - array
       - boolean
       - integer
       - number
       - object
       - string
3. Click Create.
   The schema details are displayed for further editing; see Editing a schema component.

Editing a schema component

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
Open the details form for a schema. For details of the areas in your API definition from where you can edit a schema, see the following topics:

- Editing a content definition
- Editing a header
- Editing a parameter
- Defining schema components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The table view presents the properties within a schema alongside their essential attributes, such as name, type, description, and required status. The secondary pop-up enables access for viewing and editing the more detailed and less commonly used attributes that are associated with each data field.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

You can configure the following schema settings:

- Schema Name: Available if you are editing a schema component, this name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

  `#/components/schemas/Name`

To change the name, click the Source icon, change the value in the field, then click Save
- Optional: Title: The schema title.
- Optional: Type: The schema data type; select one of the following:
  -
    - array
    - boolean
    - integer
    - number
    - object
    - string

  Note: If you change the type of an existing schema, any existing settings that are not relevant to the new type are still retained in the OpenAPI source even though they are no longer displayed in the user interface. You should therefore avoid porting a schema from one type to another but instead either create a new schema or modify the OpenAPI source directly; to open the source editor, click the Source icon </> .
- Properties: The schema property. To add a property to the schema, click Add alongside the Properties section heading, complete the details and click Save.
- Additional schema settings dependent on the selected Type of property. To view and edit these schema settings, click the Options menu next to the property you want to view and select Details.
  - boolean: no type specific settings.
  - integer:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Multiple Of: Division of an integer instance by this value must result in an integer.
    - Maximum: An integer instance must be less than or equal to this value.
    - Exclusive Maximum: An integer instance must be strictly less than this value.
    - Minimum: An integer instance must be greater than or equal to this value.
    - Exclusive Minimum: An integer instance must be strictly greater than this value.
  - number:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Multiple Of: Division of a number instance by this value must result in an integer.
    - Maximum: A number instance must be less than or equal to this value.
    - Exclusive Maximum: A number instance must be strictly less than this value.
    - Minimum: A number instance must be greater than or equal to this value.
    - Exclusive Minimum: A number instance must be strictly greater than this value.
  - object:
    - Max Properties: The number of properties in an object instance must be less than or equal to this value.
    - Min Properties: The number of properties in an object instance must be greater than or equal to this value.
    - Required Properties: An array of property names; every property name in the array must be the name of a property in an object instance. To add a required property name, click Add alongside the Required Properties section heading, enter the name, then click Create.
  - string:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Pattern: A regular expression; a string instance must successfully match the expression.
    - Max Length: The maximum allowed number of characters in a string instance.
    - Min Length: The minimum allowed number of characters in a string instance.
    - Enum: An array of string values; a string instance must match one of the array values. To add an enum value, click Add, enter the value, then click Create.
- General settings; select the required options:
  - Required: A property associated with this schema is required.
  - Read Only: A property associated with this schema can be returned in a response but should not be included in a request. For example, properties whose values are system generated identifiers will be defined as Read Only because application clients wouldn't be able to set these.
- Example Value: An example value. Whatever you enter here is displayed as-is in the Developer Portal.
- External Documentation: An external resource for extended documentation; provide the following information:
  - URL (required): The URL for the target documentation.
  - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
- Xml: Metadata that allows for more fine-tuned XML model definitions; provide the following information:
  - Name: Replaces the name of the element or attribute used for the described schema property.
  - Namespace: The URL of the namespace definition.
  - Prefix: The prefix to be used for the Name.
  - Attribute: Specifies whether the property definition translates to an attribute instead of an element.
  - Wrapped: For an array definition, Specifies whether the array is wrapped (for example, **<books><book/><book/></books>**) or unwrapped (**<book/> <book/>**).
- Click Save when done.

Example

By defining properties, you can create more complex data structures. For example, you could define an "Address" schema that has the following properties:

PROPERTY NAME	PROPERTY TYPE
street1	string
street2	string
city	string
state	string
zip_code	string

and then define a "BankBranch" schema that has the following properties, one of which is a reference to the Address schema:

PROPERTY NAME	PROPERTY TYPE
address	address
type	string
id	string

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining response components

Response components define reusable response objects that specify the HTTP status code and data returned in a response body and headers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a response component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more response components defined, expand Responses.
3. You can create a new response component, or edit any existing response component.
   - To create a response component, click the add icon ⊕ alongside Responses, then refer to Creating a response.
   - To edit an existing response component, click the response component name in the navigation pane, then refer to Editing a response.

- **Creating a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.
- **Editing a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.
- **Creating a content definition**
  A content definition describes the content of an API request, response, or parameter. You can create content definitions in various places in your API definition.
- **Editing a content definition**
  A content definition describes the content of an API request, response, or parameter. You can edit content definitions that have been previously created in various places in your API definition.
- **Creating an encoding definition**
  An encoding definition defines a map between a specific schema property and its encoding information.
- **Editing an encoding definition**
  An encoding definition defines a map between a specific schema property and its encoding information

Creating a response

Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.

Before you begin

Launch the response creation window. For details of the areas in your API definition from where you can create a response, see the following topics:

- Defining responses for an operation
- Defining response components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the response; you can either create a response from scratch, or you can reference a response that is defined in a response component.
   - To create the response from scratch, provide the following information on the Definition tab:
     - Response name: A name for the response.
       If you are creating an operation response, this name is the HTTP status code.

If you are creating a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

`#/components/responses/Name`

- Description (required): A description of the response. You can use CommonMark syntax for rich text representation.

- To reference a response that is defined in a response component, provide the following information on the Reference tab:
  - Response name: A name for the response.
    If you are creating an operation response, this name is the HTTP status code.

    If you are creating a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

    `#/components/responses/Name`

  - Reference from: Select a reference to a response component.

2. Click Create.
   The response details are displayed for further editing; see Editing a response.

Editing a response

Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Before you begin

Open the details form for a response. For details of the areas in your API definition from where you can edit a response, see the following topics:

- Defining responses for an operation
- Defining response components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Response name: A name for the response.
     If you are editing an operation response, this name is the HTTP status code.

     If you are editing a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/responses/Name`

     To change the name, click Update, then click Save when done.

   - Description: A description of the response. You can use CommonMark syntax for rich text representation.
   - Headers: Headers define information that can be returned in the response.
     To define a new header for the response, click Add, then refer to Creating a header.

     To edit an existing header, click the header name, then refer to Editing a header.

   - Content: A content definition describes the content of the response.
     To define a new content definition for the response, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.

   - Links: Links describe how various values returned by one operation can be used as input for other operations.
     To define a new link for the response, click Add, then refer to Creating a link.

     To edit an existing link, click the link name, then refer to Editing a link.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Creating a content definition

A content definition describes the content of an API request, response, or parameter. You can create content definitions in various places in your API definition.

Before you begin

Launch the content definition creation window. For details of the areas in your API definition from where you can create a content definition, see the following topics:

- Editing a header
- Editing a request body
- Defining the request body for an operation
- Editing a response

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Content Type: Select the content type; for example, application/json.
     Note: While the Content Type field in the editor provides a selection list of media types, by editing the OpenAPI source for the API directly you can specify a media type range; for example, `text/*`, `*/json`, or `*/*`. For requests or responses that match multiple types, only the most specific type is applicable;. for example, `text/plain` overrides `text/*`.
2. Click Create.
   The content definition details are displayed for further editing; see Editing a content definition.

Editing a content definition

A content definition describes the content of an API request, response, or parameter. You can edit content definitions that have been previously created in various places in your API definition.

Before you begin

Open the details form for a content definition. For details of the areas in your API definition from where you can edit a content definition, see the following topics:

- Editing a header
- Editing a request body
- Defining the request body for an operation
- Editing a response

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Content Type: Select the content type; for example, application/json.
     Note: While the Content Type field in the editor provides a selection list of media types, by editing the OpenAPI source for the API directly you can specify a media type range; for example, `text/*`, `*/json`, or `*/*`. For requests or responses that match multiple types, only the most specific type is applicable;. for example, `text/plain` overrides `text/*`.
   - Schema:
     To define a schema for the content definition, click Create, then refer to Creating a schema component.

If the content definition already has a schema defined, click View to edit the schema.

For full details on editing a schema, see Editing a schema component.
Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.

- Example Value: An example of a parameter value. Whatever you enter here is displayed as-is in the Developer Portal.
- Examples:
  To add an example of the content, click Add, then refer to Creating an example.

  To edit an existing example, click the example name, then refer to Editing an example.

- Encoding: An encoding definition describes how a specific schema property is encoded.
  To add an encoding definition, click Add, then refer to Creating an encoding definition.

  To edit an existing encoding definition, click the name, then refer to Editing an encoding definition.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Creating an encoding definition

An encoding definition defines a map between a specific schema property and its encoding information.

Before you begin

Launch the encoding definition creation window when configuring a content definition; see Editing a content definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The name of the schema property.
   - Content Type: The Content-Type for encoding the property; for example, `application/xml; charset=utf-8`, `image/png, image/jpeg`.
   - Style: Describes how the property value will be serialized depending on the type of the property value. Select one of the following options:
     - form: Form style properties defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form properties.
   - Explode: When selected, property values of type `array` or `object` generate separate properties for each value of the array or key-value pair of the map.
   - Allow Reserved: Determines whether the property value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding.
2. Click Create.
   The encoding definition details are displayed for further editing; see Editing an encoding definition.

Editing an encoding definition

An encoding definition defines a map between a specific schema property and its encoding information

Before you begin

Open the details form for an encoding definition when configuring a content definition; see Editing a content definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The name of the schema property. To change the name, click Update, then click Save when done.
   - Content Type: The Content-Type for encoding the property; for example:
     - `application/xml; charset=utf-8`
     - `image/png, image/jpeg`.
   - Headers: A map allowing additional information to be provided as headers.
     To add a new header, click Add, then refer to Creating a header.

     To edit an existing header, click the header name, then refer to Editing a header.

   - Style: Describes how the property value will be serialized depending on the type of the property value. Select one of the following options:
     - form: Form style properties defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form properties.
   - Explode: When selected, property values of type `array` or `object` generate separate properties for each value of the array or key-value pair of the map.
   - Allow Reserved: Determines whether the property value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining parameter components

Parameter components define reusable parameters that can specify variable elements of a URL path, query parameters, headers, or a request body.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a parameter component, you must reference it from elsewhere in your API definition.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to `header`.
- A parameter can have various format styles, the style of a header is always `simple`.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more parameter components defined, expand Parameters.
3. You can create a new parameter component, or edit any existing parameter component.
   - To create a parameter component, click the add icon ⊕ alongside Parameters, then refer to Creating a parameter.
   - To edit an existing parameter component, click the parameter component name in the navigation pane, then refer to Editing a parameter.

- **Creating a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.
- **Editing a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for Paths and Path operations in your API definition.

Creating a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.

Before you begin

Launch the parameter creation window. For details of the areas in your API definition from where you can create a parameter, see the following topics:

- Defining parameters for a Path
- Defining parameters for an operation
- Defining parameter components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the parameter; you can either create a parameter from scratch, or you can reference a parameter that is defined in a parameter component.
   - To create the parameter from scratch, provide the following information on the Definition tab:
     - Name: Available if you are creating a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/parameters/`*`Name`*

     - Parameter name (required): The name of the parameter.
     - Located In (required): The location of the parameter. Select one of the following options:
       - query: Parameters that are appended to the URL. For example, ***`url_path`*`?myparam=myvalue`**.
       - header: Custom headers that are expected as part of the request.
       - path: The parameter value is part of the operation's URL, enclosed in {}.
       - cookie: Used to pass a specific cookie value to the API.
     - Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
     - Style: Describes how the parameter value will be serialized depending on the type of the parameter value. Select one of the following options:
       - matrix: Path-style parameters defined by RFC6570.
       - label: Label style parameters defined by RFC6570.
       - simple: Simple style parameters defined by RFC6570.
       - form: Form style parameters defined by RFC6570.
       - spaceDelimited: Space separated array values.
       - pipeDelimited: Pipe separated array values.
       - deepObject: Provides a simple way of rendering nested objects using form parameters.
     - Select the following options as required:
       - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
       - Deprecated: Specifies that a parameter is deprecated and should be transitioned out of usage.
       - Allows Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
       - Explode: When selected, parameter values of type **`array`** or **`object`** generate separate parameters for each value of the array or key-value pair of the map.
       - Allow Reserved: Determines whether the parameter value should allow reserved characters, as defined by RFC3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding. This property applies only if the Located In property is set to query.
   - To reference a parameter that is defined in a parameter component, provide the following information on the Reference tab:
     - Name: Available if you are creating a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/parameters/`*`Name`*

     - Parameter name (required, available if you are creating a path or operation parameter): The name of the parameter.
     - Reference from: Select a reference to a parameter component.
2. Click Create.
   The parameter details are displayed for further editing; see Editing a parameter.

Editing a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for Paths and Path operations in your API definition.

Before you begin

Open the details form for a parameter. For details of the areas in your API definition from where you can edit a parameter, see the following topics:

- Defining parameters for a Path
- Defining parameters for an operation
- Defining parameter components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: Available if you are editing a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/parameters/`*`Name`*

     To change the name, click Update, then click Save when done.
   - Parameter name (required): The name of the parameter.
   - Located In (required): The location of the parameter. Select one of the following options:
     - query: Parameters that are appended to the URL. For example, ***`url_path`*`?myparam=myvalue`**.
     - header: Custom headers that are expected as part of the request.
     - path: The parameter value is part of the operation's URL, enclosed in {}.
     - cookie: Used to pass a specific cookie value to the API.
   - Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
   - Style: Describes how the parameter value will be serialized depending on the type of the parameter value. Select one of the following options:
     - matrix: Path-style parameters defined by RFC6570.
     - label: Label style parameters defined by RFC6570.
     - simple: Simple style parameters defined by RFC6570.
     - form: Form style parameters defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form parameters.
   - Select the following options as required:
     - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
     - Deprecated: Specifies that a parameter is deprecated and should be transitioned out of usage.
     - Allows Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
     - Explode: When selected, parameter values of type **`array`** or **`object`** generate separate parameters for each value of the array or key-value pair of the map.
     - Allow Reserved: Determines whether the parameter value should allow reserved characters, as defined by RFC3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding. This property applies only if the Located In property is set to query.
   - Schema:
     To define a schema for the parameter, click Create, then refer to Creating a schema component.

     If the parameter already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing a schema component.
     Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
   - Example Value: An example of a parameter value. Whatever you enter here is displayed as-is in the Developer Portal.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining example components

An example component is a reusable example that you can add to an API to make the specification of your API clearer.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an example component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more example components defined, expand Examples.
3. You can create a new example component, or edit any existing example component.
   - To create an example component, click the add icon ⊕ alongside Examples, then refer to Creating an example.
   - To edit an existing example component, click the example component name in the navigation pane, then refer to Editing an example.

- **Creating an example**
  You add examples to an API to make the specification of your API clearer.
- **Editing an example**
  You add examples to an API to make the specification of your API clearer.

Creating an example

You add examples to an API to make the specification of your API clearer.

Before you begin

Launch the example creation window. For details of the areas in your API definition from where you can create an example, see the following topics:

- Editing a content definition
- Defining example components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the example; you can either create an example from scratch, or you can reference an example that is defined in an example component.
   - To create the example from scratch, provide the following information on the Definition tab:
     - Example Name: If you are creating an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/Name`

     - Summary: A summary description of the example.
     - Description: A full description of the example. You can use CommonMark syntax for rich text representation.
     - External Value: A URL that points to a literal example. This provides the capability to reference examples that cannot easily be included in JSON or YAML documents. This could a PDF, for example.

- To reference an example that is defined in an example component, provide the following information on the Reference tab:
  - Example Name: If you are creating an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

    `#/components/examples/Name`

  - Reference from: Select a reference to an example component.

2. Click Create.
   The example details are displayed for further editing; see Editing an example.

Editing an example

You add examples to an API to make the specification of your API clearer.

Before you begin

Open the details form for an example. For details of the areas in your API definition from where you can edit an example, see the following topics:

- Editing a content definition
- Defining example components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   -
     - Example Name: If you are editing an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/Name`

       To change the name, click Update, then click Save when done.
     - Summary: A summary description of the example.
     - Description: A full description of the example. You can use CommonMark syntax for rich text representation.
     - Example Value: A literal example.
     - External Value: A URL that points to a literal example. This provides the capability to reference examples that cannot easily be included in JSON or YAML documents. This could a PDF, for example.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining request body components

A request body component is a reusable definition of the structure of the body of an API request.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more request body components defined, expand Request Bodies.
3. You can create a new request body component, or edit any existing request body component.
   - To create a request body component, click the add icon ⊕ alongside Request Bodies, then refer to Creating a request body.
   - To edit an existing request body component, click the request body component name in the navigation pane, then refer to Editing a request body.

- **Creating a request body**
  A request body defines the structure of the body of an API request.
- **Editing a request body**
  A request body defines the structure of the body of an API request.

Creating a request body

A request body defines the structure of the body of an API request.

Before you begin

Launch the request body creation window; see Defining request body components.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the request body; you can either create a request body from scratch, or you can reference a request body that is defined in a request body component.
   - To create the request body from scratch, provide the following information on the Definition tab:
     - Name: A name for the request body.
       If you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/requestBodies/Name`

     - Description: A description of the request body. You can use CommonMark syntax for rich text representation.
     - Required: Determines if the request body is required in the request.
   - To reference a request body that is defined in a request body component, provide the following information on the Reference tab:
     - Name: A name for the request body.
       If you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/requestBodies/Name`

     - Reference from: Select a reference to a request body component.
2. Click Create.
   The request body details are displayed for further editing; see Editing a request body.

Editing a request body

A request body defines the structure of the body of an API request.

Before you begin

Open the details form for a request body; see Defining request body components.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: A name for the request body.
     Available if you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/requestBodies/Name`

   - Description: A description of the request body. You can use CommonMark syntax for rich text representation.
   - Content: A content definition describes the content of the request body.
     To define a new content definition for the request body, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.

   - Required: Determines if the request body is required in the request.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining header components

A header component defines a reusable custom header that can be sent in an API request or returned in an API response.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a header component, you must reference it from elsewhere in your API definition.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to `header`.
- A parameter can have various format styles, the style of a header is always `simple`.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more header components defined, expand Headers.
3. You can create a new header component, or edit any existing header component.
   - To create a header component, click the add icon alongside Headers, then refer to Creating a header.
   - To edit an existing header component, click the header component name in the navigation pane, then refer to Editing a header.

- **Creating a header**
  A header defines information that can be sent in an API request or returned in an API response. You can create headers in various places in your API definition.
- **Editing a header**
  A header defines information that can be sent in an API request or returned in an API response. You can edit headers that have been previously created in various places in your API definition.

Creating a header

A header defines information that can be sent in an API request or returned in an API response. You can create headers in various places in your API definition.

Before you begin

Launch the header creation window. For details of the areas in your API definition from where you can create a header, see the following topics:

- Editing a response
- Editing an encoding definition

- Defining header components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the header; you can either create a header from scratch, or you can reference a header that is defined in a header component.
   - To create the header from scratch, provide the following information on the Definition tab:
     - Header name: If you are creating a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/headers/`*`Name`*

     - Description: A description of the header. You can use CommonMark syntax for rich text representation.
     - Required: Determines whether this header is mandatory.
     - Deprecated: Specifies that this header is deprecated and should be transitioned out of usage.
     - Allow Empty Value: The header can be sent with an empty value.
     - Explode: When selected, header values of type **`array`** or **`object`** generate separate headers for each value of the array or key-value pair of the map.
     - Allow Reserved: Determines whether the header value should allow reserved characters, as defined by RFC3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding.
   - To reference a header that is defined in a header component, provide the following information on the Reference tab:.
     - Header name: If you are creating a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/headers/`*`Name`*

     - Reference from: Select a reference to a header component.
2. Click Create.
   The header details are displayed for further editing; see Editing a header.

Editing a header

A header defines information that can be sent in an API request or returned in an API response. You can edit headers that have been previously created in various places in your API definition.

Before you begin

Open the details form for a header. For details of the areas in your API definition from where you can edit a header, see the following topics:

- Editing a response
- Editing an encoding definition
- Defining header components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Header name: If you are editing a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/headers/Name`

     To change the name, click Update, then click Save when done.
   - Description: A description of the header. You can use CommonMark syntax for rich text representation.
   - Required: Determines whether this header is mandatory.
   - Deprecated: Specifies that this header is deprecated and should be transitioned out of usage.
   - Allow Empty Value: The header can be sent with an empty value.
   - Explode: When selected, header values of type **array** or **object** generate separate headers for each value of the array or key-value pair of the map.
   - Allow Reserved: Determines whether the header value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding.
   - Schema:
     To define a schema for the header, click Create, then refer to Creating a schema component.

     If the header already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing a schema component.
     Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
   - Content: A content definition describes the content of the header.
     To define a new content definition for the header, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining security scheme components

A security scheme component specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create security definitions of the following types:

Type	Description
Basic authentication	Use a basic authentication security definition to specify a user registry or an authentication URL to be used to authenticate access to the API.
API key	Use an API key security definition to specify what application credentials are required to call an API.
OAuth2	Use an OAuth2 security definition to specify settings for OAuth token based authentication for your API.
HTTP Bearer	Use an HTTP Bearer definition to specify how to validate the Bearer token that is required to call an API.

- **Defining basic authentication security scheme components**
  A basic authentication security scheme component is used when an application that calls the API is required to authenticate through a user registry.
- **Defining API key security scheme components**
  An API key security component is used to specify the credentials that an application must provide to identify itself when calling the API operations.
- **Defining OAuth2 security scheme components**
  An OAuth2 security scheme component defines the settings for controlling access to the API operations through the OAuth authorization standard.
- **Defining an HTTP bearer security scheme**
  An HTTP bearer security scheme is used to generate access tokens that are exchanged between the server and the client when calling the API operations.

Defining basic authentication security scheme components

A basic authentication security scheme component is used when an application that calls the API is required to authenticate through a user registry.

Before you begin

For authenticating access to the operations of APIs that are enforced on the API Connect gateway, the following user registry types are supported:

- Authentication URL
- LDAP

The following user registry types are **not** supported:

- OpenID Connect (OIDC)
- Local User Registry (LUR)
- A custom user registry

Before you can create a basic authentication security definition in an API, the user registry must exist. To create a user registry, you can use either API Manager or Cloud Manager. When you create a registry in API Manager, it is visible only to your provider organization. When you create a registry in Cloud Manager, you can make it visible to multiple provider organizations.

To create a user registry with API Manager, see Working with user registries.

To create a user registry with Cloud Manager, see User registries overview.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you use basic authentication, you require API users to provide a valid user name and password to access selected operations. The application developer must also provide an HTTP authorization header in requests that are sent to operations that require basic authentication.

When you use an authentication URL, the user credentials that are provided in the authorization header are validated by the endpoint specified in the URL. If the user is authenticated, IBM API Connect expects an authentication URL to return an HTTP `200 OK` response status code. All other HTTP response status codes result in an authentication failure and access is denied.

For more information about using an LDAP user registry for authentication, see LDAP authentication.

For information about using an Authentication URL, see Authentication URL user registry.

To make use of a basic authentication security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create a basic authentication security scheme component, click the add icon ⊕ alongside Security Schemes. To edit an existing basic authentication security scheme component, click the component name in the navigation pane.
4. If you are creating a new basic authentication security scheme component, you can either create it from scratch or you can reference another basic authentication security scheme component.
   To create a basic authentication security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name (required): A key that enables this basic authentication security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/`*`Security_Scheme_Name`*

   - Security Scheme Type (required): Select http.
   - Scheme (required): The name of the HTTP Authorization scheme to be used in the Authorization header as defined in RFC7235.
   - Authenticate using User Registry: The name of the user registry to be used for authentication. This is the value of the **`name`** field that was auto-generated when the user registry was created.
   - Bearer format: A hint to the client to identify how the bearer token is formatted. Bearer tokens are usually generated by an authorization server, so this information is primarily for documentation purposes.
   - Description: An optional description of the basic authentication security scheme. You can use CommonMark syntax for rich text representation.

   To reference another basic authentication security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name (required): A key that enables this basic authentication security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/`*`Security_Scheme_Name`*

   - Reference from: Select a reference to another basic authentication security scheme component.
5. If you are creating a new basic authentication security scheme component, click Create.
   The security scheme component details are displayed for further editing.
6. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Fore more information on LDAP and Authentication URL, see LDAP authentication and Authentication URL user registry.

Defining API key security scheme components

An API key security component is used to specify the credentials that an application must provide to identify itself when calling the API operations.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can require that, when calling an API operation, an application must provide either a client ID, or a client ID and client secret; you create an API key security scheme component to specify a credentials requirement. If you require that an application must provide both a client ID and client secret, you must create two API key security scheme components, one for each type of credentials.

To make use of an API key security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create an API key security scheme component, click the add icon alongside Security Schemes. To edit an API key existing security scheme component, click the component name in the navigation pane.
4. If you are creating a new API key security scheme component, you can either create it from scratch or you can reference another API key security scheme component.
   To create an API key security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name: A key that enables this API key security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Security Scheme Type: Select apiKey.
   - Name: The name of the header, query or cookie parameter to be used. For a key of type client secret you must include the string "secret", ignoring case, in the value you specify in the Name field; if the value does not contain the string "secret" then the key is assumed to be of type client ID.
     Note: The client ID and client secret headers that are specified in the request when the API is called are **not** added automatically to the message context. If you need these headers in the message context for subsequent processing, include a `set-variable` policy in your API assembly that adds the headers to the message content, taking the values specified in the request; you can do this in either of the following ways:
     - In the Assemble tab, add a Set Variable policy to your API assembly that defines the appropriate actions; for example:

       Table 1.

Action	Set	Type	Value
Set	message.headers.X-IBM-Client-Id	string	$(request.headers.X-IBM-Client-Id)
Set	message.headers.X-IBM-Client-Secret	string	$(request.headers.X-IBM-Client-Secret)

       For more information on configuring a Set Variable policy, see Set Variable.
     - In the Source tab, add a `set-variable` policy directly to the assembly section in your OpenAPI source; for example:

```
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-IBM-Client-Id
            value: $(request.headers.X-IBM-Client-Id)
            type: string
          - set: message.headers.X-IBM-Client-Secret
            value: $(request.headers.X-IBM-Client-Secret)
            type: string
```

       For more information on defining a `set-variable` policy in your OpenAPI source, see set-variable.
     You should position the `set-variable` before any policy that needs to access the API key headers; for example, an invoke policy that calls a back-end service that is required to identify the application that made the initial request.
   - Key Type: Select client_id or client_secret.
     Important: The client_id is not confidential and functions as a "SecurityScheme" only in the meaning of the OpenAPI specification.
     If you use only the client_id (without the client_secret) as your API Key, be aware that the client_id is not considered a confidential value in the API Manager UI; for example, it might be displayed to other authenticated members of the provider organization. The client_id is treated as a public identifier for apps and cannot be kept private.

     If authentication of the identity of the app calling an API is needed, then the API Key should use both a client_id to identify the app, plus a client_secret to authenticate it. The client_secret is designed to be known only to the app and the authorization server, and it should be protected. IBM API Connect protects

the client_secret: it is only available when first generated, it can be stored as a one-way hash to prevent retrieval or leaks, and it can be changed and reset without changing the corresponding client_id. When an API Key is not marked as a client_secret, it will not be protected in the API Manager UI.

- Located In: Select one of the following options, to specify how the credentials are sent:
  - header: The credentials are sent in the request header.
  - query: The credentials are sent as query parameters. This method is less secure because the client secret could be exposed in a log file.

  Note: If you migrated from API Connect V5, API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. For information about the differences, see Client ID behavior in API key security definitions.
- Description: An optional description of the API key security scheme. You can use CommonMark syntax for rich text representation.

5. To reference another API key security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name: A key that enables this API key security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Reference from: Select a reference to another API key security scheme component.
6. If you are creating a new API key security scheme component, click Create.
   The security scheme component details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

- **Client ID behavior in API key security definitions**
  How the Client ID behaves in API key security definitions in IBM API Connect 10 compared to Version 5.

Client ID behavior in API key security definitions

How the Client ID behaves in API key security definitions in IBM® API Connect 10 compared to Version 5.

API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. Refer to the following table to understand the differences in Client ID behavior for different use cases.
Note: Although a client_id in the request body is supported, this data is not used during security requirement processing.

Table 1. Client ID behavior in V5 and V10

Use case	Description of security requirement	V5 behavior	V10 behavior
1	Allows client_id in the query, and the request contains multiple client_ids in the query.	Uses the first client ID in the request.	401 invalid client ID or secret.
2	Allows client_id in the header, and the request contains multiple client_ids in the header.	401 invalid client ID or secret.	401 invalid client ID or secret.
3	Allows client_id in the header, and the request contains multiple client_ids in the query and the header (1 in the query, 1 in the header).	401 client ID in wrong location.	Client ID in query is ignored.
4	Allows client_id in the query, and the request contains multiple client_ids in the query and the header.	Client ID in header is ignored.	Client ID in header is ignored.
5	Allows client_id in the query or header, and both the query and header contain multiple client_ids.	Header returns 401 client ID in wrong location. Query uses the first client ID in the request.	401 invalid client ID or secret.
6	Allows client_id in the header, and the request contains a valid client_id in the query, and an invalid client_id in the header.	401 client ID in wrong location.	401 invalid client ID or secret.
7	Allows client_id in the query, and the request contains a valid client_id in the header, and an invalid client_id in the query.	401 invalid client ID or secret.	401 invalid client ID or secret.
8	Allows client_id in the query or header, and both the query and header contain valid client_ids.	200 OK.	403 multiple client IDs.
9	Allows client_id in the query or header, and both the query and header contain invalid client_ids.	401 client ID in wrong location.	401 invalid client ID or secret.
10	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the query is valid.	200 OK.	Uses the valid one 200 OK.
11	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the header is valid.	401 client ID in wrong location.	Uses the valid one 200 OK.
12	Allows client_id in the query or header, and both the query and client_id is missing in the request (no security requirement, but client security is defined in the assembly).	401 invalid client ID or secret.	• When Return V5 Responses compatibility option is off: 401 client ID is missing. • When Return V5 Responses compatibility option is on: 401 invalid client ID or secret. For information about setting compatibility options, see Configuring v5 compatibility options.

Defining OAuth2 security scheme components

An OAuth2 security scheme component defines the settings for controlling access to the API operations through the OAuth authorization standard.

Before you begin

Before you can create an OAuth2 security scheme component, you must:

1. Create an OAuth provider.
   - To use Cloud Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
   - To use API Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
2. Add the OAuth provider to a catalog. If you have not created any catalogs, use the Sandbox Catalog. See the OAuth instructions step in Creating and configuring Catalogs.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an OAuth2 security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create an OAuth2 security scheme component, click the add icon ⊕ alongside Security Schemes. To edit an existing OAuth2 security scheme component, click the component name in the navigation pane.
4. If you are creating a new OAuth2 security scheme component, you can either create it from scratch or you can reference another OAuth2 security scheme component.
   To create an OAuth2 security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name: A key that enables this OAuth2 security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Security Definition Type: Select oauth2.
   - Flow: Select one or more of the following options:
     - Implicit
     - Resource Owner - Password
     - Application
     - Access Code

     Note: The flow options that are available for selection depend on which options are supported by the selected OAuth provider.
     If you selected Resource owner - JWT as the supported grant type when you created the OAuth provider, you must select Resource owner - Password as the Flow for this security scheme.
   - OAuth Provider: The name of the OAuth provider to be used. This is the value of the **name** field that was auto-generated when the OAuth provider was created.
   - Description: An optional description of the OAuth2 security scheme. You can use CommonMark syntax for rich text representation.
   - Optionally select your OIDC provider from the list to add the provider's URL to the OpenId Connect URL field on the Resources > OAuth Providers > OpenID Connect page, which enables a client to send a request for information about the provider's publicly visible configuration.

   To reference another OAuth2 security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name: A key that enables this OAuth2 security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Reference from: Select a reference to another OAuth2 security scheme component.
5. If you are editing an existing OAuth2 security scheme component, provide the following information:
   - The URL endpoints (the applicable endpoints depend on the flow type):
     - Authorization URL
     - Refresh URL
     - Token URL

     Note: The URL endpoint values supplied here are maintained only for informative purposes, no validation or other action is applied to them by API Connect. The OAuth security that is applied depends on the specified OAuth provider.
   - Scopes:
     - To add a new scope, click Add. To edit an existing scope, click the options icon ⋮ alongside the required scope, then click Edit.
     - Provide the following information:
       - Scope: The scope identifier.
       - Description: An optional description of the scope. You can use CommonMark syntax for rich text representation.
6. If you are creating a new OAuth2 security scheme component, click Create.
   The security scheme component details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Defining an HTTP bearer security scheme

An HTTP bearer security scheme is used to generate access tokens that are exchanged between the server and the client when calling the API operations.

About this task

For information on the use of bearer tokens with OpenAPI 3 APIs, see Bearer Authentication in the OpenAPI 3 specification.

If an HTTP bearer token is found in the request, its value is stored within the context as **`api->security->bearer_token`**. If an external URL validation is invoked, any response with a status code of 200 is stored within the context as **`api->security->bearer_validation_response`**.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components > Security Schemes.
3. Click Add.
4. In the Add Object dialog box, provide the following information:
   - Security Scheme Name (Key) - Provide a descriptive name for the new scheme.
   - Security Scheme Type - Select http.
   - Scheme - Select Bearer.
   - Bearer Format - Select JWT.
   - Validation Method - Select a method. If you select external-url, provide the following additional information:
     - Validation Endpoint - Provide the URL of the server used for validation. To ensure a secure connect, the URL should use the **`https`** protocol.
     - TLS Profile name - If the validation endpoint uses the **`https`** protocol, select the name of the TLS client profile to use for a secure connection.
   - Description - Provide a description of the JWT scheme.
5. Click Create to create the new scheme.
6. Click Save in the page header.

Defining link components

A link component is a reusable link definition that can be used to describe how various values returned by one operation can be used as input for other operations. In this way, links provide a known relationship and traversal mechanism between the operations.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a link component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more link components defined, expand Links.
3. You can create a new link component, or edit any existing link component.
   - To create a link component, click the add icon ⊕ alongside Links, then refer to Creating a link.
   - To edit an existing link component, click the link component name in the navigation pane, then refer to Editing a link.

- **Creating a link**
  Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.
- **Editing a link**
  Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Creating a link

Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Before you begin

Launch the link creation window. For details of the areas in your API definition from where you can create a link, see the following topics:

- Editing a response
- Defining link components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the link; you can either create a link from scratch, or you can reference a link that is defined in a link component.
   - To create the link from scratch, provide the following information on the Definition tab:
     - Name: If you are creating a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/links/Name`

     - Operation ID: The ID of an existing operation; this field is mutually exclusive of the Operation Ref field. For details on defining operations, see Defining operations for a Path.
     - Operation Ref: A relative or absolute URI reference to an existing operation; this field is mutually exclusive of the Operation ID field. For details on defining operations, see Defining operations for a Path.
     - Description: A description of the link. You can use CommonMark syntax for rich text representation.
   - To reference a link that is defined in a link component, provide the following information on the Reference tab:
     - Name: If you are creating a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/links/Name`

     - Reference from: Select a reference to a link component.
2. Click Create.
   The link details are displayed for further editing; see Editing a link.

Editing a link

Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Before you begin

Open the details form for a link. For details of the areas in your API definition from where you can edit a link, see the following topics:

- Editing a response
- Defining link components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.

- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: If you are editing a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/links/Name`

     To change the name, click Update, then click Save when done.
   - Operation ID: The ID of an existing operation; this field is mutually exclusive of the Operation Ref field. For details on defining operations, see Defining operations for a Path.
   - Operation Ref: A relative or absolute URI reference to an existing operation; this field is mutually exclusive of the Operation ID field. For details on defining operations, see Defining operations for a Path.
   - Parameters: A map representing parameters to pass to an operation as specified with Operation ID or identified via Operation Ref. The key is the parameter name to be used, whereas the value can be a constant or an expression to be evaluated and passed to the linked operation.
   - Request Body: The request body to use when calling the target operation.
   - Description: A description of the link. You can use CommonMark syntax for rich text representation.
   - Server: A server to be used by the target operation. Provide the following information:
     - Server URL The specified URL is used to determine the full URL endpoint for the calling the API, according to any vanity endpoint configuration in the Catalog in which the API is published. For full details, see Configuring vanity endpoints for a Catalog.
     - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
     - Server Variables A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
       - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
       - Provide the following information:
         - Server Variable Name (required).
         - Default value (required).
         - An optional rich text description. You can use CommonMark syntax for rich text representation.
         - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
       - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Specifying gateway and portal settings

Define general configuration settings for your API.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, then click Gateway and portal settings.
3. Provide the following information:
   - Phase: The phase of the lifecycle that your API is in; select one of the following options:
     - Realized (default) - The API is in the implementation phase.
     - Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
     - Specified - The API has been fully designed and passed an internal milestone but has not yet been implemented.
   - Testable: Select this option to allow the API's operations to be tested using the test tool in the Developer Portal.
     Note: For the test tool to work, an API must be included in a Plan in a Product that is staged in a Catalog.
   - CORS: Enable and configure cross-origin resource sharing (CORS) support for your API. For details, see Enabling CORS support for an API.
   - Target Services: Define web services that you want to use in your API definition. For details, see Defining target services for an API.

- Enforced: Select this option to enforce the API by using the DataPower API Gateway. Clear this option if you are managing the API on a gateway other than the DataPower API Gateway. Although not published to a gateway by API Connect, an unenforced API is still available in the Developer Portal for subscription by application developers.
- Properties: Add properties that can be referenced in your API definition. For details, see Setting API properties.
- Catalog Properties: Define property values that are specific to a particular Catalog. For details, see Defining Catalog specific property values.
- Activity Log: Configure your logging preferences for the API activity that is stored in analytics. For details, see Configuring activity logging.
- Exxtensions: Extensions added to the API to extend the OpenAPI specification. For details, see Adding an OpenAPI extension to an API.

Defining target services for an API

A target service defines a web service that you want to use in your API definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more target services defined, expand Target Services.
3. To define a new API target service, complete the following steps:
   a. Click the add icon ⊕ alongside Target Services in the navigation pane.
   b. Upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, by either dragging and dropping your file, or browsing and selecting the file that you want to use.
   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.
4. Select the service that you want to add.
5. Click Save to save your changes.
6. To view the source for an existing target service, click the target service name in the navigation pane.

Results

The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see Including elements in your API assembly.

Setting API properties

In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API properties include property name, value, and, optionally a specific Catalog to which a property value applies. For a list of pre-supplied API properties relating to various policies, see API properties.
Note: Once defined, an API property is read only.
For information on how to reference a property in an API definition, see Variable references in API Connect.

It is also possible to define properties that are specific to a Catalog and can be referenced by any of the APIs in that Catalog; for more information, see Creating and configuring Catalogs. Note that if you define a Catalog property of the same name as an API property, the API property takes precedence over the Catalog property.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more API properties defined, expand Properties.
3. Configure an API property.
   - To define a new API property, complete the following steps:
     - Click the add icon alongside Properties in the navigation pane.
     - Provide the following information:
       - Property Name: Enter a name for the property; this name is used to reference the property. The following character set is supported for the Name of an API property: `[A-Za-z0-9_-]+`. Spaces are allowed.
       - Value: A default value for the property. Leave blank if the property is to have a null vale by default.
       - Description: An optional description of the property. You can use CommonMark syntax for rich text representation.
       - Select Encoded if you want to hide the property values, or protect user passwords from casual observance.
         Note: If you encode a property value, it is saved in Base64 encoded form; it is **not** encrypted. If you subsequently clear the Encoded check box, the original property value is restored in its unencoded form.
     - Click Create.
   - To modify an existing API property, click the property name in the navigation pane. You can then change any of the configuration settings.
4. Click Save to save your changes.

What to do next

Optionally, define a value for the property that is specific to a particular Catalog; see Defining Catalog specific property values.

- **Defining Catalog specific property values**
  For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Defining Catalog specific property values

For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Before you begin

You must have previously created the API property that you now want to define a Catalog specific value for; see Setting API properties.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more Catalog specific property values defined, expand Catalog Properties.
3. Configure a Catalog specific property value.
   - To define a new Catalog specific property value, complete the following steps:
     - Click the add icon alongside Catalog Properties in the navigation pane.
     - Type the Catalog Name exactly as it displays in the **name** field for the selected Catalog.
       Tip: For the best result, manually type the catalog's name instead of selecting its title. Using the catalog name is safer than using its title, because the title might not be unique within the provider organization and might be modified later (which breaks the association between the property and the catalog). The catalog's name is always unique within the provider organization and cannot be changed.
     - Click Create. The Catalog properties details for the specified catalog are displayed for further editing.
     - Alongside Property Overrides, click Add.
     - Provide the following information:
       - Property Name: Enter the name of the API property that you want to define a Catalog specific value for. The name **must** match the name of a previously defined API property; see Setting API properties.
       - Property Value: The Catalog specific property value. Leave blank if the property is to have a null value by default.
     - Click Create.
   - To modify an existing Catalog specific property value, click the Catalog name in the navigation pane. You can then change the Catalog name, and add, modify, or delete property override settings.
4. Click Save to save your changes.

Configuring application authentication for an API

Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.

About this task

Note: This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Enable application authentication, as follows:
   Note: To identify the application, you must enable a security requirement of type **`clientID`**.
   a. Select the Gateway tab, expand Gateway and portal settings, then click Application Authentication.
   b. Select Certificate.
3. Specify how the client certificate is sent to the gateway, as follows:
   a. In the navigation pane, click Application Authentication Source.
      Any existing application authentication source definitions are listed.
   b. Alongside Application Authentication Source, click Add.
   c. Select the required option, header or tls-cert.
      You can separately add one or both of the options.
      When the API is called, an X509 client certificate must be supplied, either in the specified HTTP header, or as a TLS client certificate from TLS mutual authentication. For any Developer Portal application that calls the API, the certificate must be entered in the Developer Portal user interface; for details, see Registering an application.

      The Gateway service to which the API is published can be configured to use TLS mutual authentication to secure API calls made to that Gateway service; for details, see Configuring the initial Gateway service. If you select this option, continue to sub-step d.

      If you are using a load balancer, you must configure the load balancer to use the specified HTTP header to relay the appropriate client certificate to the Gateway service after the load balancer terminates the TLS communication.

   d. If you select the tls-cert option, enable mTLS at the Gateway level.
      This can be done by enabling "Mutual authentication: Required" in the TLS Server Profile configured in the Gateway Service in the Cloud Manager Topology (requires cloud administrator permissions). For information, see Registering a gateway service.

      You can create a Truststore (with the root or intermediate CA certificate) for use with the TLS Server Profile.

      The following example cURL command uses a client-cert during SSL:

      ```
      **curl -X GET 'https://GW-Server:9443/test/sandbox/mtls-testing/callmtls-call' -H 'X-IBM-Client-Id:
      1872xxxxxxxxxxxx' --cert my-leaf-cert.pem --key my-leaf-cert.key -k -v**
      ```

      Note: This feature is intended for the scenario where different applications will be registered with different end certificates in the Developer Portal, which will have the same intermediate or root CA issuer. The certificate will pass Gateway-level mTLS if it matches the issuer available in the Truststore, but will only allow access the to API that matches the correct end certificate.
4. Click Create.
5. Click Save to save your changes.

Configuring activity logging

You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An API event record exists for each API execution event in the Gateway server. By default, the content type for a successful API execution is activity, and payload for an API call the results in an error code. When you compose your API definition, you can change the type of content to log in these API event records. During API execution, the activity data is stored in the **`log`** context variable, which populates the API event record on completion of the API execution; for more information, see API activity logging context variables.

Note:
Activity logging that calls for logging of analytics data upon success doesn't apply for the OAuth provider. The OAuth provider logs analytics data for failure cases, but doesn't log successful cases.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click Activity Log.
3. Select Enabled, then select options for the Success Content and Error Content fields as follows:

Field label	Description
Success Content	Defines the type of content to be logged when the operation is successful. • none: API events are not logged. • activity: Logs the API resource URI. • header: Logs the API resource URI and HTTP headers. • payload: Logs API resource URI, HTTP headers, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is activity.
Error Content	Indicates what content to log when an error occurs. • none: API events are not logged. • activity: Logs the API resource URI. • header: Logs the API resource URI and HTTP headers. • payload: Logs API resource URI, HTTP headers, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is payload.

4. Click Save to save your changes.

Including elements in your API assembly

An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

In the Policies view of IBM API Connect, you can add and configure elements in your assembly. You can also directly add elements to the OpenAPI definition of your API.

- **The assembly editor**
  The API Designer of IBM API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.
- **Adding elements to your assembly**
  Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.
- **Handling errors in the assembly**
  Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

The assembly editor

The API Designer of IBM® API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM API Connect.

You can access the Assemble view by clicking the Gateway tab in the API editor, and then click Policies. This tab includes the following options:

- Palette - lists the available elements in the assembly flow.
- Canvas - used to arrange and visualize the elements in the assembly.
- Property sheet - used to configure the elements in the assembly.

The palette

The palette is a list of different elements that you can include in your assembly. To view the palette, click the plus icon on the canvas. You can use the Rotate icon to rotate the palette as you prefer. To maximize and minimize the palette view, click the Maximize and Minimize icons.

You can release the palette by clicking the Close icon .

The canvas

You can use the canvas to create a graphical representation of the assembly flow. To add an element to the assembly flow from the palette, click the plus icon ⊕ at the appropriate location on the canvas and select the required element from the available list. To delete an element from the canvas, hover over the element and click the Delete icon 🗑.

Note: You must click Save in the Assemble view to save your assembly updates, and to make them appear in the Source view.
API calls are made at the initial, unfilled, circle, and returned at the final, filled, circle. You can insert elements between the two circles to modify the data received from the call, or returned by the response.

You can use the Show catches toggle to show and hide error catches in the palette. A catch is a section of the assembly that is applied when an API call results in the corresponding HTTP status code being returned. Click the catch section to open the property sheet for all your catches.

You can zoom the view of your canvas in and out by clicking the + and - icons. To fit the canvas to the screen size, click the Fit to screen icon ⛶.

The property sheet

When you select an element that is in the assembly by clicking it, details about the element are displayed in the property sheet. In this pane, you can configure the element's properties. The options available to you in the property sheet are specific to the type of element you are working with. For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down menu.

You can release the property sheet by clicking the Close icon ✕.

The behavior of an assembly

The assembly runs policies in order and acts on different contexts of the API call. When an API call is made, security and rate limits are enforced before the assembly is executed. During the assembly, the flow can be branched, thrown, and caught according to the policies available. The message context flows through the assembly, being used and altered by various policies. In addition to the message, other contexts can be accessed and created.

Security and rate limiting
: Before the assembly is executed, security and then rate limits are enforced.
First, security definitions and CORS access control are used to authenticate an API call. Any API Key security definitions are used to identify applications that have subscriptions to a Product containing the API. If a security definition does not allow access, the API call is rejected.

If an application is identified by its client ID or client secret, a rate limit can be enforced based on the Plan or operation called.

The assembly execution sequence
: The assembly is executed in order from the initial, filled, circle to the final, unfilled, circle. However, there is room for branching, when **`if`** and **`operation-switch`** logic constructs are used, or for the remaining assembly to be ignored when a **`throw`** policy is executed.
The message is the context that is acted upon by any policy that isn't otherwise configured. At the beginning of the API call, the message is empty and, at the end of the API call, the message is used as the response.

The request context contains the information that is sent by the API caller and varies with the type of operation called and the configuration of that operation. For example, a GET operation can never have a populated **`request.body`**, and you can configure an operation to have **`request.parameters`** (query parameters).
The first policy in an assembly acts on the request and produces the first instance of the message. If there are no policies, the request is returned to the caller.

Managing contexts
: Because the message can be overwritten, it is useful to create and reference new contexts where possible so that they are saved and reused during the API call.

- Use the **`map`** policy to overwrite the message context when you need to execute a policy that only acts on the message.
- Use the request context when you want to use the original request made to the API.
- Use the **`map`**, **`invoke`**, and **`proxy`** policies to create new contexts when you want to save your message.
  Note: When you create a new context, unless you are also mapping to the message, the message is overwritten with an empty object.

For example, **`invoke`** is the first policy in the assembly and its response overwrites the request as the message. The message is then acted upon by a **`validate`** policy, and a **`map`** policy then saves the message as a new context, ready for a second **`invoke`** policy to overwrite the message without losing the first **`invoke`** policy's output.

You can also access contexts outside of the message or your custom contexts, but these contexts cannot be written to. For a list of contexts, see API Connect context variables.

Branches and catches
: Using logic constructs, such as **`operation-switch`** or **`if`**, you can execute different sections of the assembly when certain conditions are fulfilled. When the assembly branches, the subsection of the assembly contained by the construct is executed in the same manner as a complete assembly. However, contexts are shared with the complete assembly.
When a catch is triggered, either by an error occurring during the execution of a policy, or because a **`throw`** policy is encountered, the rest of the assembly flow is ignored. All contexts are shared by the catch being executed and when the end of the catch is reached, the API call is completed. There is no way to return from a catch to the rest of the assembly.

Adding elements to your assembly

Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can use the assembly tool in the UI to create assemblies that are used to manipulate requests made to or responses made by any of your API's operations.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

If you want to use the Source view to edit the source of your API definition, see execute OpenAPI extension for more information about how to configure the OpenAPI YAML.

For more information about the use of the assembly tool, see The assembly editor.

Procedure

To add elements to your assembly using the assembly tool, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Use the Policies view to add an element.
   Note: You must specify a version for the policy. To prevent errors due to incompatible versions of a policy between the API and the gateway, API Connect will only publish an API to the gateway if the policy version in the API exactly matches the version that is present on the gateway.
   a. Select the Gateway tab, then click Policies in the navigation pane.
   b. Click the plus icon ⊕ at the appropriate location on the canvas to view the palette that lists the available elements.
   c. Select the element that you want to add from the palette to the canvas by clicking it.
      Note:
      - Elements are applied in order from the initial, unfilled, circle to the final, filled, circle.
      - Unless an Operation Switch element is used, the whole assembly applies to every operation in the API.
   d. Add and edit properties of the element by clicking the element and using the property sheet.
      For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down list. For information about the properties of policy elements, see API policies and logic constructs. For information about the properties of logic constructs, see Logic Constructs.
   e. Specify a version for the policy.
      To add a version, click the Source icon </>, and complete the `version` section of the policy YAML. For example:

      ```
      execute:
        - invoke:
            version: 2.2.0
            title: invoke
      ...
      ```

      You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions. For more information about how to configure the policy OpenAPI YAML, see execute OpenAPI extension.
4. Optional: Repeat Steps 3.b to 3.e for any additional elements that you want to add.
5. Click Save to save your changes.

Results

You have added one or more elements to your assembly.

Handling errors in the assembly

Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.

- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The catch section of the assembly is used to implement an assembly in the instance that an error is thrown during the assembly execution. For example, the assembly could contain a **throw** element, the API caller could fail to authenticate, or a policy could fail to execute correctly. Each error can be handled with a different catch and each catch can handle multiple status errors.

Procedure

To create a catch and include elements in it, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to apply a catch to.
3. Select the Gateway tab, then click Policies in the navigation pane.
4. Set the Show catches toggle in the menu bar of the canvas to the Show position.
5. Click Catches in the canvas, or a Catch icon if one is displayed.
   The property sheet for the API's catches opens.
6. To add a default catch that is executed when an otherwise uncaught error is thrown, click Add default catch.
   Note: If you have a default catch before another catch in precedence, the default catch will activate even when the other catch's error is thrown.
7. To add a new catch, click Add catch.
8. To specify which errors the catch applies to, use the Select errors field to select the appropriate error.
9. Optional: To remove an error case from a catch, clear the corresponding checkbox from the Select errors drop-down. To clear all the error cases from a catch, click the cross corresponding to the total number of error cases in the Select errors field.
10. Optional: To change the precedence of your catches, use the Move up or Move down icons.
    If an error case is handled by multiple catches, the catch at the beginning of the list is applied.
11. To add an element to a catch from the palette, click the plus icon at the appropriate location in the assembly flow. Select an element that you want to apply to the catch by clicking it.
12. Click Save to save your changes.

What to do next

If you added a catch for ConnectionError, SOAPError, or OperationError, you must add the same error to the Stop on error setting for the **Invoke** policy in your assembly. Otherwise, if the error occurs during the execution of the **Invoke** policy, it is not caught, the policy execution is allowed to complete, and the assembly flow continues. For details on configuring an **Invoke** policy, see Invoke.

For details of all the errors that can be returned by the assembly and are available to the catch function, see Error cases supported by assembly catches.

Validating the OpenAPI YAML source

How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.

About this task

When you're configuring an API in the API editor, you can validate the OpenAPI YAML source by clicking Validate > With specifications. If any swagger parser validation errors are found, an error icon is displayed that you can then click to see the individual errors, and where they occur in the YAML. You can then fix the errors, save the updates, and continue to validate the OpenAPI YAML throughout the API configuration process.
Note:

- OpenAPI validation does not show gateway or policy errors that will stop your API from being staged or published. This type of validation occurs only when you try to stage or publish your API. For more information, see Staging an API or Publishing an API.
- You can also validate your API document by using API governance rulesets. For more information, see Validating an API document by using API governance.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To validate the OpenAPI YAML source, complete the following steps.

1. Open the required API for editing, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
2. Click Validate > With specifications from the menu bar in the header.

3. If any swagger parser validation errors are found, an error icon is displayed on the header menu bar, with the number of OpenAPI errors found displayed next to the icon.

   For example, 1 .
4. You can then click the error icon to see a detailed list of the errors, and their location in the YAML. If you're in Form view, you can click an individual error to navigate directly to the relevant API section in the form.
5. After you fix the error, click Save to save your updates, and then click Validate again.

6. When all of the errors are fixed, the validation returns a success message.

   For example, 
.

Validating an API document by using API governance

How to use API governance rulesets to validate and enforce organizational governance policies and best practices. You can validate APIs from the API Manager UI, the API Designer UI, or the toolkit CLI.

Before you begin

Before you can use API governance rulesets to validate your API documents, the API governance optional add-on must be enabled on your management subsystem by your system administrator. See Enabling API governance on Kubernetes, and Enabling API governance on VMware for more information. If API governance is enabled in your deployment, the API governance resource is displayed on the Resources page in the API Manager.

The API governance service is available to all user roles.

Tip: Before using the API governance service to validate your API document, you should run Validate > With specifications to validate the OpenAPI YAML source. For more information, see Validating the OpenAPI YAML source.

About this task

API governance is an IBM® API Connect service that can be used to validate and enforce organizational governance policies and best practices to your API development process. API governance contains the following types of rulesets:

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization.
- Global rulesets - these are preconfigured IBM and Spectral rulesets that contain the rules that are shared with your provider organization, and cannot be edited. Note that the Spectral ruleset names are prefixed by spectral-, and that their version matches the version of that ruleset that's available in Spectral.

You can create your own provider organization rulesets to validate your Swagger, OpenAPI, and AsyncAPI documents against, or use the global rulesets that are provided by default. For more information about configuring rulesets, see Configuring API governance in the API Manager.

API governance in IBM API Connect is based on the open-source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

You can complete this task by using the API Manager UI, and by using API Designer when the UI is online, and is connected to a cloud instance that has the API governance microservice enabled on it. You can also use the toolkit CLI; for details see Validating an API document by using the toolkit CLI.

The following methods can be used to validate your API documents with rulesets by using the API Manager or the API Designer UIs:

- From within an API
- From within the Rulesets tab

Procedure

- To validate an API document from within the API, complete the following steps.
  1. Open the required API for validating, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
  2. Click Validate > With rulesets from the menu bar in the header.

  3. Select the rulesets that you want to validate your API document against, and click Next.
  4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  5. Click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. You can click on an error to take you to the specific section of the API that needs correcting. The API can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
  6. Optional: You can click Download to download the results of the validation into a .csv file.
  7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
  8. Click Done when finished.
- To validate one or more draft API documents from within the Rulesets tab, complete the following steps.
  1. In the API Manager, click Resources.
  2. In the Resources navigation menu, select API governance.
  3. Click Validate.

4. Select the rulesets that you want to validate your API document against, and click Next.
5. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
6. Select the APIs that you want to validate, and click Validate.
   If any validation errors are found, a scorecard is displayed showing the results of the validation. You can click on an error to take you to the specific section of the API that needs correcting. If no errors are found, a success message is displayed.
7. Optional: You can click Download to download the results of the validation into a .csv file.
8. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
9. Click Done when finished.

Results

Your API document is validated against one or more rulesets.

What to do next

You can use the results of the validation to help you improve your API document. You can also use the results to help you edit the rulesets, and create new rulesets; see Configuring API governance in the API Manager for more information.

- **Validating an API document by using the toolkit CLI**
  How to use the API Connect toolkit CLI to run API governance validation scans on your API documents.

Related information

- The API governance ruleset lifecycle

Validating an API document by using the toolkit CLI

How to use the API Connect toolkit CLI to run API governance validation scans on your API documents.

About

API governance is an IBM® API Connect service that can be used to validate and enforce organizational governance policies and best practices to your API development process. The following information provides details of the toolkit CLI commands for running and managing validation scans on your API documents. You can also validate an API document by using the API Manager and the API Designer UIs. For more information about validation scanning, see Validating an API document by using API governance.

The following methods can be used to validate your API documents with rulesets by using the toolkit CLI:

- Validate a single API document that is stored locally
- Validate one or more draft APIs that are stored on the management server

Validate a single API document that is stored locally

To validate a single API document against one or more rulesets, complete the following steps. The OpenAPI document must be stored locally.

1. Log in to the toolkit as the owner or an admin of your provider organization.
   For example:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Run the **compliance:validate** toolkit command in `governance` mode.

   ```
   apic --mode governance compliance:validate --org <target_org> --server <server_url> --rulesets <ruleset_name_1>,
   <ruleset_name_2> API_FILE
   ```

   where:
   - `<target_org>` is the name of the provider organization that owns the APIs to be validated.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.

- `<ruleset_name_1>,<ruleset_name_2>` is a comma-delimited list specifying the names of the rulesets to be applied to the API. (Specify each ruleset name; do not use the ruleset IDs.)
- `API_FILE` is the path and filename of the OpenAPI document to be validated.

Validate one or more draft APIs that are stored on the management server

The APIs must be stored as draft APIs in your provider organization; this operation validates all of the draft APIs that are listed in the `COMPLIANCE_REQUEST_FILE`.

1. Create a JSON `COMPLIANCE_REQUEST_FILE` that specifies the location of the draft APIs and the rulesets to use during validation.
   The following example shows a configuration file that specifies two draft APIs, and two rulesets. In the `spectral-oas` ruleset, the `info-contact` rule is disabled and will be ignored during validation.

```
{
  "apiUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/a08898fe-b422-41d3-b058-c3280d632e93","https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/26692eab-f43b-4af3-985c-2deaa401eb7f"]
  "config" : {
    "rulesets": [
      {
        "rulesetName": "spectral-oas",
        "disabled": ["info-contact"]
      },
      {
        "rulesetName": "spectral-owasp",
        "disabled": []
      }
      ]
 }
}
```

   where:
   - `apiUrls` is a comma-delimited list of URLs. Each URL specifies the location of the draft APIs in a particular provider organization.
   - `rulesetName` is a list of rulesets to be applied to the APIs during validation.
     For each ruleset in the list, you can optionally add the `disabled` property with a comma-delimited list of rules to ignore during validation.

2. Log in to the toolkit as the owner or an admin of your provider organization. See Step 1 for details.
3. Run the **compliance:validate_all** toolkit command in `governance mode`.

```
apic --mode governance compliance:validate_all --org <target_org> --server <server_url> COMPLIANCE_REQUEST_FILE
```

   where:
   - `<target_org>` is the name of the provider organization that owns catalog containing the APIs to be validated.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `COMPLIANCE_REQUEST_FILE` is the path and filename of the configuration file that lists the APIs and rulesets to be used during the validation (for example, validate-apis.json).

LDAP authentication

The Lightweight Directory Access Protocol (LDAP) is an internet protocol for accessing and maintaining distributed directory information services over a network. If you rely on LDAP to authenticate users for web applications, take a minute to review the contents of this topic before beginning.

Programming guidelines

When authenticating with LDAP, observe the following guidelines:

- Use only a LDAP interface -- Users can only be authenticated via a connection to an LDAP server.
- Active Directory -- Use of an Active Directory interface is prohibited, however, LDAP authentication with Active Directory is supported.
- Administrator properties -- The LDAP administrator must have access to all user's LDAP properties.

LDAP attributes read by IBM® API Connect are as follows:

Attribute	Definition
`mail`	User's SMTP email address.
`cn`	Used internally to determine user's common name.
`sn`	Used internally to determine user's last name or surname.
`givenname`	Used internally to determine user's first name.
Prefix from `Search dn`	Used as username.

Using an LDAP Server for User Authentication

Every entry in an LDAP directory server has a distinguished name (DN). The DN is the name that uniquely identifies an entry in the directory. A DN is made up of `attribute=value` pairs, separated by commas. For example:

```
cn=Ben Gray,ou=editing,o=New York Times,c=US
cn=Lucille White,ou=editing,o=New York Times,c=US
cn=Tom Brown,ou=reporting,o=New York Times,c=US
```

Any of the attributes defined in the directory schema can be used to make up a DN. The order of the component attribute value pairs is important. The DN contains one component for each level of the directory hierarchy from the root down to the level where the entry resides. LDAP DNs begin with the most specific attribute (usually some sort of name) and continue with progressively broader attributes, often ending with a country attribute. The first component of the DN is referred to as the Relative

Distinguished Name (RDN). It identifies an entry distinctly from any other entries that have the same parent. In the previous examples, the RDN "cn=Ben Gray" separates the first entry from the second entry, (with RDN "cn=Lucille White"). These two example DNs are otherwise equivalent. The attribute=value pair making up the RDN for an entry must also be present in the entry. (This is not true of the other components of the DN.)

Examples

In the following examples, a user search is performed from Base DN. The search is done anonymously, or if authenticated bind is used, an authenticated user is used. Search DN appends the prefix, the given user name, and the suffix. If the prefix used is (**uid=** and the suffix used is "**)**", **uid** becomes the user name attribute. The default search filter used is: **(|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}))** and attributes used for prefix are also added to the search filter. In this case, where '(**uid=**' is the prefix, when searching for users, the search filter becomes:

```
  (|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}*)(uid={filter}*))
```

where **{filter}** is replaced by actual text.
The authenticated bind DN is a user on the external LDAP server permitted to get base DNs and search the LDAP directory within the defined search base. It should also be able to read other user properties and be used if anonymous access to LDAP to get base DNs and to search and get access to user attributes is not allowed. When a search is performed for *Steve*, the LDAP query filter shown in the following example is used and search is done from base DN specified in UI. When the user's DN is returned, the DN and password are used to authenticate the user:

```
(|(cn=Steve*)(sn=Steve*)(mail=Steve*)(givenName=Steve*)(uid=Steve*)).
```

For bind during login calls, the search string used is the prefix. For example, if the prefix is '(**uid=**', the search string used to search for a user during log in becomes: (**uid=Steve**).

Using the mail attribute as the user name

When you want to use an email address as the user name, (for example *steve@company.com*), you typically use the mail attribute as the prefix '(**mail=**'. In this case, use the following search string to perform the search internally (assuming '(**mail=**' as prefix):

```
(|(cn=steve@company.com*)(sn=steve@company.com*)(mail=steve@company.com*)
(givenName=steve@company.com*)(mail=steve@company.com*))
```

In the previous example, if DN is found, the password is used with the DN to perform a bind. The first result is taken, so be sure to use a unique attribute for username. Next, the LDAP properties for the user are read (**cn**, **sn**, **mail**, **givenName**). If LDAP properties cannot be read using the logged-in user, they are read from the user's DN using authenticated bind credentials. If the user name attribute differs, it is also queried for. For example, if the prefix is '(**uid=**', the **uid** attribute is also read from the user's DN object:

```
(|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}*))
```

Note: The prefix and suffix cannot be used to get a user's DN directly. For example, the following attempt to directly get a user's DN fails:

```
Prefix: "uid="_home_markdown_jenkins_workspace_Transform_in_SSMNED_v10cd_com.ibm.apic.toolkit.doc_con_ldap_requirements_,
Suffix: ",ou=users,dc=company,dc=com"
```

LDAP referrals

LDAP referrals allow a directory tree to be partitioned and distributed between multiple LDAP servers. An LDAP referral is a domain controller's way of indicating to a client application that it does not have a copy of a requested object, while giving the client a location that is more likely to hold the object. The client then uses the object as the basis for a DNS search for a domain controller.

API Connect support for LDAP referral includes:

- Searching for users that are part of multiple Active Directory trees and forests.
- Authenticating users in the Cloud Manager, API Manager and the Developer Portal.

Note: API Connect LDAP referral support is dependent on the following conditions:

- A single LDAP host/port is configured with administrator credentials and all users are referred to from the tree/server's base DN.
- As part of the user search following the LDAP referral , the same administrator credentials are used in the downstream trees/forests.
- LDAP API authentication does not support external LDAP referral. Internal LDAP referral is supported.

Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service to manage user authentication, and to optionally provide additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs-in with user name: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes **cn=spoon,o=eatery**. The credential is kept in the OAuth **access_token** to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the **access_token**.
- Overriding the **scope** that the application receives after a successful OAuth protocol processing. By responding with a specific header, the Authentication URL endpoint can replace the **scope** value that the application receives. For example, you can provide a specific resource owner an account number within the **scope** header response for use in future processing steps.

When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect will use **cn=spoon,o=eatery** as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
```

`X-API-Authenticated-Credential: cn=spoon,o=eatery`

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see User Security policy.

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see Example - using multiple OAuth policies in an OAuth provider assembly.

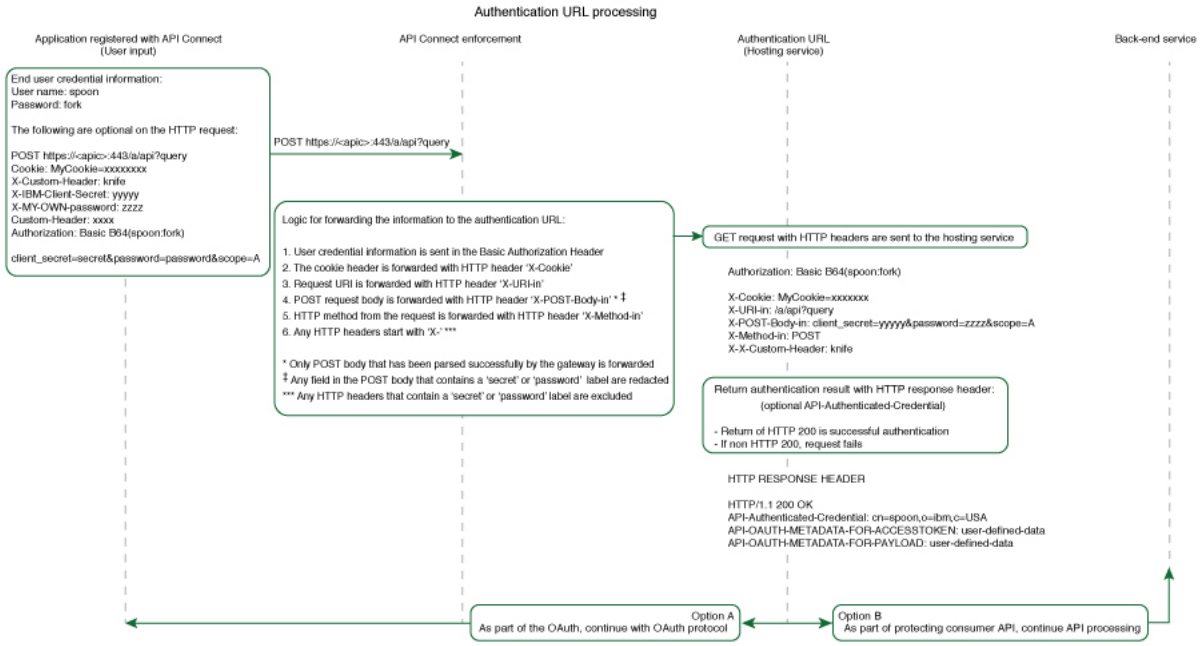
API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see OAuth external URL and authentication URL. The two metadata response headers are:

`API-OAUTH-METADATA-FOR-ACCESSTOKEN`
`API-OAUTH-METADATA-FOR-PAYLOAD`

When an Authentication URL is invoked, an HTTP response header is available to override the requested `scope` from the application. For more information, see Scope. The response header is:

`x-selected-scope`



If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Activating an API

After you have created an API definition you can activate it to auto-publish your API document and make it available for testing.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you activate an API, API Connect automatically completes the following actions:

- Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title *api_title* auto product. Note that if you later want to delete the draft Product, you cannot delete it directly; instead, delete the API and the draft Product is deleted together with the API; see Deleting an API definition. If you want to remove the Product from any Catalogs to which it is published, you must do this separately; see Removing a Product from a Catalog
- Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.

To activate an API, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Note:

- The API activation will not complete successfully if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to activate an API they must be disabled; for information on lifecycle approval settings, see Creating and configuring Catalogs.
- To activate an API from the API Designer user interface, you must be connected to a Management server; API activation is not available with API Designer in offline mode. For more information, see Logging in from API Designer.
- Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0,
col: 0)
400
```

Procedure

To activate an API and auto-publish your API document, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Under Testtab, click Target Configuration. The Preferences page opens.
4. Set the Auto-publish toggle to the On position: 
Results

On successful completion, the API is shown as On: 
You can stop the API by moving the activation slider control to the Off position:

If you stop an API, the application subscription is deleted, and the auto Product is removed from the Sandbox Catalog.
Note: You can select a Catalog of your choice, or you can opt to use the Sandbox Catalog by selecting **Use the default built-in Sandbox Catalog**. For more information, see Specifying the testing preferences for an API.
If you make a change to the API, it is republished automatically, You can also republish a running API manually by stopping it and then re-activating it.

The error indicator shows whether there are validation errors in the OpenAPI source for the API definition. If there are errors, click the icon for more details:

You can also activate an API during the creation process, and on the API test page; see Creating an API definition and Testing an API.

Note: If an OpenAPI 3 API contains a response wildcard (which is not supported), publishing is disabled for that API. You must correct the problem before you can publish the API.

Testing an API

Select a test tool and verify that your API works as you intended.

Before you publish an API where customers can access it, you need to test it and ensure that it is defined and implemented correctly. API Connect offers tools for running both simple and complex tests, in different environments. Use the following list of options to choose the test tool that best meets your needs:

- Execute and debug the API in the Test tab
  On the Test tab, you can quickly invoke your API from the API Connect UI with minimal preparation. The Test tab offers full control over the API call through a simple set of fields where you can define your request. The response includes both a visual flow diagram and a code trace that shows how the API's process flow is executed. Note: the Test tab tool is only available to APIs that use the DataPower API Gateway.
- Call the API externally from the Automated API behavior testing application as explained in Testing an API with Automated API behavior testing
  Automated API behavior testing provides a simple set of fields where you can quickly invoke your API. You can automate tests and define schedules for running them. You can even set up API monitoring and receive alerts on your API health before issues occur.
- Call the API from a local test environment
  The Local Test Environment is a lightweight API Manager, running on your computer, that allows you to rapidly test APIs without connecting to an API Connect management server.
- Run a simple test in the Policies editor
  Note: The Test panel is deprecated and might be removed without warning.
- Use the Try it tool in the Explorer tab to run simple tests
  You can use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can check the descriptions of the different artifacts, and review any schemas or examples, and you can also use the Try it tool to test the behavior of the API.

Note: Due to CORS, when a test call is made with a browser-based API test tool, an HTTP OPTIONS call is made to the API first. The OPTIONS call:

- Does not use any credentials, so is not attributed to any consumer organization.
- Is logged as an API event in the analytics data. Because the OPTIONS call does not use credentials, the API events are only visible in analytics data in the Cloud Manager and API Manager UIs. The OPTIONS events are not visible in the developer portal analytics view, which includes only analytics data for a single consumer organization.
- Is not included in consumer rate limits.
- Is included in consumption-based licensing (if used).

- **Locating API information on the Endpoints tab**
  The assembly tool's Endpoints tab opens a page that displays information for use when you call APIs externally. This tab displays only when an API's status is Online (the API was activated).
- **Using the Test tab to debug your API**
  Use the Test tab to execute calls and trace the API's actions in API Connect.
- **Testing an API with Automated API behavior testing**
  Use the IBM Automated API behavior testing application to invoke an API from outside of the API Connect Assembly page so that you can verify that it executes properly.
- **Testing an API with the Policies editor**
  IBM API Connect provides a basic test environment in the Policies editor so that you can ensure that your APIs are defined and implemented correctly.
- **Testing an API with the Local Test Environment**
  Use the Local Test Environment to test APIs on your local machine, without the need to connect to an API Connect management server. The Local Test Environment is a lightweight API Manager running on your local machine. It allows you to rapidly test APIs locally.
- **Testing an API with the Explorer tab**
  Use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can also use the Try it tool to test the behavior of the API.

Locating API information on the Endpoints tab

The assembly tool's Endpoints tab opens a page that displays information for use when you call APIs externally. This tab displays only when an API's status is Online (the API was activated).

Use the Endpoints tab to retrieve information that you can use when you call the API from an application.

Note: The fields in the Sandbox Sample Application Credentials section apply to the assembly tool's built-in client application and not to any application that you created. The credentials that display here are the default credentials that display in the assembly tool Test panel's "Identification" section.

To copy information from the Endpoints tab, click next to a field.

The following values for the API are displayed in the Endpoints tab so that you can copy them and paste them into calls:

Base API Endpoint
: The URL representing the endpoint of the API that you are editing and testing. To invoke the API, append one of its supported queries (path and parameters) to this URL.

Client ID and Client Secret
: The values of the built-in test application's client ID and client secret. You can invoke APIs externally by providing the application's credentials in the request header.

OAuth Token URL
: If you specified an OAuth provider in the API's security definition, then this field displays the URL where you can obtain an access token for calling the API.

OAuth Auth URL
: If you specified an OAuth provider in the API's security definition, then this field displays the URL where you can submit an access token and receive an authorization token in exchange. You then use the authorization token when calling the API.

Rate Limit
: If you specified a rate limit on the Security panel when you created the API, the limit is displayed here for reference. If you did not specify a rate limit, the default rate limit displays.

Using the Test tab to debug your API

Use the Test tab to execute calls and trace the API's actions in API Connect.

The Test tab not only lets you quickly invoke an API with any needed headers and parameters, but lets you view the content of the response in both parsed and raw format. Additionally, you can view a trace of the actions execute as the API's process flow operates to complete the call. Viewing the trace can help you debug problems with the API's execution.

Note: The Test tab tool is only available to APIs that use the DataPower API Gateway.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Complete the following tasks to prepare your API for testing, execute requests, and debug responses.

1. Preparing an API for debugging with the Test tab
   Ensure that your API's definition meets the requirements for debugging it in the API Connect Test tab.
2. Specifying the testing preferences for an API
   By default, when you test an API with the Test tab, a range of test parameters are preconfigured. For example, a default Product is automatically generated, to which the API is added, and that Product is published to the Sandbox Catalog. However, you can configure testing preferences for each of your APIs, including the required Product and target Catalog.
3. Sending the API request
   Fill in fields to set up the request for an API that you want to debug on the Test tab.
4. Reviewing the API response and trace
   Review the response to an API that was invoked in the API Connect Test tab. You can use the included trace information to debug the API's execution.
5. Testing a GraphQL API with the Test tab
   For a GraphQL API definition, the Test tab contains a GraphiQL editor. You can use the GraphiQL editor to help construct a GraphQL query. When you test your GraphQL API, the response is displayed in the GraphiQL editor.

Preparing an API for debugging with the Test tab

Ensure that your API's definition meets the requirements for debugging it in the API Connect Test tab.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To invoke your API in the Test tab, the following requirements must be satisfied:

The DataPower API Gateway is configured to support the API probe
: To enable the Test tab's trace feature, the DataPower API Gateway must be configured to support gateway peering and the gateway probe. In a gateway service running in Kubernetes, the API probe is automatically enabled. In a gateway service running external to Kubernetes, the DataPower configuration must be added to the application domain supporting API Connect. Check with your administrator to confirm that gateway peering and the gateway probe are enabled as explained in Configuring DataPower API Gateway.

The API uses the DataPower API Gateway
: A gateway exposes APIs to calling applications, and provides processing actions that enable the APIs to integrate with various endpoints. API Connect supports two versions of the DataPower Gateway, but you can only debug APIs that use the DataPower API Gateway. The v5-compatible gateway is not supported. If your API definition has CORS enabled but you cannot see the Test tab, the API is probably configured to use the wrong version of the gateway.
You can determine which gateway your API uses by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click Develop, then select the APIs tab.
3. Click the title of the API you want to test.
4. On the API's Design page, locate the Gateway field and note which option is selected.

You can change the gateway selection for an API on the Design page, but you must ensure that the policies used in the API's process flow are compatible with the new selection. For information on changing the gateway for an API, see Specifying the gateway type for an API definition.

CORS is enabled in the API definition
: Cross-Origin Resource Sharing support ensures that the API can be accessed from another domain. CORS support must be enabled for your API to be properly invoked and traced. If your API uses the API Gateway but you cannot open the Test tab, it's possible that CORS was not enabled in the API definition.
You can enable CORS for you API by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click Develop.
3. On the Develop page, click the name of the API you want to test. The API's Design page appears.
4. Under the Gateway tab, locate the CORS field and select it to enable support.
5. Click Save in the page header.

The API is published in the Sandbox catalog with the default Product/Plan, or a specified catalog and Product/Plan
: By default, when you test an API with the Test tab, a default Product/Plan is generated for the API and published to the built-in Sandbox Catalog. However, you can optionally specify a range of API testing preferences including an alternative Product/Plan, and target Catalog; for more information, see Specifying the testing preferences for an API. When you publish (activate) an API, the API is enabled online and becomes available for use. You cannot execute an offline API, even for testing purposes. You can set an API online by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click Develop.
3. On the Develop page, click the name of the API you want to test.
4. In the Design page header, click the settings icon . The **Preferences** page appears.
5. Set the Auto-publish toggle to On position.

Next topic: Specifying the testing preferences for an API

Specifying the testing preferences for an API

By default, when you test an API with the Test tab, a range of test parameters are preconfigured. For example, a default Product is automatically generated, to which the API is added, and that Product is published to the Sandbox Catalog. However, you can configure testing preferences for each of your APIs, including the required Product and target Catalog.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: This feature is not available if you are using the Local Test Environment.

Procedure

1. Open the required API for editing, in either of the following ways:
   - During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
   - To open an existing API for editing, complete the following steps:
     - In the navigation pane, click Develop, then select the APIs tab.
     - Click the title of the API version that you want to work with.
2. Under the Test tab, click Target Configuration.
   The Preferences page opens.
3. Use the Edit links to configure the following testing preferences, as required:

   Auto-publish

In order to execute an API for testing purposes, you must make it online. To make the API online and auto-publish your API document, set the Auto-publish toggle to the On position.

Target catalog
: The Catalog to which you want to publish the Product that contains the API. The selected Catalog is used as the scope for the other preference settings. You can select a Catalog of your choice, or you can opt to use the Sandbox Catalog by selecting Use the default built-in Sandbox Catalog.

Target Gateway service
: The gateway service to which you want to publish the Product that contains the API.

Target product
: The Product that will contain the API; you can select any of the Products from the selected Target catalog, or you can opt to use an automatically generated Product by selecting Generate Product on Save. The auto-generated Product has the title *api_title* auto product.

Target product rate limit
: If you opted to use an automatically generated Product, you can configure a rate limit to control calls to the API. If you selected your own Product, the Target product rate limit option is not available; instead, the rate limits that are configured in the selected Product and Plan are applied.

Target Plan
: The Plan in the selected Product that you want the test application to subscribe to. If you opted to use an automatically generated Product, the Target Plan option is not available; instead, the application is subscribed to the Default Plan in the automatically generated Product.

Test application
: The application that you want to subscribe to the selected Plan. You can select an application of your choice or, if you opted to use the Sandbox Catalog, you can instead use the pre-supplied test application by selecting Use the built-in Test Application.

Test Consumer Org
: The consumer organization that you want to subscribe to the selected Plan. If you selected your own application, the consumer organization is preset to that which contains the application, and cannot be changed. If you opted to use the pre-supplied test application you can, if required, select a consumer organization of your choice.
Click Reset to reset preferences to the default values.

4. Click Save Preferences when done.
   The Test page header displays the following details:
   - The target catalog.
   - The target gateway services.
   - The target product associated with the current API.
   - If the current status of API is Online or Offline. You can configure this in the API's Design page header.

Results

The next time you bring the API online, the API is published as specified by the preference settings, ready for testing.
Note: These settings are stored in your browser's local storage and will be used for your API testing in subsequent sessions. The following settings are specific to each individual API:

- Target product
- Target product rate limit
- Target Plan

The remaining settings will be applied to all your APIs.
Previous topic: Preparing an API for debugging with the Test tab
Next topic: Sending the API request

Sending the API request

Fill in fields to set up the request for an API that you want to debug on the Test tab.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Open the Test tab

1. Log in to API Manager or API Designer.
2. In the navigation list, click Develop, then select the APIs tab.
3. Click the title of the API you want to test.
4. On the API Design page, click the Test tab in the page header.

Fill in the "Request" section

Use the Request section of the page to set up the request URL, the authentication mechanism, and the request parameters. Complete the following steps to fill in the fields needed for configuring the request.

Note: The Test tab does not support vanity endpoints; you must specify the gateway endpoint at which the API is invoked. The **Request** field uses the gateway endpoint by default.

1. Select an operation and request URL from the list provided.
2. On the Parameters tab, define header, query and path parameters.
   An empty row is provided for you to define parameters; enter the parameter name in the Key field, select query, header, or path in the Located in field as appropriate, and supply a string value in the Value field. As you begin to define a new parameter, a further empty row is added automatically.

   Default header parameters and values are provided. For example, if the API has client ID or client secret definitions applied, the corresponding keys are added as header parameters, with the values preset; for details on configuring client ID and client security definitions, see Creating an API key security definition.

   The following table lists some common header definitions that are used in a request:

Table 1. Common request headers

Key	Value	Comments
Accepts	*media_type/sub type*	Specify the type of content that the response headers should use. The default is `application/json`.
X-IBM-Client-Id	*client_ID_val*	If you are using the built-in test application in the Sandbox catalog, the value is pre-populated automatically. If you are using your own client application, replace the value with the client ID of your application.
X-IBM-Client-Secret	*client_secret_val ue*	If you are using the built-in test application in the Sandbox catalog, the value is pre-populated automatically. If you are using your own client application, replace the value with the client secret of your application..
Authorization	Bearer *access_token*	Encode the token in base64. API Connect cannot encode the token for you.
Content-Type	*media_type/sub type*	Specify the type of content that the response body should use; for example, `application/json` or `image/png`.

If the API has path or query parameters defined, these are added to the parameters list, ready for you to supply values; for details on configuring path and query parameters, see Defining Paths for a REST API and Configuring an operation.

3. If your API definition uses Basic authorization for the security setting, click the Authentication tab and provide the User name and Password needed for authenticating with the user registry.
   When you invoke the API, API Connect populates a header using the provided information.

   If you API definition does not use Basic authorization, the Authentication tab is not available.

4. If the operation is POST or PUT, set up the request body.
   a. Click the Body tab.
   b. Type the information for the body of the request.

Send the request

When your API request is configured, click Send to execute the call.

If a message displays indicating "No Response", the API call cannot be completed. Possible causes of this problem are as follows::

- CORS is not enabled in the API's definition
  Edit the API's definition and enable CORS. Then, save the change and publish the API. If you are using your own client app, remember to subscribe it to the API again after publishing.
- The gateway service URL has an invalid certificate
  Follow the instructions to accept the certificate and continue testing.
- The browser cannot connect to the gateway service

Previous topic: Specifying the testing preferences for an API
Next topic: Reviewing the API response and trace

Reviewing the API response and trace

Review the response to an API that was invoked in the API Connect Test tab. You can use the included trace information to debug the API's execution.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When the API request is invoked, the response displays in the "Response" section of the Test tab. The response always includes the HTTP status code the amount of time it took to receive a response. If the call completes (even if it returns an error), the response also includes headers and a body.

Click the Body tab to see the body of the response. When you review the body of the response, click the Parsed tab to view the response using the format that you specified in the "Accepts" request header. Click the Raw tab to view the unformatted response body.

Click the Headers tab to see the content of request headers and response headers.
Attention: If the assembly or back-end API returns a Cache-Control header, add the `Cache-Control: no-store` request header to prevent the browser from caching the request. Depending on your server, you might want to use the `Cache-Control: no-cache` header instead.
Click the Trace tab to display a record of the API execution so you can see what actions were triggered and the code that we executed for each action.

Examine the trace

Use the Trace tab to see exactly how the API call was executed. This is helpful when the call returned an error and you don't know why. You can debug the API by reviewing the trace to see each step of the API's execution.

Note: The Trace works only with the default Gateway's URL. You cannot select a different Gateway for the trace.
The Trace tab contains the following components to help you debug the API:

Process flow diagram
: In the diagram, the policies (actions) that were executed during the call are highlighted while the rest of the process flow is dimmed. The highlights make it easy to see where the executed actions occurred in the overall flow while clarifying the actual flow of execution for the call. For example, if the process flow includes a switch with three options, only the option that was selected during the call is highlighted.

Policies list
: A list of the highlighted policies lets you select a policy to examine its trace.

Advanced toggle
: The Advanced toggle that lets you control the level of detail in the trace. A basic trace shows the code for the input and output of the selected policy. An advanced trace shows the full code for the policy's execution.

Code box
: The selected level of code for the current policy displays in the code box, where you can review it in detail to see exactly how that policy was executed. By default, a minimal version of the response displays (the endpoint, the request, and the response, and the status message), with sections collapsed. You can expand individual sections by clicking the expand icon next to each. To see the complete response, click the Advanced toggle.

Previous topic: Sending the API request
Next topic: Testing a GraphQL API with the Test tab

Testing a GraphQL API with the Test tab

For a GraphQL API definition, the Test tab contains a GraphiQL editor. You can use the GraphiQL editor to help construct a GraphQL query. When you test your GraphQL API, the response is displayed in the GraphiQL editor.

You can test a GraphQL query in either of the following ways:

- Use a **`POST`** operation, in which case the query is sent in the body of the operation request.
- Use a **`GET`** operation, in which case the query is sent as a query parameter.

For each operation type, you can test the query against either the GraphQL API endpoint itself, or against the cost endpoint that returns details of the cost of a request to the GraphQL API endpoint.

Whichever method and endpoint you use, you can either supply the query directly, or you can use the GraphiQL editor to help construct the query; the editor provides type ahead assistance based on the schema that is defined for the API, and highlights errors along with correction suggestions. The schema was initially uploaded when the GraphQL API definition was created, but might have been modified subsequently. For details on creating a GraphQL API definition, see Creating a GraphQL proxy API. For details on modifying the schema, see Using the GraphQL schema editor.

Before you begin

See Preparing an API for debugging with the Test tab for the requirements that your API definition must meet for you to test it with the Test tab.

Procedure

1. In the Request section, select the required operation type and endpoint; for example:
   - **`POST https://myserver.com/myorg/sandbox/mybasepath/graphql`**
   - **`GET https://myserver.com/myorg/sandbox/mybasepath/graphql/cost`**
2. On the GraphiQL tab, in the left hand pane of the editor, supply the query; for example:

```
{
  accounts(limit: 100) {
    name {
      first
      last
    }
  }
}
```

3. If required, you can supply additional request headers on the Parameters tab.
4. If your query includes variables, you can supply values for the variables in the Query Variables pane. For example, if the query is as follows:

```
query MyQuery($Query__accounts__limit: Int)
{
  accounts(limit: $Query__accounts__limit) {
    name {
      first
      last
    }
  }
}
```

   you can set a value for the **`Query__accounts__limit`** by entering the following in the Query Variables pane:

```
{
  "Query__accounts__limit": variable_value
}
```

   where *variable_value* is the required value.
5. Click either Send, or the Execute Query icon ▶ in the editor. The response is displayed in the GraphiQL editor, and the Trace section shows you how the API call was executed. For details on the trace information, see Examine the trace.

Previous topic: Reviewing the API response and trace

Testing an API with Automated API behavior testing

Use the IBM® Automated API behavior testing application to invoke an API from outside of the API Connect Assembly page so that you can verify that it executes properly.

Automated API behavior testing provides a simple set of fields where you can quickly invoke your API. You can automate tests and define schedules for running them.

Automated API behavior testing is an optional add-on to API Connect, and must be deployed by your administrator. If Automated API behavior testing is available in your deployment, a Test API displays on the Home page in API Manager.

Known limitations:

- AutoTest Assist is only available in Cloud Pak for Integration 2022.2.1 and later.
- Insights-Driven Test Generation is only available in Cloud Pak for Integration 2021.2.1 and later.

The following OpenAPI 3.0 features are not currently supported in Automated API behavior testing, but their usage doesn't impact on any other supported features:

- The `links` object; allows developers to describe how various values returned by one operation can be used as input for other operations.
- The `callbacks` object; enables asynchronous, out-of-band requests that your service sends to some other service in response to certain events.
- The `oneOf` keyword for defining complex schemas; allows developers to define more sophisticated validation rules. Automated API behavior testing doesn't generate a valid test for this keyword.

Note that you can add checks for missing assertions manually by using the `Add Request/Assertions` option.
If you want to use Automated API behavior testing for validating an API, complete the following steps to get started.

1. Log in to API Manager.
2. Publish your API to make sure that it's available online.
3. Create a client application and copy its client ID and client secret.
4. Subscribe the client app to the API.
5. Open the Test application.
    - Cloud Pak for Integration only: Click Design in the page header, and then click Test APIs; or
    - All users: Click API Manager in the banner to return to the Home page, and then click the Test API tile.

Getting started

The Automated API behavior testing interface provides collaborative and powerful API testing capabilities.

- **Create automated and simple to use API tests quickly and easily.**
    - Produce high quality APIs consistently, with automated and simple to use API testing that you can rely on.
- **Intelligent validation of API payload accuracy.**
    - Add more intelligence to your tests to verify the accuracy of the payload. You can easily make logical assertions to create flexible and powerful conditions for validation, with no code necessary.
- **Collaborative testing.**
    - Accelerate your API development and testing, by sharing your tests and results.
- **Easily integrate into your CI/CD pipeline to execute tests as part of your deployment.**
    - Create API Hooks to allow your tests to be run via the command line and become part of your automated build processes.
- **No code necessary.**

How to get started

Creating a test involves the following steps:

1. Creating a test suite
2. Creating test cases in a test suite
3. Defining variables
4. Running the test
5. Publishing the test

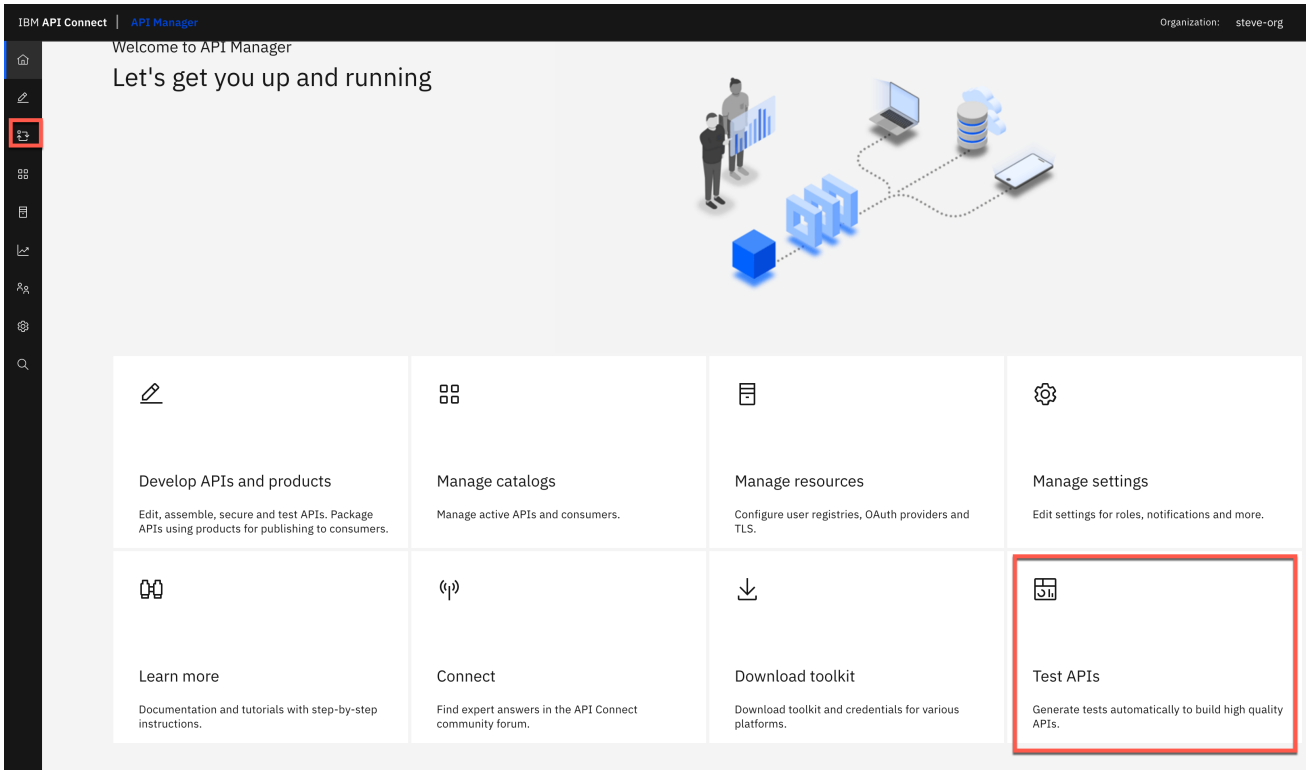
Explore the following tasks for detailed instructions:

- Creating a test suite
- Modifying a test suite
- Deleting a test suite
- Creating a test case
- Modifying a test case
- Defining variables
- Deleting a test case
- Running a test case
- Viewing the test report
- Publishing a test

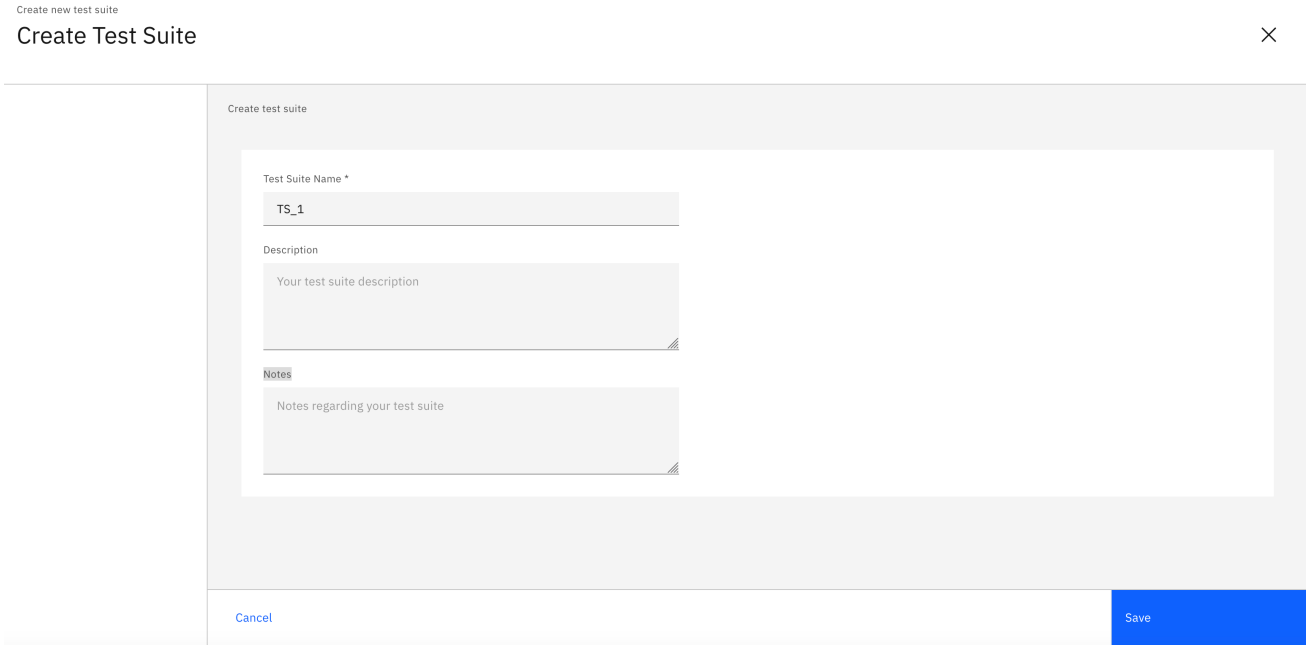
Creating a test suite

The following instructions show you how to create a test suite using the **API Manager**.

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.



3. On the Test page, click **Add test suite**.



4. In the Create Test Suite page, enter a test suite name, description, and any relevant notes for the test suite.
5. Click **Save**. Once the test suite is created, you can add multiple test cases.

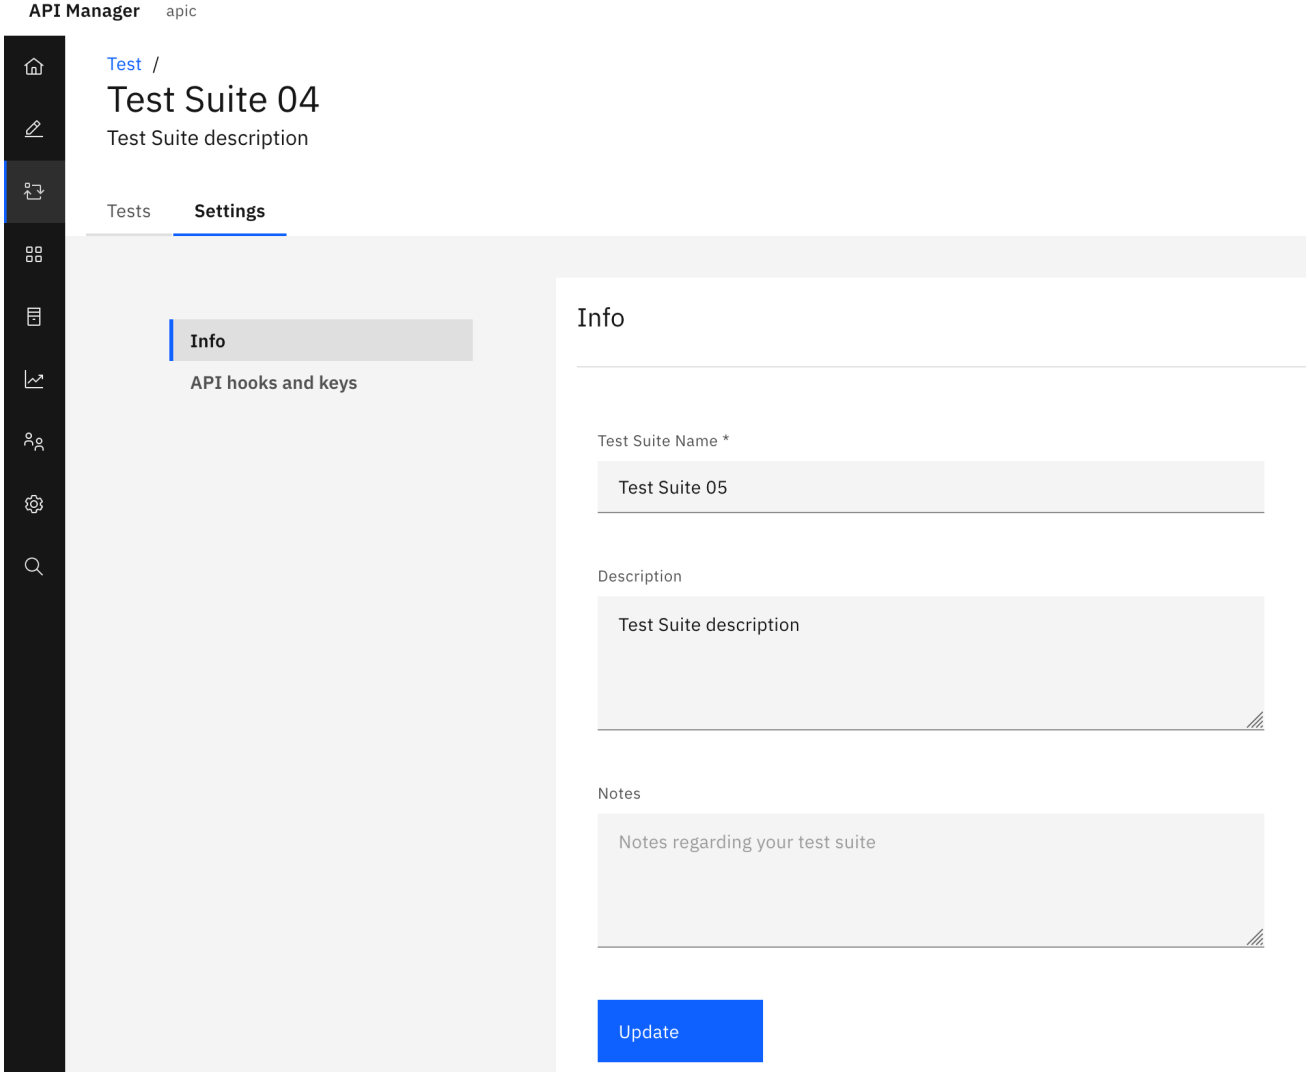
What to do next

- Next topic: Creating a test case

Modifying a test suite

The following instructions show you how to modify a test suite using the **API Manager**.

1. Log in to the API Manager.
2. Click the Test APIs tile.
3. Select a test suite to modify.
4. Go to the **Settings** tab.



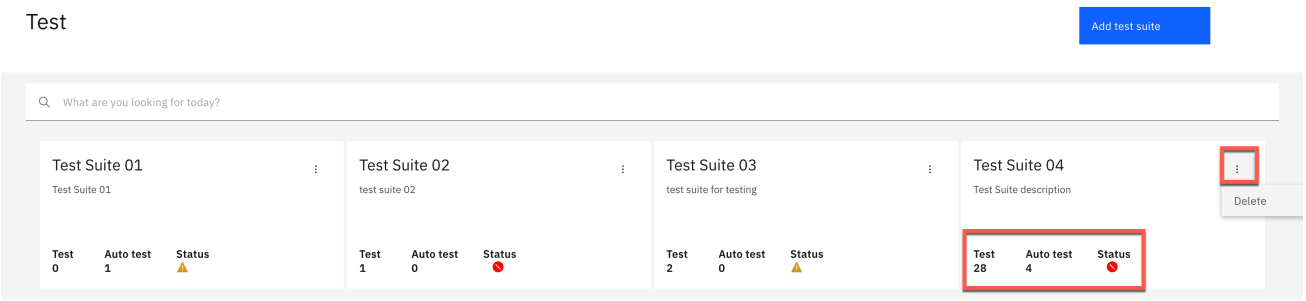
5. In the **Info** tab, update the following:
   - Test Suite Name
   - Description
   - Notes
6. Click **Update**.

- Next topic: Modify a test case

Deleting a test suite

To delete a test suite, complete the following steps:

1. Login to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, locate the test suite you want to delete and determine whether it contains any tests by observing the displayed **Test** count.



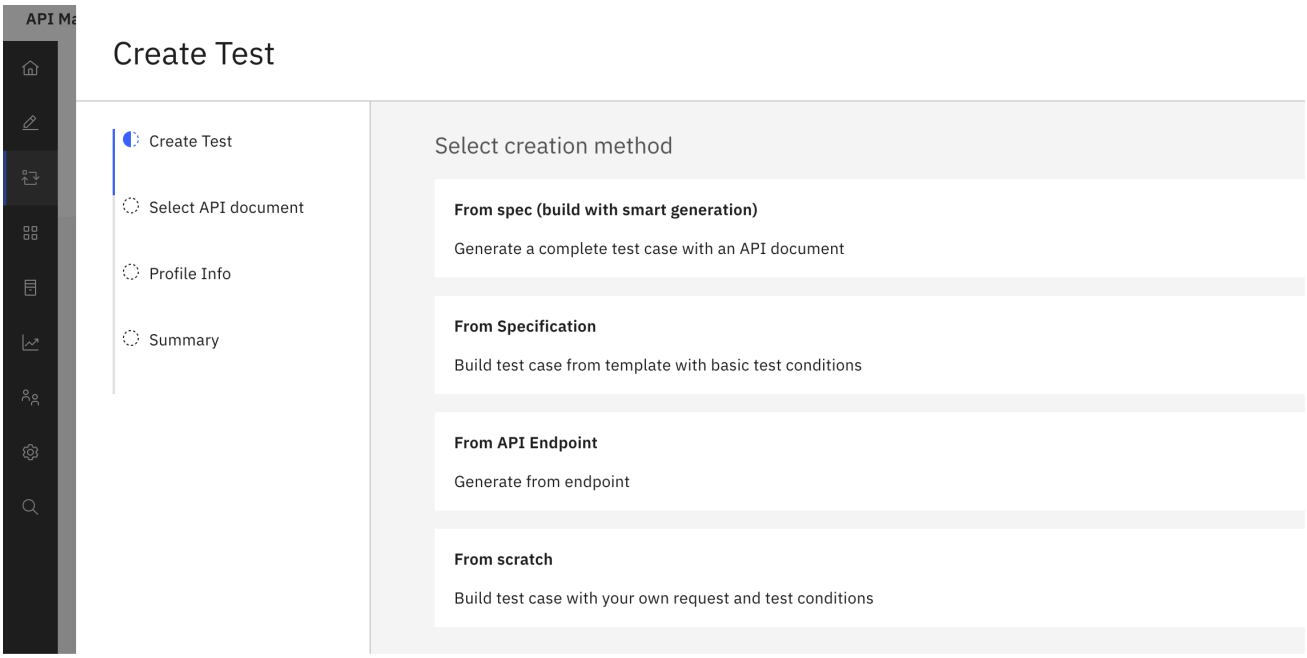
Note: You can't delete a test suite that contains tests, so if your test suite does contain any tests you must delete them first; see Deleting a test.

4. To delete the test suite, click its **Options** icon, then click **Delete**.

Creating a test case

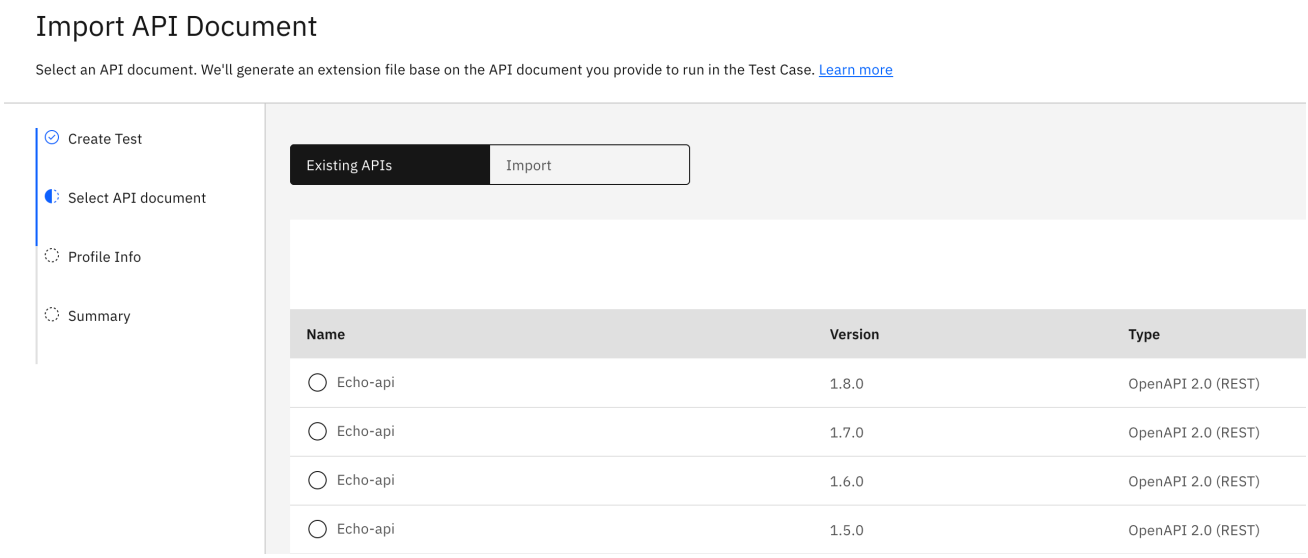
The following instructions show you how to create a test case using the **API Manager**.

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. In the Create Test page, go to the **Tests > Test Cases** tab, and click **Add**.
5. Select a test case creation method:



- From spec (build with smart generation): This feature is available only in *API Connect Enterprise as a Service.* The application generates a complete test case that leverages NLP to help developers and QAs test their APIs effectively in an efficient way.
- From Specification: Builds test case from OpenAPI specification
- From API Endpoint: Generates test case from a specified endpoint
- From scratch: Creates a test case with your own request and test conditions

6. If you selected **From spec (build with smart generation)**, click **Next**, then perform one of the following steps:



1. Go to the **Existing APIs** tab:
    1. Select a predefined API.
    2. Click **Next**.
    3. Select a path.
    4. Enter the API name.
    5. Provide a brief description.
    6. Add tags.
    7. Click **Next**. You will see the message that the test case has been generated.
    8. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
    9. Click **Save**.
    10. Click **Run Test**.
2. Go to the **Import** tab, do one of the following:
    - Drag and drop a JSON or YAML file that has the API test case definition OR
    - Enter an URL for the API test case. Provide username, and password if required, for authentication.
    1. Click **Next**.
    2. Select a path.
    3. Enter the API name.
    4. Provide a brief description.
    5. Add tags.
    6. Click **Next**. You will see the message that the test case has been generated.
    7. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
    8. Click **Save**.
    9. Click **Run Test**.
