

*IBM API Connect 2018.x*

**IBM**

---

# Tables of Contents

<b>Welcome</b>	1
<b>API Connect overview</b>	2
What's new in the latest release (Version 2018.4.1.24)	3
What's new in Version 2018.4.1.20	4
What's new in Version 2018.4.1.19	4
What's new in Version 2018.4.1.17	4
What's new in Version 2018.4.1.16	5
What's new in Version 2018.4.1.15	5
What's new in Version 2018.4.1.13	6
Version 2018.4.1 known limitations	6
Available deployment options of API Connect	11
API Connect concepts	12
Packaging strategy and terminology in API Connect	12
Understanding rate limits for APIs and Plans	15
API Connect components	16
API Connect: End-to-end solution example	18
API Connect gateway types	20
API Connect user roles	20
API Connect support	24
API Connect glossary	25
Accessibility features for IBM API Connect	27
Legal information	28
License updates	28
Tracking API volume for auditing and compliance	28
Notices	29
Terms and conditions for information centers	30
IBM API Connect Considerations for GDPR Readiness	31
Essential reading	33
<b>Tutorials</b>	34
<b>Installing and maintaining your IBM API Connect cloud</b>	35
Kubernetes	36
Installing and upgrading on Kubernetes	36
IBM API Connect Version 2018 software product compatibility requirements	36
Estimating internal storage space for Analytics	37
Working with certificates	39
Certificate management: Read This First	39
Setting and managing certificates	40
Setting default certificates	40
Setting custom certificates	42
Replacing custom certificates	44
Setting common certificates	45
Setting the encryption-secret for the management database	45
Clearing certificates	46
Reference for certificates, commands, and validations	46
Certificate reference	46
Command reference	50
Validation reference	52
Tips and tricks for using APICUP	53
Deploying to a Kubernetes environment	56
Requirements for a Kubernetes deployment	56
Requirements for deploying IBM API Connect into a Kubernetes environment	56
Deployment overview for endpoints and certificates	59
Firewall requirements on Kubernetes	60
Kubernetes ingress controller prerequisites	63
Load balancer configuration in a Kubernetes deployment	64
Configuring logging for a Kubernetes deployment	66
Installing API Connect into a Kubernetes environment	66
First steps for installing API Connect: Upload files to registry	67
Installing the Management subsystem into a Kubernetes environment	69
Installing the Analytics subsystem into a Kubernetes environment	73
Installing the Developer Portal subsystem into a Kubernetes environment	77
Defining multiple portal endpoints for a Kubernetes environment	80
Installing the Gateway subsystem into a Kubernetes environment	80
Deploying pods to specific worker nodes in a multi-node cluster	83
Manually creating a CustomResourceDefinition in a Kubernetes environment	85
Creating an extra values file in a Kubernetes environment	86
Configuring user-defined policies on the API Gateway in a Kubernetes deployment	88
Installing the toolkit	90
Upgrading API Connect in a Kubernetes environment	91
Requirements for upgrading	92

Requirements for upgrading from v2018.4.1.8 or later	92
Requirements for upgrading from v2018.4.1.5, v2018.4.1.6, or v2018.4.1.7	93
Requirements for upgrading from Version 2018.4.1.4 or earlier	94
Upgrading API Connect subsystems	95
Adding a monitor pod during gateway upgrade	97
Verifying Portal upgrade	98
Troubleshooting the upgrade	98
Deleting the API Connect deployment in a Kubernetes runtime environment	100
Maintaining a Kubernetes deployment	100
Backing up and restoring	101
Backing up the management database in a Kubernetes environment	101
Restoring the management database in a Kubernetes environment	103
Troubleshooting restoration of management database	105
Backing up and restoring the Developer Portal in a Kubernetes environment	109
List of the Developer Portal exec commands	111
Backing up and restoring the analytics database	112
Adding certificates for Analytics for back-up and restore	115
Using APICUP to reconfigure	116
Converting installation mode	117
Converting dev mode to standard mode on Kubernetes	118
Converting standard mode to dev mode on Kubernetes	119
Increasing the memory allocation for the management database	119
Enabling Analytics ingestion-only on Kubernetes	120
Disabling Analytics ingestion-only on Kubernetes	121
Configuring maximum size of client requests to the Management subsystem	121
Increasing memory allocation for Cassandra operator on OpenShift	122
Setting rate limits for public APIs on the management service for a Kubernetes environment	122
Enabling high performance peering for DataPower API Gateway on Kubernetes	123
Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment	124
Monitoring and logging a Kubernetes deployment	125
Checking cluster health on Kubernetes	126
Determining status of a cluster on Kubernetes	126
Obtaining simple health check data of Developer Portal sites by using a REST API call	128
Gathering logs for a Kubernetes environment	129
Changing logging levels	129
Disabling the Analytics subsystem on Kubernetes	130
VMware	131
Installing and upgrading on VMware	132
IBM API Connect Version 2018 software product compatibility requirements	132
Estimating internal storage space for Analytics	132
Working with certificates	134
Certificate management: Read This First	135
Setting and managing certificates	135
Setting default certificates	136
Setting custom certificates	137
Replacing custom certificates	139
Setting common certificates	140
Setting the encryption-secret for the management database	141
Clearing certificates	141
Reference for certificates, commands, and validations	142
Certificate reference	142
Command reference	146
Validation reference	148
Tips and tricks for using APICUP	149
Deploying to a VMware environment	151
Requirements for deploying on VMware	152
Deployment overview for endpoints and certificates	152
Firewall requirements on VMware	154
Firewall enabled ports for clustered OVA deployments	156
Load balancer ports for clustered OVA deployments	157
Requirements for initial deployment on VMware	157
Load balancer configuration in a VMware deployment	160
Configuring remote logging for a VMware deployment	163
First steps for deploying in a VMware environment	164
Deploying the Management subsystem in a VMware environment	165
Deploying the Analytics subsystem in a VMware environment	171
Deploying the Developer Portal in a VMware environment	176
Defining multiple portal endpoints for a VMware environment	182
Access the Cloud Manager and begin API Connect Cloud Configuration	183
Configuring API Connect subsystems in a cluster on VMware	183
Installing the IBM License Metric Tool for VMware	187
Adding a static route on a virtual machine	187

Configuring use of an external NTP server	188
Deploying DataPower Gateway	189
Installing DataPower Gateway	189
Configuring DataPower Gateway for API Connect	190
Configuring DataPower API Gateway	190
Configuring DataPower Gateway (v5 compatible)	193
Sample configuration for multiple peering objects on gateway services external to Kubernetes	195
Installing the toolkit	90
Upgrading in a VMware environment	200
Requirements for upgrading on VMware	201
Requirements for upgrading from v2018.4.1.8 or later on VMware	201
Requirements for upgrading from v2018.4.1.7 on VMware	202
Requirements for upgrading from v2018.4.1.5 or v2018.4.1.6 on VMware	203
Requirements for upgrading from v2018.4.1.4 or earlier on VMware	204
Upgrading API Connect subsystems in a VMware environment	206
Control planes needed for upgrading to earlier fix packs	210
Troubleshooting the API Connect upgrade on VMware	214
Upgrading DataPower Gateway Service	214
Maintaining a VMware deployment	215
Backing up and restoring	216
Backing up the management subsystem in VMware environments	216
Restoring a management subsystem in a VMware environment	218
Troubleshooting restoration of management database on VMware	220
Backing up and restoring the Developer Portal in a VMware environment	224
List of the Developer Portal exec commands	226
Backing up and restoring the analytics database	227
Adding certificates for Analytics for back-up and restore on VMware	230
Disabling the Analytics subsystem on VMware	231
Using VM snapshots for infrastructure backup and disaster recovery	232
Using APICUP to reconfigure	233
Converting installation mode	234
Converting dev mode to standard mode on VMware	235
Converting standard mode to dev mode on VMware	236
Increasing the memory allocation for the management database	236
Enabling Analytics ingestion-only on VMware	237
Disabling Analytics ingestion-only on VMware	238
Setting rate limits for public APIs on the management service for a VMware environment	238
Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment	239
Adding disk space to a VMware appliance	240
Running a filesystem check on a VMware root partition	241
Managing an appliance data disk	241
Troubleshooting the API Connect upgrade on VMware	214
Checking cluster health on VMware	243
Determining status of a cluster on VMware	243
Obtaining simple health check data of Developer Portal sites by using a REST API call	246
Monitoring the network with SNMP	246
Gathering logs for a VMware environment	247
Changing logging levels	248
IBM Cloud Private	249
Installing and upgrading on IBM Cloud Private	249
Deployment overview for endpoints and certificates	250
Deploying to an IBM Cloud Private environment	251
Deploying with the IBM Cloud Private catalog	251
Deploying with the Install Assist tool	254
Migrating an IBM Cloud Private catalog install to apicup	256
Installing the toolkit	90
Upgrading with IBM Cloud Private Catalog	258
Upgrading from Version 2018.4.1 with the IBM Cloud Private Catalog	258
Upgrading Version 2018.3.7 with the IBM Private Cloud Catalog	259
Backing up and restoring an IBM Cloud Private catalog deployment	259
Backing up and restoring the management database on IBM Cloud Private	259
Backing up and restoring the Developer Portal on IBM Cloud Private	260
OpenShift	261
Installing API Connect on OpenShift	261
Disabling the Analytics subsystem on OpenShift	263
IBM Cloud Pak for Integration	264
Backing up and restoring on Cloud Pak for Integration	265
Disabling the Analytics subsystem on Cloud Pak for Integration	265
Migrating a Version 5 deployment	266
Using the API Connect operations command line interface	266
Identify Services State	267
<b>Configuring and managing your server environment</b>	<b>267</b>

Activating your Cloud Manager user account	268
Accessing the Cloud Manager user interface	269
Defining your topology	270
Configuring the Management service	272
Creating an Availability Zone	272
Registering a gateway service	273
Registering an analytics service	275
Registering a portal service	276
Associating an analytics service with a gateway service	277
Setting visibility for a service	278
Managing authentication and security	279
User registries overview	279
Configuring an Authentication URL user registry	281
Configuring an LDAP user registry in the Cloud Manager	282
Using the CLI to configure a shared LDAP user registry	284
Configuring a Local User Registry	290
Configuring an OIDC user registry	291
Setting visibility for a user registry	295
Deleting a user registry	296
Removing a user from a user registry	297
Removing yourself from a user registry	297
Removing another user from a user registry	297
TLS profiles overview	298
Viewing TLS Profiles, Keystores, and Truststores	299
Creating a TLS Server Profile	300
Creating a TLS Client Profile	301
Setting visibility for a TLS Client Profile	302
Defining elliptic curve cryptographic schemes for a TLS client profile	302
Creating a Keystore	304
Creating a Truststore	304
Viewing certificate details and adding certificates to a keystore or truststore	305
Generating a self-signed certificate using OpenSSL	306
Generating a PKCS#12 file for Certificate Authority	307
Binding a TLS server profile to a gateway service	308
Updating the PKCS#12 certificate for a TLS server profile	308
OAuth Provider overview	309
Configuring a native OAuth provider	310
Configuring basic settings for a native OAuth provider	311
Configuring scopes for a native OAuth provider	312
Configuring user security for a native OAuth provider	313
Configuring tokens for a native OAuth provider	314
Configuring token management and revocation for a native OAuth provider	315
Configuring introspection for a native OAuth provider	316
Configuring metadata for a native OAuth provider	316
Configuring the OIDC parameters for a native OAuth provider	317
Editing a native OAuth provider by using the API Editor	318
Configuring a third-party OAuth provider	319
Setting the visibility for OAuth providers	320
OAuth concepts for API Connect	320
OAuth user scenario	321
OAuth introspection for third-party OAuth providers	321
OAuth metadata URL and authentication URL	323
Scope	326
Tokens	330
Refresh tokens	330
OAuth revocation URL	331
Authenticating and authorizing through a redirect URL	333
Token management with the DataPower Gateway (v5 compatible)	335
Token management with the DataPower API Gateway	337
Authentication URL	338
Custom forms for user security	339
Creating a custom HTML login form for user security	340
Creating a custom HTML authorization form for user security	341
Securing an API with a JSON Web Token	342
Troubleshooting OAuth	342
Configuring the cloud settings	343
Using the CLI to modify cloud settings	344
Change the name of your cloud	345
Configuring an email server for notifications	345
Setting up notifications	346
Customizing email notification templates	347
Configuring invitation timeouts	348
Configuring the password-reset notification and timeout	348
Selecting user registries for Cloud Manager and API Manager	349

Setting a default user registry for Cloud Manager and API Manager	350
Configuring timeouts for access tokens and refresh tokens	350
Viewing platform and UI endpoints	351
Configuring the default gateway services for Catalogs	351
Administering provider organizations	352
Creating a provider organization	352
Editing a provider organization	353
Deleting a provider organization	354
Viewing current provider organizations	354
Administering members and roles	355
Creating roles in the admin organization	356
Editing roles in the admin organization	356
Deleting roles in the admin organization	357
Viewing members and roles	357
Adding members to the admin organization	358
Assigning roles to members	359
Deleting a member	359
Role Defaults overview	360
Managing role defaults for provider organizations	360
Managing role defaults for consumer organizations	361
Monitoring the cloud	362
Counting total API calls for your Analytics service	362
Creating a script to count API calls	364
Customizing Analytics data with filters	365
Sample filters for customizing Analytics data	366
Configuring data retention and index rollover time periods	368
Configuring analytics offload for API Connect	369
Supported event types for analytics offload	370
Supported third-party systems for analytics offload	371
Providing a custom certificate for analytics offload	372
Configuring output plugins for analytics offload	373
Configuring the analytics message queue	376
Configuration files for analytics offload customization	376
Disabling access to analytics event data in API Connect	377
Troubleshooting your analytics offload	378
Configuring the audit log to track API calls	379
Configure the audit settings	381
Changing your Cloud Manager password and profile information	382
Resolving login problems by increasing HTTP header size	383
Extending the Gateway server behavior	384
Gateway extension guidelines - DataPower Gateway (v5 compatible)	384
Gateway extension guidelines - DataPower API Gateway	385
Configuring your Gateway server extensions	387
Cloud Manager Tutorials	388
Tutorial: Configuring the Cloud	389
Tutorial: Creating a Provider Organization	398
<b>Developing your APIs and applications</b>	<b>402</b>
Working with the toolkit	403
Installing the toolkit	90
Logging in from API Designer	404
Switching clouds from API Designer	406
Working offline with API Designer	406
Using the developer toolkit command-line tool	407
Overview of the command-line tool	407
Logging in to a management server	409
Cloud administration commands	410
API development and management commands	414
Creating APIs and applications	420
Publishing APIs and applications	421
Managing API Products	422
Working with Drafts	425
Reading input from the command line	425
Scripting with the toolkit commands	427
Working with OpenAPI extensions	428
Viewing application performance metrics	432
Viewing the application metrics dashboard	433
Viewing application metrics using third-party consoles	434
[Technical Preview] Searching for items in API Manager	436
Working with API definitions	439
Creating an API definition	439
Creating a REST proxy API from a target service	441
Creating a REST proxy API from an existing OpenAPI service	441
Creating a REST proxy API from an existing WSDL service	443
Creating a SOAP proxy API from an existing WSDL service	444
Creating a new REST OpenAPI definition	446

Adding a REST API by importing an OpenAPI definition file	446
Adding a SOAP API by importing a zip file	448
Editing an API definition	449
Defining Paths for a REST API	451
Configuring an operation	453
Organizing your APIs and Products into categories	454
Activity logging with the DataPower API Gateway	454
The Assemble view	455
Including components in your assembly	456
Adding components to your assembly	457
Handling errors in the assembly	457
Error cases supported by assembly catches	458
OpenAPI and assembly components	458
The behavior of an assembly	459
Creating a new version of an API definition	459
Specifying the gateway type for an API definition	460
Converting an API definition for deployment to the DataPower API Gateway	461
API properties	461
Setting API properties	466
Variable references in API Connect	467
Activating an API	470
Testing an API with the assembly test tool	471
Testing an API with the Local Test Environment	472
Staging an API	475
Publishing an API	476
Downloading an API definition	477
Deleting an API definition	478
Using an options file when importing a WSDL service	478
API policies and logic constructs	479
Built-in policies	480
Activity Log	481
Client Security	482
GatewayScript	483
GatewayScript code examples	484
Generate JWT	487
Validate JWT	489
Invoke	490
JSON to XML	494
Log	495
Map	496
The Map policy structure	496
Configuring the Map policy in the user interface	500
Map policy examples	503
OAuth	506
Example - using multiple OAuth policies in an OAuth provider assembly	508
Parse	511
Proxy	512
Rate Limit	514
Configuring a rate or burst limit on the DataPower API Gateway	514
Redaction - DataPower API Gateway	515
Constructing JSONata expressions to redact fields	516
Redaction - DataPower Gateway (v5 compatible)	518
Constructing XPath expressions to redact fields	519
Set Variable	521
User Security	522
Validate - DataPower API Gateway	524
Validate - DataPower Gateway (v5 compatible)	525
Validate Username Token	526
XML to JSON	528
XSLT	529
XSLT policy examples	530
Implementation code examples	533
Logic Constructs	538
if	538
operation-switch	539
switch	540
Using the switch policy condition editor	540
throw	543
Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway	543
Tags in API Connect	546
Configuring API security	547
Creating a security definition	548
Creating a basic authentication security definition	548

Creating an API key security definition	549
Creating an OAuth security definition	550
Applying security definitions to an API	551
Applying security definitions to an API operation	552
Enabling CORS support for an API	553
LDAP authentication	553
Authentication URL user registry	555
Working with Products	556
Creating a draft Product	557
Downloading a draft Product	559
Importing a draft Product	559
Editing a draft Product	560
Defining rate limits for an API operation	562
Staging a draft Product	563
Publishing a draft Product	564
Creating a new version of your Product	565
Specifying the gateway type for a Product	566
Deleting a draft Product	566
Creating and validating API and Product definitions by using the CLI	567
Creating an OpenAPI definition file	567
IBM extensions to the OpenAPI specification	568
execute	569
activity-log	571
client-security	572
gatewayscript	573
if	574
invoke	575
json-to-xml	578
jwt-generate	579
jwt-validate	581
log	582
map	583
operation-switch	587
oauth	589
Example - using multiple OAuth policies in an OAuth provider assembly	508
parse	593
proxy	595
ratelimit	596
redact - DataPower API Gateway	597
redact - DataPower Gateway (v5 compatible)	598
set-variable	600
switch	601
Writing switch condition scripts - DataPower API Gateway	602
Writing switch condition scripts - DataPower Gateway (v5 compatible)	604
throw	605
user-security	606
validate - DataPower API Gateway	608
validate - DataPower Gateway (v5 compatible)	610
validate-username token	611
xml-to-json	612
xslt	613
catch	613
properties	614
catalogs	615
activity-log	615
Specifying a gateway type for an API definition	616
Referring to an extension in an API definition	617
Using \$ref to reuse code fragments in your OpenAPI files	618
Creating a Product definition file	619
Product definition schema	620
Completing the information section of your Product description	627
Specifying a gateway type for your Product	629
Converting a Product YAML file to use DataPower API Gateway	629
Specifying the visibility of your Product	630
Referencing the APIs for your Product	631
Describing Plans in your Product	632
An example YAML representation of a Product	634
Using x-ibm-languages to create multilingual API and Product documentation	635
Using x-example to control the examples displayed in the Developer Portal	638
Using x-embedded-doc to add additional documentation to products and APIs	638
Using x-pathaliases to give consistent URLs for products and APIs	641
Validating the YAML or JSON definition of an API or Product	642
Creating and using API and Product definitions templates	642
OpenAPI 3.0 support in IBM API Connect	643

Working with global policies	644
Reference	646
API Connect context variables	646
OAuth context variables	649
API and Product definition template examples	652
Template variables for API and Product definitions	658
<b>Managing your APIs</b>	<b>659</b>
Activating your API Manager user account	660
Accessing the API Manager user interface	661
[Technical Preview] Searching for items in API Manager	662
Working with Catalogs	665
Creating and configuring Catalogs	666
Configuring sub paths for Developer Portal sites	669
Managing Catalog membership	670
Importing a user-defined policy into a Catalog	671
Using syndication in API Connect	672
Enabling Spaces in a Catalog	673
Creating, modifying, and deleting Spaces	674
Working with Spaces	674
Managing Products in a Space	675
Managing subscription requests in a Space	675
Managing application subscriptions in a Space	676
Managing Space membership	676
Managing user access in a Space	677
Managing Gateways in a Space	677
Administering Consumer organizations	678
Creating a Consumer organization	678
Editing a Consumer organization	679
Deleting a Consumer organization	680
Working with Consumer organization groups	680
Managing developer applications	681
Security and authentication	682
Creating a TLS client profile	682
Creating a Keystore	683
Creating a Truststore	684
Generating a PKCS#12 file for Certificate Authority	685
Generating a self-signed certificate using OpenSSL	686
Viewing certificate details and adding certificates to a keystore or truststore	687
Defining elliptic curve cryptographic schemes for a TLS client profile	687
Authenticating by using your enterprise user registry	688
Working with user registries	689
Creating an LDAP user registry in API Manager	689
Using the CLI to create an organization-specific LDAP user registry	692
Creating an Authentication URL user registry	696
Creating a Local User Registry	698
Creating an OIDC user registry	698
Modifying the configuration details for a user registry	703
Password lockout criteria	703
Configuring a native OAuth provider	703
Configuring basic settings for a native OAuth provider	705
Configuring scopes for a native OAuth provider	706
Configuring user security for a native OAuth provider	707
Configuring tokens for a native OAuth provider	708
Configuring token management and revocation for a native OAuth provider	709
Configuring introspection for a native OAuth provider	709
Configuring metadata for a native OAuth provider	710
Configuring the OIDC parameters for a native OAuth provider	711
Editing a native OAuth provider by using the API Editor	711
Configuring a third-party OAuth provider	712
OAuth concepts for API Connect	320
OAuth user scenario	321
OAuth introspection for third-party OAuth providers	321
OAuth external URL and authentication URL	323
Scope	326
Tokens	330
Refresh tokens	330
Token revocation	331
Authenticating and authorizing through a redirect URL	333
Token management with the DataPower Gateway (v5 compatible)	335
Token management with the DataPower API Gateway	337
Authentication URL user registry	338
Custom forms for user security	339
Creating a custom HTML login form for user security	340
Creating a custom HTML authorization form for user security	341

Securing an API with a JSON Web Token	342
Troubleshooting OAuth	342
Working with Products in the API Manager	736
The Product lifecycle	736
Managing your Products	737
Publishing a Product	738
Publishing a new Product	739
Replacing a Product with another Product	740
Superseding a Product with another Product	741
Changing the availability of a Product	743
Deprecating a Product	743
Retiring a Product	744
Re-staging a Product	745
Updating the gateway services for a Product	746
Removing a Product from a Catalog	746
Approving Product lifecycle and subscription requests	747
Managing the APIs in a Product	748
API Analytics	749
Catalogs, Spaces, and Analytics	749
Accessing analytics	752
The applications landing page	752
Dashboard application page	753
Default dashboards	755
Cloning a dashboard	756
Creating custom dashboards	756
Importing dashboards	757
Editing dashboards	758
Exporting dashboards	759
Backing up and restoring dashboards	759
Deleting custom dashboards	760
Visualization application page	760
Visualizations	762
Applying filters to change the sampling of data displayed in visualizations	763
Creating visualizations	765
Configuring visualizations	766
Editing visualizations	767
Importing visualizations	768
Exporting visualizations	768
Backing up and restoring visualizations	769
Deleting custom visualizations	769
Working with searches (Discover)	770
Creating searches	771
Editing searches	773
Exporting searches	776
Importing searches	777
Backing up and restoring searches	779
Deleting searches	779
Exporting API event data	780
Using the UI to export API event data	781
Exporting aggregated analytics data from a visualization	781
Using REST APIs to export events data to JSON or YAML	783
API event record fields	783
Troubleshooting Analytics start-up	790
Administering user access	791
Viewing your user information	791
Adding provider organization users and assigning roles	791
Creating custom roles	792
Removing a user from a provider organization	793
Changing your API Manager password	793
Resolving login problems by increasing HTTP header size	794
Reference	795
API gateway response codes	795
API Manager tutorials	795
Tutorial: Creating a proxy REST API definition	796

<b>Authoring policies</b>	<b>903</b>
Authoring policies for the DataPower Gateway (v5 compatible)	904
Describing your policy	904
Creating a new user-defined policy	907
Implementing your policy	908
Packaging and importing your policies into IBM API Connect	910
Reference	911
Implementation code examples	911
Authoring policies for the DataPower API Gateway	915
Defining and packaging your user-defined policy for the DataPower API Gateway	915
Publishing your user-defined policy to the DataPower API Gateway	917
<b>Developer Portal: socialize your APIs</b>	<b>918</b>
Using the Developer Portal	918
Exploring APIs and Products in the Developer Portal	919
Testing an API by using the Developer Portal test tool	919
Calling an API	920
Calling an API by using CORS	921
Applications in the Developer Portal	922
Registering an application	922
Managing applications	923
Editing an application	924
Deleting an application	924
Changing an application image	924
Verifying an application client secret	925
Analytics in the Developer Portal	925
Application analytics in the Developer Portal	925
Organization analytics in the Developer Portal	926
Consumer organizations in the Developer Portal	926
Adding a Consumer organization from within the Developer Portal	926
Editing the name of a Consumer organization	927
Switching Consumer organizations	927
Adding users to a Consumer organization	927
Removing a user from a Consumer organization	928
Changing the ownership of a Consumer organization	928
Deleting a Consumer organization	929
User accounts, passwords, and support in the Developer Portal	930
Creating a new developer account	931
Changing your account settings	931
Deleting your developer account	931
Configuring the Developer Portal site	932
Concepts in the Developer Portal	933
Getting started configuring the Developer Portal site	934
Appearance	936
Controlling general appearance elements in the Developer Portal	936
Changing the shortcut icon	936
Changing the site email address	937
Changing the site logo	937
Changing the site name or site slogan	938
Changing the visibility of site branding	938
Adding custom JavaScript to a custom theme	939
Applying a modified content type template	939
Creating a sub-theme	940
Installing additional themes	942
Deleting themes	942
Content	943
Adding content elements in the Developer Portal	943
Adding and configuring meta tags	944
Disabling external search engine indexing	944
Adding custom pages	945
Integrating Twitter data into the social block	945
Editing the social block	946
Adding content in multiple languages	946
Adding custom pages to APIs and Products	947
Adding new frequently asked questions	948
Applying an image to an API or Product	948
Attaching a documentation file to APIs	949
Configuring blogs	949
Configuring the taxonomy menu block	950
Customizing the URL alias for a specific API or Product page	950
Embedding multimedia in site content	951
Linking from one piece of site content to another	951
Linking to social media sites	951
Managing tags in the Developer Portal	952

Tagging APIs based on their lifecycle phase	952
Posting a poll	953
Adding images to site content	953
Configuring and restricting content in the Developer Portal	954
Creating content types	954
Adding fields to content types	955
Configuring documentation upload limitations	955
Configuring image upload limitations	956
Configuring the appearance of ratings in the Developer Portal	956
Customizing the privacy policy statement	957
Customizing the terms of use statement	957
Editing a site comment	958
Editing sample content	958
Editing tags for a specific item	959
Turning content on or off in the Developer Portal	959
Deleting a site comment	960
Deleting blocks	960
Disabling blogs	960
Deleting forums from the front page	961
Turning comments for specific content types on or off in the Developer Portal	962
Turning comments off for an individual item	962
Turning off ratings for specific content types in the Developer Portal	963
Turning the ability to tag specific content types off in the Developer Portal	963
Structure	963
Configuring the front page	964
Disabling blogs	960
Deleting forums from the front page	961
Adding a menu	966
Adding and changing the blocks displayed on Developer Portal pages	967
Changing the front page banner block	968
Changing the front page Featured Content block	969
Changing the items in the main menu	969
Changing the ratings display	970
Displaying APIs and Products in categories	972
Enabling dynamic category creation	972
Implementing an image carousel	973
Making your application's image public	974
Providing navigation by tag hierarchy	974
Using the Views module in the Developer Portal	975
Creating views in the Developer Portal	975
Configuring the search results view in the Developer Portal	976
Configuring the default number of items in a view list in the Developer Portal	977
Configuration	977
Configuring content moderation	977
Editing, reviewing, and publishing moderated content	980
General configuration tasks	980
Adding a page load progress indicator	981
Adding custom fields to user records	982
Checking the site status report	982
Clearing the server caches	983
Configuring a proxy	983
Configuring cron to run scheduled tasks	984
Configuring search indexes and servers	984
Configuring the date and time	985
Configuring the settings of a Consumer organization	985
Configuring the site default timezone	986
Configuring the site error handling	986
Configuring which buttons are displayed in the WYSIWYG rich text editor	987
Configuring which languages are available	987
Customizing user account settings	988
Disabling languages	988
Disabling test tool restrictions	990
Enabling a cookie compliance banner	990
Enabling code languages for code snippets	991
Enabling code snippets for SOAP APIs	991
Forcing new users to accept terms and conditions	992
Hiding the admin registry on the login form	993
Hiding the certificate in the header for APIs secured with mutual TLS	994
Importing and exporting taxonomies	994
Restricting access by IP address	996
Restricting or preventing access from search engines	998
Toggling the site in and out of maintenance mode	999

Viewing available updates	999
Managing Developer Portal security	1000
Configuring CAPTCHA	1000
Configuring reCAPTCHA	1001
Configuring session timeout and limit	1002
Configuring the timeout length for the password reset link	1002
Configuring your site password policy	1003
Disabling CORS warnings	1003
Disabling live testing of APIs	1004
How to enable penetration testing, and information about Developer Portal cookies	1004
How to manage IP security in the Developer Portal	1006
Managing banned IP addresses	1007
Using flood control for login security	1007
Login security	1008
Using the Security kit	1008
Using Honeypot for spam protection	1009

## API Connect overview

IBM® API Connect is an integrated API management offering, with capabilities and tooling for all phases of the API lifecycle. Key steps of the API lifecycle include create, secure, manage, socialize, and analyze. IBM API Connect Version 2018 delivers enhanced capabilities for the market-leading IBM API management solution. In addition to the ability to deploy in complex, multi-cloud topologies, this version provides enhanced experiences for developers and cloud administrators in your organization.

Use of inclusive terminology: While IBM values the use of inclusive language, terms that are outside of IBM's direct influence are sometimes required for the sake of maintaining user understanding. As other industry leaders join IBM in embracing the use of inclusive language, IBM will continue to update the product interface to reflect those changes.

IBM API Connect has two main focuses: the first is providing best in class API Management tooling, and the second is having a cloud native solution. This allows users to create, manage, and secure applications that are deployed across a variety of on-premises and cloud environments.

The following table explains the key phases in the API lifecycle in more detail.

Table 1. Key phases of the API lifecycle

Lifecycle Phase	Description
Create	Develop and write API definitions from an API development environment, eventually bundling these APIs into consumable products, and deploying them to production environments. For tutorials, walk-throughs, and in-depth guides for building, testing, and deploying APIs and Products in API Connect, see <a href="#">Tutorials</a> , and <a href="#">Developing your APIs and applications</a> .
Secure	Leverage the best-in-class API Gateway, gateway policies, and more, to manage access to your APIs and back-end systems. To learn more about adding security to your API, see <a href="#">Configuring API security</a> .  To learn more about how to add API Gateway policies to your API, see <a href="#">API policies and logic constructs</a> .
Manage	Governance structures are built in to the entire API lifecycle, from managing the view/edit permissions of APIs and Products being deployed, to managing what application developers can view and subscribe to when APIs are deployed. To understand and leverage API Connect management and governance controls along the API lifecycle, see <a href="#">Managing your APIs</a> .
Socialize	API Connect comes with an advanced Developer Portal that streamlines the onboarding process of application developers, and can be completely customized to an organization's marketing standards. To understand more about using the Developer Portal, see <a href="#">Developer Portal: Socialize your APIs</a> .
Analyze	Developers and Product Managers alike are given the tooling in API Connect to understand their API traffic patterns, latency, consumption, and more to make data driven insights into their API initiatives. To learn more about how to leverage API Connect analytics tooling, see <a href="#">API Analytics</a> .

API Connect has four major components: API Manager, Analytics, Developer Portal, and Gateway. These four components can be deployed in a variety of hybrid and multi-cloud topologies. The API Connect infrastructure can either be deployed and managed by an IBM team in an IBM Cloud environment, or it can be deployed and managed by the customers in their own dedicated environment or third-party cloud. There is also the option for having hybrid scenarios, for example, with the API Connect Reserved Instance Offering, users are able to have their API Manager and Developer Portal running in the IBM Cloud, but then place remote gateways next to their back-end services.

Configuration of customer deployed API Connect clouds is done through the Cloud Manager. For in-depth guides and instructions see [Configuring and managing your server environment](#).

For information about the API Connect components that provide these capabilities, and details about the strategy for packaging and publishing APIs for use by API consumers, see:

- [Packaging strategy and terminology in API Connect](#)
- [API Connect components](#)

Note: For a comprehensive technical guide to best practices, considerations, and deployment options for API Connect, see the [API Connect 2018.4.1.x Whitepaper](#).

- **What's new in the latest release (Version 2018.4.1.24)**  
IBM API Connect 2018.4.1.24 contains fixes and the following enhancements. Note that fix packs 2018.4.1.21, 2018.4.1.22, and 2018.4.1.23 were not released. These fix packs were skipped to resume synchronized release numbering with IBM DataPower®.
- **Version 2018.4.1 known limitations**  
This page describes known limitations for IBM API Connect Version 2018.4.1.
- **Available deployment options of API Connect**  
IBM API Connect is offered as several deployment options, depending on your needs.
- **API Connect concepts**  
To help you get started, read about the API Connect concepts and obtain a high level understanding of the API management solution.
- **API Connect gateway types**  
IBM API Connect provides two gateway types, DataPower API Gateway and DataPower Gateway (v5 compatible).
- **API Connect user roles**  
The IBM API Connect solution provides an infrastructure, tools, and facilities that allows users to create, manage, and stage APIs. The ability to perform tasks in the API Connect user interfaces is controlled through user roles, and the permissions that are assigned to those roles.
- **API Connect support**  
If you experience a problem with IBM API Connect that you cannot resolve, you can check the IBM Support website for the most recent technical bulletins and fixes. Otherwise, you can contact IBM Support.
- **API Connect glossary**  
The IBM API Connect and Cloud Manager glossary of terms and definitions.
- **Accessibility features for IBM API Connect**  
Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.
- **Legal information**  
Notices, and terms and conditions for information centers.
- **IBM API Connect Considerations for GDPR Readiness**  
Information about features of IBM API Connect that you can configure, and aspects of the product's use, that you should consider to help your organization with GDPR readiness.
- **Essential reading**  
These articles by IBM API Connect product specialists provide a wealth of supporting information on APIs and the API economy.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## What's new in the latest release (Version 2018.4.1.24)

IBM® API Connect 2018.4.1.24 contains fixes and the following enhancements. Note that fix packs 2018.4.1.21, 2018.4.1.22, and 2018.4.1.23 were not released. These fix packs were skipped to resume synchronized release numbering with IBM DataPower®.

Note: You can access the latest files from [Fix Packs Available for IBM API Connect v2018.x](#).

VMware only: You must upgrade to 2018.4.1.20 before upgrading to 2018.4.1.24

On VMware, the only upgrade that is supported for version 2018.4.1.24 is from 2018.4.1.20; you cannot upgrade directly from older releases.

Ability to disable the Portal web endpoint check

When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully.

To disable the endpoint check, complete one of the following updates depending on your platform:

On Kubernetes

Add the following section to the Portal custom resource (CR) template:

```
spec:
  template:
    - containers:
      - env:
        - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
          value: "true"
        name: admin
        name: www
```

On VMware

In your `apicup` project, create a file called `ptl-extra-values.yaml` (or edit the file if one already exists), and add the following section:

```
spec:
  template:
    - containers:
      - env:
        - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
          value: "true"
        name: admin
        name: www
```

For more information, see [Registering a Portal service](#).

IBM API Connect Version 2018.4.1.13 includes the following enhancements.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## What's new in Version 2018.4.1.20

IBM® API Connect 2018.4.1.20 contains fixes and the following enhancements.

Note: You can access the latest files from [Fix Packs Available for IBM API Connect v2018.x](#).

Upgrading to 2018.4.1.20 from 2018.4.1.19 on VMware requires intermediate control plane files

Upgrading to 2018.4.1.20 from 2018.4.1.19 on VMware requires intermediate control plane files as explained in the topic, [Upgrading API Connect subsystems in a VMware environment](#).

Upgrading to 2018.4.1.20 on OpenShift requires upgrading API Connect first

If you are upgrading from 2018.4.1.19 or earlier to 2018.4.1.20 on OpenShift, you must upgrade API Connect before upgrading OpenShift to version 4.10.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## What's new in Version 2018.4.1.19

IBM® API Connect 2018.4.1.19 includes the following enhancements. Note: 2018.4.1.18 was not released. This fix pack was skipped to resume synchronized release numbering with IBM DataPower®.

Note: You can access the latest files from [Fix Packs Available for IBM API Connect v2018.x](#).

Drupal 9 upgrade compatibility check now added to the Developer Portal upgrade process

A compatibility check has been added to the Developer Portal upgrade process to verify that any additional contributed modules, custom modules, or sub-themes, declare that they are compatible with Drupal 9. Any Developer Portal sites that contain modules or sub-themes that don't have this version declaration will fail to upgrade. For information about how to make the Drupal 9 version declaration in custom modules or sub-themes, see [Installing Drupal 8 based custom modules or sub-themes into the Drupal 9 based Developer Portal](#). For more information about Drupal 9, see [About Drupal 9](#) on the drupal.org website.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## What's new in Version 2018.4.1.17

IBM® API Connect Version 2018.4.1.17 includes the following enhancements.

Note: You can access the latest files from [Fix Packs Available for IBM API Connect v2018.x](#).

Prevent the `Access-Control-Allow-Credentials` header from being returned in a CORS response

By default, when CORS is enabled for an API, every response to a CORS request contains the following header:

```
Access-Control-Allow-Credentials: true
```

However, the inclusion of this header does not provide optimal security. A new `x-ibm-gateway-cors-allow-credentials-when-no-cors-policy` API property is provided to allow you to prevent the return of this header. For more information, see [API properties](#).

Upgrade from Drupal 8 to Drupal 9 content management system

The Developer Portal is now based on the Drupal 9 content management system. This is an in-place upgrade, so no specific steps need to be taken. However, if you are using additional contributed modules, or custom modules or sub-themes, you should check that they are compatible with Drupal 9, and not using any deprecated APIs for example. There are tools available for checking your custom code, such as [drupal\\_check](#) on GitHub, which checks Drupal code for

deprecations. For information about how to make the core version of custom modules or sub-themes compatible with Drupal 9, see [Installing Drupal 8 based custom modules or sub-themes into the Drupal 9 based Developer Portal](#). For more information about Drupal 9, see [About Drupal 9](#) on the drupal.org website.

Timestamp format changed for Developer Portal restore operations

The timestamp format that is used in Developer Portal restore operations has changed from `YYYY-MM-DD HH:MM:SS` to `YYYYMMDD.HHMMSS`. For more information, see:

- [Backing up and restoring the Developer Portal in a Kubernetes environment](#)
- [Backing up and restoring the Developer Portal in a VMware environment](#)
- [Backing up and restoring the Developer Portal on IBM Cloud Private](#)

New IP security command available in the Developer Portal

IP security is enabled by default, but you can now use an internal Developer Portal command to toggle the IP security between enabled and disabled at the Portal service level. For more information, see [How to manage IP security in the Developer Portal](#).

Directly navigate to specific APIs and operations in the Open API Explorer Documentation

You can now use the URL to navigate directly to specific APIs and operations in the OpenAPI Explorer Documentation for the API Connect REST APIs. You can also select the APIs for a specific version by using the drop-down menu in the header bar. See [Open API Explorer Documentation for Version 2018](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## What's new in Version 2018.4.1.16

IBM® API Connect Version 2018.4.1.16 includes the following enhancements.

Note: You can access the latest files from [Fix Packs Available for IBM API Connect v2018.x](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## What's new in Version 2018.4.1.15

IBM® API Connect Version 2018.4.1.15 includes the following enhancements.

Note: You can access the latest files from [Fix Packs Available for IBM API Connect v2018.x](#).

Planning to upgrade to IBM API Connect V10?

Be sure to review the [Upgrade requirements and limitations](#) in the V10 documentation before you begin.

Helm v3 is required

For v2018.4.1.15, Kubernetes deployments must use Helm v3. For new installations, see [Requirements for deploying API Connect into a Kubernetes environment](#).

When upgrading from a prior version of API Connect, you must upgrade from Helm v2 to Helm v3. See [Upgrading API Connect subsystems](#).

Adding additional documentation to products and APIs

You can embed additional documentation pages within the api swagger documentation. These pages can be base64 encoded strings or markdown strings of the html content of the page. These pages show up in the navigation, on the left side, underneath the overview for that product or API, and above the paths. Any styling that is needed to theme the documentation can be included in the Developer Portal custom theme. For more information, see [Using x-embedded-doc to add additional documentation to products and APIs](#).

Ability to send API Manager metadata from the Developer Portal

For content created or updated after Version 2018.4.1.13, the Developer Portal propagates more metadata to API Manager for **consumerorgs**, **users**, and **applications**.

This metadata might be values that the user provided by adding extra fields to content types, or added programmatically by using custom modules.

The benefit of this is that when you add custom fields to **consumerorgs**, **users**, and **applications**, this data is now also stored as metadata in API Manager. Storing this data allows the Developer Portal to correct or repopulate the custom fields from a webhook or a snapshot.

Detect illegal XML characters in API request headers

A new `x-ibm-gateway-inspect-request-headers` API property enables the inspection of the HTTP headers in the API request to check for characters in the header values that are illegal XML characters. By default, there is no inspection, and such characters cause the API request to fail with an HTTP 500 Internal Server Error, but with this property you can choose to replace these characters with `?`, or to have the API request fail with an HTTP 400 Bad Request if any such characters are found. For more information, see [API properties](#).

Badgerfish support for handling of empty XML elements by the map policy

The `x-ibm-gateway-map-xml-empty-element` API property provides new options that enable empty XML input element values to be placed into JSON badgerfish value properties. For more information, see [API properties](#).

New Invoke policy properties for HTTP support

With the DataPower® API Gateway, the Invoke policy now provides the following new properties:

- Restrict to HTTP 1.0: HTTP transactions are restricted to version 1.0.
- Allow chunked uploads: Chunked-encoded documents are sent to the server.

For more information, see [Invoke](#).

Log policy performance enhancements

Rather than sending event data to the analytics server individually, the Log policy now buffers event data and sends it to the analytics server in batches according to the time interval configured for the Analytics Endpoint on the DataPower API Gateway. For more information on the Log policy, see [Log](#).

Change to the way in which the sending of client ID and scope to a third party OAuth provider is controlled

A new **suppress-parameter** header enables you to suppress the sending of client ID and scope to a third party OAuth provider; by default these parameters are now sent. For more information, see [OAuth introspection for third-party OAuth providers](#)

When activating an account through a local user registry, the specified email address must match the invitation email address

When a user activates a Cloud Manager or API Manager account through an API Connect local user registry, the email address that the user enters on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails. Previously, a different email address could be supplied.

For other user registry types, the user supplies their existing credentials when activating their account and, upon authentication, the API Connect user record is updated from the backend identity provider.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## What's new in Version 2018.4.1.13

IBM® API Connect Version 2018.4.1.13 includes the following enhancements.

Note: You can access the latest files from [Fix Packs Available for IBM API Connect v2018.x](#).

A tutorial on how to create a drop-down menu link

You can create and use drop-down menus, or nested menus, to enhance the use of your Developer Portal.

For more information, see [Creating a drop-down menu link](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Version 2018.4.1 known limitations

This page describes known limitations for IBM® API Connect Version 2018.4.1.

Note: The limitations that are documented on this page will be removed as they are addressed in the IBM API Connect product. For the most up-to-date list of product limitations, visit the English version of this page.

You cannot upgrade to API Connect 10.0.6.0 or later from any version of 2018.

A direct upgrade from any version of 2018 to API Connect 10.0.6.0 or later is not supported. You must upgrade to 10.0.5.x as an interim step before upgrading to 10.0.6.0.

VMware only: You must upgrade to 2018.4.1.20 before upgrading to 2018.4.1.24

On VMware, the only upgrade that is supported for version 2018.4.1.24 is from 2018.4.1.20; you cannot upgrade directly from older releases.

Override plan rate limits are not displayed in the Endpoint tab

Any override plan rate limits that have been added to your API for individual operations are not displayed in the API Endpoint tab in the UI. Only the plan rate limit is displayed.

Updates to members in the UI might not automatically refresh

Updates to members in the Cloud Manager and API Manager UIs might not automatically refresh. However, you can click the Refresh icon  to manually refresh your browser.

APIC repair job fails when streaming-connection-idle-timeout is set to 0

The recommended timeout value is 1 hour. The value is set in the kubelet config file. For information on configuring this setting, see the Kubernetes kubelet documentation at <https://kubernetes.io/docs/reference/command-line-tools-reference/kubelet/>.

Viewing multiple dashboards in a non-incognito browser is not supported

Either an incognito (private) browser tab, a separate browser instance, or a full page refresh is required for viewing dashboards in multiple Analytics services simultaneously.

Default vanity API endpoints are not displayed for a Catalog with Spaces enabled

If you enable Spaces in a Catalog then, on the Settings > API Endpoints page for the Catalog, the default vanity API endpoints are not displayed.

Limitations in the analytics record of **request\_body**

Logging the API **request\_body** in Analytics is subject to the following limitations:

- A non-xml request body is not supported in the analytics record
- A non-json request body is not supported in the analytics record
- A multipart request body is not supported in the analytics record

An API returns a **Content-Type** header of **unknown**

If an API contains a GatewayScript policy that executes an **apim.setvariable** function call that manipulates **message.body**, the **Content-Type** header is set to **unknown**. This might cause issues with invoke policy target servers, or the API client. To resolve this problem, you must immediately follow the **apim.setvariable** function call with an **apim.output** function call that specifies the content type of the payload that was written to **message.body** by **apim.setvariable**.

User interfaces behave incorrectly after upgrading to a new fix pack

After upgrading to new fix pack release, the user interfaces might exhibit incorrect behavior such as missing icons, errors when attempting an action, and looping situations. To resolve this problem, first clear your browser cache before using a user interface, then if the problem persists disable your browser cache.

An OpenAPI definition that contains regular expression syntax fails validation

IBM API Connect supports the [GO regular expression syntax](#). When you import an OpenAPI definition into the API Designer or API Manager user interfaces, or validate one with the `apic validate`, the validation will fail if the OpenAPI source contains unsupported regular expression syntax, with errors that include `Does not match format 'regex'`; for example:

```
- Must validate at least one schema (anyOf) (context:
(root).paths./example/types.post.parameters.0.schema.properties.items, line: 0, col: 0)
- Must validate one and only one schema (oneOf) (context: (root).paths./example/types.post.parameters.0, line: 46164, col:
21)
- paths./example/types.post.parameters.0.schema.properties.items.properties.pattern Does not match format 'regex'
(context: (root).paths./example/types.post.parameters.0.schema.properties.items.properties.pattern, line: 0, col: 0)
```

When scaling down a Kubernetes cluster of DataPower gateways, the cluster might enter an unrecoverable state if the peering primary instance is lost

If you are scaling down a Kubernetes cluster of DataPower gateways, you must first complete the following steps to ensure that the peering primary instance is not lost:

1. List the pods in the cluster; for example:

```
$ kubectl get pods -n default --selector app=dynamic-gateway-service
NAME                                READY   STATUS    RESTARTS   AGE
rbeb67b8620-dynamic-gateway-service-0  1/1     Running   0           3h31m
rbeb67b8620-dynamic-gateway-service-1  1/1     Running   0           3h32m
rbeb67b8620-dynamic-gateway-service-2  1/1     Running   0           3h34m
```

2. Enter the DataPower admin CLI for gateway 0, by entering the following command and logging in at the prompt; for example:

```
$ kubectl attach -n default -it rbeb67b8620-dynamic-gateway-service-0
```

3. Switch to the API Connect domain and enter config mode:

```
idg# switch apiconnect
idg[apiconnect]# config
Global mode
```

4. Show the gateway peering status; for example:

```
idg[apiconnect] (config)# show gateway-peering-status
```

Address	Configuration name	Pending updates	Replication offset	Link status	Primary
1.2.3.1	gwd	0	18331896	ok	no
1.2.3.1	rate-limit	0	3091219	ok	no
1.2.3.1	subs	0	3150127	ok	no
1.2.3.1	tms	0	3063575	ok	no
1.2.3.2	gwd	0	18330948	ok	no
1.2.3.2	rate-limit	0	3091067	ok	no
1.2.3.2	subs	0	3149975	ok	no
1.2.3.2	tms	0	3063257	ok	no
1.2.3.3	gwd	0	18330948	ok	yes
1.2.3.3	rate-limit	0	3091067	ok	yes
1.2.3.3	subs	0	3149975	ok	yes
1.2.3.3	tms	0	3063257	ok	yes

5. For each of the configuration names, set gateway 0 to be the peering primary instance:

```
idg[apiconnect] (config)# gateway-peering-switch-primary gwd
The instance is now the primary in the peer group.
idg[apiconnect] (config)# gateway-peering-switch-primary rate-limit
The instance is now the primary in the peer group.
idg[apiconnect] (config)# gateway-peering-switch-primary subs
The instance is now the primary in the peer group.
idg[apiconnect] (config)# gateway-peering-switch-primary tms
The instance is now the primary in the peer group.
```

6. Show the gateway peering status to confirm the changes; for example:

```
idg[apiconnect] (config)# show gateway-peering-status
```

Address	Configuration name	Pending updates	Replication offset	Link status	Primary
1.2.3.1	gwd	0	19067953	ok	yes
1.2.3.1	rate-limit	0	3218172	ok	yes
1.2.3.1	subs	0	3277032	ok	yes
1.2.3.1	tms	0	3189160	ok	yes
1.2.3.2	gwd	0	19067953	ok	no
1.2.3.2	rate-limit	0	3218172	ok	no
1.2.3.2	subs	0	3277200	ok	no
1.2.3.2	tms	0	3189160	ok	no
1.2.3.3	gwd	0	19069241	ok	no
1.2.3.3	rate-limit	0	3218172	ok	no
1.2.3.3	subs	0	3277508	ok	no
1.2.3.3	tms	0	3189312	ok	no

Truststore and keystore settings in a shared TLS client profile are not reflected in API Manager

If you create a shared TLS client profile in the Cloud Manager user interface and assign a truststore and a keystore, these truststore and keystore settings are not reflected in that TLS client profile in the API Manager user interface and cannot be set there. Furthermore, the TLS client profile list views display the value shared for the truststore and keystore rather than the correct values. To workaround this problem, create the truststore, keystore, and TLS client profile separately for each provider organization in the API Manager user interface, then enable the TLS client profile in your Catalogs as required.

An invited Space owner cannot work with consumer organization groups

If you enable Spaces in a Catalog and invite a user with Space Owner permission, the invited user cannot create, edit, or manager consumer organization groups, and cannot add consumer organizations to an existing consumer organization group.

Install Assist utility not supported on Windows when upgrading to v2018.4.1.10

A known limitation prevents successful use of the Windows platform version of the Install Assist utility, when upgrading to v2018.4.10. The workaround is to use a Linux or macOS version of the binary to complete the upgrade.

The `apic cloud-settings:topology` command doesn't return a topology object

If you use the `apic`

`cloud-settings:topology` command without a `--format` parameter, it returns only the string `CloudTopology` rather than the cloud topology. To retrieve the topology object, include the `--format` parameter, with a value of either `yaml` or `json` as required.

The `apic cloud-settings:mail-server-configured` command response is incorrect

If you use the `apic`

`cloud-settings:mail-server-configured` without a `--format` parameter, it returns only the string `MailServerConfigured` rather than a boolean value to indicate whether an email server has been configured in the cloud settings. To retrieve the correct response, include the `--format` parameter, with a value of either `yaml` or `json` as required.

API Designer user interface might not open correctly if there are badly formed OpenAPI YAML files in the startup directory

If, when launching the API Designer user interface, the startup directory that you select contains one or more badly formed OpenAPI YAML files, the interface might fail to load correctly, with an error such as the following:

```
Cannot read property 'type' of null
```

To resolve this problem, remove any invalid OpenAPI YAML files from the startup directory, then restart the API Designer user interface.

Pagination setting is global across the API Connect user interfaces

If you set the Items per page value on any page in either the Cloud Manager or API Manager user interface, that setting is then applied to all pages in both user interfaces in the same browser session. If you want to set the value separately for a specific page, open it in a private browser window. Such a setting in a private browser window is specific to that window and is lost when the window is closed.

In Catalina, testing the WSDL-SOAP flow in designer assembly editor has no dependencies

In Catalina, for designer, if you want to use test functions inside the assembly editor for the WSDL-SOAP flow, the Invoke button is disabled. Also, you cannot generate the parameter body.

To resolve this situation, you can directly publish the WSDL-SOAP APIs to the API Manager UI. Then, use the test function inside the API Manager UI - Assembly Editor. However, when you generate the body you must remove the comments `<-- . . . -->`, as in some cases the comments are not processed correctly.

The User Security policy in API Designer does not make user registries available for selection

If, in the API Designer user interface, you add a User Security policy to an API assembly, the User registry list in the policy configuration window does not contain any user registries to select from. To work around this problem, add the user registry to the policy directly on the Source tab; define the following property in the `user-security` policy configuration:

```
user-registry: user_registry_name
```

where `user_registry_name` is the value of the `name` property of the required user registry.

Ingress timeout settings might need adjustment to enable improved synchronization in Version 4.1.8

API Connect Version 4.1.8 contains a set of core updates designed to improve synchronization, and to strengthen stability and data integrity. Due to the changes, we recommend increasing the ingress time-out settings if you see 504 or 409 errors when trying to create or delete a provider organization or catalog. The increased stability also means that APIs and Products take longer to process, compared to versions prior to 2018.4.1.8.

To change ingress timeout settings, see the section "Kubernetes/ingress-nginx ingress controller config.map settings" in the topic [Kubernetes ingress controller prerequisites](#).

Upgrade of management server to Version 2018.4.1.8 can take longer than during previous upgrades

The upgrade of the management server from prior versions to Version 2018.4.1.8 may take longer than during previous fix pack upgrades. The extended time is due to underlying schema changes, and can be as long as several hours for long established deployments with a large amount of data.

Manual backup required when upgrading to Version 2018.4.1.8 iFix 2 or later

When upgrading to Version 2018.4.1.8 iFix 2 or later, you must complete a manual backup just prior to starting the upgrade. The manual backup is required because the upgrade can take an extended period of time. See [Requirements for upgrading on VMware](#) and [Requirements for upgrading](#) on Kubernetes.

Manual backup required when increasing memory allocation for the management database on Version 2018.4.1.8 iFix 2 or later

When changing memory allocation for the management database on Version 2018.4.1.8 iFix 2 or later, you must complete a manual backup just prior to changing the allocation. See [Increasing the memory allocation for the management database](#) on VMware and [Increasing the memory allocation for the management database](#) on Kubernetes.

If you are using API Connect v2018.4.1.8 or later, there can be a temporary delay in data sync between Management server and other services

Because of changes to improve stability, certain conditions can cause a temporary delay in the syncing of data between the Management server and other services such as the Gateway or Developer Portal. For example, there can be a temporary delay before a newly published Product runs on the Gateway, or is displayed on the Developer Portal. No action is needed to resolve the delay. Wait a few minutes and the Gateway and Developer Portal should be back in sync.

Deletion of organizations, catalogs, and applications can fail

The deletion of organizations, catalogs, or applications can fail, if they or resources inside them (like draft APIs inside provider organizations) were created with Version 2018.4.1.6 or earlier. This problem does not exist if organizations, catalogs or applications, and resources inside them were created with Version 2018.4.1.7 or later. For Version 2018.4.1.6 or earlier, internal locks can remain in place and prevent successful deletion. If you encounter this problem, please contact IBM Support and open a support ticket. IBM Support can help you to clear the locks so that the deletions complete successfully.

Management of refresh tokens not available in the UI

You must use the command line interface (CLI) to enable and manage refresh tokens. The use of refresh tokens is supported in API Manager, API Designer, the Developer Portal, and the CLI Toolkit, provided that the user logs in with a non-OIDC Provider user registry. If the registry type used for user login is OIDC, then the refresh setting is ignored. When the token expires, the user is always redirected to the login page. For more information, see [Specifying cloud settings for refresh tokens](#).

The Applications page doesn't indicate how many applications there are in the list

On the Applications page in a Catalog, there is no indication of how many applications there are in total. Therefore, if the total number of applications exceeds the Items per page setting, the list is incomplete with no indication that there are further applications that aren't displayed. To ensure that you view all applications, set the Items per page setting to the maximum value, then use the next page arrow to scroll through the complete list.

The API republish icon isn't enabled after an API update

If you make a change to an API definition in the Assemble view and save your changes, the API republish icon might not be enabled automatically, preventing you from republishing your updates. In such situations, enable the republish icon by refreshing the page, or by navigating to another view and then returning to the Assemble view.

Upgrade of DataPower API Gateway to Version 2018.4.1.7 or later requires installation of the DataPower monitor pod

API Connect Version 2018.4.1.7 introduces a new monitor pod for DataPower API Gateway. The monitor pod is required for all deployments of Version 2018.4.1.7 on Kubernetes. Installation of the monitor pod is required when upgrading DataPower Gateway from prior versions to version 2018.4.1.7 or later. For upgrade

instructions, see [Upgrading API Connect in a Kubernetes environment](#).

Enablement of DataPower Gateway high performance peering on a currently deployed system requires interruption to API transaction processing.

API Connect Version 2018.4.1.7 introduces high performance peering to DataPower API Gateway. If you do not enable high performance peering during initial installation, you can reconfigure to enable it later. Note that the reconfiguration process requires an interruption to API transaction processing, so you should plan accordingly. For Kubernetes, see [Enabling high performance peering for DataPower API Gateway on Kubernetes](#). For VMware environments, see [Enabling multiple peering objects on gateway services external to Kubernetes](#).

Setting resource limits in Kubernetes can cause containers to behave oddly at run time

In Kubernetes, you can set resource limits for each container. However, limiting CPU means that the container processes might slow down if they try to use too much. Limiting memory means that the Kubernetes code kills processes that try to allocate memory that would take the container over its limit. These limits can result in odd behavior such as the containers continually trying to start a daemon process, such as nginx or node, and exiting with success immediately.

Field validation for the Client security policy is incorrect

When configuring a Client Security policy in an API assembly in the API Designer or API Manager user interfaces, there is the following incorrect validation behavior:

- The ID Name field is required, but the API definition can be saved without entering a value in the field.
- The Secret Name field is required only when the Secret Required option is selected, but the user interface indicates that the Secret Name field is required regardless. Furthermore, when the field is required, the API definition can be save without entering a value.
- If the Authenticate Client Method is set to Third party, the User Registry Name field is required, but the API definition can be saved without entering a value in this field.

The title of a WSDL API can't be changed

If, when editing a WSDL API definition, you attempt to change the Title field, an error is returned. You can, however, change the title by modifying the `title` property in the OpenAPI source on the Source tab.

A WSDL API cannot be saved as a new version

If, when editing a WSDL API definition, you attempt to change the Version field, or use the Create new version option, an error is returned.

User interface URL returns 404 error on OpenShift

If IBM API Connect is deployed to an OpenShift environment, attempts to open the API Manager user interface at the URL `https://api_manager_ui_endpoint` returns a 404 error because the redirect to the full URL fails. To avoid this problem, use the full URLs for the user interfaces, as follows:

- API Manager user interface: `https://api_manager_ui_endpoint/manager`
- Cloud Manager user interface: `https://cloud_admin_ui_endpoint/admin`

User interface does not provide the option to assign roles when inviting Space members

When you invite a user to join as a member of a Space by using the API Manager user interface, it is not possible to assign roles to the user. This means that when the user receives the invitation, activates their account, and logs in, they have no permissions. To resolve this problem, assign the required roles to the user after they have activated their account, by selecting the roles alongside the user on the Members page in the Space.

You can, however, assign roles when adding a member to a Space, and when adding or inviting members to a Catalog.

Requests that take longer than the value of the nginx timeout cause a 409 error

Requests that take longer than the value of the `nginx` timeout can cause a 409 error, such as:

```
Another request is operating on portal-subsystem-03729230-4df7-4419-94c9-e7691b616382 with the same name, please try again.
```

The error occurs because the ingress controller is sending a repeat request when the previous one timed out. Your request will still continue processing in the background.

In some scenarios, applications crash due to lack of sufficient memory for Cassandra

Some applications that consume extensive amounts of memory can crash because the memory requirements exceed the memory allocation for Cassandra. For example, a large number of subscription tables, or upgrade requirements. Sample error from Cassandra logs:

```
r7430a60641-apiconnect-cc-0.log:io.netty.util.internal.OutOfDirectMemoryError: failed to allocate 16921 byte(s) of direct memory (used: 67100185, max: 67108864)
```

**Workaround:** Choose one of the following:

- Allocate more memory on Cassandra. See [Increasing the memory allocation for the management database](#).
- Scale up Cassandra by adding a node, which increases the memory in the cluster

Adding members to a provider organization might fail

When adding members to a provider organization, the Cloud Manager user interface lists the current owner and members as well. If existing members are selected, the add action will fail.

Upgrading with new certificates breaks analytics ingestion

If the analytics subsystem certificates are modified after installation ( by using the `apicup certs set` command , followed by the `apicup install` command to deploy the change to the cluster), the analytics ingestion ingress will no longer be recognized by the Gateway. The analytics service must be re-registered in the Cloud Manager interface so that the new certificates are recognized.

Publishing a large Product might result in an out of memory error

Publishing a Product that contains large numbers of APIs might result in an out of memory error. To resolve this problem, divide the Product into multiple Products with fewer APIs, or increase or tune the memory settings for API Connect/Cassandra.

Users are not logged out of the user interfaces after tokens expire

If an API Manager or Cloud Manager user interface session times out, the user does not get redirected to the login page and might see an error. To redirect to the login page, refresh the browser window.

User interfaces are not supported in Microsoft Edge

The API Manager and Cloud Manager user interfaces are not supported in the Microsoft Edge web browser. To work in the user interfaces, use a different browser.

New gateways cannot connect to existing gateways after the gateway peering certificates are changed

Changing the gateway peering SSL certificates after gateway installation causes new gateways to be unable to connect to existing gateways, resulting in an outage. A full restart of the gateway StatefulSet (by deleting all the StatefulSet pods) is required for the gateways to come back online.

Changes to an OAuth provider are not reflected in the consuming APIs

If you modify the endpoints, scopes, or grants for an OAuth provider, the APIs that consume that OAuth provider will be affected. You might need to update the consuming APIs accordingly.

Deletion of a non-empty provider organizations, Catalogs, or Spaces might fail

The deletion of provider organization, Catalog, or Space that contains a large number of resources might fail. Before deleting provider organizations, Catalogs, or Spaces, first delete the contained resources.

No option to bulk delete APIs or Products

In the API Designer and API Manager user interfaces, there is currently no option to delete multiple APIs or Products in a single operation; in the user interfaces, APIs and Products must be deleted individually. However, you can bulk delete APIs and Products by using the REST API or CLI interfaces.

Cannot publish an imported API that was generated with IBM API Connect Version 5.0 LoopBack®

If you import an API YAML file that was generated with IBM API Connect Version 5.0 LoopBack, attempts to publish the API fail. Before publishing, remove the catalogs section, and the invoke policy named `tls-invoke-profile`, from the YAML source of the API definition; for example:

```
catalogs:
  apic-dev:
    properties:
      runtime-url: $(TARGET_URL)
  sb:
    properties:
      runtime-url: 'http://localhost:4001'
```

Can't publish an API that has duplicate security definition entries

The API Designer and API Manager user interfaces allow you to add duplicate security definitions to an API. However, attempts to publish the API will fail with OpenAPI validation errors. Ensure that the security definitions in an API are unique.

API import can fail if there are validation errors

Validation errors in the OpenAPI definition of an API can cause the importing of the API to fail. The errors must be corrected in the OpenAPI source before the API can be imported successfully. You can use the `apic validate` CLI command to validate the OpenAPI definition before importing.

Kubernetes might excessively evict pods

In Kubernetes, if insufficient memory, CPU, or storage resources are provided then pods are evicted randomly. To avoid this problem, allocate sufficient resources to the pods. In addition, there are known issues with log rotation in Kubernetes that are documented here: <https://github.com/kubernetes/kubernetes/issues/59902>. The lack of log rotation can cause logs to grow, limited only by the amount of storage on the node, eventually causing pods to restart. Therefore ensure that appropriate log levels are configured for all API Connect components. You may also follow the instructions described here <https://success.docker.com/article/how-to-setup-log-rotation-post-installation> to set the maximum size of the log before it is rolled (max-size) and the maximum number of log files that can be present (max-files). More information about the Docker JSON File logging driver is available here: <https://docs.docker.com/config/containers/logging/json-file/>.

A Product that was defined in API Connect Version 5 might fail to publish

If you import a Product and it's referenced APIs, and the Product and APIs were defined in API Connect Version 5, attempts to publish the Product fail because the API references are lost from the Product. To resolve this situation, add the APIs to the Product, by using either the Product Design page or Source page, before publishing again.

API Manager pods might restart due to an out of memory condition

It is possible that during heavy workloads over long periods of time the API Manager pods might reach an out-of-memory condition causing them to restart. The multiple node design of the environment will handle the load while the pod restarts.

Changing the analytics association for a Gateway service might result in an error 504

If you change the analytics association for a Gateway service in the Cloud Manager user interface, and the Gateway service is enabled in multiple Catalogs, the user interface operation might timeout with an error 504. However, the operation itself completes successfully.

The migration of many subscriptions in a single operation might fail

If you use any of the following CLI commands, or their API Manager user interface equivalents where available, and the resulting number of application subscriptions that need to be migrated is large, the operation might fail:

- `apic products:replace`
- `apic products:execute-migration-target`
- `apic products:migrate-subscriptions`

You can resolve the problem in either of the following ways:

- Use the `apic products:migrate-subscriptions` to migrate the subscriptions in small batches. If you are replacing a Product, repeat the `apic products:replace` command after migrating all the subscriptions.
- Set a migration target, by using either the `apic products:set-migration-target` command or the Set migration target operation on the Product in the API Manager user interface. to allow users to migrate their subscriptions individually.

The deletion of many subscriptions in a single operation might fail

If you use any of the following CLI commands, or their API Manager user interface equivalents where available, and they result in many consumer organizations needing to be deleted in turn, the operation might fail:

- `apic orgs:delete`
- `apic catalogs:delete`
- `apic catalogs:clear`
- `apic spaces:delete`
- `apic spaces:clear`
- `apic consumer-orgs:clear`

The operations might fail due to the large number of child resources that need to be deleted in conjunction with the resources you are trying to delete. As a workaround, delete the child resources, such as the consumer organizations, individually prior to deleting the parent resource.

Logging in to the API Connect user interfaces fails when using the Safari web browser

If you are using the Safari web browser and a Basic Authorization header exists for the same DNS domain in which API Connect is running, attempts to log in to the API Connect user interfaces, or to sign up by using an activation link, fail. To avoid this problem, use an alternative web browser.

**Endpoints cannot be changed by using APICUP after they have been configured in Cloud Manager**

The changing of endpoints with APICUP after they have been configured in Cloud Manager is not supported. Any such endpoint changes will not be propagated to a running deployment.

If the name of an API is changed, Products that contain the API fail to publish

If you change the `x-ibm-name` field of an API in the Source tab, or you change the Title field of an API in the Design tab, thereby causing the `x-ibm-name` field to be updated, any Products that contain the API fail to publish because the API name reference in the Product is not updated. To resolve this problem, open the Source tab for the Product and update the API `name` references to match the new name.

If an API is deleted from a Product, it is not deleted from Plans in the Product

If an API is deleted from a Product, it is not deleted from any Plans in the Product that contain that API. After deleting an API from a Product you must manually delete the API from any Plans to which it was previously added.

The `apicup` utility appears to hang after executing a backup or restore command

On Version 2018.4.1, the `apicup` utility might appear to hang after you run a `backup` or `restore` command. You can verify that `apicup` is still running, or succeeded:

- For a backup command, such as `apicup subsys exec backup`:
  - Verify that the backup job is created. Enter `kubect1 get jobs -n <namespace>` and verify that the job **successful** status is **1**.
  - Verify that the backup pod is created. Enter `kubect1 get pods -n <namespace>` `-a` and verify that the pod status is either still running or **completed**.
- For a restore command, such as `apicup subsys exec restore`:
  - Verify that the restore job is created. Enter `kubect1 get jobs -n <namespace>` and verify that the job **successful** status is **1**.
  - Verify that the restore pod is created. Enter `kubect1 get pods -n <namespace>` `-a` and verify that the pod status is either still running or **completed**.

Unenforced APIs are not supported in the user interfaces

The setting of the Enforced API option to false, meaning that the API is to run on a gateway other than an API Connect gateway, is not currently supported in the API Designer or API Manager user interfaces. Attempts to publish, from the user interfaces, a Product that contains a non-enforced API will fail. To publish such a Product, use the developer toolkit CLI, or the REST APIs.

The API Designer user interface cannot be used with an OIDC user registry

You cannot use an OIDC user registry for logging in to the API Designer user interface. Either configure a non-OIDC registry for API Designer use, or use the equivalent capability in the API Manager user interface.

API Designer limitation when running on IBM Cloud

API Designer cannot establish a connection to the management server in order to create a cloud connection when the management server is running on the IBM Cloud platform.

Terms of use cannot be enforced for OIDC Developer Portal users.

You can configure terms of use for users of the Developer Portal so that the user must accept the terms and conditions before they can register or log in. This feature does not work if the user is using OIDC.

For more information, see [Forcing new users to accept terms and conditions](#).

An OAuth provider fails if the resources that it references aren't enabled in the Catalog

If you enable an OAuth provider in a Catalog then any resources that it references, such as API user registries or TLS client profiles, must be enabled in the same Catalog; if not, then although the OAuth provider might publish successfully it will fail at run time. For information on enabling resources in a Catalog, see [Creating and configuring Catalogs](#).

API Connect does not support resizing storage capacity or modifying storage class of the Cassandra database

If you updated `cassandra-volume-size-gb` or `storage-class` in `apiconnect-up.yml` prior to upgrading the management server, the upgrade completes successfully but the Cassandra servers are not upgraded. You can correct this problem by following the troubleshooting steps in [Upgrading in a Kubernetes environment](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Available deployment options of API Connect

IBM® API Connect is offered as several deployment options, depending on your needs.

### V2018 Reserved Instance

---

IBM API Connect V2018 Reserved Instance offers an individual API Connect instance that runs on IBM-managed infrastructure. V2018 Reserved Instance provides value by balancing the flexibility of a shared V2018 Reserved Instance infrastructure with the isolation of a single-tenant deployment based on the topology and functionality of API Connect.

V2018 Reserved Instance offers the following key features:

- Common log-in with other IBM services that use IBMid.
- Isolation from other users of the IBM Cloud public service.
- Managed, monitored, and operated by the API Connect Operations team.
- Deployed across multiple pods within the datacenter-zone for resilience.
- Optionally deployed as a High Availability (HA) deployment with a 99.95% SLA, for an additional cost.

For more information, see the [API Connect V2018 Reserved Instance](#) documentation.

### IBM Cloud Private

---

The IBM Cloud Private format provides some of the advantages of the public cloud, but with more security and control. The IBM Cloud Private deployment includes the following key features:

- Cloud environment that is set up on a private server.
- Security precautions can be added, including a private firewall.
- Control the timing of updates.

### On premises

---

The on premises format provides an installed version of API Connect. The on premises deployment includes the following key features:

- Highest level of security, as it is installed on your company server that can be behind a firewall.
- Control the timing of updates.

## Comparison table

The following table provides a convenient comparison of the different formats:

Feature	V2018 Reserved Instance	IBM Cloud Private	On-premises
Managed by IBM operations	Yes	No	No
Additional P-Orgs	By request	Yes	Yes
Shared gateways	No	No	No
Single Tenant gateways	Yes	Yes	Yes
Remote gateways	Yes	Yes	Yes
VPN connectivity	No	Yes	Yes
Single-DC HA	Yes	Yes	Yes
Multi-DC HA	Available at an extra cost	Yes	Yes
Custom branding	Yes	Yes	Yes
CMC access	No	Yes	Yes
API Manager access	Yes	Yes	Yes
DataPower UI access	No	Yes	Yes
User-defined policies	Yes <sup>1</sup>	Yes	Yes
Gateway log offload	Yes <sup>1</sup>	Yes	Yes
Analytics offload	Yes <sup>1</sup>	Yes	Yes
Custom extensions	Yes <sup>1</sup>	Yes	Yes

<sup>1</sup> If any custom code is required for these features, IBM agrees to apply code (supplied by you) to your reserved instance of API Connect; however, IBM cannot write or maintain custom code in the SaaS environment.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## API Connect concepts

To help you get started, read about the API Connect concepts and obtain a high level understanding of the API management solution.

- [Packaging strategy and terminology in API Connect](#)  
API Connect uses a proprietary packaging strategy for creating and publishing collections of APIs.
- [API Connect components](#)  
The API Connect components provide a unified user experience across the API lifecycle. Changes in one stage of the API lifecycle are automatically reflected in the other components of API Connect.
- [API Connect: End-to-end solution example](#)  
This example summarizes the concepts relating to the creation and use of APIs in the API Connect on-premises solution. It depicts the workflow and highlights some of the default roles for the tasks completed during the API lifecycle.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Packaging strategy and terminology in API Connect

API Connect uses a proprietary packaging strategy for creating and publishing collections of APIs.

The packaging strategy supports API providers in meeting the requirements of the API consumers. An understanding of the concepts and terminology behind the packaging strategy is required before developing and deploying APIs using IBM® API Connect.

The following sections describe the concepts and terminology behind the packaging strategy for IBM API Connect:

- [APIs](#)
- [Plans and Products](#)
- [Catalog and Spaces](#)
- [Organizations and users](#)
- [LoopBack® applications](#)
- [Sample provider organization with two Catalogs](#)

## APIs

An Application Programming Interface (API) is an industry-standard software technology. An API is a set of routines, protocols, and tools for building software applications. An API specifies how software components interact and provides quick access to common assets and processes. APIs can be public (such as offered on

GitHub), can require client credentials, or can be kept private within an application. Thus, APIs are classified as external (public), partner (protected), or internal (private), based on how they are consumed.

An API is composed of operations, called methods, which are offered in one of the following styles in API Connect:

- A REST API is structured according to the principles of Representational State Transfer. REST APIs use HTTP or HTTPS requests to PUT, GET, POST, and DELETE data (also referred to as CRUD operations). REST identifies resources using URIs. Data can be described in a variety of formats (XML, HTML, JSON, TXT, etc.), with JSON being the popular choice. REST APIs specify MIME (Multipurpose Internet Mail Extensions) types. REST is platform- and language-independent and works across firewalls using HTTPS. REST APIs leverage HTTP standards for security, caching, and status codes. HTTP clients and servers are available for all major programming languages and operating system/hardware platforms. REST implementations are easily scaled due to use of HTTP and browsers as a uniform interface.
- A SOAP (Simple Object Access Protocol) API is a web service that is exposed as an API. SOAP interfaces are described in WSDL (Web Services Description Language) format. The WSDL is an XML document describing the structure for headers, messages, URL endpoints, and datatypes used to access a web service. SOAP is considered more secure than REST as it supports WS-Security as well as SSL. SOAP also contains WS-Reliable Messaging for reliability, rather than relying on retrying the operation (as does REST). SOAP requires a client application and is better suited for enterprise applications that require secure transactions.

APIs can be versioned and packaged into multiple Products for distribution to API consumers on the Developer Portal. For information about creating and managing APIs, see [Developing your APIs and applications](#) and [Managing your APIs](#).

## Plans and Products

Plans and Products are proprietary packaging constructs that are unique to API Connect. API providers use Products to offer one or more APIs to the application developers who will consume the APIs (API consumers). The providers use Plans to control access to APIs and to manage API usage. Products are packages that contain both the APIs and the accompanying Plans. See [Working with Products](#).

To make an API available to an application developer, it must be included in at least one Product and at least one Plan.

Plans perform the following functions:

- Control which APIs an application developer can use
- Make available a collection of operations from one or more APIs
- Apply rate limits to APIs to differentiate between offerings
- Implement different rate limits to specify how many requests a consuming application is allowed to make during a specified time interval

Plans can use differing rate limits to provide different levels of service to API consumers. For example, a "Demo Plan" might enforce a rate limit of ten calls per minute, while a "Full Plan" might permit up to 1000 calls per second.

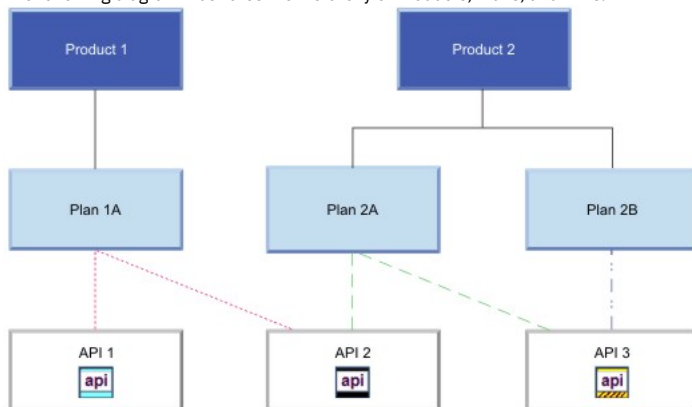

A Product in API Connect bundles a set of APIs and Plans into one offering that is intended for a particular use. You can create Plans only within Products, and these Products are then published in a Catalog. The following rules apply for the relationship between Products and Plans:

- A Plan can belong to only one Product.
- A Product can have multiple Plans that each contain a different set of APIs.
- A Plan in one Product can share APIs with Plans from any other Product.

Multiple Plans within a single Product provide different levels of performance for the same offering. For example, a Product can include a "Demo Plan" that makes a single API available, and a "Full Plan" that makes several APIs available.

Products are used to manage the lifecycle of the APIs they contain. The states in the Product lifecycle include draft, staged, published, deprecated, and retired. A Product in draft state is moved to the staged state when it is staged to a *Catalog*. A Product moves to the published state when the Product is published. The APIs in a Product become accessible to API consumers when the Product is in the published state and they then become visible on a *Developer Portal*. After a Product is published, application developers can use the Developer Portal to gain access to its APIs by registering applications to one or more Plans in the Product.

The following diagram illustrates the hierarchy of Products, Plans, and APIs.

For more information about managing the lifecycle of Products, see [Working with Products in the API Manager](#).

## Catalogs and Spaces

A Catalog contains a collection of Products. Catalogs are staging targets through which Products (together with the accompanying Plans and APIs) are published on a Developer Portal. Catalogs are used to separate Products and APIs for testing before publishing them on a Developer Portal. In a typical workflow, an API provider uses a development Catalog when developing and testing APIs, and uses a production Catalog for publishing APIs that are ready for external use. Each Catalog has an associated Developer Portal for exposing the published Products. A Catalog includes runtime capability through an associated gateway service that handles any API requests for the APIs in that Catalog.

API Connect includes a syndication feature that enables API providers to partition a Catalog into multiple staging targets (or *Spaces*) for API development purposes. Each API provider development team can use its own dedicated Space to manage its Products independently of other teams. A Space has its own set of capabilities relating

specifically to the Products and APIs that are created and published to that Space. Products and APIs in all Spaces in a given Catalog are published to the same Developer Portal. Spaces are not visible on the Developer Portal. Application developers who consume the APIs on the Developer Portal are unaware of the Space configuration used by the API Developers. On the Developer Portal, the APIs are seen as a coordinated offering within a Catalog.

For more information about Catalogs and Spaces, see [Working with Catalogs](#) and [Using syndication to partition Catalogs into Spaces](#).

## Organizations and users

In the context of API Connect, there are two types of organizations: provider and consumer. An organization can encompass a project team, department, or division.

A provider organization owns APIs, and associated Plans and Products, and can additionally own *provider* applications that are called by APIs. To complete the various functions in the API lifecycle, a provider organization assigns responsibilities for certain tasks. Some standard responsibilities within a provider organization include:

- A provider organization owner who has the full set of access permissions to API Connect functions, and can also commission APIs and track their business adoption.
- API developers who design and develop APIs and applications for the provider organizations to which they belong.
- An administrator who manages the lifecycles of APIs and publishes APIs for discovery and use.
- A "community" manager who manages the relationship between the provider organization and application developers, provides information about API usage, and provides support to application developers.

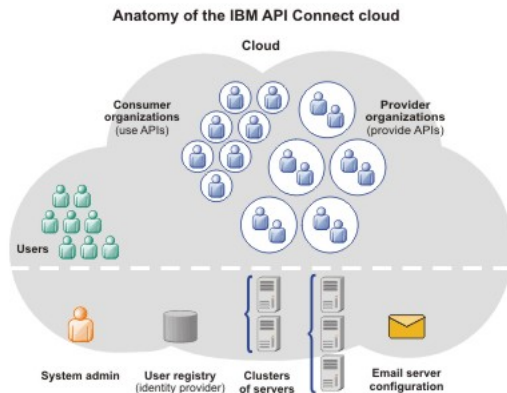

A consumer organization owns only *developer* applications, and consumes the APIs and applications produced by the provider organization. Standard responsibilities within a consumer organization include:

- A consumer organization owner who adds application developers to the consumer organization, views the Products and APIs that the provider organization has made available on the Developer Portal, and subscribes to APIs to use them in applications.
- Application developers who view the Products and APIs that the provider organization has made available on the Developer Portal, and subscribe to use these APIs in applications.

The provider and consumer organization responsibilities map to *roles* within API Connect. Some roles are independent of an organization; for example, an administrator who manages the cloud infrastructure and keeps the system running. For information about the full set of defined roles and access permissions, see [API Connect user roles](#).

Users have an existence in the API Connect ecosystem that is independent of an organization. A user can be a member of more than one provider or consumer organization.

There can be multiple provider organizations in one API Connect cloud, to provide an API development environment for each line of business of an enterprise. The API Connect cloud is a collection of servers that comprise an API Connect installation, including the configuration information and metadata that they contain. The cloud infrastructure is shared by all organizations, and managed independently of them (by a cloud or system administrator). The following diagram shows the relationship between the provider organizations, consumer organizations, and users. The clusters shown are logical groupings of servers with the same capability.

For more information about organizations, see [Administering provider organizations](#) and [Administering consumer organizations](#).

## LoopBack applications

In addition to APIs, provider organizations can also create applications (with associated APIs), which are built using Node.js and Java technology. When published, these APIs and applications are called by developer applications. The developer applications contain client code that accesses APIs to interact with a service, system, or content. The developer applications are typically mobile or web applications that use the HTTP protocol.

For information about creating LoopBack applications, see [Creating APIs and applications](#).

## Sample provider organization with two Catalogs

The following diagram shows an example for how APIs, Plans, Products, Catalogs, and Spaces fit within provider and consumer organizations. In this example, two Catalogs are created in the provider organization to act as staging targets for different sets of requirements.

- Catalog 1 does not require separation of the Products for use by individual provider development teams, and so does not have Spaces enabled. API developers with access to this Catalog create draft APIs, and stage and publish them as Products to the Catalog. Several consumer organizations are granted permission to explore,

discover, and use the published Products and APIs. In each of the consumer organizations, the published Products and APIs from Catalog 1 are exposed on a single Developer Portal.

- Catalog 2 is partitioned into two Spaces (X and Y) so that two provider development teams can manage their Products independently. These teams stage and publish their APIs (as Products) separately to the individual Spaces, to make them accessible to application developers in multiple consumer organizations. In each of the developer organizations, the published Products and APIs from both Spaces are exposed in the same Developer Portal, and application developers who access this portal will see the APIs from both Spaces as a coordinated offering.

- **Understanding rate limits for APIs and Plans**

In API Connect, you can configure rate limiting on APIs and Plans to manage network traffic and API usage.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Understanding rate limits for APIs and Plans

In API Connect, you can configure rate limiting on APIs and Plans to manage network traffic and API usage.

### What are rate limits and burst limits?

A rate limit is the maximum number of calls you want to allow in a particular time interval. Setting rate limits enables you to manage the network traffic for your APIs and for specific operations within your APIs. API Connect supports two types of rate limiting:

#### Rate limit

A specified number of calls to be accepted within a defined time period; for example, 100 calls per minute. In API Connect, rate limits can be defined as unlimited, or with a specified number of calls per second, minute, hour, day, or week. When the limit is reached, no more calls are accepted from that customer until the beginning of the next time period. For example, you might want to permit a total of 1000 calls per hour (rate limit). If a customer makes 1000 calls in the first 10 minutes, they cannot complete any more calls until the hour has expired.

#### Burst limit

A rate limit that is applied to a very small time period. In API Connect, burst limits are defined for multiples of seconds or minutes. When a burst limit is reached, calls are not accepted until the time period has expired. Once that pause is over, calls continue to be accepted until the rate limit is reached. Configuring a burst limit prevents usage spikes and ensures that the rate limit is evenly spread across its overall time period. For example, you might want to permit a total of 1000 calls per hour (rate limit) and a maximum spike of 50 calls per second (burst limit).

### Where can you apply rate limits?

You can configure rate limiting at several levels of an API and the Plan containing it. Use the different settings to fine-tune your rate limits for your customers and environment. The more granular settings on APIs override the settings defined in a Plan that contains that API. For example, if you set a rate limit to 100 calls per minute on a Plan, that limit only affects APIs in the Plan that don't already have a more granular rate limit defined. The following list explains where you can configure rate limits, in decreasing levels of granularity:

1. API assembly

You can define a rate limit within the API's assembly (its process flow). This is useful when you want to dynamically set the rate limit based on a GatewayScript action; for example, you might want to increase the base rate limit only for certain users, IP addresses, or server names. For more information on configuring a rate limit on an API assembly, see the following documentation:

- [Rate Limit policy](#)
- [GatewayScript policy](#)
- [Using context variables in a GatewayScript policy](#)

2. Plan: API path and operation

You can define a rate limit for a specific path and operation of an API within a Plan; for example, you might allow unlimited calls to a GET operation but enforce a limit on PUT operations for the same API. You can even define multiple rate limits on the same path and operation. For more information on configuring rate limits on API paths and operations within a plan, see the following topics:

- [Defining rate limits for an API operation](#)
- [Describing Plans in your Product](#)

3. Plan: all APIs

You can additionally define a general rate limit at the Plan level. This limit is applied as a default for each API in the plan. Any rate limit defined at a more granular level overrides the general Plan-level limit. For more information, see [Editing a draft Product](#).

Note: If the subscriber changes to a different Plan, only the Plan-level rates limit are reset. If there is a rate limit specified in the API's definition or assembly, that rate limit is still enforced under the new Plan.

---

## How can you test rate limits?

When you're ready to test rate limits on an API or Plan, make sure you deploy it in a test Catalog where automatic subscriptions are not enabled. Execute a larger number of calls than specified by your rate limit, within a shorter period of time. Then verify that calls exceeding the limit were not accepted. If you enabled the use of a hard limit, each API call that is over the limit is returned with an error message.

The built-in test application that is used by the API Manager and API Designer Test tool is not subject to rate limits if you enabled automatic subscriptions for the Catalog where you are testing. To ensure that your rate limits are applied as intended, create a new test Catalog that requires manual subscriptions and test your API and Plan there. For more information on creating and configuring Catalogs, see [Working with Catalogs](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## API Connect components

The API Connect components provide a unified user experience across the API lifecycle. Changes in one stage of the API lifecycle are automatically reflected in the other components of API Connect.

- [Cloud Manager](#)
- [The developer toolkit](#)
- [API Manager](#)
- [API Gateways](#)
- [Runtime](#)
- [Developer Portal](#)
- [API Analytics](#)
- [Typical tasks per interface component](#)
- [API Connect server requirements](#)

---

## Cloud Manager

The API Connect Cloud Manager component is used to manage the API Connect on-premises cloud. The Cloud Administrator uses this UI to:

- Define the cluster of *Management servers*, *Gateway servers*, and *containers* that are required in the cloud, and configure the topology. For information about Management servers and Gateway servers, see [API Connect server requirements](#). For information about containers, see [Runtime](#).
- Manage (modify, move, remove, restart, reboot) the servers in the cloud.
- Monitor the health of the cloud.
- Define and manage the provider organizations that develop APIs. (Assigned managers or owners of provider organizations can also complete this task.)
- Define additional cloud administrators, or set up users with roles that enable access to specific capabilities.
- Add user registries for authenticating users and securing APIs, and configure the secure transmission of data (for example, through websites).

For more information about the Cloud Manager, see [Managing your cloud](#).

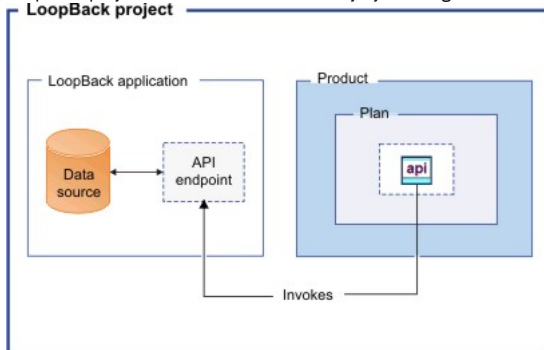

---

## The developer toolkit

The developer toolkit provides the tools for modeling, developing, and testing APIs and LoopBack® applications. The developer toolkit includes a command line interface (CLI). It also incorporates LoopBack, an open source Node.js framework.

API developers use the API management functions in the API Manager or the CLI to create draft API definitions for REST and SOAP APIs, or for OAuth provider endpoints that are used for OAuth 2.0 authentication. The API definitions can be configured to add the API to a Product, add a policy assembly flow (to manipulate requests/responses), and to define security options and other settings. APIs can then be tested locally prior to publishing, to ensure they are defined and implemented correctly.

Using LoopBack, an API developer can create a Node.js application, connect to a data source such as a back-end database or a REST API to be consumed, and then expose the application as a REST API by creating a model definition. A LoopBack model defines the application data, validation rules, data access capabilities, and business logic for an API, and provides a REST API by default. This REST API can then be used by a REST API definition that was created using the API Manager or CLI and exposed to your users. The API and its associated application, which are implemented as a LoopBack project, must both be published to enable the project to be run. LoopBack projects can also be tested locally by creating a local runtime environment. The following diagram illustrates the LoopBack project architecture:

Draft APIs (in their containing Products) that are created by using the API Manager, CLI, or LoopBack are published to Catalogs. Applications created using LoopBack are published to containers, from where they run when called. (For information about containers, see [Runtime](#).)

The developer toolkit is installed locally, for offline API and application development. For more information about the developer toolkit, see [Developing your APIs and applications](#). For more information about LoopBack, see [LoopBack: The Node.js API Framework](#).

## API Manager

The API Manager provides a user interface that facilitates promotion and tracking of APIs that are packaged within Products and Plans. API providers can move the Products through their lifecycle, and manage the availability and visibility of APIs and Plans.

Catalogs and Spaces are created in the API Manager to act as staging targets through which APIs, Plans, and Products are published to consumer organizations. API providers can stage their Products to Catalogs or Spaces, and then publish them to make the APIs in those Products visible on a *Developer Portal* for external discovery.

To control access to the available API management functions, users in the provider organization can be set up in the API Manager UI with assigned roles and permissions. API providers can also use the UI to manage the consumer organizations that sign up to access their APIs and Plans. Developer *communities* can additionally be created as a way of grouping together a collection of consumer organizations to whom a particular set of Products and Plans can be made available.

The API Manager UI also includes functions to manage the security of the API environment, and provides access to analytics information about API invocation metrics within customizable dashboard views.

For more information about the API Manager, see [Managing your APIs](#).

## API Gateways

Gateways enforce runtime policies to secure and control API traffic, provide the endpoints that expose APIs to the calling applications, and provide assembly functions that enable APIs to integrate with various endpoints. They also log and report all API interactions to the API Connect analytics engine, for real-time and historical analytics and reporting. The following Gateway is available for use in API Connect:

- The DataPower® Gateway is an enterprise API Gateway that is built for departments and cross-enterprise usage. This Gateway provides a comprehensive set of API policies for security, traffic management, mediation, acceleration, and non-HTTP protocol support. The DataPower Gateway is deployed on a virtual or physical DataPower appliance and supports multiple Catalogs per instance or cluster. The DataPower Gateway can handle enterprise level complex integration, and supports containers for flexible runtime management.

Your API Connect offering (or *edition*) can include a virtual DataPower Gateway, and support for a physical DataPower Gateway is also available, subject to certain conditions.

## Runtime

You can run applications and API implementations in API Connect in a containerized runtime.

### Containerized runtime

A containerized runtime environment provides a lightweight deployment location for APIs and applications. A container wraps an application in a complete file system that includes everything it needs to run, such as code, runtime, system tools, and system libraries. You can use Docker Swarm or Kubernetes containers to run your APIs and applications being managed by API Connect.

## Developer Portal

The Developer Portal provides a customizable self-service web-based portal to application developers to explore, discover, and subscribe to APIs.

When API providers publish APIs in the API Manager, those APIs are exposed in the Developer Portal for discovery and usage by application developers in consumer organizations. Application developers can access the Developer Portal UI to register their applications, discover APIs, use the required APIs in their applications (with access approval where necessary), and subsequently deploy those applications.

The Developer Portal provides additional features, such as forums, blogs, comments, and ratings, for socialization and collaboration. API consumers can also view analytics information about the APIs that are used by an application, or used within a consumer organization. For more information, see [Developer Portal: socialize your APIs](#).

## API Analytics

API Connect provides the capability to filter, sort, and aggregate your API event data. This data is then presented within correlated charts, tables, and maps, to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends. API analytics is built on the Kibana V5.5.1 open source analytics and visualization platform, which is designed to work with the Elasticsearch real-time distributed search and analytics engine.

## API Connect server requirements

From an on-premises cloud, you can create, promote, use, and track APIs. An on-premises cloud is composed of various appliances, where each appliance is a server of a specific type. The collection of servers defines your cloud and determines how to distribute the work of managing, analyzing, routing, and storing data.

Your on-premises cloud can be a combination of new and existing physical appliances and virtual appliances, or can be entirely composed of virtual appliances. The type and quantity of servers in an API Connect environment are determined by the individual needs of each enterprise, but the minimum requirement is one Management server, one Analytics server, one Gateway server, and one server to host the Developer Portal.

The API Connect on-premises cloud includes the following server types:

- **Management server.** Stores all of the cloud configuration, and controls communication between the other servers within API Connect. Manages the operations of the various servers in the API Connect cloud and provides the tools to interface with the various servers. The Cloud Manager and API Manager user interfaces run on the Management server.
- **Analytics server.** Provides analytic functions that collect and store information about APIs and API users.
- **Gateway server.** Processes and manages security protocols and stores relevant user and appliance authentication data. The Gateway server also provides assembly functions that enable APIs to integrate with various endpoints, such as databases or HTTP-based endpoints.
- **Developer Portal server.** Provides a customizable social developer portal with a full-featured content management system, and includes clustering capability. Enables API providers to build portals for their application developers, and provides the interface for application developers to discover APIs and subscribe to usage Plans contained in the published Products for use in their applications.

Note: All Management appliances in an API Connect cloud must run at the same firmware level as each other. Gateway appliances can run on different firmware levels to each other, but it is recommended that all of the Gateway appliances run on the same level as each other.

## Typical tasks per interface component

API Connect offers both command line and graphical user interfaces. Provider and consumer organizations use different interfaces for completing typical tasks. Refer to the following table to locate the interface that corresponds to a specific task.

Table 1. API Connect Tasks per interface component

Organization Type	Interface Component	Tasks
API Provider	Command Line Interface (CLI)	Create APIs, Plans, and Products
	API Manager UI	Create APIs, Plans, and Products
	API Manager UI	Create Catalogs and Spaces; Create Consumer Organizations
	Cloud Manager UI	Create Provider Organizations
API Consumer (application developer)	Developer Portal	Access APIs to create and run applications; Create Consumer Organizations

- If self-service onboarding is enabled for a Catalog, a consumer organization is automatically created when an application developer signs up or is invited by the API provider to a Developer Portal, and the application developer then becomes the owner of that consumer organization.

## Related concepts

- [Packaging strategy and terminology in API Connect](#)

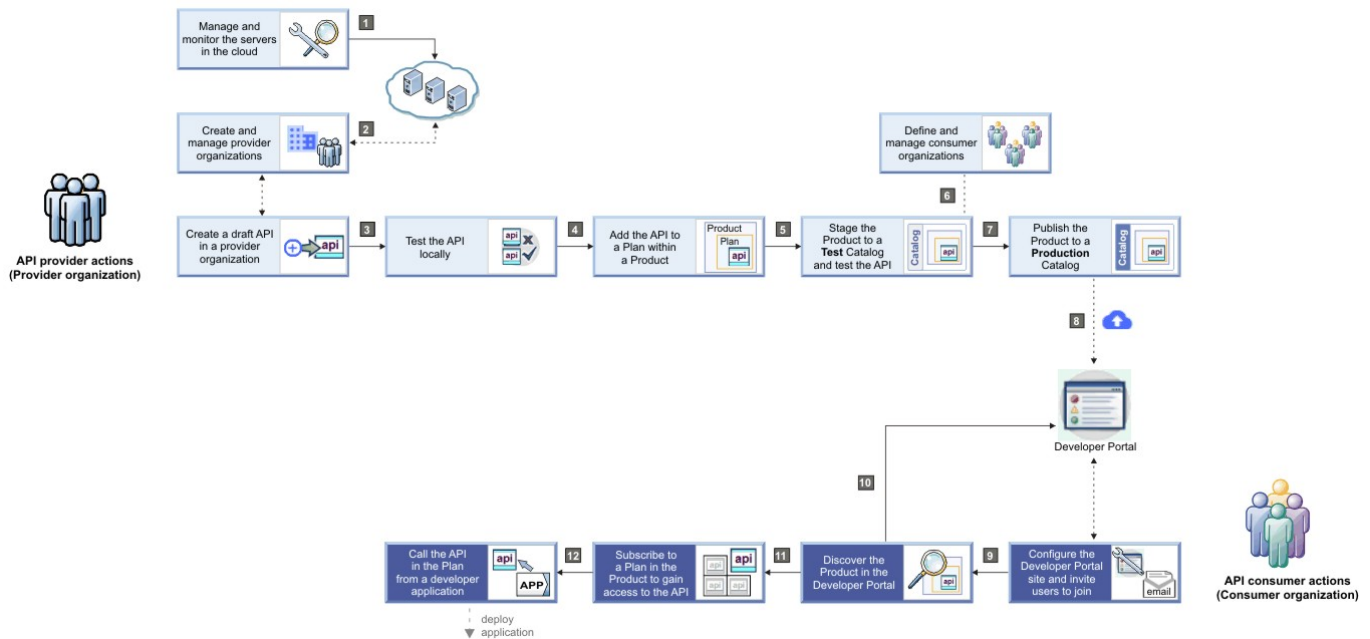

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## API Connect: End-to-end solution example

This example summarizes the concepts relating to the creation and use of APIs in the API Connect on-premises solution. It depicts the workflow and highlights some of the default roles for the tasks completed during the API lifecycle.

The following diagram shows an example of the workflow steps that are completed by the provider and consumer organizations.

## Action: 1

**Cloud Owner** **Cloud Administrator** The minimum requirements for an on-premises API Connect solution consist of one Management server to manage APIs, one Gateway server to direct API traffic, one Analytics server to analyze the APIs, and a server to host the Developer Portal. As a Cloud Owner or Cloud Administrator, you gather a collection of Management, Analytics, Gateway, and Developer Portal servers to create *clusters* to load balance and isolate traffic. A cluster has a single network address through which you can access its capabilities.

## Action: 2

**Organization Manager** **Organization Owner** With the infrastructure in place, Organization Managers and Organization Owners can manage *organizations* of users who create APIs, provider applications, and associated Products. Users belong to one or more provider organizations and individually or collectively work on the APIs or applications that belong to the organization. Project teams, departments, and company divisions are all examples of groups of users that might be members of the same provider organization in API Connect.

## Action: 3 4 5

**API Developer** Once defined as a user in a provider organization and assigned access permissions, API Developers (who might be assigned more than one role) can design, develop, and test APIs, and associate them with Plans and Products. As an API Developer, you specify policy settings to limit the usage of the APIs exposed by the Plan. You can define a single quota policy that applies to all the API resources accessed through the Plan, or you can define separate quota policies for specific API resources. You can also define policies on API resources to configure capabilities such as security, logging, routing of requests to target services, and transformation of data from one format to another. Such policies control aspects of processing in the Gateway during the handling of an API invocation, and are the building blocks of assembly flows. While developing and maintaining APIs, you can also create separate deployment targets called *Catalogs* for testing and production. Each Catalog is associated with a specific Developer Portal and endpoints. If you have administrative privileges, you can restrict deployment access to a Catalog and require actions, such as approving deployment of new API versions.

## Action: 6

**Product Manager** To control access to APIs that are ready for publication and ready to be included in applications, a Product Manager defines and manages *organizations* of users who own developer applications and call published APIs from these applications. A consumer organization is assigned an owner, and might represent a business partner, or a group of internal or external developers. Consumer organizations can also be grouped into *communities* to which one or more APIs (in their containing Plans and Products) can be collectively published. As a Product Manager, you manage access to APIs, manage the relationship between the provider organization and consumer organizations, provide support to application developers when needed, and analyze API usage.

## Action: 7 8

**API Administrator** After APIs are created and successfully tested, an API Administrator publishes one or more *Products* to expose the APIs on the Developer Portal for discovery and use. APIs are included in a *Plan*, which is contained in a *Product*, before being published, and can be published to one or more consumer organizations, thereby restricting visibility of the API. Only application developers in the specified organizations can see the API on the Developer Portal and obtain application keys to access it. The API Administrator is also responsible for managing the lifecycle of Products and their associated APIs, and uses analytics to track API usage and determine whether an API is fulfilling its intended purpose.

## Action: 9

**Consumer Organization Owner** After a consumer organization is created, its designated Consumer Organization Owner can invite other users to join the consumer organization so that they can access the Developer Portal and use the APIs that have been made available to the consumer organization. The Consumer Organization Owner, or another

user with relevant access, can also configure the Developer Portal site; for example, customize its appearance, create and control forums, post blog entries, and configure blogs.

## Action: 10 11 12

**App Developer** After a Product is published, authorized App Developers gain access to its APIs by registering applications to access the Plans in that Product. An application developer uses the Developer Portal to browse for a required API, subscribe to its associated Plan, and then includes the API in an application that can subsequently be deployed to a device.

When the API is invoked from the deployed application on a device, a sample request/response flow of the API Connect runtime interactions might be as follows:

1. The device user opens the application, which then issues the API request.
2. The request is handled by the Gateway (which performs load balancing and security validation for all API requests) and the API runtime:
  - a. The Gateway validates access policies with the API Manager and invokes the API.
  - b. The API runtime executes the API and obtains the data payload from the back-end system.
  - c. The API response is sent back to the Gateway.
  - d. The Gateway forwards the response to the calling application.
  - e. The Gateway reports analytics data to the Analytics server.

All members of the consumer organization can optionally view API analytics information relating to individual applications or the entire organization.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## API Connect gateway types

IBM® API Connect provides two gateway types, DataPower® API Gateway and DataPower Gateway (v5 compatible).

### DataPower API Gateway

The DataPower API Gateway has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible). Where DataPower Gateway (v5 compatible) was built for flexibility, DataPower API Gateway is built specifically for the API use case, with resulting performance benefits.

DataPower API Gateway was built and optimized for the cloud. Use this gateway if you are running applications in a public or private cloud and want to expose them as APIs.

### DataPower Gateway (v5 compatible)

DataPower Gateway (v5 compatible) provides compatibility with the IBM DataPower Gateway that was provided with IBM API Connect Version 5 and earlier releases.

Consider using DataPower Gateway (v5 compatible) if you are an existing DataPower user and want to utilize your DataPower resources and knowledge.

## Gateway comparison

Table 1. Comparison of the DataPower Gateway (v5 compatible) and DataPower API Gateway

Feature	DataPower Gateway (v5 compatible)	DataPower API Gateway
Native policies	No	Yes
OAuth provider	Full OAuth 2.0 Support	Full OAuth 2.0 Support
OAuth policy	No	Yes
OpenID Connect	Supported through a template	Supported natively
Invoke policy	Yes	Yes
Custom policies	Yes	Yes
Conditional policies	if, operation-switch, switch	switch
Activity logging	Implicitly executed at the end of API assembly	Configured in the API design, outside of the API assembly.
Parse policy (threat detection)	No	Yes
Gateway extensions	Yes	Yes
Support for mutual TLS (mTLS)	Yes	Yes

- [Specifying a gateway type for an API definition](#)
- [Specifying a gateway type for your Product](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## API Connect user roles

The IBM® API Connect solution provides an infrastructure, tools, and facilities that allows users to create, manage, and stage APIs. The ability to perform tasks in the API Connect user interfaces is controlled through user roles, and the permissions that are assigned to those roles.

The roles described here are the default API Connect roles. In the API Manager user interface, you can create custom roles; for more information, see: [Creating custom roles](#). You can also create custom roles in the Developer Portal user interface.

The following sections describe the roles and permissions for each of the API Connect user interfaces:

- [User roles in the Cloud Manager UI](#).
- [User roles in the API Manager UI](#).
- [User roles in the Developer Portal UI](#).

## User roles and permissions in the Cloud Manager UI

The following table describes the Cloud Manager UI user permissions as configured in the base product. Certain roles can be edited as indicated in Table 2, and custom roles can be created. For instructions on how to create custom roles for the Admin organization (Cloud Manager users), see [Creating roles in the admin organization](#).

Table 1. Cloud Manager UI permissions

Permission	Action	Meaning
Cloud Settings	View	View all items on the Cloud Manager > Settings menu (except Roles)
	Manage	Add, update, and delete all items on the Cloud Manager > Settings menu (except Roles)
Member	View	View members on the members list located at Cloud Manager > Members
	Manage	Add and invite members from Cloud Manager > Members
Org	View	Org:View is a permission assigned to all Roles in Cloud Manager. It does not provide access to any functionality. It allows a user to activate their membership. It is the only permission in the Member role.
Provider-Org	View	View the list of provider organizations at Cloud Manager > Provider Organizations
	Manage	Add, edit, and delete provider organizations and invite owners from Cloud Manager > Provider Organizations
Settings	View	View the items on the Cloud Manager > Resources menu plus Roles located at Cloud Manager > Settings > Roles
	Manage	Add, edit, and delete the items on the Cloud Manager > Resources menu plus Roles located at Cloud Manager > Settings > Roles
Topology	View	View the items on the Cloud Manager > Topology menu
	Manage	Add, edit, and delete the items on the Cloud Manager > Topology menu

The following table lists the various Cloud Manager UI roles and the permissions assigned to them.

Table 2. Cloud Manager UI roles

Role	Permissions	Actions	Default role provides access to	Notes
Owner	All permissions	All actions	All menus	Cannot be modified or deleted.
Administrator	All permissions	All actions	All menus	Can be modified and deleted.
Member	Org	View	Membership activation only	Cannot be modified or deleted. Member role is automatically assigned to all users when they activate their membership from the invitation. It allows them to activate but does not provide access to any menus.
Organization Manager	Org	View	N/A	Can be modified and deleted.
	Provider-Org	View, Manage	Provider Organizations menu	
Topology Administrator	Org	View	N/A	Can be modified and deleted.
	Topology	View, Manage	Topology Menu	
	Settings	View, Manage	Resources menu plus Settings > Roles	
Viewer	All permissions	View	All menus, view only	Cannot be modified or deleted.

## User roles and permissions in the API Manager UI

The following tables describe the API Manager UI user permissions.

A user with Roles permission can change the permission assignments, and can create custom roles; for more information, see [Creating custom roles](#) in the section, [Managing your APIs](#).

Note: In API Manager, the Owner role has full access and cannot be edited or deleted. All other roles, including custom roles, can be deleted. If you delete a role, users lose that role. If a user loses that role, their account remains in API Manager, enabling you to add a role to the user at a future date.

Table 3. Organization permissions

Permissions	Action	Permits the member to
Member	View	View organization's members

Permissions	Action	Permits the member to
	Manage	Manage organization's members
Settings	View	View organization's configuration settings, including roles, TLS profiles, and user registries. View configuration settings for a Catalog or Space, including policies and OpenAPI extensions.
	Manage	Manage organization's configuration settings, including roles, TLS profiles, and user registries. Manage configuration settings for a Catalog or Space, including policies and OpenAPI extensions.
Topology	View	View topology permissions for configuring portal and gateway services. Also view the clusters.
	Manage	Manage topology permissions for configuring portal and gateway services. Also manage the clusters.
Org	View	View organization
Product-Drafts	View	View draft APIs and Products
	Edit	View draft APIs and edit draft Products
Api-Drafts	View	View draft APIs
	Edit	Edit draft APIs and view draft Products
Product	View	View Products
	Stage	Stage Product
	Manage	Manage Product
Product-Approval	View	View Product lifecycle changes
	Stage	Approve the staging of a Product
	Publish	Approve the publishing of a Product
	Supersede	Approve the superseding of a Product
	Replace	Approve the replacement a Product
	Deprecate	Approve the deprecation of a Product
	Retire	Approve the retiring of a Product
Consumer-Org	View	View consumer organization and developers
	Manage	Manage consumer organization and developers
App	View	View both production and development applications.
	Manage	Manage both production and development applications. A member with this permission can also request the promotion of a development app to a production app. This request triggers a task that needs approval by a member with the App-approval Manage permission.
App-dev	Manage	Manage development applications. This permission does not include the ability to manage production apps.
App-Approval	View	View application approvals, for requests to promote a development app to a production app.
	Manage	Manage (Approve or Decline) requests for approval to promote a development app to a production app.
Subscription	View	View application Plan subscriptions that have been created by application developers in the Developer Portal.
	Manage	Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.
Subscription-Approval	View	View application Plan subscription approvals
	Manage	Manage (Approve or Decline) application Plan subscriptions
Api-Analytics	View	View analytics
	Manage	Manage analytics
Child	View	At the provider organization level, view Catalogs in the provider organization. At the Catalog level, view Spaces in the Catalog.
	Create	At the provider organization level, create Catalogs in the provider organization. At the Catalog level, create Spaces in the Catalog.
	Manage	At the provider organization level, manage Catalogs in the provider organization. At the catalog level, manage Spaces in the Catalog. Management tasks including deleting a Catalog or Space, or transferring ownership of a Catalog or Space.

A user with Settings > Manage permission can change the permission assignments, and can create custom roles; for more information, see [Creating custom roles](#) in the section, [Managing your APIs](#).

Table 4. Default API Manager UI roles and the default permissions assigned to those roles.

Role	Role description	Permissions	Actions
Organization Owner	A provider organization owner has the full set of access permissions to API Connect functions, and also commission APIs and tracks their business adoption.	All permissions	All actions.
Administrator	A provider organization administrator has, by default, the full set of access permissions to API Connect functions, and also commission APIs and tracks their business adoption.	All permissions	All actions.
API Administrator	API administrators manage the lifecycle of APIs and publish APIs for discovery and use.	All permissions	All actions except cannot manage the following permissions: Member, Settings, Topology, and Child.
Community Manager	A community manager manages the relationship between the provider organization and application developers, provides information about API usage, and provides support to application developers.	Member	View
		Settings	View
		Topology	View gateway services or portal services at the provider organization.
		Org	View

Role	Role description	Permissions	Actions
		Drafts	View, Edit
		Product	View
		Product-approval	View
		Consumer-org	View, Manage
		App	View, Manage
		App-dev	Manage
		App-approval	View, Manage
		Subscription	View, Manage
		Subscription-approval	View, Manage
		Api-analytics	View, Manage
		Child	View
Developer	API developers design and develop APIs and applications for the provider organizations to which they belong. Note: The Developer role allows the creation of Products and APIs, and the staging and publishing of Products to a Catalog or Space, when assigned to a user at the provider organization level, but <b>not</b> when assigned to a user who is a member only of a Catalog or Space within a provider organization. A Developer in a Catalog or Space can, however, manage Products that have been staged or published to the Catalog or Space.	Member	View
		Settings	View
		Topology	View gateway services or portal services at the provider organization.
		Org	View
		Drafts	View, Edit
		Product	View, Stage, Manage
		Product-approval	View, Stage, Publish, Supersede, Replace, Deprecate, Retire
		Consumer-org	View
		App	View, Manage
		App-dev	Manage
		App-approval	View, Manage
		Subscription	View, Manage
		Subscription-approval	View, Manage
		Api-analytics	View, Manage
		Child	View, Create
Member	Member of a provider organization	Org	View
Viewer	Viewer of a provider organization	Member	View
		Topology	View gateway services or portal services at the provider organization.
		Org	View
		Drafts	View
		Product-approval	View
		Consumer-org	View
		App	View
		App-approval	View
		Subscription	View
		Subscription-approval	View
		Api-analytics	View
		Child	View

Note: In API Manager, the Organization Owner role has full access and cannot be edited or deleted. All other roles, including custom roles, can be deleted. If you delete a role, users lose that role. If a user loses that role, their account remains in API Manager, enabling you to add a role to the user at a future date.

## User roles in the Developer Portal UI

The following table describes the various Developer Portal UI roles that relate to working with APIs and applications. In addition, you can create custom roles for the Developer Portal site itself.

Table 5. Developer Portal UI roles

Role	Role Description	Permission	Actions
Owner	Owns and administers the app developer organization	Organization member	View, Manage
		Organization settings	View, Manage
		Organization view	View
		Consumer product	View
		Consumer app	View or Manage production or development applications
		Consumer app-dev	Manage development applications
		Consumer subscription	View or Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.
		Consumer app-analytics	View application analytics
Administrator	Administers the app developer organization	Organization member	View, Manage
		Organization settings	View, Manage
		Organization	View
		Consumer product	View
		Consumer app	View, Manage production or development applications
		Consumer app-dev	Manage development applications
		Consumer subscription	View or Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.
		Consumer app-analytics	View application analytics
Developer	Builds and manages apps in the developer organization	Organization member	View
		Organization	View
		Consumer product	View
		Consumer app	View or Manage production or development applications.
		Consumer app-dev	Manage development applications
		Consumer app-analytics	View
Member	Member of the app developer organization	Organization	View
Viewer	Viewer of the app developer organization	Organization member	View
		Organization settings	View
		Organization	View
		Consumer product	View
		Consumer app	View applications
		Consumer production-app	View production applications
		Consumer app-analytics	View application analytics

Note: A user called admin is created automatically, that has full administrator access to the Developer Portal site. The admin user can view Products and APIs but has no access to use APIs. The admin user assumes the email address of the owner of the provider organization associated with the Developer Portal.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## API Connect support

If you experience a problem with IBM® API Connect that you cannot resolve, you can check the IBM Support website for the most recent technical bulletins and fixes. Otherwise, you can contact IBM Support.

For the most recent API Connect technical information, see the [IBM Support Community](#).

If you cannot find a resolution, before you contact IBM Support, you must gather information about the problem. For details of the information you must gather before contacting IBM Support, see [MustGather - Collecting data: API Connect problem determination](#).

Providing IBM Support with a good description of the problem together with the details of your API Connect configuration, helps to expedite the problem resolution.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## API Connect glossary

The IBM® API Connect and Cloud Manager glossary of terms and definitions.

### API Administrator (role)

Manages the API product lifecycle for the Provider Organizations for which they are a member.

### API Event

An event captured for use by API Connect Analytics or third-party analytics, such as response time, HTTP response code, payload of the request and response body, and so on. An API event is logged each time an API operation is invoked via the Gateway server.

### API gateway

Service that acts as a single entry point or “front door” for provider APIs and back-end services. An API Gateway accepts and processes concurrent API calls, and performs traffic management, authorization and access control, monitoring, and API version management. See also [IBM DataPower Gateway](#).

### API Manager

Graphical tool in API Connect that enables you to manage Catalogs, Spaces, and APIs, users and roles in the Provider organization, consumer organizations and communities, publish Products to the Developer Portal, and analyze API usage.

### API Designer

Graphical tool that runs locally on a laptop or desktop system that enables you to create and modify APIs and LoopBack® apps, and publish them to IBM Cloud or container runtimes.

### API operation

REST API call consisting of an HTTP verb and a URL path (endpoint). For example, `GET http://myserver.com/api/users` that returns a list of users.

### Application

Software that consumes (calls) an API. One or more Applications are registered by a consumer organization to subscribe to APIs. The application is allocated client ID and client secret credentials that it supplies when invoking API calls.

### assembly

Makes side calls to external services and then transforms and aggregates the response before a response is relayed to the calling application.

### Availability zones

Isolated locations within data centers from which public cloud services originate and operate. Businesses choose one or multiple worldwide availability zones for their services depending on business needs. Availability Zones provide high availability for services by providing redundancy across regions.

### Availability zone (primary)

For Kubernetes form factor, contains the management service. Other zones can contain other services such as the Developer Portal, but not the management service.

### Catalog

A staging target that behaves as a logical partition of the gateway and the Developer Portal. The URLs for API calls and for the Developer Portal are specific to a particular Catalog.

### client ID

A piece of information that identifies an individual application. An application can invoke an API only if it passes an application key that is recognized by the IBM API Connect system and is granted access to the API. The application key is passed by the client by using an HTTP query parameter.

### client secret

A piece of information used together with the application key to verify the identity of an application. An API can be configured to require that client applications supply their client secret with their client ID. The client secret functions effectively as a password known only to the application. The client secret is passed by the client by using an HTTP query parameter.

### Cloud Manager (tool)

Graphical tool in API Connect on-premises installation that enables you to define servers, administer and scale system resources, monitor runtime health and create Provider organizations. The Cloud Administrator is the primary user of the Cloud Manager.

### Cloud Administrator (role)

Manages the configuration of resources, regions, and availability zones for the Admin Organization.

### cluster

A collection of one or more servers that provide a specific function.

### Cold standby

A deployment configuration in which failover servers are in a stopped state until a failover is required, resulting in a longer time window to restore the normal operation of the solution.

### community

A collection of consumer organizations. It is used as a grouping construct when publishing APIs. Communities are used to restrict the visibility and accessibility of APIs. An API can be published to selected communities, which means that only application developers within those organizations can see the API.

### Community Manager (role)

Manages application developer communities for the Provider Organizations for which they are a member.

### Consumer organization

Within a catalog, representation of a business entity that wishes to consume APIs exposed by the Catalog. For example, a third-party application development company would register themselves as a consumer organization (via the Developer Portal). Each developer in their company can then be registered as a user inside that consumer organization.

**IBM DataPower® Gateway**

API Gateway service component of API Connect that helps provide security, control, integration and optimized access to APIs. Due to its security and hardening, it is well-suited for a deployment in the demilitarized zone (DMZ) for externally-facing production scenarios. Available in physical, virtual, cloud, Linux and Docker form factors. There are two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway; for details, see [API Connect gateway types](#).

**Developer (role)**

Creates and configures APIs, Products, and policies for the Provider Organizations for which they are a member. An API Developer can be a member of one or more Provider Organizations. The API Developer focuses on the technical implementation of APIs more than they do on the business relationship with application developers.

**Development Catalog**

Catalog used for testing APIs that are under development and in which approvals are bypassed for publishing and lifecycle actions. Pending approvals are canceled when a non-Development Catalog is converted to a Development Catalog.

**Developer Portal**

Component of API Connect that provides a customizable graphical web portal for developers to discover APIs, register applications that consume APIs, subscribe to usage plans, and test and use APIs.

**Developer Toolkit**

Locally-installed package that includes API Designer and the `apic` command-line tool that enables you to create, edit, manage, and publish APIs and apps.

**Gateway**

See [API gateway](#).

**Gateway service**

API Connect service that provides API gateway functionality, such as microgateway or IBM DataPower.

**Hot standby**

A deployment configuration in which a set of servers are actively running ready to instantaneously take over in the event of a failure, but not actively serving traffic until that failover.

**Identity provider**

Provides identifiers for users looking to interact with a system, assert to such a system that such an identifier presented by a user is known to the provider, and possibly provide other information about the user that is known to the provider. API Connect supports LDAP, AuthURL, and Local User Registries.

**Integrations**

Third-party tools to build on and improve your API Connect workflow; for example, Slack, Auth0, etc.

**Integration profile**

Standard API that you can use to integrate with management services for things like identity, notifications, API analytics, and so on.

**Keystore**

A repository of security certificates, either authorization certificates or public key certificates, and corresponding private keys, used in SSL encryption. The Keystore file has a `.jks` extension.

**LoopBack model**

A JavaScript object that represents application data and includes validation rules, data access capabilities, and business logic. LoopBack models provide a REST API by default, and connect to data sources for access to back-end data

**LoopBack data source**

A JavaScript object that represents a back-end service such as a database, REST API (to be consumed), or SOAP web service. Data sources are backed by connectors that communicate directly with the database or other back-end service.

**Management server**

Stores all of the cloud configuration, and controls communication between the other servers within API Connect.

**Management service**

Consists of one or more Management servers.

**Member (role)**

The default role for all users in both the Admin and Provider Organization. All users are assigned the Member role in addition to other roles they may require.

**microservice**

Modular, independently-deployable application service that communicates with other microservices through a REST API. Microservices are typically organized around capabilities, for example, recommendation, inventory, shipping, or billing.

**Mutual authentication**

Process in which both entities on a network authenticate each other. In a network environment, the client authenticates the server and vice-versa. It is optional for TLS. Also called two-way authentication.

**Notification settings**

How you configure notifications for API Connect users (API providers and consumers).

**Notification services**

Integrations that provide notification capabilities, such as email.

**Notification templates**

The configuration of the message format and wording for a notification service.

**OAuth provider**

The OAuth provider supplies the OAuth authentication for logins. API Connect supports both Native and Third Party OAuth providers. Some common third-party OAuth providers are Google and Facebook.

**OpenAPI Components**

Part of API specification that contains a set of reusable objects for aspects of an API specification, such as schemas, responses, requestBodies, and headers. For more information, see [OpenAPI v3 specification](<https://github.com/OAI/OpenAPI-Specification/blob/OpenAPI.next/versions/3.0.md#components-object>).

**organization**

The entity that owns APIs or applications that use APIs. A provider organization owns APIs and associated Plans, and can additionally own applications. A consumer organization owns only applications. An organization has at least one owner. An organization can be a project team, department, or division.

**Organization Manager (role)**

The Organization Manager manages Provider Organizations for the Admin Organization.

**Path**

Defines the route through which users access REST APIs. A path consists of one or more HTTP operations such as GET or POST.

**Plan**

The packaging construct by which APIs are made available to developers. A Plan makes a collection of operations from one or more APIs available, and is published to communities of application developers. Application developers gain access to APIs by registering applications to access Plans. A Plan carries with it a collection of policy settings. In the simplest form, a Plan defines a single quota policy that applies to all the API operations that are accessed through the Plan. In more advanced cases, additional policies can be associated with a Plan.

**policy**

A configuration that controls a specific aspect of processing in the Gateway server during the handling of an API invocation at run time. Policies are the building blocks of assembly flows. Policies provide the means to configure capability, such as security, logging, routing of requests to target services, and transformation of data from one format to another. Policies can be configured in the context of an API or in the context of a Plan.

**Product**

Provide a method by which you can group APIs into a package that is intended for a particular use. Additionally, they contain Plans, which can be used to differentiate between different offerings. You can create Plans only within Products, and these Products are then published in a Catalog.

**Provider Organization Owner**

Owns and administers API provider organizations, manages application developer communities, authors APIs and defines products, manages the API product lifecycle. Owners are invited by the Cloud Administrator to join API Connect as an owner of a provider organization.

**proxy**

Application programming interface that forwards requests to a user-defined back-end resource and relays responses back to the calling application.

**Region**

A physical location (site or data center) hosting infrastructure isolated from other locations, with independent power and networking connectivity. A region may or may not have further sub-isolation characteristics such as semi-independent pods or availability zones.

**Resources (User registries, TLS Profiles, Notifications)**

Resources supply necessary functions for the API Connect cloud, such as user authentication, SSL security, and sending system-generated emails.

**role**

Defines permissions that can enable functionality for users. Each role has a different set of permissions.

**security definition**

Specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

**server**

A single appliance, such as an IBM WebSphere IBM DataPower appliance.

**service**

A user-configurable element implemented through one or more server processes in the API Connect runtime, such as microgateway, Analytics, IBM DataPower, and Developer Portal.

**SNMP**

Simple Network Management Protocol (SNMP) is a popular protocol for network management. It is used for collecting information from, and configuring, network devices, such as servers, printers, hubs, switches, and routers on an Internet Protocol (IP) network. The SNMP hosts are configured in the API Connect Cloud Manager.

**Space**

A subdivision of a Catalog. Each Space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that Space, enabling each team to manage their APIs independently.

**SSL (TLS) Profile**

An SSL/TLS profile is used to secure the transmission of data through web sites. SSL certificates guarantee that information you submit to web sites will not be stolen or tampered with.

**subscription**

The means by which an application developer gains access to the resources provided by an API. An application developer uses the Developer Portal to subscribe to the plan in which the API is published.

**TLS**

Transport Layer Security - a cryptographic protocol that provides secure communication over a network to prevent eavesdropping and tampering. It is a successor to SSL and runs over TCP.

**TLS Profiles**

The Cloud Manager and API Manager use TLS profiles to secure transmission of data through web sites. TLS certificates guarantee that information you submit to web sites will not be stolen or tampered with. A TLS Profile consists of Server name, Protocol used (SSL or TLS), and whether Mutual Authentication is required.

**Toolkit**

See Developer Toolkit.

**Topology administrator (role)**

Configures gateway services for the Admin Organization.

**Truststore**

Stores certificates from trusted Certificate authorities(CA) which are used to verify certificate presented by Server in SSL/TSL Connection. While a keystore stores a server's credentials, the truststore stores certificates from a third-party CA.

**User registry**

A database or other collection containing credentials for users such as provider organization members, consumer organization members, and API Connect administrators. The users are authenticated by an identity provider such as LDAP. User registries authenticate users at login time when accessing the Cloud Manager or API Manager applications. User registries are also used to protect APIs so that user credentials must be supplied when an API is called.

**vendor extension**

An extension to OpenAPI (Swagger) specification required by a particular use case.

**Visibility**

Setting visibility determines whether a Provider Organization has access to an Availability Zone, or other service.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Accessibility features for IBM API Connect

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

### Accessibility features

The following list includes the major accessibility features in IBM® App Connect Enterprise. You can use screen-reader software to hear what is displayed on the screen.

- Supports keyboard-only operation.
- Supports interfaces commonly used by screen readers.

Tip: This product documentation, and its related publications, are accessibility-enabled for the IBM Home Page Reader. You can operate all features by using the keyboard instead of the mouse.

If you are reading a PDF file with a screen reader, the default reading option typically returns the best results. In some cases, how the PDF file is generated might require you to select one of the other reading options. For example, Use reading order in raw print stream.

---

## Keyboard navigation

---

This product uses standard Linux® and Microsoft Windows navigation keys.

For more information about the commitments that IBM makes towards accessibility, see the [IBM Accessibility Center](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## License updates

---

IBM API Connect v2018 is changing the way licenses are created to better serve customers in these dynamic times and reduce the number of licenses that need to be managed.

Currently, licenses follow the product numbering standard based on IBM V.R.M.F (Version.Release.Mod.FixPack) structure and API Connect v2018 creates a new license for every fix pack.

Starting in June 2022, API Connect v2018 future release licenses will be updated to use the single V.R.M Mod-level license that covers all fixes and security roll-ups underneath it. For example, the next license covering the 2018.4.1.x stream will be listed as "2018.4.1". This will be the master mod-level license for all Fix Pack and security roll-up releases in this stream. New licensing applies to v2018.4.1.20 and later. There are no changes to license terms, only updates to open-source notices documented in the notes for each.

Note: For v2018.4.1.20, some API Connect components, such as Analytics, still use the v2018.4.1.19 license even though the platform and most components use the newer license. The use of the v2018.4.1.19 license for the affected components will not cause installation problems. All components of API Connect v2018.4.1.20 are covered by the 2018.4.1 license.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Tracking API volume for auditing and compliance

---

For client security reasons, IBM entrusts its clients with monitoring their own API volume and ensuring that it is within the limits of the contract.

---

## Usage archiving

---

You should periodically record the number of your API calls from the Analytics tool to maintain a record of your yearly usage. To ensure the most accurate results, you should capture the counts of the API Calls on a daily basis. For information about creating a query that counts API calls for different response status codes and for a specified time range, see [Counting total API calls for your Analytics service](#).

---

## Overage charging

---

If you exceed your allotted usage, it is your responsibility to report this to IBM in the form of a CSV file so the correct overage charge can be applied. IBM has the right to audit customer usage data at any time. If unreported overages are found, there are severe penalties.

Overage is based on the measurement period. For example, overage for a contract might be measured by the year. If your API volume exceeds the entitlement after 6 months, you must either pay overages for the remaining period or purchase additional volume.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Notices

This information was developed for products and services offered in the U.S.A.

IBM® may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement, or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

#### COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs.

Each copy or any portion of these sample programs or any derivative work, must include a copyright notice as follows:

© (your company name) (year). Portions of this code are derived from IBM Corp. Sample Programs. © Copyright IBM Corp. \_enter the year or years\_. All rights reserved.

## Trademarks

---

IBM, the IBM logo, and [ibm.com](http://www.ibm.com)® are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Copyright and trademark information page at <https://www.ibm.com/legal/copytrade.shtml>.

Java™ and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

Linux® is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft and Windows are trademarks of Microsoft Corporation in the United States, other countries, or both.

Other company, product, and service names might be trademarks of IBM or other companies.

## Privacy Policy Considerations

---

IBM Software products, including software as a service solutions, (*Software Offerings*) may use cookies or other technologies to collect product usage information, to help improve the user experience, to tailor interactions with the user or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth in the following paragraphs.

Depending upon the configurations deployed, this Software Offering may use session and persistent cookies that collect each user's session ID for purposes of session management, or functional purposes. These cookies can be disabled, but disabling them will also eliminate the functionality they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, See IBM's Privacy Policy at <https://www.ibm.com/privacy> and IBM's Online Privacy Statement at <https://www.ibm.com/privacy/details> the section entitled *Cookies, Web Beacons and Other Technologies* and the *IBM Software Products and Software-as-a-Service Privacy Statement* at <https://www.ibm.com/software/info/product-privacy>.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Terms and conditions for information centers

Permissions for the use of these publications are granted subject to the following terms and conditions.

### Applicability

---

These terms and conditions are in addition to any terms of use for the IBM® website.

### Personal use

---

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

### Commercial use

---

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

### Rights

---

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the aforementioned instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## IBM API Connect Considerations for GDPR Readiness

Information about features of IBM® API Connect that you can configure, and aspects of the product's use, that you should consider to help your organization with GDPR readiness.

### For PID(s): 5725-Z22 5725-Z63

---

#### Notice:

---

This document is intended to help you in your preparations for GDPR readiness. It provides information about features of API Connect that you can configure, and aspects of the product's use, that you should consider to help your organization with GDPR readiness. This information is not an exhaustive list, due to the many ways that clients can choose and configure features, and the large variety of ways that the product can be used in itself and with third-party applications and systems.

**Clients are responsible for ensuring their own compliance with various laws and regulations, including the European Union General Data Protection Regulation. Clients are solely responsible for obtaining advice of competent legal counsel as to the identification and interpretation of any relevant laws and regulations that may affect the clients' business and any actions the clients may need to take to comply with such laws and regulations.**

**The products, services, and other capabilities described herein are not suitable for all client situations and may have restricted availability. IBM does not provide legal, accounting, or auditing advice or represent or warrant that its services or products will ensure that clients are in compliance with any law or regulation.**

#### Table of Contents

---

10. [Capability for Restricting Use of Personal Data](#)

## GDPR

---

General Data Protection Regulation (GDPR) has been adopted by the European Union ("EU") and applies from May 25, 2018.

#### Why is GDPR important?

GDPR establishes a stronger data protection regulatory framework for processing of personal data of individuals. GDPR brings:

- New and enhanced rights for individuals
- Widened definition of personal data
- New obligations for processors
- Potential for significant financial penalties for non-compliance
- Compulsory data breach notification

#### Read more about GDPR

- [EU GDPR Information Portal](#)
- [ibm.com/GDPR website](http://ibm.com/GDPR)

## Product Configuration - considerations for GDPR Readiness

---

The following sections provide considerations for configuring API Connect to help your organization with GDPR readiness.

#### Configuration to support data handling requirements

The GDPR legislation requires that personal data is strictly controlled and that the integrity of the data is maintained. This requires the data to be secured against loss through system failure and also through unauthorized access or via theft of computer equipment or storage media.

IBM API Connect stores identity data in a local database. This encompasses both clients' employee identity data and end users' identity data. Direct access to this database is not available. This data is encrypted by default in IBM API Connect Version 5.0 - refer to [Disk encryption](#) for details. Identity information collected is protected in transit, refer to [TLS profiles](#) for details on configuring TLS profiles.

API Connect supports a variety of user registry types for authenticating users. Refer to [Authenticating by using your enterprise user registry](#) for details. When using a local user registry, passwords are stored in encrypted form in the local API Connect database. If you want alternative password management, leverage a non-user registry option to manage passwords.

Administrators, that you define, can view identity information. Administrators can take backups that include identity information. It is your responsibility to protect these backups.

A core component for an API Connect deployment are gateways. Refer to [API Gateways](#) for details about gateways. DataPower® Gateways are commonly leveraged, refer to [DataPower Gateway Version 7.7 Documentation](#) for details on DataPower Gateways. Refer to the DataPower Gateway deployment guidelines document for considerations for configuring DataPower Gateways to help your organization with GDPR readiness.

Configuration to support Data Privacy

For Developer Portal, you can customize the privacy policy statement, refer to [Customizing the privacy policy statement](#) for details.

Configuration to support Data Security

To learn about securing your solution, use the API Connect product documentation ([https://www.ibm.com/support/knowledgecenter/en/SSMNE5\\_5.0.0](https://www.ibm.com/support/knowledgecenter/en/SSMNE5_5.0.0)) and search for "security".

## Data Life Cycle

---

GDPR requires that personal data is:

- Processed lawfully, fairly and in a transparent manner in relation to individuals.
- Collected for specified, explicit and legitimate purposes.
- Adequate, relevant and limited to what is necessary.
- Accurate and, where necessary, kept up to date. Every reasonable step must be taken to ensure that inaccurate personal data are erased or rectified without delay.
- Kept in a form which permits identification of the data subject for no longer than necessary.

### What is the end-to-end process through which personal data go through when using our offering?

API Connect collects and stores identity information, including first and last name, and email address, for the purposes of user registration. Cloud Manager and API Manager accounts are for your employees (or designated actors). Developer Portal accounts are for your consumers of your APIs. Identity information can be collected directly from users or can be copied from LDAP registries. In situations where non-local user registries are used, only email address is copied from LDAP registry. Developer Portal user accounts can be deleted - refer to [Deleting your Developer account](#) for details. Cloud Manager and API Manager user accounts' identity information can be anonymized by users.

Users of the API Manager UI can publish Products and APIs to the Developer Portal for Application Developers to access and use. Refer to [Developer Portal: discover and use APIs](#) to learn about Developer Portal. Developer Portal accounts are for consumers of your APIs. You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal - refer to [Customizing the terms and conditions statement](#) for details.

API Connect optionally logs information related to API invocations. This capability in API Connect is known as API Analytics. Refer to [API Analytics](#) for details about API Analytics.

The API Analytics log information can optionally include unknown / unclassified information such as query headers and request and response information related to API calls - you control defining the APIs and data associated with API invocations. To disable API Analytics, refer to [Enabling or disabling access to analytics event data in API Connect](#). Logging preferences can be configured at the API level, refer to [Activity Log](#) for details.

The retention period for Analytics data is configurable - refer to [Specifying the cloud settings](#) for details. Backup capability for this information is not available.

API Connect logs collect technical information related to service use including tracing of service execution and sequences of operation use. Other technical data related to service use includes data values that define the mechanisms used to connect to the service, for example, IP address. This data is collected for debugging and service improvement. Service diagnostics are collected during unexpected or error situations to allow the offering team to correct the situation and hopefully prevent it from occurring in the future. There is no direct access available to these logs. These logs are managed by API Connect and rollover based on size and time criteria. The logs can be downloaded from the system, refer to [Gathering postmortem information about your servers](#) for details.

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization. For example, publishing a product or creating an organization would trigger this event. The audit event record contains information about the changes to the API lifecycle or organization. Refer to [Audit event fields](#) for details. The retention for these events is the Analytics retention period.

## Data Collection

---

Developer Portal accounts are for consumers of your APIs. You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal - refer to [Customizing the terms and conditions statement](#) for details. You can customize the privacy policy statement for Developer Portal, refer to [Customizing the privacy policy statement](#) for details.

### Types of Data Collected

API Connect collects and stores identity information, including first and last name, and email address, for the purposes of user registration. Cloud Manager and API Manager accounts are for your employees (or designated actors). Developer Portal accounts are for your consumers of your APIs. Identity information can be collected directly from users or can be copied from LDAP registries. In situations where non-local user registries are used, only email address is copied from LDAP registry. Developer Portal user accounts can be deleted - refer to [Deleting your Developer account](#) for details. Cloud Manager and API Manager user accounts' identity information can be anonymized by users.

You can customize the privacy policy statement for Developer Portal, refer to [Customizing the privacy policy statement](#) for details.

## Data Storage

---

Identity data is stored in API Connect local data store. There is no direct access available to this data store.

API Analytics leverages Elasticsearch real-time distributed search and analytics engine for storage of logged data. There is no direct access available to this data store.

Identity data is included in backups, refer to [Creating a backup of an API Connect configuration](#) for details on taking backups. It is your responsibility to protect and discard backups.

## Data Access

---

Identity information can be viewed by administrators that you define.

Analytics information can be accessed via a variety of means. Refer to [Viewing and exporting analytics and API event data](#) and [Analytics in the Developer Portal](#) for details.

Analytics information can be offloaded to third party systems. Refer to [Specifying the cloud settings](#) for details.

Technical information related to service use is collected in logs. The logs can be downloaded from the system, refer to [Gathering postmortem information about your servers](#) for details. These logs are managed by API Connect and rollover based on size and time criteria. Downloaded logs can be provided to IBM Support for use in problem determination.

API Connect can generate audit events. Refer to [Audit event fields](#) for details. Audit events can be offloaded to third party systems, refer to [Configuring the offload of analytics event data to third-party systems](#) for details. Administrators can view audit events as notifications - refer to [Viewing information about activities](#) for details. Audit events can be emitted as syslog messages, refer to [Syslog auditing and your cloud](#) for details.

API Connect logs collect technical information related to service use including tracing of service execution and sequences of operation use. Other technical data related to service use includes data values that define the mechanisms used to connect to the service, for example, IP address. This data is collected for debugging and service improvement. Service diagnostics are collected during unexpected or error situations to allow the offering team to correct the situation and hopefully prevent it from occurring in the future. There is no direct access available to these logs. The logs can be downloaded from the system, refer to [Gathering postmortem information about your servers](#) for details. These logs are managed by API Connect and rollover based on size and time criteria.

## Data Processing

---

Data collected by API Connect or to gateways via API invocations is protected by TLS in transit. Refer to [TLS profiles](#) for details.

Data is stored in API Connect local database on the API Connect appliances. There is no direct access available to this data. This data is encrypted by default in IBM API Connect Version 5.0 - refer to [Disk encryption](#) for details.

Cloud Manager and API Manager administrators (defined by you) have read access to identity data.

## Data Deletion

---

### Right to Erasure

Article 17 of the GDPR states that data subjects have the right to have their personal data removed from the systems of controllers and processors - without undue delay - under a set of circumstances.

### Data Deletion characteristics

Users can delete Developer Portal user accounts - refer to [Deleting your Developer account](#) for details. Cloud Manager and API Manager user account identity data can be anonymized by the users thus deleting users association to the account data.

Technical information related to service use collected in logs is rolled over based on size and time criteria.

To disable API Analytics, refer to [Enabling or disabling access to analytics event data in API Connect](#). API Analytics data retention period is configurable - refer to [Specifying the cloud settings](#) for details. IBM Support personnel can delete API Analytics data, this capability is only available through screen sharing with your authorized personnel. Analytics information can be offloaded to other systems - refer to [Specifying the cloud settings](#) and [Syslog auditing and your cloud](#) for details. You are responsible for protection and discarding of offloaded data.

Identity information for accounts is included in system backups. You manage the deletion of system backups.

## Data Monitoring

---

Customers should regularly test, assess, and evaluate the effectiveness of their technical and organizational measures to comply with GDPR. These measures should include ongoing privacy assessments, threat modeling, centralized security logging and monitoring among others.

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization. For example, publishing a product or creating an organization would trigger this event. The audit event record contains information about the changes to the API lifecycle or organization. Refer to [Audit event fields](#) for details. Audit events can be offloaded to a third party system, refer to [Configuring destination targets for API Connect analytics data](#) for more information. Audit events can be emitted as syslog messages - refer to [Syslog auditing and your cloud](#) for details.

## Capability for Restricting Use of Personal Data

---

Users of the API Manager UI can publish Products and APIs to the Developer Portal for Application Developers to access and use. Refer to [Developer Portal: discover and use APIs](#) to learn about Developer Portal. Developer Portal accounts are for consumers of your APIs. You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal - refer to [Customizing the terms and conditions statement](#) for details. You can customize the privacy policy statement for Developer Portal, refer to [Customizing the privacy policy statement](#) for details.

Developer Portal users can modify their own account information, and delete their account.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Essential reading

These articles by IBM® API Connect product specialists provide a wealth of supporting information on APIs and the API economy.

### [Why Become a Digital Business?](#)

Executing a Digital Transformation to become a Digital Business is among the hottest initiatives now – crossing both business and IT. But, is this just the latest buzzword or is there something to this that is different? Do you know **why** you should become a “Digital Business”?

### [Creating A Digital Ecosystem – Past, Present, and Future](#)

The ability to create a digital ecosystem is critical to digital transformation success. Your success is your network reach.

### [Agile integration](#)

Your business needs a modern, agile approach to integration. It should empower extended teams to create integrations, leverages a complete set of integration styles and capabilities, and increases overall productivity.

### [What is an API? and What is the API Economy?](#)

Businesses start to consider APIs and the API Economy at various times. Many are long down their API journeys, while others are still considering whether to start. This article looks at some of the basics that companies considering APIs might want to know.

### [What is API Management?](#)

APIs are not new. Software and hardware have had APIs (Application Programming Interfaces) for decades. However, *having* an API and *managing* an API are not the same thing.

### [Providing APIs or Managing APIs – There is a Big Difference](#)

A discussion of the potential for confusion between APIs that are provided and APIs that are managed.

### [Recommendations for an API Economy Center of Excellence](#)

What roles are required to drive a successful API initiative, how should this fit in the current organization, and how do these roles relate to existing roles in the company?

### [Focus on the API Developer](#)

A productive developer is a happy developer. One of the most frequently discussed topics in the API economy is focusing on the needs of the Application developer – the consumer target for your APIs.

### [Agile API development](#)

Agile API Development Customer expectations and behavior are continuously changing. To deliver exceptional customer experience, a business must be nimble to adapt to these changing needs.

### [API Products – Who, What, Where, When, Why and How”](#)

An API Product is an API offering made available for consumer use that is offered to a target market to satisfy a customer’s needs.

### [Changing Culture – How Committed Are You?](#)

How do we change the culture in our organization to create an API culture?

### [Plan Ahead! Don't Build an API Superhighway into a Cul-de-sac](#)

Without proper planning, a business can start their API initiatives, build incredible excitement quickly, but find that the path they have taken leads them into a cul-de-sac (or dead end) that cannot handle the demand they have created.

### [IBM API Connect 2018.4.1.x Deployment WhitePaper](#)

A technical deep dive on the deployment options for IBM API Connect.

### [Principles for API Security - White Paper](#)

API security is of paramount importance in gaining the promised benefits without exposure to negative consequences.

### [Can you trust your APIs?](#)

As enterprises are continuously expanding their digital footprint, they must ensure the API behavior is intact, as it has a far-reaching effect on an application's execution and end-user experience.

### [Istio Service Mesh and APIConnect/DataPower Gateway integration](#)

What is Istio, and how can DataPower API Gateway integrate in an Istio Service Mesh.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Tutorials

These tutorials guide you through the steps typically required to set up, configure and run an API Connect cloud. These tutorials cover topics such as creating the cloud topology, creating Provider organizations, developing and publishing API Products, and promoting those products to external developers.

## Introduction

---

These tutorials are arranged according to the desired goal, such as creating and publishing an API, or managing catalogs of products, or consuming published API products. These goals can be grouped into categories as follows.

Table 1. Tutorial Categories

Category	Description
Cloud Administration	Setting up and configuring the API Connect cloud, including the creation of Provider Organizations.
API Provider Administration	Setting up and managing catalogs, inviting organization members (such as developers), creating Developer Portals, managing resources.
API Product Development and Management	Developing and publishing APIs, products and plans, managing product life cycles.
API Product Promotion and Usage	Managing the Developer Portal presentation and user administration, as well as consuming published API products as an external developer.

---

## Time required

Each tutorial should take approximately 20 - 30 minutes to finish. If you explore other concepts that are related to this tutorial, it might take longer.

Use the links in the following sections to access the tutorials that fit your goals.

## Cloud Administration

---

Table 2. Cloud Administration Tasks. Setting up and configuring the API Connect cloud, including the creation of Provider Organizations.

Category	Tutorials
Initial Configuration	<ul style="list-style-type: none"><li><a href="#">Initial Cloud Configuration</a></li></ul>
Provider Organization	<ul style="list-style-type: none"><li><a href="#">Creating a Provider Organization</a></li></ul>

## API Provider Administration

---

Table 3. API Provider Tasks. Setting up and managing catalogs, inviting organization members (such as developers), creating Developer Portals, managing resources.

Category	Tutorials
Developer Portal Set Up	<ul style="list-style-type: none"><li><a href="#">Creating the Portal</a></li><li><a href="#">Register a Consumer Application</a></li></ul>

## API Product Development and Management

---

Table 4. API Development. Developing and publishing APIs, products and plans, managing product life cycles.

Note: All tutorials listed here use the API Manager interface. The user experience using the API Designer may differ.

Category	Tutorials
Getting Started	<ul style="list-style-type: none"><li><a href="#">Invoke a REST API</a></li><li><a href="#">Create a SOAP API from WSDL</a></li><li><a href="#">Import an API</a></li></ul>
Building APIs	<ul style="list-style-type: none"><li><a href="#">Expose SOAP as REST API</a></li><li><a href="#">Mapping JSON Content</a></li></ul>
Security	<ul style="list-style-type: none"><li><a href="#">Using OAuth Password Grant Tokens</a></li><li><a href="#">Using OpenID Connect security</a></li><li><a href="#">Generating a JSON Web Token (JWT)</a></li><li><a href="#">Validating a JSON Web Token (JWT)</a></li></ul>
Managing APIs	<ul style="list-style-type: none"><li><a href="#">Supercede an Existing API</a></li></ul>

## API Product Promotion and Usage through the Developer Portal

---

There are many tutorials available for the Developer Portal from getting started to advanced customization. For more information, see [Developer Portal tutorials](#).

## Prerequisites

---

- You must have a web browser available, whether you are working online or offline.
- When publishing Products in any of the tutorials you must have the permissions of an Organization Manager or Administrator. However, you can complete several of the tutorials with fewer permissions. For more information about user roles, see [Administering user access](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Installing and maintaining your IBM API Connect cloud

To ensure that your IBM® API Connect cloud functions, your cloud must have the necessary system requirements to support the installation. During the installation process, the components of IBM API Connect can be configured to satisfy your requirements.

Note: For a comprehensive technical guide to best practices, considerations, and deployment options for API Connect, see the [API Connect 2018.4.1.x Whitepaper](#).

- [Kubernetes](#)  
Use the instructions in this section to install, upgrade, and maintain API Connect on Kubernetes.
- [VMware](#)  
Use the instructions in this section to install, upgrade, and maintain API Connect on VMware.
- [IBM Cloud Private](#)  
Use the instructions in this section to install, upgrade, and maintain API Connect on IBM Cloud Private.
- [OpenShift](#)  
You can install API Connect on OpenShift.
- [IBM Cloud Pak for Integration](#)  
IBM API Connect provides the API management capability in IBM Cloud Pak for Integration.
- [Migrating a Version 5 deployment](#)  
The current migration path from v5 is to API Connect v10. You can get more information about migrating to v10 here: [https://www.ibm.com/support/knowledgecenter/SSMNEJ\\_v10/com.ibm.apic.install.doc/migrating.html](https://www.ibm.com/support/knowledgecenter/SSMNEJ_v10/com.ibm.apic.install.doc/migrating.html).
- [Using the API Connect operations command line interface](#)  
The IBM API Connect v2018 `apicops` command line interface is targeted at Operations teams. It contains commands to check the health of the system and some commands to fix specific problems that might be encountered.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Kubernetes

Use the instructions in this section to install, upgrade, and maintain API Connect on Kubernetes.

- [Installing and upgrading on Kubernetes](#)  
Use these instructions to install or upgrade a deployment of API Connect on Kubernetes.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Installing and upgrading on Kubernetes

Use these instructions to install or upgrade a deployment of API Connect on Kubernetes.

- [IBM API Connect Version 2018 software product compatibility requirements](#)  
Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.
- [Estimating internal storage space for Analytics](#)  
If you plan to store data locally in your IBM API Connect Analytics deployment, estimate disk space requirements.
- [Working with certificates](#)  
Use the `certs` command included in the APICUP installer to set and manage certificates for each subsystem. Default certificates are automatically applied, but defaults can be overridden by user-supplied custom certificates.
- [Tips and tricks for using APICUP](#)  
The APICUP installer in Install Assist contains built-in time saving functions.
- [Deploying to a Kubernetes environment](#)  
Install Assist provides script-based installation using the APICUP tool into a Kubernetes runtime environment.
- [Upgrading API Connect in a Kubernetes environment](#)  
Upgrades are performed from the same project directory used for the initial installation.
- [Deleting the API Connect deployment in a Kubernetes runtime environment](#)  
To delete the Kubernetes deployment of API Connect, you delete the Helm charts, Custom Resource Definitions, the Persistent Volumes, and the namespace.
- [Maintaining a Kubernetes deployment](#)  
You can use utilities to complete maintenance tasks such as backup, restore, and certificate management on Kubernetes.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## IBM API Connect Version 2018 software product compatibility requirements

Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.

To generate an API Connect requirements report, complete the following steps:

1. Open the [Detailed system requirements for a specific product](#) page on the IBM Software Product Compatibility Reports site.
2. Search for the IBM API Connect product.

3. In the Search results list, select IBM API Connect.
4. From the Version list, select the required version.
5. Use the Filters to refine the contents of the requirements report.
6. Click Submit to generate your requirements report.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Estimating internal storage space for Analytics

If you plan to store data locally in your IBM® API Connect Analytics deployment, estimate disk space requirements.

This information applies only to Analytics deployments where the ingestion-only option is set to false (the default setting). The formula and guidelines are based on known information about how the Analytics service stores data, and cannot be directly applied to any other storage system.

Use the following guidelines to calculate a rough estimate of the amount disk space you need for storing stateful data in the API Connect Analytics microservices.

### Data storage: calculate how much data you want to store

---

This section applies if you have chosen a topology that uses the analytics-storage-data or analytics-storage-basic microservices.

The amount of disk space needed for storing analytics data is determined by the following factors:

#### Number of copies of the analytics data

Each copy of the analytics data must live on a separate node. The number of nodes in your deployment determines the number of copies of analytics data that is stored in your deployment. With the **Production** deployment profile, analytics data is replicated to three nodes (two replicas and one primary copy of the data) for storage. In the **Nonproduction** profile, you only need to store one copy of the data.

Number of copies of data:

```
Copies of data = [1 | 3]
```

#### Number of days that data is retained

By default, analytics data is retained for 90 days, but you can [modify the retention setting](#) as needed. Make sure you know how long you want to store the data before attempting to calculate required disk space.

Number of days that data is retained:

```
Data retention = [90 days | preferred length]
```

#### Amount of each type of data stored

The required storage space for each type of logging is highly dependent on your APIs and usage. For each API, you can [configure logging](#) for the API activity, header, and payload. You can also [customize the data](#) to add, redact, or remove fields, which also impacts the amount of data that you store.

To estimate storage needs, calculate the average size of each type of log. When calculating your estimates, remember that the header logging size is the sum of activity logging size and the average size of your headers. The payload logging size is the sum of the header logging size and the average size of your payloads.

Typically the average size of an activity logged event is 600-1000 bytes depending on the uniqueness and complexity of your analytics data. This number is highly dependent on your APIs and your implementations. For a rough estimate, you can use an average of 800 bytes per activity logged event.

If you choose to add fields, calculate the average size of the new fields as well, and add that number to all types of log policies. If you choose to remove fields, you should not subtract this size from the log policies unless you are also removing headers and/or payloads.

Amount of each type of data that is stored:

```
Activity log bytes per call = [600-1000 bytes]
Header log bytes per call = Activity log bytes per call + Average size of headers
Payload log bytes per call = Header log bytes per call + Average size of payloads
```

#### Percentage of each type of data

Estimate the percentage of each type of log (activity, header, payload) for all API calls.

If you follow best practices of using only activity logging for production environments and using only payload logging for test environments, this number is easy to determine. If you use different log policies per API, and they depend on "success" or "error" factors, the percentage is more difficult to determine. Typically, if you do not use an all-or-nothing method for logging, error rates range from 3% to 25% with subsequent payload logging in test and production environments. However, this is entirely dependent on your use case and your APIs.

Percentage of each type of data that is stored:

```
% of Activity log = [0, 100 or other estimate]
% of Header log = [0, 100 or other estimate]
% of Payload log = [0, 100 or other estimate]
```

#### Estimated number of API calls per month

When planning your API Connect deployment, this number is helpful. When estimating analytics storage, this number is vital because it is directly correlated to how much storage you need for your deployment.

If you do not know the number of calls per month, but you do know the number of calls per second, use the following formula to convert it to calls per month:

```
Calls per month = Calls per second * 86400 seconds per day * 30 days per month
```

Number of API calls per month:

```
Calls per month = [any estimate]
```

## Calculating your disk space requirement

Estimate the disk space requirement for each storage node by completing following calculations.

### Formula

```
Bytes per call = (% of Activity Log * Activity Log bytes per call) + (% of Header Log * Header Log bytes per call) + (% of Payload Log * Payload Log bytes per call)
Calls per retention period = Calls per month * (Number of days retained / 30 days per month)
Storage for API calls = Calls per retention period * Bytes per call * Copies of data
Total storage = Storage for API calls + Overhead
Storage per node = Total storage / Nodes
```

### Details

#### 1. Bytes per call:

Estimate the number of bytes that are logged for a single copy of each API call. This can be calculated from the prerequisites of the percentage of each data type and the amount of each data type stored.

```
Bytes per call = (% of Activity Log * Activity Log bytes per call) + (% of Header Log * Header Log bytes per call) + (% of Payload Log * Payload Log bytes per call)
```

#### 2. Calls per retention period:

Calculate the anticipated number of API calls per retention period. This can be calculated from the prerequisites of the estimated calls per month and your desired data retention.

```
Calls per retention period = Calls per month * (Number of days retained / 30 days per month)
```

#### 3. Storage for API Calls:

Calculate the storage needed for all copies of your api calls for your retention period. This can be calculated from steps 1 and 2, as well as the prerequisite of your total copies of your data.

```
Storage for API calls = Calls per retention period * Bytes per call * Copies of data
```

#### 4. Total Storage:

Calculate the total storage you need by adding buffer space to the value from step 3. The Analytics service requires the some overhead space to complete its operations; for example, to contain system data and temporary debug header or payload logging. In addition, allowing extra space provides a buffer in case you underestimated the number of calls, or experience an unexpected increase.

There is no specific value for the buffer because it's based on your own situation. One approach is to use a value that brings the Storage for API calls result from step 3 up to the next round number. Make sure the rounding leaves you with a comfortable amount of additional space. For example, if the result from step 3 is 380 GB, then adding 20 GB to reach 400 GB is probably not sufficient and you should consider rounding to the a larger value such as 500 GB.

```
Total storage = Storage for API calls + Buffer
```

#### 5. Storage per node:

Calculate the total storage amount required per storage node. The number of storage nodes is dependent on your deployment profile. For the **development** profile, use 1. For the **production** profile, it defaults to 3. If you manually scaled the analytics-storage-data or analytics-storage-basic microservices to be greater than 3, use your actual values.

```
Storage per node = Total storage / Nodes
```

Remember: This result is only an estimate. You should monitor the use of space over time and adjust storage as needed.

### Example

Deployment information:

```
Copies of data = 3
Data retention = 90 days
Activity log bytes per call = 850 bytes
Header log bytes per call = 15k bytes
Payload log bytes per call = 30.5k bytes
% of Activity log = 100%
% of Header log = 0%
% of Payload log = 0%
Calls per month = 64 million
```

Formula:

```
Bytes per call = (% of Activity Log * Activity Log bytes per call) + (% of Header Log * Header Log bytes per call) + (% of Payload Log * Payload Log bytes per call)
Calls per retention period = Calls per month * (Number of days retained / 30 days per month)
Storage for API calls = Calls per retention period * Bytes per call * Copies of data
Total storage = Storage for API calls + Overhead
Storage per node = Total storage / Nodes
```

Details:

#### 1. Bytes per call = 850 bytes

```
(100% of Activity Log * 850 bytes) + (0% of Header Log * 15k bytes) + (0% of Payload Log * 30.5 bytes)
```

#### 2. Calls per retention period = 192 million calls

```
64 million calls per month * (90 days retained / 30 days per month)
```

#### 3. Storage for API calls = 489.6 GB

```
192 million calls per period * 850 bytes per call * 3 copies of data
```

#### 4. Total storage = 600 GB

#### 489.6GB storage + Buffer

Since rounding to 500 GB only provides 10.4 GB of extra space, it's good practice to round to 600 GB instead.

5. Storage per node = 200 GB

#### 600GB Total storage / 3 nodes

In this example, the estimated disk needed on each node for analytics-storage-data and analytics-storage-basic microservices is 200GB.

## Master storage: estimate disk space needs

This section applies if you are planning a topology with the analytics-storage-master microservice enabled.

For the analytics-storage-master microservice, estimating the amount of disk space you need is much easier. For a production environment, set this value to 10GB. For a development environment, you can optionally reduce the value to 5GB.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Working with certificates

Use the `certs` command included in the APICUP installer to set and manage certificates for each subsystem. Default certificates are automatically applied, but defaults can be overridden by user-supplied custom certificates.

### About this task

Note: Use a single APICUP project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

- **Certificate management: Read This First**  
Requirements and best practices for managing API Connect certificates.
- **Setting and managing certificates**  
Default certificates are automatically applied, but defaults can be overridden by custom certificates.
- **Reference for certificates, commands, and validations**  
This section contains the reference information for certificates, commands for working with certificates, and validations.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Certificate management: Read This First

Requirements and best practices for managing API Connect certificates.

Important: Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged. For management purposes, API Connect certificates can be grouped by type (default, custom, and common) and by usage (public, public and user-facing, and internal). Understand each type and usage before you change any certificates.

- A default certificate is a private certificate that is uniquely generated by the installer for the current project directory, and will pass validation. Default certificates are automatically generated for each subsystem by the `apicup subsys install` command, unless the certificates were explicitly set by using the `apicup certs set` command. Note that the default certificates are self-signed, so they might not provide a level of trust suitable for external communication.
- For optimal trust levels, we recommend that you explicitly set all public and user-facing certificates by creating custom certificates.
- Some certificates are common across subsystems. Subsystems require the common certificates to allow them to register with the management subsystem. When installing any one subsystem, the common certificates are set for that subsystem and for all the other subsystems. If you use custom certificates for the common certificates, the custom certificates must be set prior to setting any other custom certificates.
- We do not recommend the explicit setting of internal certificates. The changing of internal certificates creates a risk of incompatibility with other internal certificates.

To review the usage (public, public and user-facing, or internal) of each certificate, see the following [Table 1](#) table.

Table 1. Certificate management best practice

Certificate usage	Certificate name	Best practice management
Public	<ul style="list-style-type: none"><li>• apic-gw-service-ingress</li></ul>	For optimal trust levels, set these explicitly. If certificates are not explicitly set by using the <code>apicup certs set</code> command, then default self-signed certificates are automatically generated by <code>apicup subsys install</code> . Typically you usually want to customize them, to ensure a level of trust suitable for external communication.

Certificate usage	Certificate name	Best practice management
Public and User-facing	<ul style="list-style-type: none"> <li>platform-api, api-manager-ui, cloud-admin-ui</li> <li>consumer-api</li> <li>portal-www-ingress</li> </ul>	For optimal trust levels, set these explicitly. Recommended to be explicitly set as custom certificates because they are presented to an end user through a browser or Command Line Interface (CLI).
Internal	<ul style="list-style-type: none"> <li>root-ca, ingress-ca</li> <li>mgmt-db-ca, mgmt-ca, service-server, service-client, db-server, db-client, service-plugin</li> <li>portal-admin-ingress, portal-client, portal-ca, portal-db-ca, service-server, service-client, apim-client</li> <li>analytics-client-ingress, analytics-ingestion-ingress, analytics-ingestion-client, analytics-client-client</li> <li>analytics-ca, service-server, service-client</li> <li>gw-ca, gateway-peering</li> </ul> <p>For VMware appliance deployments only: k8s-ca, appliance-client</p>	<p>Do not change. Accept the default certificates. It is possible to change these certificates (except ingress-ca) but is strongly discouraged because you risk creating incompatibilities that can block internal communications.</p> <p>Each intermediate cert (mgmt-db-ca, mgmt-ca, portal-ca, portal-db-ca, analytics-ca, gw-ca), is used to generate other internal certs. If, for example, you change an intermediate cert, the certs generated from it might not work with internal certs generated from other intermediate certs.</p> <p>Note that ingress-ca is auto-generated and cannot be set using the <code>apicup certs set</code> command.</p>

## Setting and managing certificates

Default certificates are automatically applied, but defaults can be overridden by custom certificates.

- [Setting default certificates](#)  
Default certificates are automatically generated by APICUP when the subsystem is installed.
- [Setting custom certificates](#)  
Use the APICUP installer `certs` commands to set custom certificates.
- [Replacing custom certificates](#)  
Use the APICUP installer `certs` commands to replace existing certificates.
- [Setting common certificates](#)  
Common certificates are set for one subsystem, but are applied to all subsystems. Use the APICUP installer `certs` commands to set the common certificates.
- [Setting the encryption-secret for the management database](#)  
Use the APICUP installer `certs` commands to set the encryption-secret for the management database.
- [Clearing certificates](#)  
Certificates can be cleared in order to set new certificates.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Setting default certificates

Default certificates are automatically generated by APICUP when the subsystem is installed.

### About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see [Certificate management: Read This First](#). For details on each certificate, see [Certificate reference](#).
- Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Upgrading API Connect in a Kubernetes environment](#)

Default certificates are generated for each subsystem by the `apicup subsys install` command. If certificates are not explicitly set by using the `apicup certs`

set command, then default certificates are automatically generated by APICUP. The default certificates are self-signed, so they might not provide a level of trust suitable for external communication.

## Procedure

1. Enter the settings for the subsystem by using `apicup subsys set <SUBSYS>` and validate the subsystem settings by using `apicup subsys get <SUBSYS> --validate`. The subsystem must pass validation before setting the certificates.
2. Install the subsystem by using the `apicup subsys install` command.
3. The default certificates are created for the subsystem. A default certificate is a private certificate that is uniquely generated by the installer for this project directory, they are self-signed and always pass validation.
4. List all certificates that are set for a subsystem by using the `apicup certs list` command.

```
apicup certs list -help
```

```
List all configured certificates
```

```
Usage:
```

```
apicup certs list SUBSYS [flags]
```

```
Flags:
```

```
-h, --help help for list
```

```
Global Flags:
```

```
--accept-license Accept the license for API Connect
--debug Enable debug logging
```

Following is example output from the `apicup certs list` command:

```
Common certificates
```

```
=====
```

---

## Setting custom certificates

Use the APICUP installer `certs` commands to set custom certificates.

---

### About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see [Certificate management: Read This First](#). For details on each certificate, see [Certificate reference](#).
- Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Upgrading API Connect in a Kubernetes environment](#)

The APICUP installer can be used to set certificates for each subsystem during installation. If certificates are not explicitly set by using the `apicup certs set` command, then default certificates are generated by APICUP. The default certificates are self-signed, so they might not provide a level of trust suitable for external communication.

Requirements for custom certificates:

- Extended Key Usage (EKU), either `serverAuth` or `clientAuth` depending upon the type of certificate. Certificates of type *Server* must have an Extended Key Usage with `serverAuth` purpose. Certificates of type *Client* must have an Extended Key Usage with `clientAuth` purpose.
- Subject Alternative Name (SAN) for the required hosts
- Any custom common certificates that are being used must be set prior to setting any custom certificates for a subsystem.

See [Certificate Reference](#) to view the list of common certificates and to determine whether an EKU is needed for a certificate and which type of EKU (`serverAuth` or `clientAuth`).

Precedence order for TLS certificates for Management endpoints:

The Management subsystem has four public endpoints: `api-manager-ui`, `cloud-admin-ui`, `platform-api`, and `consumer-api`. Distinct TLS certificates can be set for each endpoint. However, if any two endpoints identical, only one TLS certificate will be effective. The order of precedence is: `api-manager-ui`, `cloud-admin-ui`, `platform-api`, `consumer-api`.

Following are examples for how precedence is determined for TLS certificates for endpoints:

- If all four endpoints are distinct, then all four TLS certificates will be effective for their respective endpoints.
- If all four endpoints are identical, then only the `api-manager-ui` TLS certificate will be effective for all endpoints, as it is first in the precedence order.
- If the `api-manager-ui`, `cloud-admin-ui`, and `platform-api` endpoints are the same, and `consumer-api` is a different endpoint, then the `api-manager-ui` TLS certificate will be effective for the `api-manager-ui/cloud-admin-ui/platform-api` endpoints, while the `consumer-api` TLS certificate will be effective for the `consumer-api` endpoint

Note: Once API Connect has been installed (meaning that the `apicup subsys install` `SUBSYS` command has been executed) with a given set of certificates, only the certificates for the public ingress endpoints (`portal-www`, `api-manager-ui`, `cloud-admin-ui`, `platform-api`, `consumer-api`) can be modified. The TLS certificates involved in mutual authentication (`portal-admin-ingress`, `portal-client`, `analytics-ingestion-ingress`, `analytics-ingestion-client`, `analytics-client-ingress`, and `analytics-client-client`) cannot be modified after the `install` command has been executed.

---

## Procedure

1. Set up and validate the subsystem. Enter the settings for the subsystem using `apicup subsys set <SUBSYS>` and validate the subsystem settings using `apicup subsys get <SUBSYS> --validate`. The subsystem must pass validation before setting the certificates.
2. Generate the custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (`platform-api-example`) with an EKU `serverAuth` and SAN using `openssl`:

```
openssl x509 -req -days 360 -in platform-api-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out platform-api-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nsubjectAltName=DNS:fqdn.myserver.com\nextendedKeyUsage=serverAuth") -extensions SAN
```

where

- `DNS:fqdn.myserver.com` is the fully qualified domain name of the endpoint the certificate applies to. This matches the endpoints entered in the APICUP installer. See [Installing the Management subsystem into a Kubernetes environment](#)
- `platform-api-example.csr` is the file name for the certificate signing request

Following is an example for how to generate a certificate (`portal-client`) with an EKU `clientAuth` and SAN using `openssl`:

```
openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out portal-client-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical, CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

3. Once the certificate has been created, set the certificate by entering the following command:  
`apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE]`

You can find definitions for commands at the following location: [Command reference](#)

If the certificate is signed by an intermediate CA, the `CA_File` argument must point to a file that concatenates the intermediate CA, followed by the root CA, in that order.

If the certificate is signed by an internal or custom CA, include the full chain in the end certificate. If you omit the full chain, then a user who uses openssl to access the endpoint will see the following error: `error:num=20:unable to get local issuer certificate`

The following example shows the full chain for an end certificate (signed by a custom CA):

```
-----BEGIN CERTIFICATE -----
Cert contents for end-cert
-----END CERTIFICATE -----
-----BEGIN CERTIFICATE -----
Cert contents for Intermediate-CA
-----END CERTIFICATE -----
-----BEGIN CERTIFICATE -----
Cert contents for Root CA
-----END CERTIFICATE -----
```

If the certificate was generated with an EKU serverAuth, it must be assigned to a server certificate. If the certificate was generated with an EKU clientAuth, it must be assigned to a client certificate.

- Repeat for additional custom certificates.
- After setting the custom certificates, you can optionally generate the remaining default certificates prior to installation by entering the `apicup certs generate` command. The `generate` command generates any certificates that have not been set, so it will create default certificates for all remaining certificates. It will not overwrite any custom certificates you have set. You can review the certificates prior to installation.
- List all certificates with `apicup certs list SUBSYS`. The results will include the generated default certificates and the custom certificates that you set.

Following is example output from the `apicup certs`

`list` command:

**Common certificates**

```

7. Install the subsystem with the certificates using `apicup subsys install`  
**SUBSYS.** Any missing certificates will be generated. The installation will not proceed if there are any validation issues with the certificates. See [Validation reference](#).
8. Repeat for other subsystems.
9. If necessary, you can replace custom certificates after installation is complete. See [Replacing custom certificates](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Replacing custom certificates

Use the APICUP installer `certs` commands to replace existing certificates.

---

### About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see [Certificate management: Read This First](#). For details on each certificate, see [Certificate reference](#).
- Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Upgrading API Connect in a Kubernetes environment](#)

The APICUP installer can be used to update certificates for each subsystem after installation.

Requirements for custom certificates:

- Extended Key Usage (EKU), either `serverAuth` or `clientAuth` depending upon the type of certificate. Certificates of type *Server* must have an Extended Key Usage with `serverAuth` purpose. Certificates of type *Client* must have an Extended Key Usage with `clientAuth` purpose.
- Subject Alternative Name (SAN) for the required hosts
- Any custom common certificates that are being used must be set prior to setting any custom certificates for a subsystem.

See [Certificate Reference](#) to view the list of common certificates and to determine whether an EKU is needed for a certificate and which type of EKU (`serverAuth` or `clientAuth`).

Precedence order for TLS certificates for Management endpoints:

The Management subsystem has four public endpoints: *api-manager-ui*, *cloud-admin-ui*, *platform-api*, and *consumer-api*. Distinct TLS certificates can be set for each endpoint. However, if any two endpoints identical, only one TLS certificate will be effective. The order of precedence is: *api-manager-ui*, *cloud-admin-ui*, *platform-api*, *consumer-api*.

Following are examples for how precedence is determined for TLS certificates for endpoints:

- If all four endpoints are distinct, then all four TLS certificates will be effective for their respective endpoints.
- If all four endpoints are identical, then only the *api-manager-ui* TLS certificate will be effective for all endpoints, as it is first in the precedence order.
- If the *api-manager-ui*, *cloud-admin-ui*, and *platform-api* endpoints are the same, and *consumer-api* is a different endpoint, then the *api-manager-ui* TLS certificate will be effective for the *api-manager-ui/cloud-admin-ui/platform-api* endpoints, while the *consumer-api* TLS certificate will be effective for the *consumer-api* endpoint

---

## Procedure

1. Generate the custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (*platform-api-example*) with an EKU `serverAuth` and SAN using `openssl`:

```
openssl x509 -req -days 360 -in platform-api-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out platform-api-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nsubjectAltName=DNS:fqdn.myserver.com\nextendedKeyUsage=serverAuth")) -extensions SAN
```

where

- `DNS:fqdn.myserver.com` is the fully qualified domain name of the endpoint the certificate applies to. This matches the endpoints entered in the APICUP installer. See [Installing the Management subsystem into a Kubernetes environment](#)
- `platform-api-example.csr` is the file name for the certificate signing request

Following is an example for how to generate a certificate (*portal-client*) with an EKU `clientAuth` and SAN using `openssl`:

```
openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out portal-client-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

2. Once the certificate has been created, set the certificate by entering the following command:  
`apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE]`

You can find definitions for commands at the following location: [Command reference](#)

If the certificate is signed by an intermediate CA, the `CA_File` argument must point to a file that concatenates the intermediate CA, followed by the root CA, in that order.

If the certificate was generated with an EKU serverAuth, it must be assigned to a server certificate. If the certificate was generated with an EKU clientAuth, it must be assigned to a client certificate.

3. Install the subsystem with the new certificate using `apicup subsys install SUBSYS`. Any missing certificates will be generated. The installation will not proceed if there are any validation issues with the certificates. See [Validation reference](#).
4. Repeat for other subsystems requiring new certificates.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Setting common certificates

Common certificates are set for one subsystem, but are applied to all subsystems. Use the APICUP installer `certs` commands to set the common certificates.

---

### About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see [Certificate management: Read This First](#). For details on each certificate, see [Certificate reference](#).
- Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Upgrading API Connect in a Kubernetes environment](#)

The common certificates are identical across subsystems. Subsystems require the common certificates to allow them to register with the management subsystem. When installing any one subsystem, the common certificates will be set for that subsystem and for all the other subsystems. If you are using custom certificates for the common certificates, they must be set prior to setting any custom certificates. See [Certificates reference](#) for a description of the common certificates.

Common certificates cannot be changed between subsystem installs. For example, you cannot set a common certificate for the management subsystem, install the management subsystem, then change a common certificate for the analytics subsystem, then install the analytics subsystem. This scenario will result in a failed installation because the common certificates are not identical.

---

### Procedure

Follow these steps to set custom common certificates. If using default certificates, the common certificates will be set for you. See [Setting custom certificates](#)

1. Set up and validate all subsystems. Enter the settings for the subsystem using `apicup subsys set <SUBSYS>` and validate the subsystem settings using `apicup subsys get <SUBSYS> --validate`. The subsystem must pass validation before setting the certificates.
2. Generate a custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (platform-api) with an EKU serverAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in platform-api.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out platform-api-sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nsubjectAltName=DNS:ac-msntest.myserver.com,DNS:ac2-msntest.myserver.com\nextendedKeyUsage=serverAuth")) -extensions SAN
```

Following is an example for how to generate a certificate (portal-client) with an EKU clientAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in portal-client.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out portal-client-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

3. Once the certificate has been created and you have a `.pem` file, set the custom common certificates in one of your subsystems. After setting the custom certificates for one subsystem, they will take effect for all subsystems. The command is targeted at a specific subsystem, but the common certificates are copied to all subsystems regardless of which subsystem they are originally set in. Following is an example for setting the `portal-client` certificate:  
`apicup certs set mgmt portal-client myCertFile.pem myKeyFile.key myCAFile.crt`
4. Set the remaining certificates for each subsystem, default or custom. See [Setting default certificates](#) and [Setting custom certificates](#).
5. List and validate the certificates for each subsystem. See [Validation reference](#)
6. Install each subsystem using `apicup subsys install SUBSYS`.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Setting the encryption-secret for the management database

Use the APICUP installer `certs` commands to set the encryption-secret for the management database.

### About this task

---

Note: Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Upgrading API Connect in a Kubernetes environment](#)

The encryption-secret is a secure random bytes password used for field level encryption in the management database. You can generate 128 random bytes using the following command in openssl:

```
openssl rand -out /path/to/secret/encryption-secret.bin 128
```

Important: The encryption-secret can only be set once and only during initial installation. See [Installing the Management subsystem into a Kubernetes environment](#).

### Procedure

---

1. Enter the `apicup certs set SUBSYS CERT_NAME [KEY_FILE]` command and complete the following values:
  - SUBSYS - The subsystem for the `encryption-secret` is the name of your management subsystem, because it is used for field-level encryption for the management database.
  - CERT\_NAME - The certificate name is `encryption-secret`.
  - KEY\_FILE - Enter the file name for a secure random bytes string that is 128 bytes in length, for example `encryption-secret.bin`.
2. Set the remaining certificates if using custom certificates and install the management subsystem.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Clearing certificates

Certificates can be cleared in order to set new certificates.

### About this task

---

Note: Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Upgrading API Connect in a Kubernetes environment](#)

Existing certificates must be cleared in order to set new certificates. When using default certificates, new certificates are created only for those certificates that are not set. Some of the use cases for clearing certificates are: expired certificates and configuration changes. For example, of endpoints are changed, the existing certificates must be cleared and new certificates created.

### Procedure

---

1. Enter the `apicup certs set SUBSYS CERT_NAME --clear` command and complete the following values:
  - SUBSYS - The name of the subsystem
  - CERT\_NAME - The name of the certificate that you want to clear.
2. The certificate will be cleared and can be reset, either as a default or custom certificate.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Reference for certificates, commands, and validations

This section contains the reference information for certificates, commands for working with certificates, and validations.

- [Certificate reference](#)  
The Certificate reference provides a description of all the certificates required in API Connect.
- [Command reference](#)  
The APICUP installer includes the `certs` commands to set and manage certificates.
- [Validation reference](#)  
Certificates are validated using several parameters.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Certificate reference

The Certificate reference provides a description of all the certificates required in API Connect.

### Before you begin

APICUP sets default certificates for each subsystem during installation. The default certificates are self-signed so may not provide a level of trust suitable for external communication. Custom certificates can be set and managed following the steps described in [Setting custom certificates](#).

The Certificates reference topic lists all certificates that are set by the `apicup certs` commands. The default certificates can be used for the majority of these certificates. The certificates that are marked as *public and user-facing* are recommended to be explicitly set as custom certificates because they are presented to an end user through a browser or Command Line Interface (CLI).

The certificates that are described as *TLS certificate used by ingress* are also considered *public* in the sense that they interact with a client that sits outside of an API Connect cluster.

The remaining certificates are considered *internal* because they interact with internal components.

Certificates that are listed as *auto-generated* cannot be set using the `apicup certs set` command. For example, the common certificate `ingress-ca` is auto-generated and used as an intermediate CA for all default ingress certificates. If you set an ingress certificate as a custom certificate, you will need to configure an intermediate CA if desired.

Important:

When setting custom certificates, additional steps must be taken to provide an Extended Key Usage (EKU) serverAuth and ClientAuth and a Subject Alternative Name (SAN) for the required hosts. These certificates are generated automatically by the `apicup certs` command when using the default certificates.

- For custom certificates of type *server*, an additional extended key usage client authentication (EKU serverAuth) certificate is required.
- For custom certificates of type *client*, an additional extended key usage server authentication (EKU clientAuth) certificate is required.

### Procedure

1. **Common certificates** - The following certificates are common to all subsystems in a deployment. Subsystems require the common certificates to allow them to register with the management subsystem. The common certificates are identical across subsystems. When installing any one subsystem, the common certificates will be set for that subsystem and for all the other subsystems. Custom common certificates must be set prior to setting any custom subsystem certificates.

Common certificates cannot be changed between subsystem installs. For example, you cannot set a common certificate for the management subsystem, install the management subsystem, then change a common certificate for the analytics subsystem, then install the analytics subsystem. This scenario will result in a failed installation because the common certificates are not identical.

Table 1. Common certificates

Certificate name (value used in <code>apicup certs</code> )	Type	Usage	Requirements	Description
root-ca	CA	internal		CA certificate which forms the root of the certificate chain
ingress-ca	CA	internal	signed by: root-ca	Auto-generated intermediate certificate used to generate certificates for subsystem ingress endpoints if not provided by user. The ingress-ca intermediate certificate cannot be set explicitly, it is always only generated. TLS certificates for the ingresses are not required to use ingress-ca as an intermediate certificate, but if a given ingress TLS certificate is left to be auto-generated then it will be signed by this ingress-ca.
mgmt-db-ca	CA	internal	signed by: root-ca	Intermediate CA certificate used to sign certificates used by Cassandra.
portal-client	Client	internal	Must be signed by the same authority as the one used for the matching ingress TLS certificate <code>portal-admin-ingress</code> .	Client certificate used by management subsystem to authenticate with the Portal admin endpoint. Requires EKU clientAuth.
analytics-client-client	Client	internal	Must be signed by the same authority as the one used for the matching ingress TLS certificate <code>analytics-client-ingress</code> .	Client certificate used by management subsystem to authenticate with analytics client endpoint. Requires EKU clientAuth.
analytics-ingestion-client	Client	internal	Must be signed by the same authority as the one used for the matching ingress TLS certificate <code>analytics-ingestion-ingress</code> .	Client certificate used by gateway subsystem to authenticate with analytics ingestion endpoint. Requires EKU clientAuth.

2. **Management certificates**

These certificates apply to a single Management subsystem.

The Management subsystem has four endpoints: `api-manager-ui`, `cloud-admin-ui`, `platform-api`, and `consumer-api`. Distinct TLS certificates can be set for each endpoint. However, if any two endpoints identical, only one TLS certificate will be effective. The order of precedence is: `api-manager-ui`, `cloud-admin-ui`, `platform-api`, `consumer-api`.

Following are examples for how precedence is determined for TLS certificates for endpoints:

- If all four endpoints are distinct, then all four TLS certificates will be effective for their respective endpoints.
- If all four endpoints are identical, then only the `api-manager-ui` TLS certificate will be effective for all endpoints, as it is first in the precedence order.

- If the api-manager-ui, cloud-admin-ui, and platform-api endpoints are the same, and consumer-api is a different endpoint, then the api-manager-ui TLS certificate will be effective for the api-manager-ui/cloud-admin-ui/platform-api endpoints, while the consumer-api TLS certificate will be effective for the consumer-api endpoint

The encryption-secret certificate is unique in that it is a secure random number. It is used to provide field level encryption in management (Cassandra) database. To set the encryption secret for the management database, use the following command: `apicup certs set SUBSYS CERT_NAME [KEY_FILE]` For example: `apicup certs set mgmt1 encryption-secret /path/to/keyfile`. See [Setting the encryption-secret for the management database](#)

Table 2. Management certificates

Certificate name	Type	Usage	Requirements	Description
encryption-secret	secure random bytes		length: 128 bytes	Encryption secret used to do field level encryption in management (Cassandra) database
platform-api	Server	public and user-facing	The host names for which the certificate is valid must include the platform-api endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for host names matching <code>*.acme.com</code> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
consumer-api	Server	public and user-facing	The host names for which the certificate is valid must include the consumer-api endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for host names matching <code>*.acme.com</code> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
api-manager-ui	Server	public and user-facing	The host names for which the certificate is valid must include the api-manager-ui endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for host names matching <code>*.acme.com</code> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
cloud-admin-ui	Server	public and user-facing	The host names for which the certificate is valid must include the cloud-admin-ui endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for host names matching <code>*.acme.com</code> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
mgmt-ca	CA	internal	signed by: root-ca	Intermediate CA used to sign management subsystem certificates
service-server	Server	internal	signed by: mgmt-ca Required hosts: <ul style="list-style-type: none"> <li>• <code>*.&lt;namespace&gt;</code></li> <li>• <code>*.&lt;namespace&gt;.svc</code></li> <li>• <code>*.&lt;namespace&gt;.svc.cluster.local</code></li> </ul>	Server certificates used by management services. Requires EKU serverAuth.
service-client	Client	internal	signed by: mgmt-ca	Client certificate used by management services. Requires EKU clientAuth.
db-server	Server	internal	signed by: mgmt-db-ca Required hosts: <ul style="list-style-type: none"> <li>• <code>*.&lt;namespace&gt;</code></li> <li>• <code>*.&lt;namespace&gt;.svc</code></li> <li>• <code>*.&lt;namespace&gt;.svc.cluster.local</code></li> </ul>	Server certificate used by management (Cassandra) database to communicate with other nodes. Requires EKU serverAuth.
db-client	Client	internal	signed by: mgmt-db-ca	Client certificate used by management services. Requires EKU clientAuth.
service-plugin	Client	internal	signed by: mgmt-ca	Client certificate used by plugin services to talk to management subsystem. Requires EKU clientAuth.
migration-client	Client		signed by: mgmt-ca	This certificate is deprecated and no longer used, and can be ignored.

### 3. Portal certificates

These certificates apply to a single portal subsystem.

Table 3. Portal certificates

Certificate name	Type	Usage	Requirements	Description
portal-admin-ingress	Server	internal	host must match admin endpoint	TLS certificate used by ingress. The <code>portal-client</code> common certificate must be set prior to setting the <code>portal-admin-ingress</code> certificate. Requires EKU serverAuth. The <code>portal-admin-ingress</code> TLS certificate does not have any specific requirement on the authority signing it. If the certificate is auto-generated, it is signed by the <code>ingress-ca</code> .
portal-www-ingress	Server	public and user-facing	host must match www endpoint	TLS certificate used by ingress. Requires EKU serverAuth.
portal-ca	CA	internal	signed by: root-ca	Intermediate CA used to sign portal subsystem certificates
portal-db-ca	CA	internal	signed by: portal-ca	Intermediate CA certificate used to sign certificates used by portal DB

Certificate name	Type	Usage	Requirements	Description
service-server	Server	internal	signed by: portal-ca  Required hosts: <ul style="list-style-type: none"> <li>*. &lt;namespace&gt;</li> <li>*. &lt;namespace&gt;.svc</li> <li>*. &lt;namespace&gt;.svc.cluster.local</li> </ul>	Server certificates used by portal services. Requires ECU serverAuth.
service-client	Client	internal	signed by: portal-ca	Client certificate used by portal services. Requires ECU clientAuth.
apim-client	Client	internal	signed by: portal-ca	Client certificate used by portal services to talk to management subsystem. Requires ECU clientAuth.

#### 4. Analytics certificates

These certificates apply to a single analytics subsystem.

Table 4. Analytics certificates

Certificate name	Type	Usage	Requirements	Description
analytics-client-ingress	Server	internal	Required hosts: <ul style="list-style-type: none"> <li>client ingress endpoint</li> <li>*. &lt;namespace&gt;</li> <li>*. &lt;namespace&gt;.svc</li> <li>*. &lt;namespace&gt;.svc.cluster.local</li> </ul>	TLS certificate used by ingress. The <b>analytics-client-client</b> common certificate must be set prior to setting the <b>analytics-client-ingress</b> certificate. Requires ECU serverAuth.  The <b>analytics-client-ingress</b> TLS certificate does not have any specific requirement on the authority signing it. If the certificate is auto-generated, it is signed by the <b>ingress-ca</b> .
analytics-ingestion-ingress	Server	internal	Required hosts: <ul style="list-style-type: none"> <li>ingestion ingress endpoint</li> <li>*. &lt;namespace&gt;</li> <li>*. &lt;namespace&gt;.svc</li> <li>*. &lt;namespace&gt;.svc.cluster.local</li> </ul>	TLS certificate used by ingress. The <b>analytics-ingestion-client</b> common certificate must be set prior to setting the <b>analytics-ingestion-ingress</b> certificate. Requires ECU serverAuth.  The <b>analytics-ingestion-ingress</b> TLS certificate does not have any specific requirement on the authority signing it. If the certificate is auto-generated, it is signed by the <b>ingress-ca</b> .
analytics-ca	CA	internal	signed by: root-ca	Intermediate CA used to sign analytics subsystem certificates
service-server	Server	internal	signed by: analytics-ca  Required hosts: <ul style="list-style-type: none"> <li>*. &lt;namespace&gt;</li> <li>*. &lt;namespace&gt;.svc</li> <li>*. &lt;namespace&gt;.svc.cluster.local</li> </ul>	Server certificates used by analytics services. Requires ECU serverAuth.
service-client	Client	internal	signed by: analytics-ca	Client certificate used by analytics services; requires ECU clientAuth.

#### 5. Gateway certificates

These certificates apply to a single gateway subsystem.

Table 5. Gateway certificates

Certificate name	Type	Usage	Requirements	Description
api-gateway-ingress	Server	public and user-facing	host must match api-gateway endpoint	TLS certificate used by ingress. Requires EKU serverAuth. (deprecated, see <b>Note</b> .)
apic-gw-service-ingress	Server	public	host must match apic-gw-service endpoint	TLS certificate used by ingress. Requires EKU serverAuth.
gw-ca	CA	internal	signed by: root-ca	Intermediate CA used to sign gateway subsystem certificates
gateway-peering	Server	internal	signed by: gw-ca	Server certificates used by gateway services. Requires EKU serverAuth.

Note: The **api-gateway-ingress** certificate is a legacy certificate which has been deprecated. It is no longer used to terminate TLS at the api-gateway endpoint. You configure a TLS profile for the termination of the api-gateway endpoint using the Cloud Manager API Invocation Endpoint and SNI settings when registering the gateway. The profiles used during configuration can be updated as needed. See [Registering a gateway service](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Command reference

The APICUP installer includes the `certs` commands to set and manage certificates.

### About this task

The APICUP installer can be used to set certificates for each subsystem during installation. If certificates are not explicitly set using the `apicup certs set` command, then default certificates are generated by APICUP. We recommend that certificates be set at installation time only (or carried over from an upgrade). The default certificates are self-signed, so they may not be optimal for external communication.

For a description of the certificates that can be set, see [Certificate reference](#). We recommend that all public and user-facing certificates be explicitly set, including `portal-www-ingress` and `api-gateway-ingress`, and the four management endpoints (`platform-api`, `consumer-api`, `api-manager-ui`, and `cloud-admin-ui`). Following is the help reference for the `apicup certs set` command:

```
apicup certs set --help
Set or clear certificates and keys

Usage:
  apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [KEY_FILE] [flags]

Flags:
  --clear    Clear out a certificate or key entry
  -h, --help help for set

Global Flags:
  --accept-license  Accept the license for API Connect
  --debug           Enable debug logging
```

## Procedure

To set and clear certificates, complete the following steps:

1. Enter the `apicup certs set` command and complete the following values:

Table 1. apicup certs set

Command	Values	Result
<code>apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [KEY_FILE] [flags]</code>	Parameters are: <ul style="list-style-type: none"> <li>SUBSYS - name of the subsystem to which the certificate applies</li> <li>CERT_NAME - name of the certificate; see <a href="#">Certificate reference</a> for a list of certificates that can be set for each subsystem.</li> <li>CERT_FILE - Path to the certificate file in PEM format.</li> <li>KEY_FILE - Path to the private key file in PEM format.</li> <li>CA_FILE - Path to the Certificate Authority (CA) file. The contents of the file may be the concatenation of an intermediate CA and the root CA (in that order). <b>Note:</b> When setting the <code>root-ca</code> certificate, omit the <code>CA_FILE</code> parameter.</li> </ul>	Applies the certificate when the subsystem is installed.
<code>apicup certs set SUBSYS CERT_NAME [KEY_FILE] [flags]</code>	<code>KEY_FILE</code> - The file containing the encryption-secret for field level encryption in the management database. Applies only to the management subsystem. The certificate name is <code>encryption-secret</code> . The type is secure random bytes with a length of 128 bytes. For example, <code>apicup certs set mgmt1 encryption-secret /path/to/encryption-secret.bin</code> . <b>Note:</b> Do not specify any of the <code>[CERT_FILE KEY_FILE CA_FILE]</code> parameters when setting the encryption-secret.	Applies the <code>encryption-secret</code> when the management subsystem is installed.
<code>flags</code> <ul style="list-style-type: none"> <li><code>--clear</code></li> <li><code>--help</code></li> </ul>	Flags are: <ul style="list-style-type: none"> <li><code>--clear</code> - Clears the specified certificate. For example, <code>apicup certs set mgmt1 encryption-secret --clear</code></li> <li><code>--help</code> - Displays help for the command.</li> </ul>	The specified certificate will be cleared. When making configuration changes such as changing endpoints, the corresponding certificate must be cleared so that a new certificate can be set.

2. The `apicup certs get` command retrieves a specific certificate for the specified subsystem.

```
apicup certs get --help
Get a certificate
```

```
Usage:
apicup certs get SUBSYS CERT_NAME [flags]
```

```
Flags:
-h, --help          help for get
-o, --output string output to file or - (stdout) (default "-")
-t, --type string   type of object to return: cert, key, ca (default "cert")
```

```
Global Flags:
--accept-license  Accept the license for API Connect
--debug          Enable debug logging
```

Table 2. apicup certs get

Command	Values	Result
<code>apicup certs get SUBSYS CERT_NAME [flags]</code>	Parameters are: <ul style="list-style-type: none"> <li>SUBSYS - name of the subsystem to which the certificate applies</li> <li>CERT_NAME - name of the certificate to retrieve; see <a href="#">Certificate reference</a> for a list of certificates</li> </ul>	Returns the specified certificate for the specified subsystem.
<b>flags</b> <ul style="list-style-type: none"> <li><code>--output string</code></li> <li><code>--type string</code></li> <li><code>--help</code></li> </ul>	Flags are: <ul style="list-style-type: none"> <li><code>--output string</code> - Specify a file for the retrieved values, or specify "-" to send to stdout. Default is "-" to send to stdout. For example, <code>apicup certs get mgmt1 --output myCertsFile</code></li> <li><code>--type string</code> - Returns only the specified type. If not specified, the type is cert. For example, <code>apicup certs get mgmt1 --type ca</code></li> <li><code>--help</code> - Displays help for the command.</li> </ul>	<ul style="list-style-type: none"> <li>For <code>--output</code>: The specified certificate will be retrieved and sent to stdout or saved to the specified file</li> <li>For <code>--type</code>: Certificates will be retrieved that match the type specified.</li> </ul>

3. List all certificates that have been set for a subsystem using the `apicup certs list` command. You can list the certificates at any time to summarize the certificates that have been set.

```
apicup certs list -help
```

```
List all configured certificates
```

```
Usage:
apicup certs list SUBSYS [flags]
```

```
Flags:
-h, --help help for list
```

```
Global Flags:
--accept-license  Accept the license for API Connect
--debug          Enable debug logging
```

Table 3. apicup certs list

Command	Values	Result
<code>apicup certs list SUBSYS [flags]</code>	Parameters are: <ul style="list-style-type: none"> <li>SUBSYS - name of the subsystem for which you want to list certificates</li> </ul>	Returns a list of certificates that are configured for the subsystem.
<b>flags</b> <ul style="list-style-type: none"> <li><code>--help</code></li> </ul>	Flags are: <ul style="list-style-type: none"> <li><code>--help</code> - Displays help for the command.</li> </ul>	Help text is displayed.

Following is example output from the `apicup certs list` command:

```
Common certificates
```

```

4. The `apicup certs generate` command generates and sets default certificates. The `generate` command only generates and sets a certificate if it is not already set; it only sets the missing default certificates that have not been explicitly set using the `set` command. Execute the `generate` command before running the `apicup subsys install <SUBSYS>` command to confirm the certificates are correct before installing. It allows you to validate all certificates before performing the installation. The `generate` command is used as a tool to assist you when entering a combination of default and custom certificates. If you need to set specific certificates you can set them upfront (using `set`) and then generate the missing ones with default certificates. Or you can generate all certificates upfront and then override specific certificates to set custom certificates. Using `generate` helps to avoid validation errors during the installation procedure. Note that you must configure the subsystems and pass the `--validate` option before generating the default certificates.

```

apicup certs generate -help
Generate all unset certificates

```

```

Usage:
  apicup certs generate SUBSYS [flags]

```

```

Flags:
  -h, --help      help for generate
Global Flags:
  --accept-license  Accept the license for API Connect
  --debug           Enable debug logging

```

Table 4. apicup certs generate

Command	Values	Result
<code>apicup certs generate SUBSYS [flags]</code>	Parameters are: <ul style="list-style-type: none"> <li>SUBSYS - name of the subsystem for which you want to generate certificates</li> </ul>	Generates certificates that have not been set for the subsystem. Generates self-signed certificates.
<code>flags</code> <ul style="list-style-type: none"> <li><code>--help</code></li> </ul>	Flags are: <ul style="list-style-type: none"> <li><code>--help</code> - Displays help for the command.</li> </ul>	Help text is displayed.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Validation reference

Certificates are validated using several parameters.

The validations described in the following table are applied for all certificates, but are most helpful for custom certificates. For default certificates, the certificate validations will always pass, as the required elements are generated by APICUP. However, with custom certificates, some of the required elements may be missing or incorrect.

Validation	Messages	Error	See also/Action
Verify the certificate is set properly.	<code>certificate &lt;cert&gt; not set</code>	The certificate is not set.	
	<code>unable to load cert &lt;cert&gt;</code>	The certificate is set but cannot be read.	
Verify certificate key usage (Extended Key Usage).	<code>unable to verify cert &lt;cert&gt;: missing key usage &lt;n&gt;</code>	The certificate is missing the required key usage.	See <a href="#">Certificates Reference</a> to see more information, including the type, for all certificates. See <a href="#">Setting custom certificates</a> for tips on how to generate the EKUs for custom certificates.

Validation	Messages	Error	See also/Action
Verify the certificate signing CA. If available, the CA file is loaded. Then the certificate is verified against the provided CA file, including enforcement of Extended Key Usage.	unable to parse CA to verify cert <cert>	The CA file could not be parsed and loaded.	
	unable to verify cert <cert>	The certificate failed verification against the provided CA file.	One possible reason for receiving this error is that the correct EKU is missing. For a custom certificate, see <a href="#">Setting custom certificates</a> for information on generating EKUs.
Verify certificate hosts. The certificate must be valid for the hosts listed for the certificate in the Requirements column in the Certificates Reference.	unable to verify cert <cert>: missing <host>	The certificate is not valid for the required host.	See <a href="#">Certificate reference</a> for the required hosts.
Verify that a certificate that is being used as a CA is actually a CA.	unable to verify cert <cert>: certificate is not a CA	The certificate is not a valid CA.	
Verify client certificate match. The portal-client, analytics-client-client, and analytics-ingestion-client certificates are verified against the CA of, respectively, portal-admin-ingress, analytics-client-ingress, and analytics-ingestion-ingress.	a CA certificate must be provided for this certificate	The CA certificate is missing for one of the portal-admin-ingress, analytics-client-ingress, and analytics-ingestion-ingress.	The common certificates portal-client, analytics-client-client, and analytics-ingestion-client must be set prior to setting any custom certificates.
	client cert cannot be verified against provided CA certificate	The verification failed.	

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Tips and tricks for using APICUP

The APICUP installer in Install Assist contains built-in time saving functions.

### Introduction

This section describes tips and techniques for working with the APICUP installation commands. The APICUP installer creates charts and secrets that are then managed by Helm.

- [Running Tiller with APICUP](#)
- [Entering multiple settings per command](#)
- [Entering multiple values](#)
- [Viewing the settings for a subsystem](#)
- [Validating the settings for a subsystem](#)
- [Output an installation plan](#)
- [Getting help for commands](#)
- [Getting help on a specific command](#)

### Running Tiller with APICUP

To run Tiller in a namespace:

```
export TILLER_NAMESPACE=apic
```

### Entering multiple settings per command

To configure multiple settings per command, enter a space between each setting and enter an equals sign (=) to configure the setting.

In the following examples, be sure to replace [spc] with an actual space.

You can set multiple database parameters on one line:

```
apicup subsys set mgmt cassandra-max-memory-gb=9 [spc] cassandra-cluster-size=3 [spc] cassandra-volume-size-gb=16 [spc] cassandra-backup-protocol=sftp
```

You can set all endpoints on one line:

```
apicup subsys set mgmt platform-api=my.platform.com [spc] api-manager-ui=my.apim.com [spc] cloud-admin-ui=my.cloud.com [spc] consumer-api=my.consumer.com
```

### Entering multiple values

Separate multiple values for a key/value pair with commas.

## Viewing the settings for a subsystem

To view the current values that are set for a subsystem, enter the following command: `apicup subsys get <subsys_name>`. For example: `apicup subsys get mgmt` outputs the current values for the subsystem named `mgmt` and provides a description of each value. The output from the `get` command is organized into Kubernetes settings and Subsystem settings. Following is an example:

Figure 1. Output for the `get` command

```
Kubernetes settings
=====

Name          Value          Description
----          -
extra-values-file (Optional) Path to additional configuration yml file
ingress-type   ingress        Ingress type (use `route` for OpenShift)
mode          standard      mode
namespace     default       K8S namespace to install into
registry      Docker image registry to use
registry-secret Docker registry credentials secret
storage-class  -            K8S storage class for persistent storage

Subsystem settings
=====

Name          Value          Description
----          -
cassandra-backup-auth-pass (Optional) Server password for DB backups
cassandra-backup-auth-user (Optional) Server username for DB backups
cassandra-backup-host (Optional) FQDN for DB backups server
cassandra-backup-path (Optional) path for DB backups server
cassandra-backup-port (Optional) Server port for DB backups
cassandra-backup-protocol (Optional) Protocol for DB backups (sftp/ftp)
cassandra-backup-schedule (Optional) Cron schedule for DB backups
cassandra-cluster-size Size of DB cluster (min 3 for HA)
cassandra-max-memory-gb Memory limit for DB
cassandra-volume-size-gb Size of DB storage volume (not resizable)
create-crd     true          Create DB cluster CRDS (Required cluster admin privilege)
external-cassandra-host (Optional) Hostname of externally hosted DB

Endpoints
=====

Name          Value          Description
----          -
api-manager-ui FQDN of API manager UI endpoint
cloud-admin-ui FQDN of Cloud admin endpoint
consumer-api  FQDN of consumer API endpoint
platform-api  FQDN of platform API endpoint

Error: Subsystem validation failure. Run with --validate to see details
```

## Validating the settings for a subsystem

The values set for a subsystem can be validated for syntax by entering the `--validate` option for the `get` command: `apicup subsys get <subsys_name> --validate`. For example: `apicup subsys get mgmt --validate` validates the current values for the subsystem named `mgmt`. In the following example of the output for the `--validate` option, the check mark indicates a valid setting. The `x` indicates an invalid setting with an error message provided.

Figure 2. Output for the `--validate` option

```
Subsystem settings
=====

Name          Value          Description
----          -
cassandra-backup-auth-pass ✓
cassandra-backup-auth-user ✓
cassandra-backup-host ✓
cassandra-backup-path /backups ✓
cassandra-backup-port 22 ✓
cassandra-backup-protocol sftp ✓
cassandra-backup-schedule 0 0 * * * ✓
cassandra-cluster-size 1 ✓
cassandra-max-memory-gb 9 ✓
cassandra-volume-size-gb 50 ✓
create-crd true ✓
external-cassandra-host ✓

Endpoints
=====

Name          Value          Description
----          -
api-manager-ui x api-manager-ui is not a valid hostname
cloud-admin-ui x cloud-admin-ui is not a valid hostname
```

```
consumer-api          ✗ consumer-api is not a valid hostname
platform-api         ✗ platform-api is not a valid hostname
```

## Output an installation plan

Using APICUP, you can generate an installation plan and confirm it is correct prior to running the installation. You can then install the subsystem from the plan.

To output an installation plan, enter the following command:

```
apicup subsys install SUBSYS --out=install-plan
```

where <install-plan> is the name of the directory where the installation plan will be stored.

In the example, a directory named install-plan is created in the project directory. The myProject/install-plan directory contains the configuration parameters for the subsystem.

To install the subsystem from the install-plan, enter the following command from the project directory:

```
apicup subsys install SUBSYS --plan-dir=<full-path-to-plan-directory>
```

where <full-path-to-plan-directory> is the full qualified path to the plan directory.

Following are general rules for installing from the installation plan:

- Never edit the files in the output directory directly. Instead, if changes are needed, update the parameters using APICUP and generate a new plan.
- Always run APICUP commands from the original project directory created during the initial product installation. The project directory contains the apiconnect-up.yml file.
- You can generate the plan in any location, but the install command must be run from the project directory. Enter the full path to the plan as the argument to `--plan-dir` to perform an installation.

The plan must be current with the project and the certificates. If the plan is older than the last modification date of the project or certificates, you will receive an error message such as:

```
the project was modified since the plan was generated, regenerate plan or skip this check
with a --no-verify flag in the command
```

or

```
the certs were changed since the plan was generated, regenerate plan or skip this check with
a --no-verify flag in the command
```

## Getting help for commands

You can get help for all commands by entering: `apicup --help`. Following is an example of the output:

Figure 3. Help for Install Assist apicup commands

```
APIConnect Install Assist
Usage:
  apicup [command]

Available Commands:
  certs          Subsystem certificates
  completion    Generates bash or zsh completion scripts
  help          Help about any command
  hosts         Commands to configure subsystem hosts
  iface         Commands to configure hosts interfaces
  init          Create a new APIConnect UP project
  registry-upload Retag and upload images to custom registry
  server        Starts the APIConnect cluster operator
  subsys        Subsystem commands
  version       Get the APIConnect UP version

Flags:
  --accept-license  Accept the license for API Connect
  --debug           Enable debug logging
  -h, --help       help for apicup

Use "apicup [command] --help" for more information about a command.
```

## Getting help on a specific command

For help on a specific command, enter `--help` after the command. For example, `apicup subsys get mgmt --help` prints out the usage and flags for the `get` command. For example:

Figure 4. Help for get command

```
Get subsystem properties

Usage:
  apicup subsys get SUBSYS [flags]

Flags:
  --endpoints  List endpoints (default true)
  -h, --help  help for get
  --platform  List platform settings (default true)
  --subsystem  List subsystem settings (default true)
```

```
--validate    Validate settings

Global Flags:
--accept-license  Accept the license for API Connect
--debug          Enable debug logging
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Deploying to a Kubernetes environment

Install Assist provides script-based installation using the APICUP tool into a Kubernetes runtime environment.

### About this task

---

The Install Assist tool contains the APICUP installation program to provide an automated installation process for API Connect in a Kubernetes environment. This section contains the software requirements, download and installation procedure, and the recommended minimum allocations for system resources in the Kubernetes cluster.

- [Requirements for a Kubernetes deployment](#)  
Ensure that your environment meets these requirements for deploying API Connect on Kubernetes.
- [Load balancer configuration in a Kubernetes deployment](#)  
When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect Kubernetes deployment.
- [Configuring logging for a Kubernetes deployment](#)  
Logs must be collected for both running and terminated containers and processes. Logging collection is required for IBM Support to assist with troubleshooting. For container-based deployments (Kubernetes), specific log commands and mechanisms vary depending on a customer's environment.
- [Installing API Connect into a Kubernetes environment](#)  
You can use Kubernetes and Docker containers to deploy and run API Connect. The Install Assist utility program automates the installation process into a Kubernetes runtime environment using an installation program called APICUP.
- [Installing the Gateway subsystem into a Kubernetes environment](#)  
Use the Install Assist utility program to install the Gateway subsystem into your Kubernetes runtime environment.
- [Deploying pods to specific worker nodes in a multi-node cluster](#)  
Use node labels to deploy Management, Analytics, and Portal pods to specific worker nodes in a multi-node cluster.
- [Manually creating a CustomResourceDefinition in a Kubernetes environment](#)  
Describes the steps for manually creating the CustomResourceDefinitions which are required for the management subsystem. If the `create-crd` command is set to false during installation, the CRDs must be manually created by the Kubernetes administrator.
- [Creating an extra values file in a Kubernetes environment](#)  
Describes the steps for creating an extra values file for configuration parameters that are not set by Install Assist, such as ingress annotations and resource limits. An example `.yaml` file is provided with entries for each subsystem.
- [Configuring user-defined policies on the API Gateway in a Kubernetes deployment](#)  
For a Kubernetes deployment that uses the DataPower API Gateway, user-defined Policies are externally configured. To distribute the user-defined policies on the DataPower API Gateway, you create a Kubernetes ConfigMap that is installed using the extra values file. The ConfigMap ensures the policies are available to the Management server.
- [Installing the toolkit](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Requirements for a Kubernetes deployment

Ensure that your environment meets these requirements for deploying API Connect on Kubernetes.

- [Requirements for deploying IBM API Connect into a Kubernetes environment](#)  
Describes the system requirements for deploying into a Kubernetes runtime environment.
- [Deployment overview for endpoints and certificates](#)  
Refer to this diagram to view the connections and dataflow among the API Connect subsystems, including the endpoints and custom certificates, and the mutual TLS points.
- [Firewall requirements on Kubernetes](#)  
Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on Kubernetes.
- [Kubernetes ingress controller prerequisites](#)  
Describes the prerequisite settings for the ingress controller for a Kubernetes runtime environment.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

# Requirements for deploying IBM API Connect into a Kubernetes environment

Describes the system requirements for deploying into a Kubernetes runtime environment.

## Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software may change and this information may become outdated. These instructions assume you have a working Kubernetes environment and understand how to manage Kubernetes.

Kubernetes is a platform for automated deployment, scaling, and operation of application containers across clusters of hosts, providing container-centric infrastructure. For more information, see <https://kubernetes.io>.

### Pre-installation Requirements

#### Important:

Use a single APICUP project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

The original project directory created with APICUP during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. A good practice is to back up the original project directory to a location from where it can always be retrieved.

- Refer to the IBM® Software Product Compatibility Reports site for detailed requirements for operating systems, supporting software, and other prerequisites. Ensure that your Helm installation is up-to-date and compatible with your Kubernetes version. See [Detailed system requirements for a specific product](#).
- The Management server and Gateway firmware versions must match, for example, API Connect 2018.4.1.3 and DataPower 2018.4.1.3.
- For API Connect v2018.4.1.15 and later, Helm v3 is required. See <https://helm.sh/>.
- Namespaces must be configured in Kubernetes before starting the installation process. We recommend that you do not use the default namespace.
- The timezone for API Connect pods is set to UTC. Do not change the timezone for the pods.
- Block storage is required. Select a block storage format of your choosing in order for API Connect components to be supported. GlusterFS is not recommended as a storage option due to severe performance degradation. For AWS, the gp2 and io1 types of Elastic Block Storage (EBS) are supported. The Developer Portal and the Analytics component additionally support the use of local volume storage and do not require block storage.
- Manually create the required CustomResourceDefinitions if you are not going to use the APICUP commands in Install Assist to create them. For more information, see [Manually creating a CustomResourceDefinition in a Kubernetes environment](#) and [Installing the Management subsystem into a Kubernetes environment](#).
- When deploying with a DataPower appliance, configure a Gateway Service Management Endpoint and API invocation Endpoint in DataPower. See [Configuring API Connect Gateway Service](#).
- Configure a remote server for logging. Follow these instructions: [Configuring remote logging for a Kubernetes deployment](#). Pods are terminated during an upgrade, and the logs will be lost if not stored remotely.
- Configure the log rotation by setting the **max-size** and **max-files** values to a setting appropriate for your deployment. In a Kubernetes deployment, insufficient values for max-size and max-files can cause logs to grow too large and eventually force pods to restart. For information, visit the Docker documentation and search for "JSON File logging driver".
- DNS must be configured with domain names that correspond to the endpoints configured at installation time for each subsystem.

Note: Host names and DNS entries may not be changed on a cluster after the initial installation.

The endpoints are also subsequently entered in the Cloud Manager UI to configure the services for your cloud. We recommend that you keep a record of the DNS entries and endpoint names, as you will need to map the DNS entries and use the same endpoints when restoring a backup of the management database. Note that endpoints are FQDNs, entered in all lowercase. See [Defining your topology](#). The following endpoints require DNS entries:

Important: For API Connect on native Kubernetes and OpenShift, do not use coreDNS 1.8.1 through 1.8.3. These releases have a defect that can prevent pods for Developer Portal from starting. See <https://coredns.io/>.

- Four domain names are recommended for the endpoints for the manager subsystem (although these may be mapped to one domain name, if desired), as follows:
  - Cloud Manager URL: `<cm>.<hostname>.<domainname>`
  - API Manager URL: `<apim>.<hostname>.<domainname>`
  - Platform REST API Endpoint for admin and provider APIs: `<api>.<hostname>.<domainname>`
  - Platform REST API Endpoint for consumer APIs: `<consumer>.<hostname>.<domainname>`

#### Note:

Kubernetes ingress limits the character set for DNS names to not support the underscore character "\_". This means you cannot specify underscores in domain names that are used as endpoints. For example, `foo_abc.bar.com` and `foo.bar_abc.com` are not supported for `<xxx>.<hostname>.<domainname>`, and will cause an error. For example:

```
Invalid value: "foo_abc.bar.com": a DNS-1123 subdomain must consist of lowercase alphanumeric characters, '-' or '.', and must start and end with an alphanumeric character (e.g. 'example.com', regex used for validation is '[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*')
```

- The Gateway service requires two domain names to correspond to the following endpoints (both of these endpoints are entered in the Cloud Manager when defining a Gateway service). See [Registering a gateway service](#).
  - The API invocation endpoint that is defined by `api-gateway`, for example, `<gw>.<hostname>.<domainname>`. This is the API Endpoint Base defined in Cloud Manager.
  - The management endpoint that is defined by `apic-gw-service`, for example, `<gwd>.<hostname>.<domainname>`. This is the Management Endpoint defined in Cloud Manager.
- The Analytics service requires two domain names to correspond to the following endpoints:
  - The `analytics-ingestion` endpoint, for example, `<ai>.<hostname>.<domainname>`.
  - The management endpoint that is defined by `analytics-client`, for example, `<ac>.<hostname>.<domainname>`. This is the endpoint that is entered when defining an analytics service in Cloud Manager (see [Registering an analytics service](#)).
- The Portal service requires two domain names to correspond to the following endpoints (both of these endpoints are entered in the Cloud Manager when defining a Portal service). See [Registering a portal service](#):
  - The `portal-admin` endpoint, for example, `<padmin>.<hostname>.<domainname>`. This is the Management Endpoint defined in Cloud Manager.
  - The `portal-www` endpoint, for example, `<portal>.<hostname>.<domainname>`. This is the Portal Website URL defined in Cloud Manager.

- IBM API Connect requires certain repositories, and APICUP automatically creates the repositories in most cases. In some instances, for example, if installing into AWS ECR, you will need to manually create the following repositories for each subsystem:

**MANAGEMENT REPOSITORIES**

```
apim
client-downloads-server
ui
juhu
lur
analytics-proxy
ldap
busybox
cassandra
cassandra-operator
cassandra-health-check
migration
k8s-init
```

**PORTAL REPOSITORIES**

```
portal-db
portal-dbproxy
portal-admin
portal-web
openresty
portal-exec-job
```

**ANALYTICS REPOSITORIES**

```
analytics-cronjobs
analytics-client
analytics-ingestion
analytics-mq-kafka
analytics-mq-zookeeper
analytics-storage
analytics-operator
k8s-init
```

**GATEWAY REPOSITORIES**

```
datapower-api-gateway
k8s-datapower-monitor
```

- Decide the *mode* to use for the installation.

Table 1. Deployment modes

Mode	Description
<b>dev</b>	Development mode ( <b>dev</b> ) deploys a subsystem with the scale of one. Development mode is recommended for development, testing, and demonstration purposes.  <code>apicup subsys set mgmt mode=dev</code>  Do not use <b>dev</b> mode for production environments. Development mode does not provide high availability.
<b>standard</b>	Standard mode ( <b>standard</b> ) deploys in high availability mode for a production environment.  <code>apicup subsys set mgmt mode=standard</code>

Usage:

- Mode is set for each subsystem type: Management, Analytics, Developer Portal, and Gateway.
- If you do not specify the mode, a default mode is applied, as follows:
  - **Version 2018.4.1.4 and later:** **dev** mode
  - **Version 2018.4.1.3 and earlier:** **standard** mode
- Use of **standard** mode is supported only on installations with three or more nodes. Installations with less than three nodes must use **dev** mode. If you install in **standard** mode with only a single node, some pods can remain in a pending state. To avoid having pods remain pending, either install in **dev** mode or add additional nodes.
- To ensure the API Connect services have time to start, we recommend increasing the *proxy-read-timeout* and *proxy-send-timeout* values in the *config.map* used to configure the *kubernetes/ingress-nginx* ingress controller. The following settings should be increased:
  - `proxy-read-timeout: "240"`
  - `proxy-send-timeout: "240"`

240 seconds (4 minutes) is a recommended minimum; actual value will vary depending upon your environment. If there is a load balancer in front of the worker node(s), then the load balancer configuration may also need to have extended timeouts.

- Ensure that your Kubernetes deployment addresses known security vulnerabilities with SSH to prevent the use of weak SSH Message Authentication Code (MAC) and Key exchange algorithms (KexAlgorithms) with TCP over port 22. Use of weak algorithms can allow an attacker to recover the plain text message from the encrypted text. If you have not yet addressed the security vulnerabilities with weak MACs and KexAlgorithms, update your configuration manually by adding the following lines to */etc/ssh/sshd\_config*:

```
KexAlgorithms curve25519-sha256@libssh.org,diffie-hellman-group-exchange-sha256
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
```

System and Software Requirements

The installation instructions have been tested with the requirements described in the Software Product Compatibility Reports. See [Detailed system requirements for a specific product](#)

Note: API Connect v2018 cannot be deployed on NFS.

Important: There are known GlusterFS issues that affect the following functionality areas:

- Elasticsearch, which is used in the API Connect analytics service.
- The Developer Portal service.

If you use GlusterFS, you might encounter severe performance degradation and, in some cases, loss of data.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
 For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

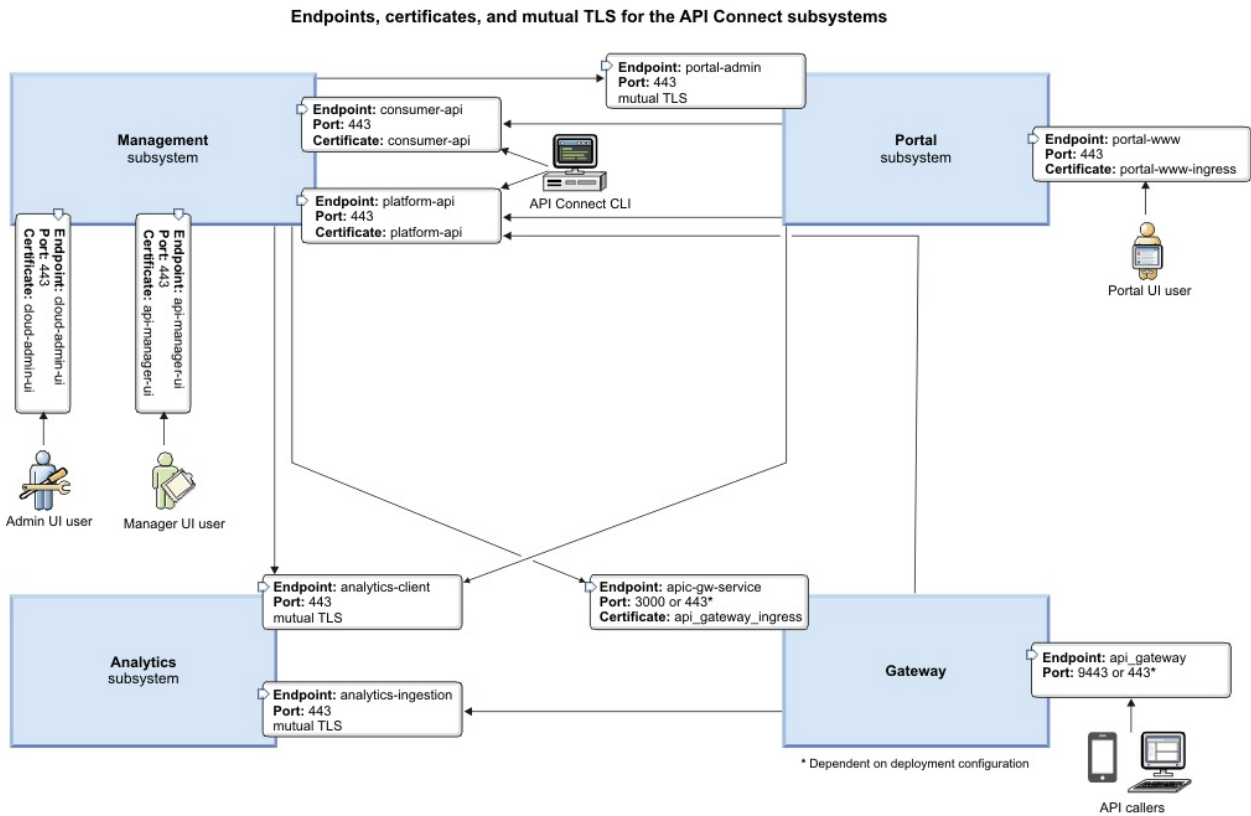

## Deployment overview for endpoints and certificates

Refer to this diagram to view the connections and dataflow among the API Connect subsystems, including the endpoints and custom certificates, and the mutual TLS points.

### Introduction

When deploying API Connect, you will create one or more endpoints for the subsystems and then configure certificates or mutual TLS for most endpoints. [Figure 1](#) shows the endpoints for each subsystem by name, the name of the certificate that secures the endpoint, and whether mutual TLS is required. It also shows the ports consumed by the endpoints, which are standard for HTTP and HTTPS.

Figure 1. Deployment Overview diagram

### Configuring endpoints

The endpoints are configured by the Install Assist program using the APICUP installer. They are set for each subsystem. Endpoints are also entered when configuring the Topology for the Gateway, Portal, and Analytics subsystems in Cloud Manager.

For instructions on configuring endpoints and installing into a Kubernetes environment, see [Installing API Connect into a Kubernetes environment](#).

Instructions for installing into an IBM Cloud Private environment are here: [Deploying to an IBM Cloud Private environment](#).

Subsystem	Endpoints	Description	Certificates
Management	cloud-admin-ui	Configured using APICUP installer. Endpoint on the management server for communication with the Cloud Manager user interface.	cloud-admin-ui
	api-manager-ui	Configured using APICUP installer. API Manager URL endpoint on the management server for communication with the API Manager user interface.	api-manager-ui
	consumer-api	Configured using APICUP installer. Platform REST API endpoint for running consumer APIs on the management server.	consumer-api
	platform-api	Configured using APICUP installer. Platform REST API endpoint for running admin and provider APIs on the management server.	platform-api
Portal	portal-admin	Configured using APICUP installer. Corresponds to Management Endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS.	mutual TLS
	portal-www	Configured using APICUP installer. Portal Web site URL entered in Cloud Manager. Used publicly to access Portal.	portal-www-ingress

Subsystem	Endpoints	Description	Certificates
Analytics	analytics-client	Configured using APICUP installer. Corresponds to Management Endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS.	mutual TLS
	analytics-ingestion	Configured using APICUP installer. The analytics-ingestion endpoint is used by the Gateway service to push data to the Analytics service. Requires a TLS profile configured with mutual TLS.	mutual TLS
Gateway	apic-gw-service	Configured using APICUP installer. This is the endpoint the gateway uses for network communication. Enter this endpoint as the Management Endpoint entered in Cloud Manager.	apic-gw-service-ingress
	api-gateway	Configured using APICUP installer. This is the endpoint the gateway uses for API traffic. Enter this endpoint as the API Invocation Endpoint in Cloud Manager.	api-gateway-ingress

## Configuring certificates

The certificates are configured by the Install Assist program using the APICUP installer. The certificates for the endpoints are usually configured as custom certificates as described in [Setting custom certificates](#).

## Configuring mutual TLS

Mutual TLS is configured for TLS profiles in Cloud Manager. See [Creating a TLS Server Profile](#).

## Configuring a proxy

If a Developer Portal is deployed externally to the management server zone, it does not have access to the consumer and product APIs. You need to configure a proxy to enable communication. For more information, see [Configuring a proxy](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Firewall requirements on Kubernetes

Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on Kubernetes.

## Required Ports between zones

The following network diagram example helps to explain which ports must be configured in an API Connect network. Specific ports must be configured to enable the communication between the various zones, both public and private, in a network.

The ports specified in the diagram are default ports. Check your deployment to understand which communication, if any, is configured to use non-default ports.

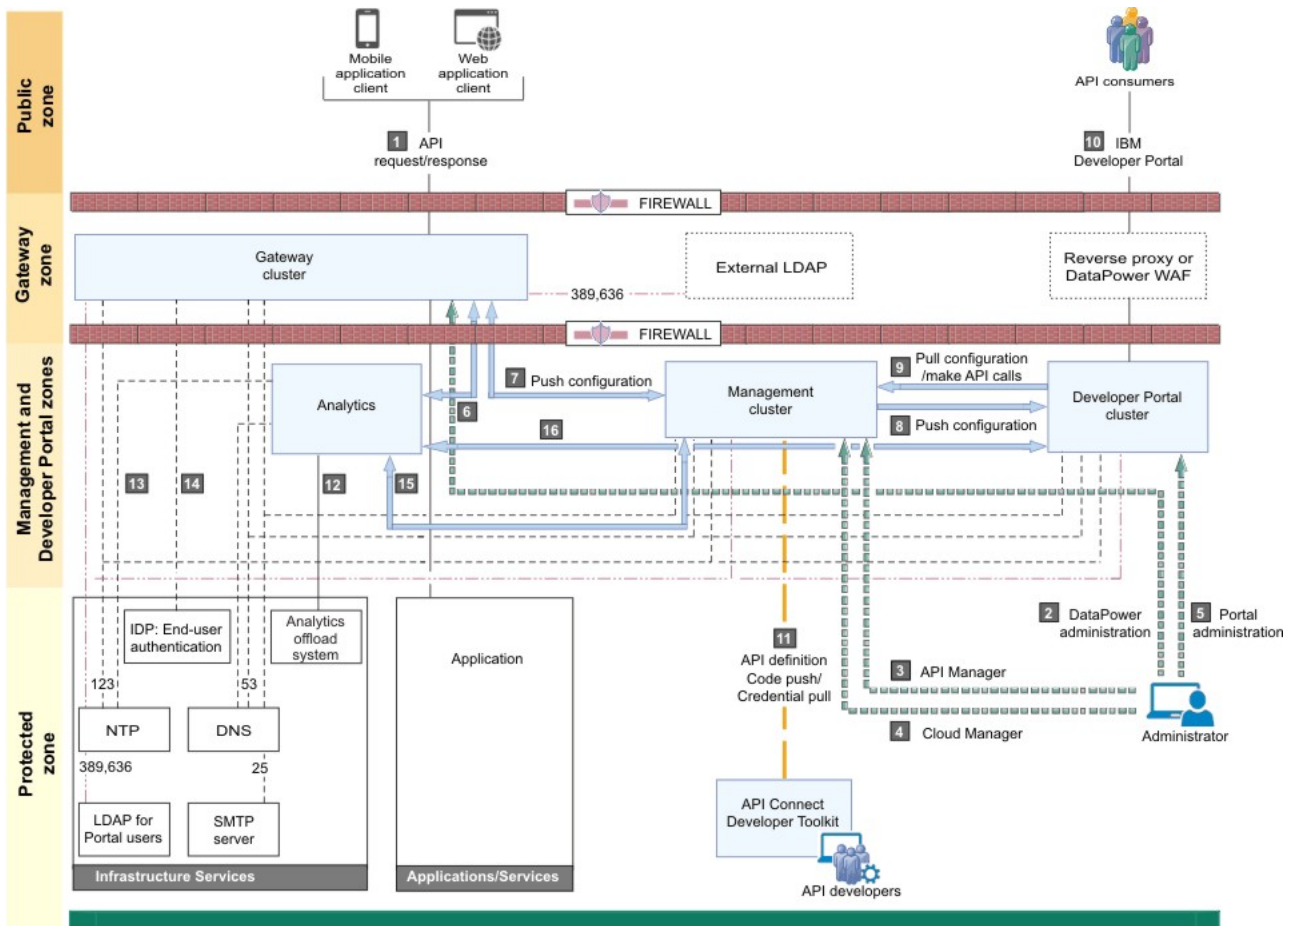

Table 1. Key for the network diagram example.  
The following table lists the port numbers with a usage description.

	Usage description	Default port number
1	API request/response – Users invoking the provided APIs.	443 HTTPS from Public zone to Gateway zone
2	DataPower® administration – Internal operators who are managing the Gateway servers.	22 SSH, 9090 HTTPS from Protected zone to Gateway zone
3	API Manager – Internal business users who are defining and monitoring APIs.	443 HTTPS from Protected zone to Management zone
4	Cloud Manager – Internal operators who are administering the Cloud.	22 SSH, 443 HTTPS from Protected zone to Management zone
5	Developer Portal administration – Internal operators who are managing the Portal servers.	22 SSH, 443 HTTPS from Protected zone to Management zone
6	Gateway servers post traffic to Analytics service.	443 HTTPS from Gateway servers to Analytics service
7	Push configuration – Management servers communicate bi-directionally with Gateway servers.	3000 or 443 (dependent on configuration) HTTPS Management servers to and from Gateway servers for webhook delivery
8	Push configuration/webhooks – Management servers push configuration and webhooks to the Developer Portal.	443 HTTPS Management servers to Developer Portal servers for webhook delivery
9	Pull configuration/make API calls – Developer Portal servers pull configuration and call REST APIs.	443 HTTPS from Developer Portal servers to Management servers within Management zone

	Usage description	Default port number
10	Developer Portal – External developers who are accessing the Developer Portal.	443 HTTPS from Public zone to Developer Portal management zone. The reverse proxy/DataPower WAF for incoming web traffic to the Developer Portal cluster must be a transparent proxy - no modification of the portal URL, port, host name or path is allowed. For more information, see <a href="#">Configuring a proxy</a> .
11	Push API definition to Management server. Pick up credential for microservice code push.	443 HTTPS from Protected zone to Management zone
12	Analytics offload	Port will depend on type of plugin and protocol used for the offload. Some possible protocols are: HTTP, HTTPS, TCP, UDP, KAFKA
13	Analytics accesses NTP	Standard NTP
14	Analytics access DNS	Standard DNS
15	Management service queries Analytics service	443 HTTPS within Management zone
16	The Portal service invokes an API (GET) on the Analytics service to retrieve data.	443 HTTPS within Management zone

## Firewall port requirements on Kubernetes

The following tables lists ports that must be open in both cluster and non-clustered deployments.

Table 2. Firewall port requirements common to all subsystems

Subsystem	Ports and description
Ports that must be open on all API Connect subsystems	<p>The following ports must be open on the Management Server, Analytics, and Developer Portal subsystems, whether in a cluster or not.</p> <ul style="list-style-type: none"> <li>• 22 (inbound and outbound) SSH</li> <li>• 53 (outbound) DNS</li> <li>• 123 (outbound) NTP</li> <li>• 443 (inbound and outbound) Used by all subsystems for communication with other subsystems</li> <li>• 44135 (inbound and outbound)</li> </ul>

Each subsystem uses ports in addition to the ports in [Table 2](#). See the following table.

Table 3. Additional firewall port requirements for each subsystem

Subsystem	Ports and description
Management Service	<p>Management Service uses the ports in <a href="#">Table 2</a> plus:</p> <ul style="list-style-type: none"> <li>• 22 remote backup server port (configurable) If backups are configured to use another port, ensure that the port is open. See <a href="#">Backing up the management database in a Kubernetes environment</a>.</li> <li>• 161 (inbound) SNMP</li> <li>• LDAP server port (if using LDAP user registry), typically 389 (outbound)</li> <li>• 3007 (outbound) LDAP</li> </ul>
Developer Portal	<p>The Developer Portal uses the ports listed in <a href="#">Table 2</a>, plus:</p> <ul style="list-style-type: none"> <li>• 22 - A remote backup server port (configurable) If backups are configured to use another port, ensure that the port is open. See <a href="#">Backing up and restoring the Developer Portal in a Kubernetes environment</a>.</li> </ul>
Analytics	<p>The Analytics subsystem uses the ports listed in <a href="#">Table 2</a>.</p> <p>Analytics port usage considerations:</p> <ul style="list-style-type: none"> <li>• 161 for SNMP is required for both non-clustered and clustered deployments</li> <li>• In a non-clustered deployment, no additional ports are required.</li> <li>• Analytics supports an optional configuration for offload of data. This configuration might require additional outbound ports to be open.</li> </ul>
Gateway Server	<p>The Gateway Server uses these ports in both non-clustered and clustered deployments:</p> <ul style="list-style-type: none"> <li>• 161 (inbound and outbound) SNMP</li> <li>• 162 (outbound) SNMP traps</li> <li>• 3000 (inbound) Gateway Service local port (configurable)</li> <li>• 5550 (inbound) XML management port (configurable)</li> <li>• 5554 (inbound) REST management port (if enabled; configurable)</li> <li>• 9022 (inbound) Gateway SSH (if enabled; configurable)</li> <li>• 9090 (inbound) Web GUI console (if enabled; configurable)</li> <li>• 9443 (inbound) Gateway local port (configurable)</li> </ul>

## Communications inside the Gateway cluster

There are a number of important points to note regarding the communications within the Gateway cluster.

- We advise that you use the same port for all Gateway servers within a cluster.
- Gateway servers communicate with each other to synchronize invocation counts.
- All Gateway servers in a Gateway cluster must be able to reach all of the other Gateway servers in the same Gateway cluster.

- Gateway servers in a Gateway cluster do not directly communicate with Gateway servers in a different Gateway cluster.
- All Gateway servers must be able to reach the management subsystem platform API endpoint, which was configured during the installation of your API Connect environment.

## Ethernet interface usage

To separate network traffic, you can use two or more Ethernet interfaces on the DataPower appliance on which a Gateway server is installed. For example, you can use one interface for internal IBM API Connect communications, and another for processing incoming API calls.

## Related concepts

- [Installing and maintaining your IBM API Connect cloud](#)

## Related reference

- [IBM API Connect Version 2018 software product compatibility requirements](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Kubernetes ingress controller prerequisites

Describes the prerequisite settings for the ingress controller for a Kubernetes runtime environment.

## Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software may change and this information may become outdated.

These instructions assume you have a working Kubernetes environment and understand how to manage Kubernetes. Kubernetes is a platform for automated deployment, scaling, and operation of application containers across clusters of hosts, providing container-centric infrastructure. For more information, see <https://kubernetes.io>.

Kubernetes/ingress-nginx ingress controller `ingress-config.yml` settings

A Kubernetes deployment for IBM® API Connect requires the `kubernetes/ingress-nginx` ingress controller implementation (see <https://github.com/kubernetes/ingress-nginx>) with SSL passthrough enabled.

Important: When deploying to an OpenShift environment, an ingress controller is not used. Setting the `ingress-type` parameter to `route` using `apicup subsys set SUBSYS ingress-type route` command completes the configuration for the ingress on OpenShift. See [Settings for OpenShift](#). API Connect v2018 currently only supports Helm2, but for the purpose of installing the ingress controller we recommend using Helm3 just for that part of the installation. Follow these steps:

1. Create a file `ingress-config.yaml` where the following values are required:

```
controller:
  admissionWebhooks:
    enabled: false
  config:
    ssl-protocols: TLSv1.2
  extraArgs:
    annotations-prefix: ingress.kubernetes.io
    enable-ssl-passthrough: true
```

You may use the following sample `ingress-config.yml` file to configure the ingress controller:

```
controller:
  admissionWebhooks:
    enabled: false
  config:
    hsts-max-age: "31536000"
    keepalive: "32"
    log-format: '{ "@timestamp": "$time_iso8601", "@version": "1", "clientip": "$remote_addr",
      "tag": "ingress", "remote user": "$remote_user", "bytes": $bytes_sent, "duration":
      $request_time, "status": $status, "request": "$request_uri", "urlpath": "$uri",
      "urlquery": "$args", "method": "$request_method", "referer": "$http_referer",
      "useragent": "$http_user_agent", "software": "nginx", "version": "$nginx_version",
      "host": "$host", "upstream": "$upstream_addr", "upstream-status": "$upstream_status"
    }'
    main-snippets: load_module "modules/nginx_stream_module.so"
    proxy-body-size: "0"
    proxy-buffering: "off"
    server-name-hash-bucket-size: "128"
    server-name-hash-max-size: "1024"
    server-tokens: "False"
    ssl-ciphers: HIGH:!aNULL!MD5
    ssl-prefer-server-ciphers: "True"
    ssl-protocols: TLSv1.2
    use-http2: "true"
    worker-connections: "10240"
    worker-cpu-affinity: auto
    worker-processes: "1"
    worker-rlimit-nofile: "65536"
    worker-shutdown-timeout: 5m
```

```
daemonset:
  useHostPort: false
extraArgs:
  annotations-prefix: ingress.kubernetes.io
  enable-ssl-passthrough: true
hostNetwork: true
kind: DaemonSet
name: controller
rbac:
  create: "true"
```

2. Run the commands:

```
helm3 repo add ingress-nginx https://kubernetes.github.io/ingress-nginx
helm3 repo update
helm3 install ingress-controller ingress-nginx/ingress-nginx --namespace kube-system --values ingress-config.yaml
```

Kubernetes/ingress-nginx ingress controller `config.map` settings

To ensure that the IBM API Connect services have time to start, increase the `proxy-read-timeout` and `proxy-send-timeout` values, which are in seconds, in the `kubernetes/ingress-nginx` ingress controller `config.map` to at least the following:

- `proxy-read-timeout: "240"`
- `proxy-send-timeout: "240"`

Depending on your environment, you might need to increase these further if the IBM API Connect services do not start. If there is a load balancer in front of the worker nodes, then the load balancer configuration might also need to have extended timeouts.

Attention: In OpenShift, you must individually annotate all routes are for the Management subsystem (updating the corresponding configuration for an ingress controller affects all ingresses). Refer to the OpenShift docs on how to annotate the routes: <https://docs.openshift.com/container-platform/4.2/networking/routes/route-configuration.html>.

System and Software Requirements

The system and software requirements are described in the Software Product Compatibility Reports. See [Detailed system requirements for a specific product](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Load balancer configuration in a Kubernetes deployment

When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect Kubernetes deployment.

---

### About this task

API Connect can be deployed on a single node cluster. In this case the ingress endpoints are host names for which the DNS resolution points to the single IP address of the corresponding node hosting a particular subsystem, and no load balancer is required. For high availability, it is recommended to have at least a three node cluster. With three nodes, the ingress endpoints cannot resolve to a single IP address. A load balancer should be placed in front of an API Connect subsystem to route traffic.

Because it is difficult to add nodes once endpoints are configured, a good practice is to configure a load balancer even for single node deployments. With the load balancer in place, you can easily add nodes when needed. Add the node to the list of servers pointed to by the load balancer and the ingress endpoints defined during installation of API Connect can remain unchanged.

To support Mutual TLS communication between the API Connect subsystems, configure the load balancer with **SSL Passthrough** and **Layer 4** load balancing. In order for Mutual TLS to be performed directly by the API Connect subsystems, the load balancer should leave the packets unmodified, as is accomplished by Layer 4. Following is a description of the communication between the endpoints that are configured with Mutual TLS:

- API Manager (with the client certificate `portal-client`) communicates with the Portal Admin endpoint `portal-admin` (with the server certificate `portal-admin-ingress`)
- API Manager (with the client certificate `analytics-client-client`) communicates with the Analytics Client endpoint `analytics-client` (with the server certificate `analytics-client-ingress`)
- API Manager (with the client certificate `analytics-ingestion-client`) communicates with the Analytics Ingestion endpoint `analytics-ingestion` (with the server certificate `analytics-ingestion-ingress`)

Set endpoints to resolve to the load balancer

When configuring a load balancer in front of the API Connect subsystems, the ingress endpoints are set to host names that resolve to a load balancer, rather than to the host name of any specific node. For an overview of endpoints, see [Deployment overview for endpoints and certificates](#).

Use these example topologies as a guideline to determine the best way to configure the load balancer for your deployment.

---

### Procedure

- **Kubernetes cluster with wildcard DNS**

In this example, API Connect is deployed to a Kubernetes cluster with three master and six worker nodes. The master nodes have the Kubernetes API server listening on port 6443. The Kubernetes API Server is used for communicating with the `kubectl` command line interface. Note that it is generally not necessary for the Kubernetes API server (on port 6443 in this example) to be exposed outside the cluster through the load balancer, this is just one possible setup shown here.

The `kubernetes/ingress-nginx` ingress controller is deployed as a daemonset, so that every worker node in the cluster has an ingress controller pod listening on port 443. The API Connect subsystems (API Manager, Developer Portal, Analytics and Gateway) are all deployed on this same cluster.

Note:

When you configure a load balancer in front of a Management subsystem, specify timeouts of at least 240 seconds. Note that large deployments might need larger values.

The default timeout is typically 50 or 60 seconds, which is not long enough to avoid **409**

**Conflict** or **504 Gateway Timeout** errors. The **409 Conflict** error can occur when the time needed to complete an operation is sufficiently long that a second request gets issued.

For example, to specify 240 seconds when using HAProxy as a load balancer, set `timeout client` and `timeout server` to **240000**.

Best practice is to ensure that the same values are specified for the timeout settings for the load balancer and for the Kubernetes ingress controller. The ingress controller timeout settings are set in the ingress controller config.map. For more information, see the `proxy-read-timeout` and `proxy-send-timeout` settings in [Kubernetes ingress controller prerequisites](#).

A host running HAProxy acts as the load balancer, with a configuration for proxies in the HAProxy configuration file such as:

```
defaults
    log          global
    mode        http
    option      httplog
    option      dontlognull
    timeout connect 5000
    timeout client 240000
    timeout server 240000
    errorfile 400 /etc/haproxy/errors/400.http
    errorfile 403 /etc/haproxy/errors/403.http
    errorfile 408 /etc/haproxy/errors/408.http
    errorfile 500 /etc/haproxy/errors/500.http
    errorfile 502 /etc/haproxy/errors/502.http
    errorfile 503 /etc/haproxy/errors/503.http
    errorfile 504 /etc/haproxy/errors/504.http

frontend apiservers
    bind *:6443
    mode tcp
    option tcplog
    option forwardfor
    default_backend k8s_apiservers

frontend ingress
    bind *:443
    mode tcp
    option tcplog
    option forwardfor
    default_backend k8s_ingress

backend k8s_apiservers
    mode tcp
    option tcplog
    option ssl-hello-chk
    option log-health-checks
    default-server inter 10s fall 2
    server cluster1-master-1 10.169.241.226:6443 check
    server cluster1-master-2 10.169.241.163:6443 check
    server cluster1-master-3 10.169.241.153:6443 check

backend k8s_ingress
    mode tcp
    option tcplog
    option ssl-hello-chk
    option log-health-checks
    default-server inter 10s fall 2
    server cluster1-worker-1 10.169.241.142:443 check
    server cluster1-worker-2 10.169.241.150:443 check
    server cluster1-worker-3 10.169.241.188:443 check
    server cluster1-worker-4 10.169.241.196:443 check
    server cluster1-worker-5 10.169.241.168:443 check
    server cluster1-worker-6 10.169.241.156:443 check
```

A wildcard DNS record allows the resolution of `*.example.com` to the IP address of the HAProxy host.

The ingress endpoints are defined as:

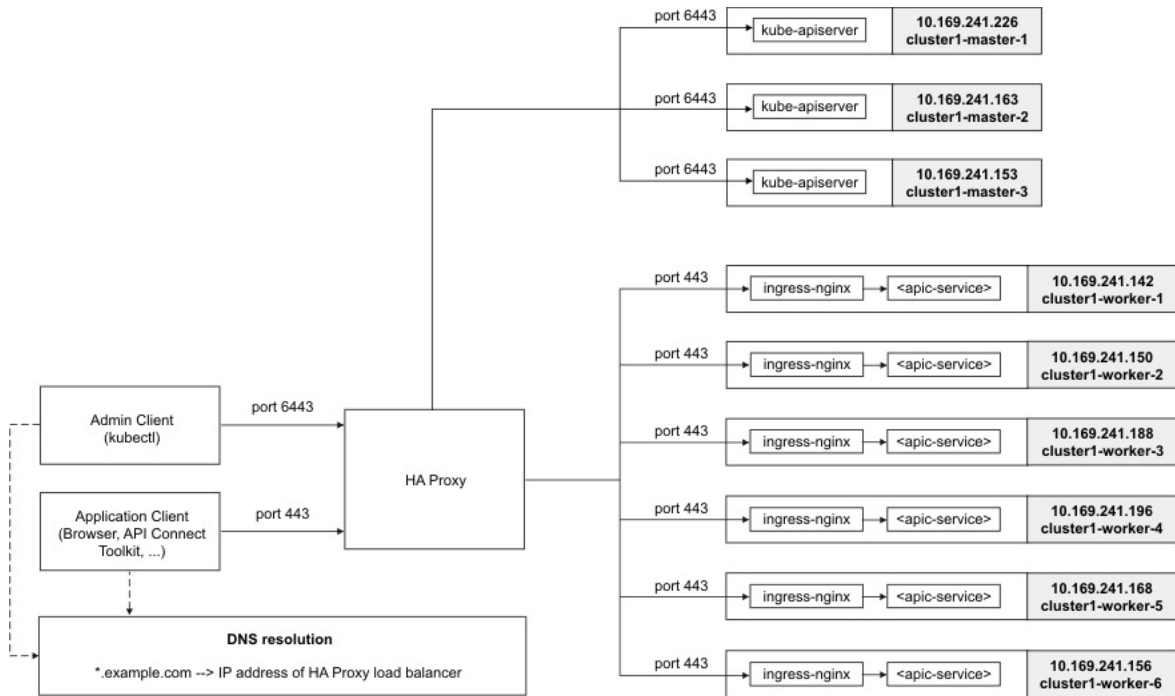

```
# API Manager
apicup subsys set mgmt api-manager-ui=apim.example.com
apicup subsys set mgmt cloud-admin-ui=apim.example.com
apicup subsys set mgmt consumer-api=apim.example.com
apicup subsys set mgmt platform-api=apim.example.com

# Developer Portal
apicup subsys set ptl portal-www=portal.example.com
apicup subsys set ptl portal-admin=portal-admin.example.com

# Analytics
apicup subsys set a7s analytics-client=a7s-client.example.com
apicup subsys set a7s analytics-ingestion=a7s-ingestion.example.com

# Gateway
apicup subsys set gw api-gateway=gw.example.com
apicup subsys set gw apic-gw-service=gwd.example.com
```

The following diagram illustrates the wildcard DNS example:

- **Kubernetes cluster without wildcard DNS**

This example uses the same topology as the previous one, except that there is no wildcard DNS resolution. Instead, individual DNS records are added, all pointing to the IP address of the load balancer. For example: `portal.example.com` and `admin.portal.example.com` resolve to the IP address of the load balancer.

The Developer Portal ingress endpoints can be defined as:

```
# Developer Portal
apicup subsys set ptl portal-www=portal.example.com
apicup subsys set ptl portal-admin=admin.portal.example.com
```

- **Kubernetes cluster with `xip.io` or `nip.io`**

This example uses the same topology as the first one, except that there is no specific DNS resolution configured and instead a service such as `xip.io` or `nip.io` provides wildcard DNS resolution. It is not recommended to use this approach for a production setup, as the ingress endpoints configured during installation of API Connect would be tied to the IP address of the load balancer. This approach can be useful when configuring a test deployment in situations where access to DNS records is not practical or would introduce delay in the deployment. If the load balancer IP is `192.168.100.100`, then the ingress endpoints are configured as:

```
# Developer Portal
apicup subsys set ptl portal-www=portal.192.168.100.100.xip.io
apicup subsys set ptl portal-admin=portal-admin.192.168.100.100.xip.io
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring logging for a Kubernetes deployment

Logs must be collected for both running and terminated containers and processes. Logging collection is required for IBM Support to assist with troubleshooting. For container-based deployments (Kubernetes), specific log commands and mechanisms vary depending on a customer's environment.

### About this task

For container-based deployments that use Kubernetes, collect logs by using a method suitable for your environment. You can run the following command:

```
kubect1 logs [-f] [-p] (POD | TYPE/NAME) [-c CONTAINER]
```

for each pod in the Kubernetes cluster. For more information about Kubect1 documentation, see <https://kubernetes.io/docs/reference/generated/kubect1/kubect1-commands#logs>

However, the logs that are generated by the `kubect1 logs` command do not include terminated pods and processes. Use ELK, or another logging infrastructure, to gather logs that include terminated pods and processes. For more information, see <https://www.elastic.co/elk-stack>.

Specific log commands and mechanisms vary depending on a customer's environment. Log collection must be enabled for all running and terminated containers.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

# Installing API Connect into a Kubernetes environment

You can use Kubernetes and Docker containers to deploy and run API Connect. The Install Assist utility program automates the installation process into a Kubernetes runtime environment using an installation program called APICUP.

## Before you begin

- **First steps for installing API Connect: Upload files to registry**  
Before installing API Connect into a Kubernetes environment, you must first download the tar files and then upload them to your registry.
- **Installing the Management subsystem into a Kubernetes environment**  
Use the Install Assist utility program to install the Management subsystem into your Kubernetes runtime environment.
- **Installing the Analytics subsystem into a Kubernetes environment**  
Use the Install Assist utility program with the APICUP installer to install the Analytics subsystem into your Kubernetes runtime environment.
- **Installing the Developer Portal subsystem into a Kubernetes environment**  
Use the Install Assist utility program to install the Developer Portal subsystem into your Kubernetes runtime environment.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## First steps for installing API Connect: Upload files to registry

Before installing API Connect into a Kubernetes environment, you must first download the tar files and then upload them to your registry.

## Before you begin

Before starting the installation into a Kubernetes runtime environment, complete the following tasks:

- Ensure you have supported software as described in the IBM® Software Product Compatibility Report for your version of API Connect. See [Detailed system requirements for a specific product](#).
- Complete the installation requirements described in [Requirements for deploying IBM API Connect into a Kubernetes environment](#).
- Install and run Docker on the local machine being used for API Connect installation.
- Login to your image registry (for example, Artifactory).

Note:

- Keep a record of the DNS entries mapped to the endpoints for each API Connect subsystem. You will need to map the DNS entries to new IP addresses when restoring the management database to a new cluster. See [Restoring the management database in a Kubernetes environment](#).
- The instructions in this section apply to an initial installation of API Connect into a Kubernetes environment. If you already have API Connect installed in a Kubernetes environment, you perform an upgrade. The upgrade instructions are available here: [Upgrading API Connect in a Kubernetes runtime environment](#)
- The Management server and Gateway firmware versions must match, for example, API Connect 2018.4.1.3 and DataPower 2018.4.1.3.
- If you plan to migrate a Version 5 deployment to Version 2018, see [Migrating a Version 5 deployment](#) before you start the installation process.

In these First Steps, you will use the APICUP installer included in Install Assist to create a project directory that contains the configuration file `apiconnect-up.yml`. Only one project directory is allowed. The configuration for all subsystems is stored in a single `apiconnect-up.yml` file contained in that project directory. All subsystems use the same project directory in order to update `apiconnect-up.yml`.

The first steps for a new Kubernetes installation are:

- Download the tar files containing the latest version of the API Connect subsystems and the Install Assist installer from Fix Central
- Upload the files to your registry
- Initialize **one** project directory for all subsystems

## Procedure

Download the appropriate files and then upload them to your image registry.

1. To obtain the most recent release, download the latest Fix Pack from IBM® Fix Central. For new installations, select ALL to list all versions, and then choose the latest version. For existing installations, choose your current installed version number to obtain the upgrade files. See [IBM Fix Central](#).
  - a. You will need a tar file for each subsystem and the Install Assist file for your operating system. Install Assist is an easy-to-use tool that automatically manages certificate creation, deployment configuration, and other technical aspects of configuring an IBM API Connect installation. The Install Assist download file contains the APICUP installation program, which automates the installation process. Following are the available files for a Kubernetes deployment:

Description	File name
IBM API Connect Management V2018.4.x.x Containers	management-images-kubernetes_lts_v2018.4.x.x.tgz
IBM API Connect Developer Portal V2018.4.x.x Containers	portal-images-kubernetes_lts_v2018.4.x.x.tgz
IBM API Connect Analytics V2018.4.x.x Containers	analytics-images-kubernetes_lts_v2018.4.x.x.tgz
IBM API Connect Install Assist V2018.4.x.x for Linux	apicup-linux_lts_v2018.4.x.x
IBM API Connect Install Assist V2018.4.x.x for Mac	apicup-mac_lts_v2018.4.x.x
IBM API Connect Install Assist V2018.4.x.x for Windows	apicup-windows_lts_v2018.4.x.x
Production DataPower Gateway	idg_dk20184xx.lts.prod.tar.gz

Description	File name
Nonproduction DataPower Gateway	idg_dk20184xx.lts.nonprod.tar.gz
Kubernetes DataPower Monitor	dpm2018417.lts.tar.gz

The production version of the Gateway is for use in a production environment. The nonproduction version is for use in a test or development environment.

- b. The toolkit files (with or without API Designer) can be downloaded from Fix Central directly, or from the Cloud Manager and API Manager UIs after installation is completed. See [Installing the toolkit](#).

2. Upload API Connect files to the registry. Ensure that the registry has sufficient disk space for the files.

For the Management, Portal, and Analytics subsystems, upload the tar files directly to the image registry using the `registry-upload` command. The `registry-upload` command creates the tags required to push the files to the registry, as follows:

```
apicup registry-upload <subsystem_type> <image_tgz> <registry_host>
```

where:

- `subsystem_type` is the name of subsystem for the file you are uploading, one of `management`, `portal`, or `analytics`.
- `image_tgz` is the name of the tar file you are uploading
- `registry_host` is the hostname of the target registry where you are uploading tar files. For IBM Container Service Registry, a namespace is required, for example: `us.icr.io/<namespace>` or `<region>.icr.io/<namespace>`. See [https://cloud.ibm.com/docs/services/Registry?topic=registry-registry-overview#registry\\_regions\\_local](https://cloud.ibm.com/docs/services/Registry?topic=registry-registry-overview#registry_regions_local)

3. Upload the DataPower Gateway images and any necessary supporting files.

Note: For API Connect Version 2018.4.1.7 or earlier, production deployments that use v5-compatible Gateway Servers also require an Application Optimization module. For these deployments, do not use Step 3.a. Instead, use the alternative instructions in the IBM technical note:

<https://www.ibm.com/support/pages/node/1283110>.

Note that for Version 2018.4.1.8 or later, all deployments use Step 3.a on this page.

- a. Upload the DataPower Gateway image (either Production or Nonproduction) that you downloaded in Step 1.

- i. Load the Gateway image to your local docker registry:

```
docker load -i idg_dk2018417.lts.prod.tar.gz
```

For these examples, the version number is 2018.4.1.7 and the production (`-prod`) version is downloaded. The image is automatically tagged in the docker registry to `ibmcom/datapower:2018.4.1.7.312001-prod`.

- ii. Re-tag the image for the new registry with the registry host, image name, and tag in the following format:

```
docker tag <existing REGISTRY_HOST>/<IMAGE_NAME>:<TAG> <new REGISTRY_HOST>/<IMAGE_NAME>:<TAG>
```

Table 1. Docker tag parameters

Parameter	Description
<REGISTRY_HOST>/<IMAGE_NAME>	Enter your registry host name and an image name, for example, <i>My Registry/MyImage</i> . The <REGISTRY_HOST>/<IMAGE_NAME> matches the value entered for installation in the <code>apicup subsys set gwy image-repository</code> command.
<TAG>	Enter a tag for the image, for example, <code>2018.4.1.7-312001-release-prod</code> . <ul style="list-style-type: none"> <li>• The &lt;TAG&gt; value must match the value entered for the gateway image tag during installation using the <code>apicup subsys set gwy image-tag</code> command.</li> <li>• You can look up required tag using the <code>./apicup version --images</code> command to list all images required by APICUP.</li> <li>• The tag must match the tag for the <code>datapower-api-gateway</code> image, for example: <code>apiconnect/datapower-api-gateway:2018.4.1.7-312001-release-prod</code>.</li> </ul>

For example:

```
docker tag ibmcom/datapower:2018.4.1.7.312001-prod MyRegistry/datapower-api-gateway:2018.4.1.7-312001-release-prod
```

- iii. Push the Gateway image to the new registry: `docker push`

<REGISTRY\_HOST>/<IMAGE\_NAME>:<TAG>. For example:

```
docker push MyRegistry/datapower-api-gateway:2018.4.1.7-312001-release-prod
```

- iv. The image is now added to your registry. You can now upload the DataPower Monitor image. Continue with Step 3.b.

- b. For the Gateway Kubernetes DataPower Monitor, load the images into your local Docker registry, re-tag them, and push them to the image repository, as follows:

- i. Load the Kubernetes DataPower Monitor image to your local docker registry:

```
docker load -i dpm2018417.lts.tar.gz
```

The image is automatically tagged in the docker registry:

```
ibmcom/k8s-datapower-monitor:2018.4.1-9-00bcbcf
```

- ii. Re-tag the image for the new registry:

```
docker tag <existing REGISTRY_HOST>/<IMAGE_NAME>:<TAG> <new REGISTRY_HOST>/<IMAGE_NAME>:<TAG>
```

Table 2. Docker tag parameters

Parameter	Description
<REGISTRY_HOST>/<IMAGE_NAME>	Enter your registry host name and an image name, for example, <i>My Registry/k8s-datapower-monitor</i> . The <REGISTRY_HOST>/<IMAGE_NAME> matches the value entered for installation in the <code>apicup subsys set gwy monitor-image-repository</code> command.

Parameter	Description
<TAG>	Enter a tag for the image, for example, 2018.4.1-9-00bcbcf. <ul style="list-style-type: none"> <li>The &lt;TAG&gt; value must match the value entered for the gateway image tag during installation using the <code>apicup subsys set gwy monitor-image-tag</code> command.</li> <li>You can look up required tag using the <code>./apicup version --images</code> command to list all images required by APICUP.</li> <li>The tag must match the tag for the Kubernetes DataPower Monitor. For example: 2018.4.1-9-00bcbcf.</li> </ul>

For example:

```
docker tag ibmcom/k8s-datapower-monitor:2018.4.1-9-00bcbcf MyRegistry/k8s-datapower-monitor:2018.4.1-9-00bcbcf
```

- iii. Push the monitor pod image to the new registry: `docker push <REGISTRY_HOST>/<IMAGE_NAME>:<TAG>`. For example:

```
docker push MyRegistry/k8s-datapower-monitor:2018.4.1-9-00bcbcf
```

- c. For DataPower Gateway, BusyBox 1.29 is required.

Note: An internet connection is required to obtain the BusyBox image from Docker Hub. If you want to download the image and copy it to the system containing the DataPower image, follow these steps:

- i. Download the Docker image for BusyBox from a system with an internet connection:

```
docker pull busybox:1.29-glibc
```

- ii. Save the image to a tar file:

```
docker save busybox:1.29-glibc > ./busybox-1.29-glibc.tar
```

- iii. Copy the image to the same location as the DataPower image and load it:

```
docker load < ./busybox-1.29-glibc.tar
```

- iv. Tag the image and push it to your local registry:

```
docker tag busybox:1.29-glibc <MyRegistry>/busybox:1.29-glibc
docker push MyRegistry/busybox:1.29-glibc
```

- i. Login to Docker Hub <https://hub.docker.com/> [/busybox?tab=tags](https://hub.docker.com/_/busybox?tab=tags) to obtain BusyBox 1.29.

- ii. Tag the image and push it to your local registry:

```
docker pull busybox:1.29-glibc
docker tag busybox:1.29-glibc <MyRegistry>/busybox:1.29-glibc
docker push MyRegistry/busybox:1.29-glibc
```

The images for all subsystems and BusyBox are now stored in the appropriate registries. The registry locations will be set by APICUP commands during the installation process.

4. Create one project directory, for example, `myProject` and change directories to the `myProject` directory. Run the `apicup init` command to initialize the project directory. An `apiconnect-up.yml` configuration file will be created. The `apiconnect-up.yml` file contains all values entered during the installation process as you move forward.

For example:

```
mkdir ./myProject
cd ./myProject
apicup init
```

Important:

Use a single APICUP project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

The original project directory created with APICUP during the initial product installation (for example, `myProject`) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. A good practice is to back up the original project directory to a location from where it can always be retrieved.

## What to do next

Install the subsystems (Management, Gateway, Analytics, and Portal) for your API Connect cloud. You can install the subsystems in any order, but the installation of all subsystems must be completed before configuring your API Connect cloud using Cloud Manager.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Installing the Management subsystem into a Kubernetes environment

Use the Install Assist utility program to install the Management subsystem into your Kubernetes runtime environment.

### Before you begin

Before installing the Management subsystem, complete the steps described in [First steps for installing API Connect: Upload files to registry](#). For instructions on using the APICUP installer, see [Tips and tricks for using APICUP](#).

## Procedure

- The commands for installing the Management subsystem are described in the following table. Sample code is also provided. These are the basic commands for installing an API Connect Management service in a Kubernetes cluster. Namespaces must be configured in Kubernetes before starting the installation process. We do not recommend that you use the default namespace. DNS domain names must be configured for the endpoints. Resource allocation sizes are recommended minimums and will depend upon your environment. It is highly recommended that you include the backup schedule for the management database.

Note:

- If the `create-crd` command is set to false, then the Kubernetes administrator is responsible for creating CRD's before installing the management subsystem. See [Manually creating a CustomResourceDefinition in a Kubernetes environment](#).
- Host names and DNS entries may not be changed on a cluster after the initial installation.
- Domain names that are used for endpoints cannot contain the underscore "\_" character. See [Pre-installation requirements](#).

A few lines in the following commands set multiple values with a single set command. For instructions on configuring multiple settings per command and other tips for using `apicup`, see [Tips and tricks for using APICUP](#)

Command	Values/Definition
<code>apicup init</code>	Initializes the <code>apicup</code> installation utility and creates the <code>apiconnect-up.yaml</code> configuration file
<code>apicup subsys create mgmt management -k8s</code>	Describes a management service in the Kubernetes cluster. The identifier <code>mgmt</code> is the name you have assigned to your management service. You can assign it any name, as long as the identifier consists of lower case alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character. The command <code>management</code> indicates that you are creating a management subsystem. The subsystem will be deployed in <code>dev</code> mode by default, unless <code>standard</code> mode is explicitly specified.
<code>apicup subsys set mgmt extra-values-file</code>	<path/file name> - Path to the extra values file. One extra values file is permitted. The extra values file requires a <code>.yaml</code> format. It contains the ingress annotations and other settings for the subsystem. For an example of an extra values file for each subsystem, see <a href="#">Creating an extra values file in a Kubernetes environment</a> .
<code>apicup subsys set mgmt ingress-type</code>	Must be explicitly set to <code>route</code> for an OpenShift environment. For a standard K8s environment, <code>ingress-type</code> defaults to <code>ingress</code> and there is no need to explicitly enter this parameter.
<code>apicup subsys set mgmt mode</code>	Determines whether the installation is for development, testing, and demo purposes or for a production environment. If not explicitly set, the mode will default to <code>dev</code> (development and testing) for versions 2018.4.1.4 and later. For versions 2018.4.1.3 and earlier, the default for mode is <code>standard</code> . <ul style="list-style-type: none"> <li><code>dev</code> - (Default) Use <code>dev</code> mode for development, testing, and demo purposes. It allows one instance of each subsystem to be created.</li> <li><code>standard</code> - Use <code>standard</code> mode for production environments. It allows three containers each containing one instance of the subsystem to be created, for a total of three instances.</li> </ul>
<code>apicup subsys set mgmt namespace</code>	<namespaceName> - Defines the namespace where the management service resides; every subsystem can be in a separate namespace. Valid namespaces are configured in Kubernetes prior to starting the API Connect installation.
<code>apicup subsys set mgmt registry</code>	<registry-url> - The location where you are running the image registry (for example, Artifactory)
<code>apicup subsys set mgmt registry-secret</code>	For example, <registrySecret> - Kubernetes secret with Docker credentials to authenticate with the image registry. The value for <code>registry-secret</code> must match the name of the secret created using the <code>kubectl create secret</code> command. It contains the Docker credentials for accessing the registry.
<code>apicup subsys set mgmt storage-class</code>	<storageClass> - Refers to a valid StorageClass object in your Kubernetes cluster that supports dynamic PersistentVolume provisioning. Static or manual PersistentVolume provisioning can be used, but it requires additional steps not covered in this documentation. Block storage is required. Select a block storage format of your choosing in order for API Connect components to be supported. GlusterFS is not recommended as a storage option due to severe performance degradation. For AWS, the gp2 and io1 types of Elastic Block Storage (EBS) are supported. Note that NFS is not supported.
<code>apicup subsys set mgmt platform-api</code>	<code>api.&lt;hostname&gt;.com</code> - The endpoint that is exposed by Kubernetes to access the admin and provider Platform REST APIs. The endpoints have to be resolvable by DNS. Requires a FQDN, in lowercase. Domain names that are used for endpoints cannot contain the underscore "_" character. See <a href="#">Pre-installation requirements</a> . Refer to the deployment overview diagram for information about endpoints and certificates: <a href="#">Deployment overview for endpoints and certificates</a> .
<code>apicup subsys set mgmt api-manager-ui</code>	<code>apim.&lt;hostname&gt;.com</code> - The endpoint that is exposed by Kubernetes to access the API Manager user interface. Requires a FQDN, in lowercase. Domain names that are used for endpoints cannot contain the underscore "_" character. See <a href="#">Pre-installation requirements</a> .
<code>apicup subsys set mgmt cloud-admin-ui</code>	<code>cm.&lt;hostname&gt;.com</code> - The endpoint that is exposed by Kubernetes to access the Cloud Manager user interface. Requires a FQDN, in lowercase. Domain names that are used for endpoints cannot contain the underscore "_" character. See <a href="#">Pre-installation requirements</a> .
<code>apicup subsys set mgmt consumer-api</code>	<code>consumer.&lt;hostname&gt;.com</code> - The endpoint that is exposed by Kubernetes to access the consumer REST APIs. Requires a FQDN, in lowercase. Domain names that are used for endpoints cannot contain the underscore "_" character. See <a href="#">Pre-installation requirements</a> .
<code>cassandra-backup-auth-user</code>	(Optional, not required to complete the installation, but highly recommended to configure backups.) The username for the server specified in <code>cassandra-backup-host</code> . If using object store, this would be the S3 Secret Key ID.
<code>cassandra-backup-auth-pass</code>	(Optional, not required to complete the installation, but highly recommended to configure backups.) The password for the server specified in <code>cassandra-backup-host</code> . If using object store, this would be the S3 Secret Access Key parameter. The password will be stored in Base64 encoded format. For example: <pre>apicup subsys set mgmt cassandra-backup-auth-pass '&lt;password&gt;'</pre>
<code>cassandra-backup-host</code>	(Optional, not required to complete the installation, but highly recommended to configure backups.) The fully qualified domain name of the backup server, in lowercase only. Ensure that the Kubernetes nodes can access this host. If using object store, enter <code>Endpoint/Region</code> . (The "/" character between the endpoint and region are required for this setting.)

Command	Values/Definition												
<code>cassandra-backup-port</code>	(Optional, not required to complete the installation, but highly recommended to configure backups.) The port for the protocol to connect to the <code>cassandra-backup-host</code> . The backup port is not required for object storage.												
<code>cassandra-backup-protocol</code>	(Optional, not required to complete the installation, but highly recommended to configure backups.) The backup protocol. Specify one of the following values: <ul style="list-style-type: none"> <li><code>sftp</code> - for secure file transfer protocol</li> <li><code>objstore</code> - for S3 compatible object storage</li> </ul>												
<code>cassandra-backup-path</code>	(Optional, not required to complete the installation, but highly recommended to configure backups.) The full path to the directory where the backup files will be stored. For object storage ( <code>objstore</code> ), the path can be set to the <code>bucket</code> value or the <code>bucket/subfolder</code> value.												
<code>cassandra-backup-schedule</code>	(Optional, not required to complete the installation, but highly recommended to configure backups.) Cron like schedule for performing automatic backups. The format for the schedule is: <ul style="list-style-type: none"> <li>* * * * *</li> <li>-----</li> <li>     </li> <li>      +----- day of week (0 - 6) (Sunday=0)</li> <li>   +----- month (1 - 12)</li> <li>    +----- day of month (1 - 31)</li> <li>  +----- hour (0 - 23)</li> <li>+----- min (0 - 59)</li> </ul> For example: <code>30 22 * * 1</code> will perform backups at 10:30 pm on Mondays. The timezone for backups is that of the node on which the Cassandra pod is scheduled. The backup schedule defaults to <code>0 0 * * *</code> . This means a backup is run every day at midnight and minute zero UTC.  When you configure a host, if you do not specify a value for <code>cassandra-backup-schedule</code> , the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed.												
<code>apicup subsys set mgmt cassandra-max-memory-gb</code>	This command sets the total memory allocated to the Cassandra server. This setting is used to calculate the <code>MAX_HEAP_SIZE</code> value of the server which is always 47% of the total memory allocated to Cassandra server. The default and minimum allowed value for <code>cassandra-max-memory-gb</code> is 9GB. The following table compares values for memory allocation for the management database: <table border="1" data-bbox="370 800 1511 940"> <thead> <tr> <th>Memory allocated to Kubernetes node where Cassandra is deployed</th> <th>Recommended cassandra-max-memory-gb</th> <th>MAX_HEAP_SIZE (47% of cassandra-max-memory-gb value)</th> </tr> </thead> <tbody> <tr> <td>16GB</td> <td>9GB (default)</td> <td>4331m</td> </tr> <tr> <td>32GB</td> <td>16GB</td> <td>7700m</td> </tr> <tr> <td>64GB</td> <td>24GB</td> <td>11550m</td> </tr> </tbody> </table>	Memory allocated to Kubernetes node where Cassandra is deployed	Recommended cassandra-max-memory-gb	MAX_HEAP_SIZE (47% of cassandra-max-memory-gb value)	16GB	9GB (default)	4331m	32GB	16GB	7700m	64GB	24GB	11550m
Memory allocated to Kubernetes node where Cassandra is deployed	Recommended cassandra-max-memory-gb	MAX_HEAP_SIZE (47% of cassandra-max-memory-gb value)											
16GB	9GB (default)	4331m											
32GB	16GB	7700m											
64GB	24GB	11550m											
<code>apicup subsys set mgmt cassandra-cluster-size</code>	3 is a recommended minimum; actual value will depend upon your environment.												
<code>apicup subsys set mgmt cassandra-volume-size-gb</code>	The default value is 50GB, which is the minimum recommended setting for a non-production environment; the minimum recommended setting for a production environment is 250GB. The actual value will depend upon your environment. The <code>cassandra-volume-size-gb</code> parameter is a PER NODE value, so the total amount of storage space for the management database will be the <code>cassandra-volume-size-gb</code> multiplied by the number of nodes. <b>IMPORTANT:</b> The storage size for the management database on a node cannot be increased once the pod is deployed to the node.												
<code>apicup subsys set mgmt create-crd</code>	Options are <code>true</code> or <code>false</code> . The default value is <code>true</code> . When set to <code>true</code> , the custom resources required by the management subsystem are automatically created at the cluster level. The management database requires the following two CustomResourceDefinitions (CRDs): <ul style="list-style-type: none"> <li><code>cassandraclusters.apic.ibm.com</code> - stores the custom resource that contains the specs for the management database cluster</li> <li><code>cassandraclusterbackups.apic.ibm.com</code> - stores the custom resource that contains information for each completed backup</li> </ul> When set to <code>false</code> , the Kubernetes administrator must manually create the CRDs before installing the management subsystem. Note that CustomResourceDefinitions require ClusterRole privileges. For instructions on how to manually create the CRDs, see <a href="#">Manually creating a CustomResourceDefinition in a Kubernetes environment</a> .												
<code>apicup subsys set mgmt external-cassandra-host</code>	<host name> - Hostname where a Cassandra database cluster can be reached, if not using the Cassandra Operator bundled with API Connect.												
<code>apicup certs set mgmt CERT_NAME</code>	<ul style="list-style-type: none"> <li><code>[CERT_FILE KEY_FILE CA_FILE] [flags]</code> - Set the required certificates for the subsystem. Custom certificates may be set, otherwise, default certificates are automatically configured. For information on what certificates are available and how to set them see: <a href="#">Working with certificates</a>.</li> <li><code>[KEY_FILE] [flags]</code> - Set the encryption secret for the management database. Important: The encryption secret can only be set once and only during initial installation. See <a href="#">Setting the encryption-secret for the management database</a>.</li> </ul>												
<code>apicup subsys set mgmt license-version &lt;license_type&gt;</code>	<license_type> - Specify the type of license, either <code>Production</code> or <code>Nonproduction</code> . If not specified, the default value is <code>Nonproduction</code> . Note that the license type does not impact which Management server image to install. The API Connect Kubernetes Pod annotations <code>productID</code> and <code>productName</code> reflect the selected license.												
<code>apicup subsys install</code>	<code>mgmt</code> - Starts the installation of the management service.												

Note: API Connect v2018 cannot be deployed on NFS.

```

apicup subsys create mgmt management --k8s
apicup subsys set mgmt extra-values-file=<path/file name>
apicup subsys set mgmt ingress-type=<route - for OpenShift environments only> <ingress - default>
apicup subsys set mgmt mode=<dev>
apicup subsys set mgmt namespace=<namespaceName>
apicup subsys set mgmt registry=<registry-url>

```

```

apicup subsys set mgmt registry-secret=<registrySecret>
apicup subsys set mgmt storage-class=<storageClass>

apicup subsys set mgmt platform-api=my.platform.com api-manager-ui=my.apim.com cloud-admin-ui=my.cloud.com consumer-
api=my.consumer.com

apicup subsys set mgmt cassandra-backup-auth-user=MyUsername cassandra-backup-auth-pass 'MyPassword'
apicup subsys set mgmt cassandra-backup-host=<hostname>
apicup subsys set mgmt cassandra-backup-path=</backups>
apicup subsys set mgmt cassandra-backup-port=<22>
apicup subsys set mgmt cassandra-backup-protocol=<sftp, objstore>
apicup subsys set mgmt cassandra-backup-schedule=<"0 0 * * *">
apicup subsys set mgmt cassandra-max-memory-gb=9 cassandra-cluster-size=3
apicup subsys set mgmt cassandra-volume-size-gb=<50>
apicup subsys set mgmt create-crd=<true>
apicup subsys set mgmt external-cassandra-host=<hostname>

//Set the certificates
apicup certs set mgmt CERT_NAME=[CERT_FILE KEY_FILE CA_FILE] [flags] <sets certificates>
apicup certs set mgmt CERT_NAME=[KEY_FILE] [flags] <sets the encryption secret>

// OPTIONAL: Write the plan to an output directory to inspect myProject/install-plan prior to installation
apicup subsys install mgmt --out=mgmt-install-plan
// Start the installation from the output directory. Enter the full path to the output directory.
apicup subsys install mgmt --plan-dir=./myProject/mgmt-install-plan
//If install-plan is not used, enter the following command to start the installation
apicup subsys install mgmt

```

Important: The management database requires mmap counts higher than the operating system defaults. To change the mmap counts on the live system, run `sudo sysctl -w vm.max_map_count=1048575` on each Kubernetes node. To persist this change when node restarts occur, add the following to the `/etc/sysctl.conf` file: `vm.max_map_count = 1048575`.

- You can use the `get` command to print out the settings for the subsystem prior to installing it. For example, `apicup subsys get mgmt`, where `mgmt` is the name of the subsystem. The `get` command displays any default settings for the subsystem and the settings from the `apiconnect-up.yml` file. The `Errors` column indicates if a parameter is invalid. Following is an example of output received from `apicup subsys get mgmt`:

#### Kubernetes settings

Name	Value	Errors
extra-values-file		
ingress-type	ingress	
mode	standard	
namespace	default	
registry		
registry-secret		
storage-class		

#### Subsystem settings

Name	Value	Errors
cassandra-backup-auth-pass		
cassandra-backup-auth-user		
cassandra-backup-host		
cassandra-backup-path	/backups	
cassandra-backup-port	22	
cassandra-backup-protocol	sftp	
cassandra-backup-schedule	0 0 * * *	
cassandra-cluster_size	1	
cassandra-max-memory-gb	9	
cassandra-volume-size-gb	100	
create-crd	true	
external-cassandra-host		

#### Endpoints

Name	Value	Errors
api-manager-ui		api-manager-ui is not a valid FQDN
cloud-admin-ui		cloud-admin-ui is not a valid FQDN
consumer-api		consumer-api is not a valid FQDN
platform-api		platform-api is not a valid FQDN

- Correct any errors indicated by the output from the `get` command and then run `apicup subsys install <SUBSYS>` to install the subsystem.
- After running the `apicup subsys install <SUBSYS>` command, run the `apicup subsys get <SUBSYS> --validate` to validate the installation. You must correct any errors indicate by `--validate` prior to continuing.

#### Kubernetes settings

## What to do next

Continue your API Connect installation in a Kubernetes runtime environment by installing the other subsystems.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Installing the Analytics subsystem into a Kubernetes environment

Use the Install Assist utility program with the APICUP installer to install the Analytics subsystem into your Kubernetes runtime environment.

### Before you begin

Before installing the Analytics subsystem, complete the steps described in [First steps for installing API Connect: Upload files to registry](#). For instructions on using the APICUP installer, see [Tips and tricks for using APICUP](#).

### About this task

By default, the Analytics subsystem is configured to store data so that users can review it in the Analytics user interface. After deploying the subsystem, you can optionally configure it to offload some data to a third-party service for review and storage, as explained in [Configuring analytics offload for API Connect](#). Any data that is not offloaded remains accessible from the Analytics user interface.

If you want to offload all Analytics data, you can optionally install the subsystem with the ingestion-only configuration. In this scenario, unused Analytics components (such as analytics-storage and analytics-client) are omitted from the topology. Only the components that are required for offloading data are deployed. The reduced topology requires less CPU, memory, and storage.

If you do not configure ingestion-only during installation, you can enable it later as explained in [Enabling Analytics ingestion-only on Kubernetes](#).

Settings that are required for the ingestion-only configuration are noted in the steps that follow.

## Procedure

- The commands for installing the Analytics subsystem are described in the following table. Sample code is also provided.

Important: There are known GlusterFS issues that affect the following functionality areas:

- Elasticsearch, which is used in the API Connect analytics service.
- The Developer Portal service.

If you use GlusterFS, you might encounter severe performance degradation and, in some cases, loss of data.

Note: Host names and DNS entries may not be changed on a cluster after the initial installation.

Command	Values/Definition
<code>apicup init</code>	Initializes the apicup installation utility and creates the <code>apiconnect-up.yml</code> configuration file.

Command	Values/Definition
<code>apicup subsys create analyt analytics -- k8s</code>	Describes an analytics subsystem in the Kubernetes cluster. The identifier <code>analyt</code> is the name you have assigned to your analytics service. You can assign it any name, as long as the identifier consists of lower case alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character. The command <code>analytics</code> indicates that you are creating an analytics subsystem.
<code>apicup subsys set analyt extra-values-file</code>	<p>&lt;path/file name&gt; - Path to the extra values file. One extra values file is permitted. The extra values file requires a <code>.yaml</code> format. It contains the ingress annotations and other settings for the subsystem. For an example of an extra values file for each subsystem, see <a href="#">Creating an extra values file in a Kubernetes environment</a>.</p> <p>For the ingestion-only configuration, specify the URL of the offload endpoint where all analytics data will be routed. You can choose the name for the file, but you must use <code>.yaml</code> as the file-name extension. Format the file as shown in the following example, making sure to include required settings for the third-party system.</p> <pre>apic-analytics-ingestion:   outputOffload:  -     elasticsearch {       hosts =&gt; "http://offload_endpoint_URL:port"       index =&gt; "api-call"     }</pre>
<code>apicup subsys set analyt analytics-ingestion</code>	<ai>.<hostname>.<domainname> - The <code>analytics-ingestion</code> endpoint is used by the Gateway service to push data to the Analytics service. All endpoints have to be resolvable by DNS. Domain names that are used for endpoints cannot contain the underscore "_" character. See <a href="#">Pre-installation requirements</a> . Refer to the deployment overview diagram for information about endpoints and certificates: <a href="#">Deployment overview for endpoints and certificates</a> .
<code>apicup subsys set analyt ingestion-only=true</code>	This setting is required for the ingestion-only configuration, and the value must be set to <code>true</code> .
<code>apicup subsys set analyt analytics-client</code>	<ac>.<hostname>.<domain name> - The management endpoint that is defined by <code>analytics-client</code> , for example, <ac>.<hostname>.<domain name>. This is the analytics service endpoint used by Cloud Manager, API Manager, and the Portal to communicate with the analytics service and is entered when configuring an analytics service in Cloud Manager. See <a href="#">Registering an analytics service</a> . All endpoints have to be resolvable by DNS. Domain names that are used for endpoints cannot contain the underscore "_" character. See <a href="#">Pre-installation requirements</a> . This setting is not needed for the ingestion-only configuration. For more information, see the note that follows this table.
<code>apicup subsys set analyt namespace</code>	<namespaceName> - Defines the namespace where the analytics service resides; every subsystem can be in a separate namespace. Valid namespaces are configured in Kubernetes prior to starting the API Connect installation
<code>apicup subsys set analyt registry</code>	<registry-uri> - The location where you are running the image registry (for example, Artifactory).
<code>apicup subsys set analyt registry-secret</code>	For example, <registrySecret> - Kubernetes secret with Docker credentials to authenticate with the image registry. The value for <code>registry-secret</code> must match the name of the secret created using the <code>kubect1 create secret</code> command. It contains the Docker credentials for accessing the registry.
<code>apicup subsys set analyt coordinating-max-memory-gb</code>	The default is 6GB. The recommended minimum is 12GB. The actual value will depend upon your environment. This setting is not needed for the ingestion-only configuration. For more information, see the note that follows this table.
<code>apicup subsys set analyt data-max-memory-gb</code>	The default is 6GB. The recommended minimum is 12GB. The actual value will depend upon your environment. This setting is not needed for the ingestion-only configuration. For more information, see the note that follows this table.
<code>apicup subsys set analyt data-storage-size-gb</code>	The default is 200GB. The recommended minimum is 200GB. The actual value will depend upon your environment. The <code>data-storage-size-gb</code> value is the amount of storage used per pod. A default installation will contain three data pods. In this example, 600GB of total space is required for the data nodes. This setting is not needed for the ingestion-only configuration. For more information, see the note that follows this table.
<code>apicup subsys set analyt master-max-memory-gb</code>	The default is 6GB. The recommended minimum is 12GB. The actual value will depend upon your environment. This setting is not needed for the ingestion-only configuration. For more information, see the note that follows this table.
<code>apicup subsys set analyt master-storage-size-gb</code>	The default is 5GB. The recommended minimum is 5GB. The actual value will depend upon your environment. This setting is not needed for the ingestion-only configuration. For more information, see the note that follows this table.
<code>apicup subsys set analyt enable-message-queue</code>	Options are <code>true</code> or <code>false</code> . The default is <code>false</code> . When set to true, the message queue will be activated and the analytics pipeline will be configured to use it. See <a href="#">Configuring the analytics message queue</a> . The message queue requires at least one 5GB PVC for each pod.
<code>apicup subsys set analyt storage-class</code>	<storageClass> - Refers to a valid StorageClass object in your Kubernetes cluster that supports dynamic PersistentVolume provisioning. Static or manual PersistentVolume provisioning can be used, but it requires additional steps not covered in this documentation. You can use local storage or block storage. For block storage, select a block storage format of your choosing in order for API Connect components to be supported. GlusterFS is not recommended as a storage option due to severe performance degradation. For AWS, the <code>gp2</code> and <code>io1</code> types of Elastic Block Storage (EBS) are supported. Note that NFS is not supported.

Command	Values/Definition
<code>apicup subsys set analyt es-storage-class</code>	<es-storageClass> - Optional Elasticsearch storage class. If the <code>es-storage-class</code> is set, analytics storage ignores other storage classes and uses the <code>es-storage-class</code> . If not set, then analytics storage uses the storage class object set by the <code>apicup subsys set analyt storage-class</code> command. This setting is not needed for the ingestion-only configuration. For more information, see the note that follows this table.
<code>apicup subsys set analyt mq-storage-class</code>	<mq-storageClass> - Optional message queue storage class. If the <code>mq-storage-class</code> is set, the message queue ignores other storage classes and uses the <code>mq-storage-class</code> . If not set, then the message queue uses the storage class object set by <code>apicup subsys set analyt storage-class</code> .
<code>apicup subsys set analyt mode</code>	Determines whether the installation is for development, testing, and demo purposes or for production. If not explicitly set, the mode will default to <code>dev</code> (development and testing) for versions 2018.4.1.4 and later. For versions 2018.4.1.3 and earlier, the default for mode is <code>standard</code> . <ul style="list-style-type: none"> <li><code>dev</code> - (Default) Use <code>dev</code> mode for development, testing, and demo purposes. It allows one instance of each subsystem to be created.</li> <li><code>standard</code> - Use <code>standard</code> mode for production environments. It allows multiple instances of each subsystem to be created.</li> </ul>
<code>apicup subsys set analyt ingress-type</code>	Must be explicitly set to <code>route</code> for an OpenShift environment. For a standard K8s environment, <code>ingress-type</code> defaults to <code>ingress</code> and there is no need to explicitly enter this parameter.
<code>apicup certs set analyt CERT_NAME</code>	[CERT_FILE KEY_FILE CA_FILE] [flags] - Set the required certificates for the subsystem. Custom certificates may be set, otherwise, default certificates are automatically configured. For information on what certificates are available and how to set them see: <a href="#">Working with certificates</a> .
<code>apicup subsys set analyt license-version &lt;license_type&gt;</code>	<license_type> - Specify the type of license, either <code>Production</code> or <code>Nonproduction</code> . If not specified, the default value is <code>Nonproduction</code> . Note that the license type does not impact which Analytics image to install. The API Connect Kubernetes Pod annotations <code>productID</code> and <code>productName</code> reflect the selected license.
<code>apicup subsys install</code>	<code>analyt</code> - Starts the installation of the analytic service

Note: If a setting is not required for the ingestion-only configuration, you can omit it. A default value is supplied automatically by `apicup` but the value is ignored during installation. When you run the validation step, the value is not actually validated but is marked as valid in the results.

Example 1: Installation commands for deployment that does not use the ingestion-only configuration.

```
apicup subsys create analyt analytics --k8s
apicup subsys set analyt extra-values-file=<path/file name>
apicup subsys set analyt analytics-ingestion=<ai>.<hostname>.<domainname>
apicup subsys set analyt analytics-client=<ac>.<hostname>.<domainname>
apicup subsys set analyt registry=<registry-uri>
apicup subsys set analyt namespace=<namespaceName>
apicup subsys set analyt registry-secret=<registrySecret>
apicup subsys set analyt coordinating-max-memory-gb=6
apicup subsys set analyt data-max-memory-gb=6
apicup subsys set analyt data-storage-size-gb=200
apicup subsys set analyt master-max-memory-gb=6
apicup subsys set analyt master-storage-size-gb=5
apicup subsys set analyt enable-message-queue=<false>
apicup subsys set analyt storage-class=<storageClass>
apicup subsys set analyt es-storage-class=<es-storageClass>
apicup subsys set analyt mq-storage-class=<mq-storageClass>
apicup subsys set analyt mode=dev
apicup subsys set analyt ingress-type=route <for OpenShift environments only>

//Set the certificates
apicup certs set analyt CERT_NAME=[CERT_FILE KEY_FILE CA_FILE] [flags]

// OPTIONAL: Write the plan to an output directory to inspect myProject/install-plan prior to installation
apicup subsys install analyt --out=analyt-install-plan
// Start the installation from the output directory. Enter the full path to the output directory.
apicup subsys install analyt --plan-dir=./myProject/analyt-install-plan

//If output file is not used, enter the following command to start the installation
apicup subsys install analyt
```

Example 2: Installation commands for the ingestion-only configuration.

```
apicup subsys create analyt analytics --k8s
apicup subsys set analyt extra-values-file=extra-values-analyt.yaml
apicup subsys set analyt ingestion-only=true
apicup subsys set analyt analytics-ingestion=<ai>.<hostname>.<domainname>
apicup subsys set analyt registry=<registry-uri>
apicup subsys set analyt namespace=<namespaceName>
apicup subsys set analyt registry-secret=<registrySecret>
apicup subsys set analyt enable-message-queue=<false>
apicup subsys set analyt storage-class=<storageClass>
apicup subsys set analyt mq-storage-class=<mq-storageClass>
apicup subsys set analyt mode=dev
apicup subsys set analyt ingress-type=route <for OpenShift environments only>
apicup subsys set analyt storage-class=<storageClass>
apicup subsys set analyt mq-storage-class=<mq-storageClass>

//Set the certificates
apicup certs set analyt CERT_NAME=[CERT_FILE KEY_FILE CA_FILE] [flags]

// OPTIONAL: Write the plan to an output directory to inspect myProject/install-plan prior to installation
apicup subsys install analyt --out=analyt-install-plan

// Start the installation from the output directory. Enter the full path to the output directory.
apicup subsys install analyt --plan-dir=./myProject/analyt-install-plan
```

//If output file is not used, enter the following command to start the installation  
 apicup subsys install analyt

An analytics installation starts the following Kubernetes pods:

- Full installation in **standard** mode:

Table 1. Kubernetes pods in a full Analytics installation

Number	Pod
2	client
2	ingestion
2	mtls
1	operator
3	storage-master
3	storage-coordinating
3	storage-data

Note that in **dev** mode, there is only one of each pod.

- Message queue deployment in **standard** mode: All of the pods shown in Table [Table 1](#), plus:

Table 2. Additional pods used for Message Queue deployments

Number	Pod
3	mq-kafka
3	mq-zookeeper

Note that in **dev** mode there is only one of each pod, with the same capability to enable or disable message queue.

- Ingestion-only installation in **standard** mode:

Table 3. Kubernetes pods in an ingestion-only Analytics installation

Number	Pods
2	ingestion
2	mtls

Note that in **dev** mode there is only one of each pod.

Important: When the Analytics service is configured to store data, (that is, it is not configured for ingestion-only), the service depends on Elasticsearch which requires map counts higher than the operating system defaults. To change the map counts on the live system, run `sudo sysctl -w vm.max_map_count=262144` on each Kubernetes node. To persist this change when node restarts occur, add the following to the `/etc/sysctl.conf` file: `vm.max_map_count = 262144`. This is the minimum recommended value. For more information see <https://www.elastic.co/guide/en/elasticsearch/reference/current/vm-max-map-count.html>

Memory settings listed are maximum sizes. The Kubernetes memory resource *request amount*, or amount of memory reserved for each analytics pod, is 3/4 of the maximum memory. Actual memory used will usually be less than the reserved amount, but depends on current analytics load.

Modifying allocation space after installation might not be possible depending on the type of persistent volume that is used.

2. After running the `apicup subsys install` command, run the `apicup subsys`

`get <analytics_subsys_name> --validate` to validate the installation. You must correct any errors indicate by `--validate` prior to continuing. Following is an example for the `--validate` output for a configuration that does not use the ingestion-only feature:

```

Kubernetes settings

## What to do next

Continue your API Connect installation in a Kubernetes runtime environment by installing the other subsystems.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Installing the Developer Portal subsystem into a Kubernetes environment

Use the Install Assist utility program to install the Developer Portal subsystem into your Kubernetes runtime environment.

### Before you begin

Before installing the Portal subsystem, complete the steps that are described in [First steps for installing API Connect: Upload files to registry](#). For instructions on using the APICUP installer, see [Tips and tricks for using APICUP](#).

Tip: To enable effective high availability for your Portal service, you need a latency that is less than 50ms between all portal-db pods to avoid the risk of performance degradation. Servers with uniform specifications are required, as any write actions occur at the speed of the slowest portal-db pod, as the write actions are synchronous across the cluster of portal-db pods. It is recommended that there are three servers in each cluster of portal-db pods for the high availability configuration. The three servers can be situated in the same availability zone, or across three availability zones to ensure the best availability. However, you can configure high availability with two availability zones.

Note:

Ensure that your kernel or Kubernetes node has the value of its `inotify` watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a `non-ready` state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of `inotify` watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take `inotify` watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.

### Procedure

1. The commands for installing the Portal subsystem are described in the following table. Sample code is also provided.

Note:

- Although the `site-backup` parameters listed in the following table are optional, it's highly recommended that you include them in your installation, so that remote server backups of the portal database are also taken. If you don't want to configure these parameters at installation, you can configure them later, see [Backing up and restoring the Developer Portal in a Kubernetes environment](#).
- Host names and DNS entries may not be changed on a cluster after the initial installation.
- The backup secret is a Kubernetes secret that contains your username and password for your backup database (sftp/s3). Only password-based authentication is supported for sftp and s3, not authentication based on public certificates and private keys. Password-based authentication for s3 requires that you generate an access key and secret. For example:
  - IBM (Cloud Object Storage): [Service credentials](#).
  - AWS: [Managing access keys](#).

Command	Values/Definition
<code>apicup init</code>	Initializes the apicup installation utility and creates the <code>apiconnect-up.yml</code> configuration file
<code>apicup subsys create ptl portal --k8s</code>	Describes a Portal subsystem in the Kubernetes cluster. The identifier <code>ptl</code> is the name that you have assigned to your Portal service. You can assign it any name, as long as the identifier consists of lower case alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character. The command <code>portal</code> indicates that you are creating a Portal subsystem.
<code>apicup subsys set ptl extra-values-file</code>	<code>&lt;path/file name&gt;</code> - Path to the extra values file. One extra values file is permitted. The extra values file requires a <code>.yaml</code> format. It contains the ingress annotations and other settings for the subsystem. For an example of an extra values file for each subsystem, see <a href="#">Creating an extra values file in a Kubernetes environment</a> .
<code>apicup subsys set ptl portal-admin</code>	<code>&lt;padmin&gt;.&lt;hostname&gt;.&lt;domainname&gt;</code> - The management endpoint for the Portal. All endpoints must be resolvable by DNS. Domain names that are used for endpoints cannot contain the underscore "_" character. See <a href="#">Pre-installation requirements</a> . Refer to the deployment overview diagram for information about endpoints and certificates: <a href="#">Deployment overview for endpoints and certificates</a> .
<code>apicup subsys set ptl portal-www</code>	<code>&lt;portal&gt;.&lt;hostname&gt;.&lt;domain name&gt;</code> - The endpoint for the public portal websites. All endpoints must be resolvable by DNS. Domain names that are used for endpoints cannot contain the underscore "_" character. See <a href="#">Pre-installation requirements</a> . Multiple portal-www endpoints may be configured, as described here: <a href="#">Defining multiple portal endpoints for a Kubernetes environment</a> .
<code>apicup subsys set ptl namespace</code>	<code>&lt;namespaceName&gt;</code> - Defines the namespace where the Portal service resides; every subsystem can be in a separate namespace. Valid namespaces are configured in Kubernetes prior to starting the API Connect installation
<code>apicup subsys set ptl storage-class</code>	<code>&lt;storageClass&gt;</code> - Refers to a valid StorageClass object in your Kubernetes cluster that supports dynamic PersistentVolume provisioning. Static or manual PersistentVolume provisioning can be used, but it requires additional steps that are not covered in this documentation. Block storage is required. Select a block storage format of your choosing in order for API Connect components to be supported. GlusterFS is not recommended as a storage option due to severe performance degradation. For AWS, the gp2 and io1 types of Elastic Block Storage (EBS) are supported. Note that NFS is not supported.
<code>apicup subsys set ptl registry</code>	<code>&lt;registry-uri&gt;</code> - The location where you are running the image registry (for example, Artifactory)

Command	Values/Definition
<code>apicup subsys set ptl registry-secret</code>	< <b>registrySecret</b> > - Kubernetes secret with Docker credentials to authenticate with the image registry. The value for <b>registry-secret</b> must match the name of the secret created by using the <code>kubectl create secret</code> command. It contains the Docker credentials for accessing the registry.
<code>apicup subsys set ptl www-storage-size-gb</code>	The default is 5GB. The recommended minimum is 5GB. The actual value depends on your environment. Used to store the php, html, and media files that comprise each Portal web site. Increase this size by at least 1GB for every 20 small sites that you want to host. Note that a single site with a lot of media can take many GB. If there is less than 128MB free, then the Portal will refuse to create new sites.
<code>apicup subsys set ptl backup-storage-size-gb</code>	The default is 5GB. The recommended minimum is 5GB. The actual value depends on your environment. Stores 7 days worth of compressed backups of each Portal website. Increase this by at least 3GB for every 20 small sites that you want to host. Note that a single site with a lot of media can take many GB per backup.
<code>apicup subsys set ptl db-storage-size-gb</code>	The default is 12GB. The recommended minimum is 12GB. The actual value might be higher than this but will depend upon your environment. Used for the database files. Increase this by at least 5GB for every 20 small sites that you want to host. Larger sites require more storage. If there is less than 2GB free, then the Portal refuses to create new sites. Note: For example, a Portal with 5 sites should set this value to 40 GB, or more. Using the default values is not recommended.
<code>apicup subsys set ptl db-logs-storage-size-gb</code>	The default is 2GB, and this size should not be changed from 2 GB. Storage used for the database logs. Reducing this value could result in the volume filling up and the database hanging. Making it larger will have no effect on the number of logs kept.
<code>apicup subsys set ptl admin-storage-size-gb</code>	The default is 1GB, and this size should not be changed from 1GB. Used for the internal state of the admin container. Reducing this value could result in the admin container failing. Making it larger will have no effect
<code>apicup subsys set ptl mode</code>	Determines whether the installation is for development, testing, and demo purposes, or for production. If not explicitly set, the mode will default to <b>dev</b> (development and testing) for versions 2018.4.1.4 and later. For versions 2018.4.1.3 and earlier, the default for mode is <b>standard</b> . <ul style="list-style-type: none"> <li><b>dev</b> - (Default) Use dev mode for development, testing, and demonstration purposes. It allows one instance of each subsystem to be created.</li> <li><b>standard</b> - Use standard mode for production environments. It allows multiple instances of each subsystem to be created.</li> </ul>
<code>apicup subsys set ptl ingress-type</code>	Must be explicitly set to <b>route</b> for an OpenShift environment. For a standard K8s environment, <b>ingress-type</b> defaults to <b>ingress</b> and there is no need to explicitly enter this parameter.
<code>apicup subsys set ptl site-backup-host</code>	The fully qualified domain name of the backup server, in lowercase only. Ensure that the Kubernetes nodes can access this host. If using object storage, enter <b>Endpoint/Region</b> . (The / character between the endpoint and region is required for the object storage setting.)
<code>apicup subsys set ptl site-backup-port</code>	The port for the protocol to connect to the <b>site-backup-host</b> . Defaults to <b>22</b> if not explicitly set. The backup port is not required for object storage.
<code>apicup subsys set ptl site-backup-auth-user</code>	The user name for the server specified in <b>site-backup-host</b> . If using object storage, the user name is the S3 Secret Key ID.
<code>apicup subsys set ptl site-backup-auth-pass</code>	The password for the server specified in <b>site-backup-host</b> . If using object storage, the password is the S3 Secret Access Key parameter. The password is stored in Base64 encoded format, and must not be edited directly in the apiconnect-up.yml file.
<code>apicup subsys set ptl site-backup-path</code>	The full path to the directory where the backup files are stored. For object storage, the path can be set to the <b>bucket</b> value or the <b>bucket/subfolder</b> value.
<code>apicup subsys set ptl site-backup-protocol</code>	The protocol that is used to communicate with your remote backup endpoint. Specify one of the following values: <ul style="list-style-type: none"> <li><b>sftp</b> - for secure file transfer protocol</li> <li><b>objstore</b> - for S3 compatible object storage</li> </ul> The default protocol is <b>sftp</b> . Note: The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: <b>x509: certificate signed by unknown authority</b> .
<code>apicup subsys set ptl site-backup-schedule</code>	The schedule for how often automatic Portal backups are run. The format for the schedule is any valid cron string, as follows:  <pre> * * * * * - - - - -                   +----- day of week (0 - 6) (Sunday=0)       +----- month (1 - 12)     +----- day of month (1 - 31)   +----- hour (0 - 23) +----- min (0 - 59) </pre> For example: <code>30 22 * * 1</code> performs backups at 10:30 pm on Mondays. The default backup schedule is <code>0 2 * * *</code> (runs every day at 2 am). The timezone for backups is UTC.
<code>apicup certs set ptl CERT_NAME</code>	[ <b>CERT_FILE</b> <b>KEY_FILE</b> <b>CA_FILE</b> ] [ <b>flags</b> ] - Set the required certificates for the subsystem. Custom certificates might be set, otherwise, default certificates are automatically configured. For information on what certificates are available and how to set them see: <a href="#">Working with certificates</a> .

Command	Values/Definition
<pre>apicup subsys set ptl license- version &lt;license_typ e&gt;</pre>	<p>&lt;license_type&gt; - Specify the type of license, either <b>Production</b> or <b>Nonproduction</b>. If not specified, the default value is <b>Nonproduction</b>. Note that the license type does not impact which Portal image to install. The API Connect Kubernetes Pod annotations <b>productID</b> and <b>productName</b> reflect the selected license.</p>
<pre>apicup subsys install ptl</pre>	<p>Starts the installation of the Portal service.</p>

```
apicup subsys create ptl portal --k8s
apicup subsys set ptl extra-values-file=<path/file name>
apicup subsys set ptl portal-admin=<padmin>.<hostname>.<domainname>
apicup subsys set ptl portal-www=<portal>.<hostname>.<domainname>
apicup subsys set ptl registry=<registry-uri>
apicup subsys set ptl namespace=<namespaceName>
apicup subsys set ptl registry-secret=<registrySecret>
apicup subsys set ptl storage-class=<storageClass>
apicup subsys set ptl www-storage-size-gb=5
apicup subsys set ptl backup-storage-size-gb=5
apicup subsys set ptl db-storage-size-gb=12
apicup subsys set ptl db-logs-storage-size-gb=2
apicup subsys set ptl admin-storage-size-gb=1
apicup subsys set ptl mode=dev
apicup subsys set ptl ingress-type=route <for OpenShift environments only>
```

```
// OPTIONAL: Set the backup parameters
apicup subsys set ptl site-backup-host=<hostname>
apicup subsys set ptl site-backup-port=<22>
apicup subsys set ptl site-backup-auth-user=<username>
apicup subsys set ptl site-backup-auth-pass=<password>
apicup subsys set ptl site-backup-path=</site-backups>
apicup subsys set ptl site-backup-protocol=<sftp, objstore>
apicup subsys set ptl site-backup-schedule=<"0 0 * * *">

// OPTIONAL: Set the certificates
apicup certs set ptl CERT_NAME=[CERT_FILE KEY_FILE CA_FILE] [flags]
```

```
// OPTIONAL: Write the plan to an output directory to inspect myProject/install-plan prior to installation
apicup subsys install ptl --out=ptl-install-plan
// Start the installation from the output directory. Enter the full path to the output directory.
apicup subsys install ptl --plan-dir=./myProject/ptl-install-plan
```

```
// If output file is not used, enter the following command to start the installation
apicup subsys install ptl
```

The Portal endpoints correspond to the values entered when configuring a Portal service in the Cloud Manager. See [Registering a Portal service](#).

- `apicup subsys set ptl portal-admin` - This is the Management Endpoint that is defined in Cloud Manager, which is used for communicating with API Manager.
- `apicup subsys set ptl portal-www` - This is the Portal Website URL defined in Cloud Manager. It determines the URL for the site that is created for each Catalog. It is used for public access to the Portal from a browser.

2. After running the `apicup subsys install` command, run the `apicup subsys`

`get <portal_subsys_name> --validate` command to validate the installation. You must correct any errors that are indicated by the `--validate` command before continuing. The following example output shows how an error in the installation is displayed:

#### Kubernetes settings

=====

Name	Value

portal-www	portal.default.minikube	✓

## What to do next

If you've not already done so, you can continue your API Connect installation by installing the other subsystems.

- [Defining multiple portal endpoints for a Kubernetes environment](#)  
Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Defining multiple portal endpoints for a Kubernetes environment

Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

### About this task

You can override the single endpoint definition for portal-www (and the associated portal-www-ingress TLS certificate), in order to support multiple portal-www endpoints.

For information about the endpoints for the Portal, see [Installing the Developer Portal subsystem into a Kubernetes environment](#).

Following are the example endpoints for configuring different sites served by the same Portal service, as configured in this task:

- https://banking.example.com/loans
- https://insurance.example.com/vehicle

These unique endpoints allow portal sites to be defined on the Portal service with different host names and domains. They replace endpoints that distinguish different sites by sub paths, as shown in the following examples:

- https://www.example.com/banking/loans
- https://www.example.com/insurance/vehicle

### Procedure

1. Create TLS secrets for each portal-www endpoint by generating certificates  
Following is an example for how to generate certificates for each portal-www endpoint using openssl:

```
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout banking-tls.key -out banking-tls.crt -subj
"/CN=banking.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout insurance-tls.key -out insurance-tls.crt -subj
"/CN=insurance.example.com"
```

2. Store the SSL certificates in a secret.

```
kubectl create secret tls -n <portal-namespace> banking-tls --key banking-tls.key --cert banking-tls.crt
kubectl create secret tls -n <portal-namespace> insurance-tls --key insurance-tls.key --cert insurance-tls.crt
```

Replace `<portal-namespace>` with the Kubernetes namespace that was used to deploy the Portal subsystem.

3. Specify the portal-www endpoints in an extra values file.  
Create an extra values file or append to your current one. Enter the name and secret for each endpoint as an ingress setting in the extra values file. (One extra values file is allowed.) For instructions on creating an extra-values-file, see [Creating an extra values file in a Kubernetes environment](#).

```
apic-portal-www:
  ingress:
    web:
      hosts:
        - name: banking.example.com
          secret: banking-tls
        - name: insurance.example.com
          secret: insurance-tls
```

4. Configure your Portal subsystem to load the extra values file with the following command:

```
apicup subsys set <portal-subsys> extra-values-file=<full-path-to-extra-values-file>
```

5. Install the portal subsystem with the new extra values file using `apicup subsys install portal-subsys`.  
For more information on installing the Portal subsystem, see [Installing the Developer Portal subsystem into a Kubernetes environment](#).
6. If your deployment had existing Portal sites when you configured multiple endpoints, ensure that the Portal site URLs specified in the Manager UI Catalog settings page are consistent with the new endpoint URLs. Access the Catalog setting page, and review the URLs of those existing sites. Modify as appropriate.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

# Installing the Gateway subsystem into a Kubernetes environment

Use the Install Assist utility program to install the Gateway subsystem into your Kubernetes runtime environment.

## Before you begin

Before installing the Gateway subsystem, complete the steps described in [First steps for installing API Connect: Upload files to registry](#). For instructions on using the APICUP installer, see [Tips and tricks for using APICUP](#).

## Procedure

1. Add a gateway service to your Kubernetes cluster by configuring a gateway subsystem.
  - The use of namespaces is required. Namespaces must be configured in Kubernetes before starting the installation process. We do not recommend that you use the default namespace.
  - DNS domain names must be configured for the endpoints. Domain names that are used for endpoints cannot contain the underscore "\_" character. See [Pre-installation requirements](#).
  - Resource allocation sizes are recommended minimums and will depend upon your environment.

Note: The steps in this procedure are not needed if you are using a DataPower appliance as your gateway.

2. The commands for installing the Gateway subsystem are described in the following table. Sample code is also provided.

Note: Host names and DNS entries may not be changed on a cluster after the initial installation.

Command	Values/Definition
<code>apicup init</code>	Initializes the apicup installation utility and creates the <code>apiconnect-up.yml</code> configuration file.
<code>apicup subsys create gw gateway -- k8s</code>	Describes a gateway subsystem in the Kubernetes cluster. The identifier <code>gw</code> is the name you have assigned to your gateway service. You can assign it any name, as long as the identifier consists of lower case alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character. The command <code>gateway</code> indicates that you are creating a gateway subsystem.
<code>apicup subsys set gw extra-values-file</code>	<code>&lt;path/file name&gt;</code> - Path to the extra values file. One extra values file is permitted. The extra values file requires a <code>.yaml</code> format. It contains the ingress annotations and other settings for the subsystem. For an example of an extra values file for each subsystem, see <a href="#">Creating an extra values file in a Kubernetes environment</a> .
<code>apicup subsys set gw api-gateway</code>	<code>gw.&lt;hostname&gt;.&lt;domainname&gt;</code> - The endpoint the gateway uses for API traffic. All endpoints have to be resolvable by DNS. Domain names that are used for endpoints cannot contain the underscore "_" character. See <a href="#">Pre-installation requirements</a> . Enter this endpoint as the API Invocation Endpoint when configuring a Gateway Service in Cloud Manager. Refer to the deployment overview diagram for information about endpoints and certificates: <a href="#">Deployment overview for endpoints and certificates</a> .
<code>apicup subsys set gw apic-gw-service</code>	<code>gwd.&lt;hostname&gt;.&lt;domain name&gt;</code> - The endpoint the gateway uses for network communication. All endpoints have to be resolvable by DNS. Domain names that are used for endpoints cannot contain the underscore "_" character. See <a href="#">Pre-installation requirements</a> . Enter this endpoint as the Management Endpoint when configuring a Gateway Service in Cloud Manager.
<code>apicup subsys set gw namespace</code>	<code>&lt;namespaceName&gt;</code> - Defines the namespace where the gateway service resides; every subsystem can be in a separate namespace. Valid namespaces are configured in Kubernetes prior to starting the API Connect installation
<code>apicup subsys set gw registry</code>	<code>&lt;registry-url&gt;</code> - The location where you are running the image registry (for example, Artifactory). If the registry-url setting is used, it takes precedence over <code>&lt;image-repository&gt;</code> and <code>&lt;image-tag&gt;</code> values that may have been set.
<code>apicup subsys set gw registry-secret</code>	For example, <code>&lt;registrySecret&gt;</code> - Kubernetes secret with Docker credentials to authenticate with the image registry. The value for <code>registry-secret</code> must match the name of the secret created using the <code>kubectl create secret</code> command. It contains the Docker credentials for accessing the registry.
<code>apicup subsys set gw image-repository</code>	Points to the repository containing the gateway service image. Must match the values set using the docker tag command for <code>&lt;REGISTRY_HOST&gt;/&lt;IMAGE_NAME&gt;</code> . For example, <code>MyRegistry/MyImage</code> .
<code>apicup subsys set gw image-tag</code>	Points to the image-tag in the local repository, use double-quotes, for example, <code>"2018.4.1.X.999999-release-prod"</code> Note: To install a non-production DataPower image, the image-tag value must be <code>datapower-api-gateway</code> .
<code>apicup subsys set gw monitor-image-repository</code>	Points to the repository containing the gateway service monitor pod image. The monitor pod watches for gateways going up or down, and removes stale gateway peer information from the pods that remain in the cluster. Removal of stale peer information improves the resiliency of the cluster. There is only one monitor pod per gateway service, regardless of how many gateway server pods (replicas) there are in the gateway service. Must match the values set using the docker tag command for <code>&lt;REGISTRY_HOST&gt;/&lt;IMAGE_NAME&gt;</code> . For example, <code>"MyRegistry/k8s-datapower-monitor"</code> . This command is required. If it is omitted, neither the DataPower monitor pod or the gateway pod will start.
<code>apicup subsys set gw monitor-image-tag</code>	Points to the monitor-image-tag in the local repository, use double-quotes, for example, <code>"2018.4.1.7"</code> . This command is required. If it is omitted, neither the DataPower monitor pod or the gateway pod will start.
<code>apicup subsys set gw image-pull-policy</code>	Determines how to obtain an image from the repository when a gateway pod is restarted. Ensures that the correct image is used by the gateway pod. <ul style="list-style-type: none"><li>• <b>Always</b> - Always pull a new image when a pod is restarted. Pulls the image that is referred to by the <code>image-tag</code>.</li><li>• <b>IfNotPresent</b> - If an image cannot be accessed locally, then pull a new image.</li><li>• <b>Never</b> - Never pull a new image. Image must be reloaded manually.</li></ul>
<code>apicup subsys set gw replica-count</code>	3 is a recommended minimum; actual value will depend upon your environment.
<code>apicup subsys set gw max-cpu</code>	The default is 4. The recommended minimum is 4. The actual value will depend upon your environment.

Command	Values/Definition
<code>apicup subsys set gwy max-memory-gb</code>	The default is 6GB. The recommended minimum is 6GB. The actual value will depend upon your environment.
<code>apicup subsys set gwy storage-class</code>	<code>&lt;storageClass&gt;</code> - Refers to a valid StorageClass object in your Kubernetes cluster that supports dynamic PersistentVolume provisioning. Static or manual PersistentVolume provisioning can be used, but it requires additional steps not covered in this documentation. Block storage is required. Select a block storage format of your choosing in order for API Connect components to be supported. GlusterFS is not recommended as a storage option due to severe performance degradation. For AWS, the gp2 and io1 types of Elastic Block Storage (EBS) are supported. Note that NFS is not supported.
<code>apicup subsys set gwy v5-compatibility-mode</code>	Determines which type of gateway to install, either a DataPower® Gateway (v5 compatible) or a DataPower API Gateway. The DataPower Gateway (v5 compatible) is a v5-compatible gateway. The compatibility mode must match the type of image pointed to by the <code>image-tag</code> value. If the image contains a DataPower Gateway (v5 compatible) release, set the compatibility mode to <code>true</code> . If the image contains a DataPower API Gateway release, set the compatibility mode to <code>false</code> . <ul style="list-style-type: none"> <li><code>false</code> - Disables the <code>v5-compatibility-mode</code> when installing a DataPower API Gateway gateway</li> <li><code>true</code> - Enables the <code>v5-compatibility-mode</code> when installing a DataPower Gateway (v5 compatible) gateway</li> </ul> For more information, see <a href="#">Installing a DataPower API Gateway or a DataPower Gateway (v5 compatible)</a>
<code>apicup subsys set gwy enable-tms</code>	Determines whether to enable the OAuth Token Management System (tms). The Token Management System is required for a DataPower API Gateway. When the <code>v5-compatibility-mode</code> is set to <code>false</code> , the <code>enable-tms</code> parameter must be set to <code>true</code> . When the <code>v5-compatibility-mode</code> is set to <code>true</code> , the <code>enable-tms</code> parameter must be set to <code>false</code> . <ul style="list-style-type: none"> <li><code>true</code> - <code>enable-tms</code> will be enabled, required when installing a DataPower API Gateway</li> <li><code>false</code> - <code>enable-tms</code> will be disabled, required when installing a DataPower Gateway (v5 compatible)</li> </ul> For more information, see <a href="#">Installing a DataPower API Gateway or a DataPower Gateway (v5 compatible)</a>
<code>apicup subsys set gwy tms-peering-storage-size-gb</code>	Size of the storage volume for the Token Management System storage. The default is 10GB. The recommended minimum is 10GB. The actual value will depend upon your environment.
<code>apicup subsys set gwy enable-high-performance-peering</code>	Determines whether to enable high performance peering mode for a DataPower API Gateway. Enabling high performance peering is <b>highly recommended</b> for new deployments. <ul style="list-style-type: none"> <li><code>"true"</code> - Enable high performance peering for DataPower API Gateways.</li> <li><code>"false"</code> - Disable high performance peering for DataPower API Gateways.</li> </ul> The values are strings, not booleans, so must be enclosed in double quotes. <p>The requirement for use of this parameter is determined by the value of your <code>v5-compatibility-mode</code> parameter:</p> <ul style="list-style-type: none"> <li>When <code>v5-compatibility-mode</code> is <code>false</code>, the <code>enable-high-performance-peering</code> parameter is <b>required</b> and must be set.</li> <li>When <code>v5-compatibility-mode</code> is <code>true</code>, the <code>enable-high-performance-peering</code> parameter has no effect, and is not required.</li> </ul> For information on enabling high performance peering on existing deployments of version 2018.4.1.7 or later, see <a href="#">Enabling high performance peering for DataPower API Gateway on Kubernetes</a> .
<code>apicup subsys set gwy mode</code>	Determines whether the installation is for development, testing, and demo purposes or for a production environment. If not explicitly set, the mode will default to <code>dev</code> (development and testing) for versions 2018.4.1.4 and later. For versions 2018.4.1.3 and earlier, the default for mode is <code>standard</code> . <ul style="list-style-type: none"> <li><code>dev</code> - (Default) Use dev mode for development, testing, and demo purposes. It allows one instance of each subsystem to be created.</li> <li><code>standard</code> - Use standard mode for production environments. It allows multiple instances of each subsystem to be created.</li> </ul>
<code>apicup subsys set gwy ingress-type</code>	Must be explicitly set to <code>route</code> for an OpenShift environment. For a standard K8s environment, <code>ingress-type</code> defaults to <code>ingress</code> and there is no need to explicitly enter this parameter.
<code>apicup subsys set gwy license-version</code>	<code>&lt;license&gt;</code> - Specify the type of gateway license, one of <code>Developers</code> , <code>Production</code> , or <code>Nonproduction</code> . If not specified, the default value is <code>Developers</code> . The Gateway server image that you are installing must match the license version. Note that this requirement does not apply to the other API Connect subsystems (Management, Analytics, and Developer Portal), because they do not have separate images for each license version.
<code>apicup certs set gwy CERT_NAME</code>	<code>[CERT_FILE KEY_FILE CA_FILE] [flags]</code> - Set the required certificates for the subsystem. Custom certificates may be set, otherwise, default certificates are automatically configured. For information on what certificates are available and how to set them see: <a href="#">Working with certificates</a> .
<code>apicup subsys install</code>	<code>gwy</code> - Starts the installation of the gateway service

```

apicup subsys create gwy gateway --k8s
apicup subsys set gwy extra-values-file=<path/file name>
apicup subsys set gwy api-gateway=gw.<hostname>.<domainname>
apicup subsys set gwy apic-gw-service=gwd.<hostname>.<domainname>
apicup subsys set gwy namespace=<namespaceName>
apicup subsys set gwy registry=<registry-uri>
apicup subsys set gwy registry-secret=<registrySecret>
apicup subsys set gwy image-repository=<ibmcom/datapower>
apicup subsys set gwy image-tag="release_name"

apicup subsys set gwy monitor-image-repository="ibmcom/k8s-datapower-monitor"

apicup subsys set gwy monitor-image-tag="2018.4.1.7"
apicup subsys set gwy image-pull-policy=Always
apicup subsys set gwy replica-count=3
apicup subsys set gwy max-cpu=4
apicup subsys set gwy max-memory-gb=6
apicup subsys set gwy storage-class=<storageClass>
apicup subsys set gwy v5-compatibility-mode=false
apicup subsys set gwy enable-high-performance-peering=true
apicup subsys set gwy enable-tms=true
apicup subsys set gwy tms-peering-storage-size-gb=10
apicup subsys set gwy mode=dev

```

```

apicup subsys set gwy ingress-type=route <for OpenShift environments only>
apicup subsys set gwy license-version=<license>

//Set the certificates
apicup certs set gwy CERT_NAME=[CERT_FILE KEY_FILE CA_FILE] [flags]

// OPTIONAL: Write the plan to an output directory to inspect myProject/install-plan prior to installation
apicup subsys install gwy --out=gwy-install-plan
// Start the installation from the output directory. Enter the full path to the output directory.
apicup subsys install gwy --plan-dir=./myProject/gwy-install-plan

//If output file is not used, enter the following command to start the installation
apicup subsys install gwy

```

### Installing a DataPower API Gateway or a DataPower Gateway (v5 compatible)

The values for the `v5-compatibility-mode` and `enable-tms` parameters determine whether you are installing a DataPower API Gateway or a DataPower Gateway (v5 compatible). The following table shows the required settings for installing both types of gateways:

	<code>v5-compatibility-mode</code>	<code>enable-tms</code>
DataPower API Gateway	false	true
DataPower Gateway (v5 compatible)	true	false

- An alternate deployment scenario is to use a physical DataPower appliance for the gateway. If you are using an appliance for the gateway, do not run any of the APICUP commands described on this page, since you do not need to configure a gateway subsystem in your Kubernetes cluster when using an appliance. For an appliance-based gateway, you must configure two endpoints in DataPower to be used as the Gateway Service Management Endpoint and the API invocation Endpoint. Enter these endpoints in the Configure Gateway Service screen in Cloud Manager. See [Configuring a DataPower Gateway on an appliance](#) for instructions for configuring a DataPower appliance.
- After running the `apicup subsys install` command, run the `apicup subsys get <gateway_subsys_name> --validate` to validate the installation. You must correct any errors indicate by `--validate` prior to continuing. Following is an example for the `--validate` output:

```

## What to do next

Continue your API Connect installation in a Kubernetes runtime environment by installing the other subsystems.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Deploying pods to specific worker nodes in a multi-node cluster

Use node labels to deploy Management, Analytics, and Portal pods to specific worker nodes in a multi-node cluster.

## About this task

A label is a key and value that is attached to an object as an annotation. For a pod to use a NodeSelector, a worker node must exist with the specified label. If no worker node exists with the required label, then the pod is not deployed and is left in the pending state.

## Procedure

1. Label the worker nodes where you want to deploy the subsystem pods:
  - a. For each worker node that you want to label, run the following command:

```
kubectl label nodes <node-name> <Label-Key>=<Label-Value>
```

Use the following <Label-Key>=<Label-Value> pairs to label a node for each subsystem:

- Management: `node-apim=apim`  
For example, to add the `apim` label to the node `worker-1.ibm.com`:  

```
kubectl label nodes worker-1.ibm.com node-apim=apim
```
- Portal: `node-ptl=ptl`  
For example, to add the `ptl` label to the node `worker-3.ibm.com`:  

```
kubectl label nodes worker-3.ibm.com node-ptl=ptl
```
- Analytics: `node-analyt=analyt`  
For example, to add the `analyt` label to the node `worker-2.ibm.com`:  

```
kubectl label nodes worker-2.ibm.com node-analyt=analyt
```

- b. Run the following command to verify that the labels were applied correctly:

```
kubectl get nodes --show-labels
```

2. Deploy the Management subsystem to the labeled node:
  - a. Create the `myapim-extra-value-files.yaml` file with the following contents:

```
cassandra:
  affinity:
    nodeAffinity:
      preferredDuringSchedulingIgnoredDuringExecution:
        - preference:
            matchExpressions:
              - key: beta.kubernetes.io/arch
                operator: In
                values:
                  - amd64
            weight: 3
          requiredDuringSchedulingIgnoredDuringExecution:
            nodeSelectorTerms:
              - matchExpressions:
                  - key: node-apim
                    operator: In
                    values:
                      - apim
            podAntiAffinity:
              preferredDuringSchedulingIgnoredDuringExecution:
                - podAffinityTerm:
                    labelSelector:
                      matchLabels:
                        app: cassandra
                    topologyKey: kubernetes.io/hostname
                weight: 1
  analytics-proxy:
    nodeSelector:
      node-apim: apim
  apim:
    nodeSelector:
      node-apim: apim
  client-downloads-server:
    nodeSelector:
      node-apim: apim
  juhu:
    nodeSelector:
      node-apim: apim
  ldap:
    nodeSelector:
      node-apim: apim
  lur:
    nodeSelector:
      node-apim: apim
  ui:
    nodeSelector:
      node-apim: apim
  nodeSelector:
    node-apim: apim
```

- b. Run the following command to set the extra-values-file for the Management subsystem:

```
./apicup subsys set mgmt extra-values-file myapim-extra-value-files.yaml
```

- c. Run the following command to install the Management subsystem:

```
./apicup subsys install mgmt
```

d. Run the following command to verify that the Management pods are running in only the worker-1.ibm.com node that you labeled:

```
kubectl get po -o wide
```

3. Deploy the Portal subsystem to the labeled node:

a. Create the myportal-extra-value-files.yaml file with the following contents:

```
apic-portal-db:
  nodeSelector:
    node-ptl: ptl
apic-portal-www:
  nodeSelector:
    node-ptl: ptl
```

b. Run the following command to set the extra-values-file for the Portal subsystem:

```
./apicup subsys set ptl extra-values-file myportal-extra-value-files.yaml
```

c. Run the following command to install the Portal subsystem:

```
./apicup subsys install ptl
```

d. Run the following command to verify that the Portal pods are running in only the worker-3.ibm.com node that you labeled:

```
kubectl get po -o wide
```

4. Deploy the Analytics subsystem to the labeled node:

a. Create the myanalytics-extra-value-files.yaml file with the following contents:

```
apic-analytics-client:
  nodeSelector:
    node-analyt: anlyt
apic-analytics-cronjobs:
  nodeSelector:
    node-analyt: anlyt
apic-analytics-ingestion:
  nodeSelector:
    node-analyt: anlyt
apic-analytics-mtls:
  nodeSelector:
    node-analyt: anlyt
apic-analytics-operator:
  nodeSelector:
    node-analyt: anlyt
apic-analytics-storage:
  nodeSelector:
    node-analyt: anlyt
```

b. Run the following command to set the extra-values-file for the Analytics subsystem:

```
./apicup subsys set analytics extra-values-file myanalytics-extra-value-files.yaml
```

c. Run the following command to install the Analytics subsystem:

```
./apicup subsys install analytics
```

d. Run the following command to verify that the analytics pods are running in only the worker-2.ibm.com node that you labeled:

```
kubectl get po -o wide
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Manually creating a CustomResourceDefinition in a Kubernetes environment

Describes the steps for manually creating the CustomResourceDefinitions which are required for the management subsystem. If the `create-crd` command is set to false during installation, the CRDs must be manually created by the Kubernetes administrator.

### Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software may change and this information may become outdated. These instructions assume you have a working Kubernetes environment and understand how to manage Kubernetes.

Kubernetes is a platform for automated deployment, scaling, and operation of application containers across clusters of hosts, providing container-centric infrastructure. For more information, see <https://kubernetes.io>.

### About this task

If the `apicup subsys set mgmt create-crd` command is set to `false` in the Install Assist script (perhaps to disallow cluster-level access during installation), then the CRDs must be created manually prior to deploying API Connect in a Kubernetes environment.

## Procedure

1. Ensure you have not already installed the CRDs by executing the following command: `kubectl get crd`
2. Download the `cassandra-crds_lts_v2018.4.1.20.yaml` CRD from IBM Fix Central at the following link: [http://www.ibm.com/support/fixcentral/quickorder?product=ibm%2FWebSphere%2FIBM+API+Connect&fixids=cassandra-crds\\_lts\\_v2018.4.1.20.yaml&source=SAR](http://www.ibm.com/support/fixcentral/quickorder?product=ibm%2FWebSphere%2FIBM+API+Connect&fixids=cassandra-crds_lts_v2018.4.1.20.yaml&source=SAR)
3. Execute `kubectl create -f <CustomResourceDefinition.yaml>` (use the same file name as the one created to define the CRDs). This installs the two required CRDs, `cassandraclusters.apic.ibm.com` and `cassandraclusterbackups.apic.ibm.com`.
4. Verify the installation by entering `kubectl get crd`. You should receive results similar to the following:

NAME	AGE
<code>cassandraclusterbackups.apic.ibm.com</code>	79d
<code>cassandraclusters.apic.ibm.com</code>	79d

5. After installing the CRDs manually, install the management subsystem following the instructions at [Installing the Management subsystem into a Kubernetes environment](#). Set the `apicup subsys set mgmt create-crd` command to `false`.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Creating an extra values file in a Kubernetes environment

Describes the steps for creating an extra values file for configuration parameters that are not set by Install Assist, such as ingress annotations and resource limits. An example `.yaml` file is provided with entries for each subsystem.

### Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software may change and this information may become outdated. These instructions assume you have a working Kubernetes environment and understand how to manage Kubernetes.

Kubernetes is a platform for automated deployment, scaling, and operation of application containers across clusters of hosts, providing container-centric infrastructure. For more information, see <https://kubernetes.io>.

### About this task

The APICUP installer exposes the most important parameters for configuring a subsystem using the `subsys set` commands. The extra values file is a `.yaml` file used to set additional configuration parameters contained in the Helm chart, further to those parameters that are set using APICUP. The `.yaml` format is required. One extra values file per subsystem is allowed. The sample file is named, for example, `myExtraValues.yaml`.

Syntax:

```
apicup subsys set <subsystem_name> extra-values-file <name_of_extra_values_file>
```

The `<name_of_extra_values_file>` parameter can include a directory path.

Example for `mgmt` subsystem:

```
apicup subsys set mgmt extra-values-file myExtraValues.yaml
```

## Procedure

- **Logging level** - If you want reduced logging for the `apim`, `lur`, and `ldap` pods, set a `DEBUG` environment variable using the extra-values file. The value for `modes` must match the mode you are using (`demo` or `standard`). In the following example, `modes` is set to `standard`:

```
apim:
  modes:
    standard:
      env:
        DEBUG: "audit,bhendi:error,bhendi:probe,bhendi:flags,apim:server,apim:error"
lur:
  modes:
    standard:
      env:
        DEBUG: "audit,bhendi:error,bhendi:probe,bhendi:flags,lur:server,lur:error"
ldap:
  modes:
    standard:
      env:
        DEBUG: "audit,bhendi:error,bhendi:probe,bhendi:flags,ldap:server,ldap:error"
```

- **Optimize subsystem sync time** - You can use the extra-values file to set the pagination limit for records that are fetched by a database query. Add the flag `VELOX_CASSANDRA_LIMIT` to the extra-values file. The recommended value is `500`. Use this setting to reduce the time needed to sync subsystems. This setting is available in Version 2018.4.1.6.iFix3, and in Version 2018.4.1.7 or later. For example:

```
apim:
  modes:
    standard:
      env:
        VELOX_CASSANDRA_LIMIT: "500"
```

```

lur:
  modes:
    standard:
      env:
        VELOX_CASSANDRA_LIMIT: "500"

```

- **Management subsystem** - The following example contains entries for the extra values file to set Kubernetes ingress annotations and resource limits for the Management subsystem. By default, the APICUP installer does not specify limits for most resources. If you are using quota enforcement when sharing Kubernetes cluster resources, resource limits may be required. Adjust the values given in this example to support your resource constraints, quotas, and expected load/capacity requirements:

Note: Setting of resource requests and limits on OpenShift is not supported for the API Connect Analytics subsystem.

```

global:
  ingress:
    # cloud-admin-ui endpoint
    cm:
      annotations:
        kubernetes.io/ingress.class: "nginx"
    # api-manager-ui endpoint
    apim:
      annotations:
        kubernetes.io/ingress.class: "nginx"
    # platform-api endpoint
    platformAPI:
      annotations:
        kubernetes.io/ingress.class: "nginx"
    # consumer-api endpoint
    consumerAPI:
      annotations:
        kubernetes.io/ingress.class: "nginx"

```

```

analytics-proxy:
  resources:
    limits:
      cpu: 100m
      memory: 128Mi

```

```

apim:
  resources:
    limits:
      cpu: 1000m
      memory: 2Gi

```

```

cassandra:
  resources:
    limits:
      cpu: 2100m
      memory: 9Gi

```

```

client-downloads-server:
  resources:
    requests:
      cpu: 10m
    limits:
      cpu: 100m
      memory: 32Mi

```

```

juhu:
  resources:
    limits:
      cpu: 200m
      memory: 512Mi

```

```

ldap:
  resources:
    limits:
      cpu: 100m
      memory: 256Mi

```

```

lur:
  resources:
    limits:
      cpu: 200m
      memory: 256Mi

```

```

ui:
  resources:
    limits:
      cpu: 200m
      memory: 64Mi

```

- **Gateway subsystem** - Refer to the following example that contains entries for the extra values file for setting Kubernetes ingress annotations, the license version (applies to v2018.4.1.4 - v2018.4.1.6 only), and an optional *customDatapowerConfig* setting to point to the *ConfigMap* for baked-in policies for the Gateway subsystem.

Note: The `licenseVersion` setting shown in the `datapower` section applies to versions v2018.4.1.4 - v2018.4.1.6 only. For v2018.4.1.7 and later versions, the license version is set using APICUP when installing the Gateway subsystem. Delete the license version setting from the extra-values-file when upgrading to v2018.4.1.7 and configure the license version using APICUP.

```

ingress:
  # api-gateway endpoint
  gateway:
    annotations:
      kubernetes.io/ingress.class: "nginx"
  # apic-gw-service endpoint
  gwd:

```

```

    annotations:
      kubernetes.io/ingress.class: "nginx"

datapower:
  licenseVersion: "version - Note: Remove this setting if using v2018.4.7 or later"
  customDatapowerConfig: "custom-dp-config"

```

- **Portal subsystem** - The following example is an extra values file that sets Kubernetes ingress annotations for the Portal subsystem and shows an example for defining multiple Portal endpoints:

```

global:
  ingress:
    # portal director endpoint. used for apim -> portal comms
    portal:
      annotations:
        kubernetes.io/ingress.class: "nginx"
    # portal web site endpoint. used to access the portal web site(s)
    web:
      annotations:
        kubernetes.io/ingress.class: "nginx"

apic-portal-www:
  ingress:
    web:
      hosts:
        - name: banking.example.com
          secret: banking-tls
        - name: insurance.example.com
          secret: insurance-tls

```

- **Analytics subsystem** - The following example is an extra values file that sets Kubernetes ingress annotations for the Analytics subsystem:

```

global:
  ingress:
    client:
      annotations:
        kubernetes.io/ingress.class: "nginx"
    ingestion:
      annotations:
        kubernetes.io/ingress.class: "nginx"

```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring user-defined policies on the API Gateway in a Kubernetes deployment

For a Kubernetes deployment that uses the DataPower API Gateway, user-defined Policies are externally configured. To distribute the user-defined policies on the DataPower API Gateway, you create a Kubernetes ConfigMap that is installed using the extra values file. The ConfigMap ensures the policies are available to the Management server.

### About this task

When to use the instructions in this task

Use the instructions in this topic for distributing user-defined policies when **both** of the following two conditions are met:

- Your Gateway services is deployed on Kubernetes. The Management service is also usually deployed on Kubernetes.
- Your topology uses the DataPower API Gateway, not the DataPower Gateway (v5 Compatible).

For an explanation of gateway types, see [API Connect gateway types](#).

For a Kubernetes deployment with the DataPower® API Gateway, you can configure user-defined policies on the Gateway subsystem for distribution to API Manager as part of the deployment process, or you can configure user-defined policies at any time, on any platform, after the deployment process is complete. With the DataPower Gateway (v5 compatible) you can configure user-defined policies only after the deployment process is complete. For details of how to configure user-defined policies after deployment with either gateway type, see [Authoring policies](#).

To configure user-defined policies on the Gateway subsystem for distribution to API Manager during deployment, you create a Kubernetes ConfigMap containing the code for the policy and then add an entry in the extra values file to point to the ConfigMap. When the APICUP installation command is executed, the externally-configured policies will be loaded into the DataPower configuration at start-up and then shared with the API Manager, which makes them available in the assembly palette. A Kubernetes ConfigMap ensures that the externally configured user-defined policies are available when the Gateway is started, across upgrades and restarts of the Gateway, and when scaling the number of pods in a cluster. The policies are uploaded directly to the `apic-gw-service` object, which was installed using the APICUP installer. See [Installing the Gateway subsystem in a Kubernetes environment](#) for instructions on installing the Gateway, including how to install the extra values file.

In cases where non-standard charts or other types of virtual or physical deployments, these policies must be mounted or placed on all the members of the Gateway service.

For topologies using a virtual or physical gateway with the DataPower API Gateway

If your topology uses a virtual (OVA) or physical DataPower Gateway and the DataPower API Gateway, then refer to the DataPower documentation for configuring an assembly function available here: [Configuring an assembly function](#).

## Procedure

- Create a configuration files containing the user-defined policies. In the following example, a configuration file named `my-echo-policy.cfg` defines a policy that sets the content of a response body from the value of a parameter.

1. Define the policy in a file named, for example, `my-echo-policy.cfg`.

The following DataPower configuration commands create an assembly-function object that represents the user-defined policy that will be advertised to the Management server in the ConfigMap. This example writes the value of the `msg` parameter provided as input to the user-defined policy to the `message.body` that is returned on the API invocation.

```
assembly-setvar "my-echo-policy_1.0.0_assembly-setvar"
  variable
    action set
      name "message.body"
      type string
      value "$(local.parameter.msg)"
    exit
  variable
    action set
      name "message.headers.content-type"
      type string
      value "text/plain"
    exit
  exit
exit

api-rule "my-echo-policy_1.0.0_api-rule"
  action my-echo-policy_1.0.0_assembly-setvar
exit

assembly "my-echo-policy_1.0.0_assembly"
  rule my-echo-policy_1.0.0_api-rule
exit

assembly-function "my-echo-policy_1.0.0"
  summary "my-echo-policy_1.0.0"
  title "My Echo Policy"
  parameter
    name "msg"
    description "The message string"
    value-type string
  exit
  assembly my-echo-policy_1.0.0_assembly
exit

apic-gw-service
  user-defined-policies my-echo-policy_1.0.0
exit
```

- Add the configuration file to the ConfigMap.
  1. To make the `.cfg` files available to the Gateway subsystem, create a Kubernetes ConfigMap named, for example, `custom-dp-config`:

```
kubectl create configmap custom-dp-config --from-file=my-echo-policy.cfg
```

- Optionally, you can add your configuration files directly to the Helm chart.
  1. You create a directory for `dynamic-gateway-service/config` and place your configuration into a compressed tar file.
  2. Use `apicup` commands as shown below to place `<your_config>` into the Helm chart, so that it can be referenced by the `values.yaml`.  
For example:

Figure 1. Using `apicup` to install configuration into the Helm Chart

```
mkdir -p dynamic-gateway-service/config
cp <your_config> dynamic-gateway-service/config/
apicup subsys install gateway --out <dir>
gunzip <dir>/helm/dynamic-gateway-service-X.X.XX.tar.gz
tar -rf <dir>/helm/dynamic-gateway-service-X.X.XX.tar dynamic-gateway-service
gzip <dir>/helm/dynamic-gateway-service-X.X.XX.tar
mv <dir>/helm/dynamic-gateway-service-X.X.XX.tar.gz <dir>/helm/dynamic-gateway-service-X.X.XX.tar.gz
```

3. In the extra values file, specify:

```
datapower:
  additionalConfig:
  - domain: <some-domain>
    config: config/<your config>
```

4. Run the following commands to install the gateway with the specified configuration:

```
apicup subsys set gateway extra-values-file <extra values file>
apicup subsys install gateway --plan-dir <dir>
```

5. If you are updating an existing install, you also need to restart the pod by running the following command:

```
kubectl delete pod/<gateway_pod_name> -n <namespace>
```

The new gateway pod is then automatically created with the new configuration.

- Optionally, you can add local files directly to the Helm charts.  
Local files can be added into the gateway deployment (Helm chart) by use of the `datapower.additionalLocalTar` value. This value is a path to a tar file which contains all the files you wish to add. This tar file should be a well formatted DataPower `local`: directory where files intended for the `default` domain are on the top level and all files intended for a different domain are in a subdirectory named for that domain.

Use the same task flow as shown in [Figure 1](#), but for the local path use `local.tar.gz`.

- Optionally, you can add certificates to the ConfigMap.

Certificates and other crypto files can be added to the `cert:` directory by use of the `datapower.additionalCerts` value. This value takes the form of a list of domain-secret pairs. The secrets are Kubernetes secrets which contain the crypto files you wish to use. To create the secrets from an existing crypto key-cert pair:

1. Create the secrets from a specified file:

```
kubectl create secret generic my-secret --from-file=/path/to/key.pem --from-file=/path/to/cert.pem
```

2. Reference the secret in the extra values file by specifying:

```
datapower:
  additionalCerts:
  - domain: "default"
    secret: "some-default-cert-secret"
  - domain: "apiconnect"
    secret: "some-apiconnect-cert-secret"
```

- Install the ConfigMap containing the policies using the extra values file and the APICUP installer.
  1. In order to configure the Gateway to use the custom policies in the `custom-dp-config` ConfigMap, set the `customDatapowerConfig` value to point to the ConfigMap in the extra values file:  
For information on the extra values file, see [Creating an extra values file in a Kubernetes environment](#).

```
datapower:
  customDatapowerConfig: "custom-dp-config"
```

2. Point to the extra values file from the Gateway subsystem by entering `apicup subsys set gwy extra-values-file path/file`.
  3. Execute the `apicup subsys install gwy` command to install the Gateway with the extra values file containing the ConfigMap entry.
- Use the externally-configured user-defined policy in an API.
    1. To use the externally-configured policy in the example from an API, create an assembly that resembles the following:

```
assembly:
  execute:
  - my-echo-policy:
    title: Echo msg
    version: 1.0.0
    msg: ${request.parameters.msg}
```

2. A request against that API should have `?msg=<text>` as a query parameter, and the response body should be equal to `<text>`, which is the value of the `msg` query parameter.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

### About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer user interface.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer user interface.

You can download the toolkit compressed file in either of the following ways:

- From IBM Fix Central.
- From either the Cloud Manager or API Manager user interface.

The following table identifies the name of the compressed file that you need to download, depending on your chosen toolkit option and platform:  
Table 1. Toolkit file names, by option and platform

Toolkit option	Mac OS X	Linux®	Windows
CLI	toolkit-mac.zip	toolkit-linux.tgz	toolkit-windows.zip
CLI + LoopBack + Designer	toolkit-loopback-designer-mac.zip	toolkit-loopback-designer-linux.tgz	toolkit-loopback-designer-windows.zip

---

## Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
  - To download the toolkit from IBM Fix Central, complete the following steps:
    - Open the [IBM Fix Central site](#) in your browser.

- In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
  - Select your installed 2018.x.y version from the Installed Version list, then click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
  - In the Text field, enter `toolkit`, then click Continue.
  - Select the required file, as identified in [Table 1](#).  
Note: When you download from IBM Fix Central, the release number is appended to the file name.
  - Click Continue, then follow the instructions to complete the download operation.
  - To download the toolkit from either the Cloud Manager or API Manager user interface, complete the following steps:
    - Cloud Manager or API Manager user interface.
    - Select Help ( ? ) in the navigation.
    - Select Install API Connect CLI & API Designer.
    - Select CLI or CLI + LoopBack + Designer according to your preferred option.
    - Select your platform to download the toolkit compressed file.
    - Close the Install API Connect CLI & API Designer window.
2. Extract the contents of the toolkit compressed file to a folder of your choice.  
The contents of the file depend on the your chosen toolkit option and platform, as follows:

Table 2. Toolkit compressed file contents, by option and platform

Toolkit option	Mac OS X	Linux	Windows
CLI	apic-slim	apic-slim	apic-slim.exe
CLI + LoopBack + Designer	apic api_designer-mac.zip: contains the API Designer user interface application.	apic api_designer-linux	apic.exe api_designer-win.exe

The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.

The apic or apic.exe file is the CLI for IBM API Connect including LoopBack support.

Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.

The `api_designer-platform` file is the API Designer user interface application for the specified platform.

3. Run the CLI.
- For the Mac OS X or Linux platforms, complete the following steps:
    - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
    - Make the CLI file an executable file by entering the following command:

```
chmod +x download_name
```

Where `download_name` is the name of the toolkit file that you downloaded, either apic or apic-slim.

- Run CLI commands as follows:

```
./apic command_name_and_parameters
```

or

```
./apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

- For the Windows platform, complete the following steps:
  - Open a terminal window and navigate to the folder where you extracted the contents of the toolkit compressed file.
  - Run CLI commands as follows:

```
apic command_name_and_parameters
```

or

```
apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.

4. Launch the API Designer user interface by running the application from the location to which you extracted the contents of the toolkit compressed file.

Note:

- To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
  - In Windows File Explorer, navigate to the `USER_HOME\AppData\Local\Programs\api-designer` folder.
  - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
- To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

## Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see [Developing your APIs and applications](#).

For information on using the toolkit CLI, see [Using the developer toolkit command-line tool](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

# Upgrading API Connect in a Kubernetes environment

Upgrades are performed from the same project directory used for the initial installation.

## About this task

---

Review the requirements before starting an upgrade. Follow the procedures in the following links to complete an upgrade.

Note: Version 2018.4.1.7 introduced a new monitor pod for gateway. If you are upgrading the gateway from Version 2018.4.1.6 or earlier to Version 2018.4.1.7 or later, you must use separate instructions to install a new monitor pod during the upgrade. See the following links.

- [Requirements for upgrading](#)  
Before upgrading API Connect on Kubernetes, ensure that your deployment meets all the upgrade requirements.
- [Upgrading API Connect subsystems](#)  
Complete the following steps to upgrade API Connect subsystems.
- [Adding a monitor pod during gateway upgrade](#)  
Version 2018.4.1.7 introduced a new Gateway monitor pod that is required during an upgrade.
- [Verifying Portal upgrade](#)  
You can monitor the progress of existing Portal sites being upgraded to the new version.
- [Troubleshooting the upgrade](#)  
Troubleshoot problems with the upgrade.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Requirements for upgrading

Before upgrading API Connect on Kubernetes, ensure that your deployment meets all the upgrade requirements.

The instructions for upgrading apply to the *latest* Fix Pack version. Ensure that you are upgrading to the latest Fix Pack version. For information on the available Fix Packs, see [What's New in the latest release](#).

Note: For more information if you are moving to v2018.4.1.10, see the Tech note at [IBM Support](#).  
See the requirements for the version you are upgrading from:

- [Requirements for upgrading from v2018.4.1.8 or later](#)  
Review the requirements for upgrading from Version 2018.4.1.8 or later.
- [Requirements for upgrading from v2018.4.1.5, v2018.4.1.6, or v2018.4.1.7](#)  
Review the requirements for upgrading from Version 2018.4.1.5, Version 2018.4.1.6, or Version 2018.4.1.7
- [Requirements for upgrading from Version 2018.4.1.4 or earlier](#)  
Review the requirements for upgrading from Version 2018.4.1.4 or earlier on Kubernetes.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Requirements for upgrading from v2018.4.1.8 or later

Review the requirements for upgrading from Version 2018.4.1.8 or later.

Restriction: A direct upgrade from any version of 2018 to API Connect 10.0.6.0 or later is not supported. You must upgrade to 10.0.5.x as an interim step before upgrading to 10.0.6.0.

- Verify the API Connect deployment is fully operational. See [Checking cluster health on Kubernetes](#).  
When upgrading to v2018.4.1.10 or later, this step is optional because a health check will be run automatically as part of the `apicup subsys install` command. Note that you might still want to run the health check when preparing for the upgrade, to ensure the health of the backup image you must create prior to running `apicup subsys install`.
- When upgrading API Connect, complete a manual backup of the management database, Portal subsystem, and Analytics subsystem just prior to starting the upgrade. Note that this backup is in addition to any scheduled backups that you have configured. The manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured.  
  
For details on creating a backup, see [Backing up the management database in a Kubernetes environment](#), [Backing up and restoring the Developer Portal](#) and [Backing up and restoring the analytics database](#).
- If not already set up, send your deployment logs to a remote server. The upgrade process terminates pods, and the logs will be lost if not stored remotely. To send your deployment logs to a remote server, see [Configuring remote logging for a Kubernetes deployment](#).
- Helm version 2.8.2 or higher is required when upgrading API Connect in a Kubernetes environment.

- The same distribution file for each API Connect subsystem is used for either upgrades or fresh installations. For an example list of the files for Kubernetes upgrades, see [First steps for installing API Connect: Upload files to registry](#).
- Download the Install Assist (APICUP) installer from the same URL where you download your Fix Pack version. You must use the latest Install Assist package with the latest product version.
- The original project directory created with the APICUP installer during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. A good practice is to back up the original project directory to a location from which it can always be retrieved.
- If the upgrade is initiated from the original project directory, the certificates are automatically copied into the upgraded version. The original project directory contains the `apiconnect-up.yml` file. An upgrade using the same project directory as the one used for installation will transfer the `encryption-secret` and all other certificates for the project to the upgraded version.
- All external traffic to the management server must be blocked during the upgrade of the management subsystem. This restriction applies to traffic from all sources via the user interfaces (Cloud Manager, API Manager), CLI, and REST API. The Cloud Manager and API Manager UIs cannot be used during the upgrade of the management subsystem. The Developer Portal also cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the time.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Analytics, (3) Portal, (4) Gateway. Analytics and Portal may be switched between second or third, but Management must be upgraded first. Gateway must be upgraded after Management for the following reasons:
  - Upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
  - After a completed upgrade, the Management server and Gateway firmware versions must match, for example, APIC 2018.4.1.2 with DP 2018.4.1.2.
 Wait until the upgrade is finished on a subsystem before proceeding to the next one.
- Downgrading any of the IBM® API Connect subsystems to an earlier fix pack level is **not** supported.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Requirements for upgrading from v2018.4.1.5, v2018.4.1.6, or v2018.4.1.7

Review the requirements for upgrading from Version 2018.4.1.5, Version 2018.4.1.6, or Version 2018.4.1.7

Restriction: A direct upgrade from any version of 2018 to API Connect 10.0.6.0 or later is not supported. You must upgrade to 10.0.5.x as an interim step before upgrading to 10.0.6.0.

- Verify the API Connect deployment is fully operational.
  - For Version 2018.4.1.6 or later, see [Checking cluster health on Kubernetes](#).  
When upgrading *from* v2018.4.1.6 or later *to* v2018.4.1.10 or later, this step is optional because a health check will be run automatically as part of the `apicup subsys install` command. Note that you might still want to run the health check when preparing for the upgrade, to ensure the health of the backup image you must create prior to running `apicup subsys install`.
  - For Version 2018.4.1.5, see [Determining status of a cluster on Kubernetes](#).
- When upgrading API Connect, complete a manual backup of the management database, Portal subsystem, and Analytics subsystem just prior to starting the upgrade. Note that this backup is in addition to any scheduled backups that you have configured. The manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured.

For details on creating a backup, see [Backing up the management database in a Kubernetes environment](#), [Backing up and restoring the Developer Portal](#) and [Backing up and restoring the analytics database](#).

- The upgrade of the management server *from* Version 2018.4.1.7 or earlier may take longer than during previous fix pack upgrades. The extended time is due to underlying schema changes, and can be as long as several hours for long established deployments with a large amount of data, such as greater than 10 GB.

To reduce the amount of time required for the upgrade of the management database, use the `apicops` command to truncate the subscriber event table and remove unused snapshots:

```
apicops subscriber-queues:clear
apicops snapshots:clean-up
```

Use the latest release of the `apicops` command. Download it from <https://github.com/ibm-apiconnect/apicops/releases>.

- When upgrading an OpenShift deployment to API Connect v4.1.6, the OpenShift router may reject the renamed route for the analytics proxy. This is caused by a bug in OpenShift. If the analytics proxy routes are rejected with the error `HostAlreadyClaimed`, restart the OpenShift router using the following command:

```
oc delete po -n default <router-x-xxxxx>
```

where `router-x-xxxxx` is the name of the router.

- If not already set up, send your deployment logs to a remote server. The upgrade process terminates pods, and the logs will be lost if not stored remotely. To send your deployment logs to a remote server, see [Configuring remote logging for a Kubernetes deployment](#).
- Helm version 2.8.2 or higher is required when upgrading API Connect in a Kubernetes environment.
- The same distribution file for each API Connect subsystem is used for either upgrades or fresh installations. For an example list of the files for Kubernetes upgrades, see [First steps for installing API Connect: Upload files to registry](#).
- Download the Install Assist (APICUP) installer from the same URL where you download your Fix Pack version. You must use the latest Install Assist package with the latest product version.
- The original project directory created with the APICUP installer during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. A good practice is to back up the original project directory to a location from which it can always be retrieved.

- If the upgrade is initiated from the original project directory, the certificates are automatically copied into the upgraded version. The original project directory contains the `apiconnect-up.yml` file. An upgrade using the same project directory as the one used for installation will transfer the `encryption-secret` and all other certificates for the project to the upgraded version.
- All external traffic to the management server must be blocked during the upgrade of the management subsystem. This restriction applies to traffic from all sources via the user interfaces (Cloud Manager, API Manager), CLI, and REST API. The Cloud Manager and API Manager UIs cannot be used during the upgrade of the management subsystem. The Developer Portal also cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the time.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Analytics, (3) Portal, (4) Gateway. Analytics and Portal may be switched between second or third, but Management must be upgraded first. Gateway must be upgraded after Management for the following reasons:
  - Upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
  - After a completed upgrade, the Management server and Gateway firmware versions must match, for example, APIC 2018.4.1.2 with DP 2018.4.1.2.
 Wait until the upgrade is finished on a subsystem before proceeding to the next one.
- Downgrading any of the IBM® API Connect subsystems to an earlier fix pack level is **not** supported.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Requirements for upgrading from Version 2018.4.1.4 or earlier

Review the requirements for upgrading from Version 2018.4.1.4 or earlier on Kubernetes.

Restriction: A direct upgrade from any version of 2018 to API Connect 10.0.6.0 or later is not supported. You must upgrade to 10.0.5.x as an interim step before upgrading to 10.0.6.0.

- Verify the API Connect deployment is fully operational. For Version 2018.4.1.5 or earlier, see [Determining status of a cluster on Kubernetes](#).
- When upgrading API Connect, complete a manual backup of the management database, Portal subsystem, and Analytics subsystem just prior to starting the upgrade. Note that this backup is in addition to any scheduled backups that you have configured. The manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured.

For details on creating a backup, see [Backing up the management database in a Kubernetes environment](#), [Backing up and restoring the Developer Portal](#) and [Backing up and restoring the analytics database](#).

- The upgrade of the management server from Version 2018.4.1.7 or earlier may take longer than during previous fix pack upgrades. The extended time is due to underlying schema changes, and can be as long as several hours for long established deployments with a large amount of data, such as greater than 10 GB.

To reduce the amount of time required for the upgrade of the management database, use the `apicops` command to truncate the subscriber event table and remove unused snapshots:

```
apicops subscriber-queues:clear
apicops snapshots:clean-up
```

Use the latest release of the `apicops` command. Download it from <https://github.com/ibm-apiconnect/apicops/releases>.

- If not already set up, send your deployment logs to a remote server. The upgrade process terminates pods, and the logs will be lost if not stored remotely. To send your deployment logs to a remote server, see [Configuring remote logging for a Kubernetes deployment](#).
- Helm version 2.8.2 or higher is required when upgrading API Connect in a Kubernetes environment.
- The same distribution file for each API Connect subsystem is used for either upgrades or fresh installations. For an example list of the files for Kubernetes upgrades, see [First steps for installing API Connect: Upload files to registry](#).
- For v2018.4.1.4 and later, the default setting for `mode` is `dev`. For v2018.4.1.3 and earlier the default setting for `mode` is `standard`. Thus, if your deployment was running in `standard` mode prior to performing the upgrade, you will need to explicitly set the mode to `standard` for each subsystem using the following command in the APICUP installer: `apicup subsys set SUBSYS mode=standard`. Note that this requirement primarily affects deployments of v2018.4.1.3 or earlier that accepted the default mode of `standard`. If you are upgrading from a v2018.4.1.3 or earlier deployment, on which you accepted the default mode of `standard`, be aware of the change in default behavior, and be sure when upgrading to the latest release to set the mode to `standard`.
- Download the Install Assist (APICUP) installer from the same URL where you download your Fix Pack version. You must use the latest Install Assist package with the latest product version.
- The original project directory created with the APICUP installer during the initial product installation (for example, `myProject`) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. A good practice is to back up the original project directory to a location from which it can always be retrieved.
- If the upgrade is initiated from the original project directory, the certificates are automatically copied into the upgraded version. The original project directory contains the `apiconnect-up.yml` file. An upgrade using the same project directory as the one used for installation will transfer the `encryption-secret` and all other certificates for the project to the upgraded version.
- All external traffic to the management server must be blocked during the upgrade of the management subsystem. This restriction applies to traffic from all sources via the user interfaces (Cloud Manager, API Manager), CLI, and REST API. The Cloud Manager and API Manager UIs cannot be used during the upgrade of the management subsystem. The Developer Portal also cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the time.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Analytics, (3) Portal, (4) Gateway. Analytics and Portal may be switched between second or third, but Management must be upgraded first. Gateway must be upgraded after Management for the following reasons:
  - Upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
  - After a completed upgrade, the Management server and Gateway firmware versions must match, for example, APIC 2018.4.1.2 with DP 2018.4.1.2.
 Wait until the upgrade is finished on a subsystem before proceeding to the next one.
- Downgrading any of the IBM® API Connect subsystems to an earlier fix pack level is **not** supported.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Upgrading API Connect subsystems

Complete the following steps to upgrade API Connect subsystems.

### Before you begin

- Ensure that you have met the requirements for upgrading API Connect subsystems in a Kubernetes environment. See [Requirements for upgrading](#).
- Ensure that you are upgrading to the *latest* Fix Pack version. These instructions apply to upgrading to the latest Fix Pack version. To access the Fix Packs, see the link in [What's New in the latest release](#).

Important: If you are upgrading from 2018.4.1.19 or earlier, to 2018.4.1.20 or later, on OpenShift then you must upgrade API Connect before upgrading OpenShift to version 4.10.

### About this task

When you apply an upgrade, the new level of the subsystem overwrites the existing level. Your user configuration, APIs, Products, and subsystem configurations (Management, Analytics, and Developer Portal) are retained.

Note: **Upgrading to 2018.4.1.13 - iFix3.0 or later:** Permissions are added to the pre-supplied API Connect user roles as follows:

- A role that had the **Api-Drafts:View** permission, but not the **Api-Drafts:Manage** permission, has the **Product-Drafts:View** permission added if not already present.
- A role that has both the **Api-Drafts:View** and **Api-Drafts:Manage** permissions has the **Product-Drafts:View** and **Product-Drafts:Manage** permissions added if not already present.

The permission settings for custom roles are not changed.

For more information on user roles, and assigning permissions to roles, see [API Connect user roles](#) and [Creating custom roles](#).

### Procedure

1. Verify the API Connect deployment is healthy and fully operational:

Version to upgrade from	Instructions
v2018.4.1.6 or later	See <a href="#">Checking cluster health on Kubernetes</a> . When upgrading from v2018.4.1.6 or later to v2018.4.1.10 or later, this step is optional because a health check is run automatically as part of the <code>apicup subsys install</code> command in step <a href="#">11</a> . Note that you might still want to run the health check now, as preparation for the manual backup in step <a href="#">2</a> .
v2018.4.1.5 or earlier	See <a href="#">Determining status of a cluster on Kubernetes</a>

2. Complete a manual backup of the API Connect subsystems. See [Backing up and restoring](#).

3. **Upgrading to Version 2018.4.1.15 or later:**

Helm v3 is required for Kubernetes upgrades. Versions of APIC prior to v2018.4.1.15 use Helm v2, so Helm v3 must be installed prior to upgrading the API Connect files. The following instructions apply to Kubernetes v1.18.x:

Note: Use the Helm version corresponding to your Kubernetes version. Review the Helm compatibility chart: [https://helm.sh/docs/topics/version\\_skew/](https://helm.sh/docs/topics/version_skew/).

- a. Backup ConfigMaps

Helm release data is stored in these ConfigMaps, and is required to go back to Helm v2.

- i. List the ConfigMaps to backup:

```
kubectl get configmaps --namespace=kube-system --selector=OWNER=TILLER --output=jsonpath='{range .items[*]}{.metadata.name} {"\n"} {end}'
```

- ii. Save each ConfigMap from the list:

```
kubectl get configmap [CONFIGMAP_NAME] -oyaml > [CONFIGMAP_NAME].yaml
```

- b. Follow the steps outlined in the official Helm documentation to migrate from Helm v2 to Helm v3. See <https://helm.sh/blog/migrate-from-helm-v2-to-helm-v3/>.

Note: The cleanup command will remove the Helm v2 Configuration, Release Data and Tiller Deployment. It cleans up all releases managed by Helm v2. It will not be possible to restore them if you haven't made a backup of the releases. Helm v2 will not be usable afterwards.

- c. Verify that `helm version` reports `v3.x.x` and `helm ls` lists all the correct releases.

4. If necessary, prepare your management database for the upgrade:

Version to upgrade from	Instructions
v2018.4.1.8 or later	No preparation required. Skip this step, go directly to Step <a href="#">5</a>

Version to upgrade from	Instructions
v2018.4.1.7 or earlier	<p>Due to schema changes, upgrade of the management database takes longer than previous upgrades. For long established deployments with a large amount of data, such as over 10 GB, upgrade can take as long as several hours. To reduce this time, use the <b>apicops</b> interface to truncate the subscriber event table and remove unused snapshots.</p> <p>Download the latest release of the <b>apicops</b> interface from <a href="https://github.com/ibm-apiconnect/apicops/releases">https://github.com/ibm-apiconnect/apicops/releases</a>, and run the following commands:</p> <pre>apicops subscriber-queues:clear apicops snapshots:clean-up</pre>

- Download the appropriate images from IBM® Fix Central. To access the Fix Packs, see the link in [What's New in the latest release](#). On the Fix Pack page, select the version you want to install. When the version contents are displayed, access the files by clicking the link **Status : Available**.

Note that for Kubernetes deployments, there is one distribution file for each API Connect subsystem. The same file is used for either upgrade or new installation.

- Change directories to your existing project directory, for example, `/myProject`, and copy the new version of the APICUP installer from the zip file into the `/myProject` directory, overwriting the previous version.
- Upload the zip files to the image registry by entering the following command: `apicup registry-upload <subsystem> <image_tgz> <registry_uri>` where:
  - subsystem\_type** is the type of the subsystem for the file you are uploading, one of **management**, **portal**, **analytics**. (The gateway image is obtained from a different location, for example, **ibmcom/datapower**).
  - image\_tgz** is the name of the tar file you are uploading.
  - registry\_uri** is the path to the registry for the tar files. Enter a new subpath within the registry for the tar files when performing an upgrade. Do not reuse the same path where you initially uploaded the tar files.
- Enter the `apicup subsys set <subsystem> registry <newImageTarget>` command from the `myProject` directory for each subsystem:

```
cd ./myProject
apicup subsys set <subsystem> registry <newImageTarget>

// apicup subsys set mgmt registry <newImageTarget>
// apicup subsys set analyt registry <newImageTarget>
// apicup subsys set ptl registry <newImageTarget>
```

**newImageTarget** refers to the registry location of new image tarballs of each subsystem. This location is same as the registry upload location (**registry\_uri**).

Warning:

The installer may request that you change the **cassandra-volume-size** during the upgrade. IBM® API Connect does not support resizing **cassandra-volume-size**. You can bypass the validation on volume sizes by using the `--no-verify` option. Before starting the upgrade, make sure that the PVC size capacities and storage class of the Cassandra pod match the values mentioned in `apiconnect-up.yml`. See the instructions in [Troubleshooting the upgrade](#) to determine the PVC size capacity and storage class for the Cassandra pod.

- For the gateway, complete the following steps:

Note:

When you upgrade a cluster of gateway pods in Kubernetes, a small number of API transactions may fail. During the upgrade, Kubernetes removes the pod from the load balancer configuration, deletes the pod and then starts a new pod. The steps are repeated for each pod. Socket hang ups occur on transactions that are in process at the time the pod is killed.

The number of transactions that fail depends on the rate of incoming transactions and the length of time needed to complete each transaction. Typically the number of failures is a very small percentage. This behavior is expected during an upgrade. If the failure level is not acceptable, schedule the upgrade during an off-hours maintenance window.

- Specify the *repository* and *image-tag* for the upgrade by entering the following commands:

```
apicup subsys set gwy image-repository=<name of repository>
apicup subsys set gwy image-tag="release_name"
```

- If you are upgrading DataPower API Gateway from Version 2018.4.1.6 or earlier to 2018.4.1.7 or later, set **enable-high-performance-peering**. High performance peering is a feature that was added for DataPower API Gateway in Version 2018.4.1.7, and must be configured during the upgrade. Version 2018.4.1.7 (and later) contains a new setting, **enable-high-performance-peering=""**. Note that the setting has no value by default.

If your deployment uses DataPower API Gateway, as specified by the configuration setting `apicup subsys set gwy v5-compatibility-mode=false`, then you must set **enable-high-performance-peering="false"** during this upgrade process:

```
apicup subsys set gwy enable-high-performance-peering="false"
```

Use of high performance peering is optional, but highly recommended. If you do not plan to use high performance peering, no further configuration is needed. If you want to use high performance peering, you must first complete the API Connect upgrade, and then follow the link in Step [15](#) at the end of these instructions.

- When upgrading a high-availability cluster, ensure that you meet the requirements:

- Gateways must be updated one at a time.
- Before starting the upgrade, a single gateway must be running as primary for all gateway-peering definitions.
- When upgrading multiple gateways, the primary gateway must be upgraded last.
- For upgrading to version 2018.4.1.9 or later, ensure that the pod with a name like `r*-dynamic-gateway-service-0` is the primary because it is the last node to be upgraded.

To determine which gateway is running as primary, use either the `show gateway-peering-status` command in the DataPower CLI, or use the Gateway Peering Status display in the WebGUI in the API Connect application domain. To move the primary to the DataPower on which you're currently working, you can issue the `gateway-peering-switch-primary <peering-object-name>` command.

To access the DataPower CLI or WebGUI, use:

```
kubectl attach -it <podname>
```

For more information, see [Configuring the API Connect Gateway Service](#).

d. To upgrade the gateway monitor pod, point to the `monitor-image-tag` for the upgrade by entering the following command:

Important: If you are upgrading from 2018.4.1.6 or earlier to 2018.4.1.7 or later, do not use this step. Instead, complete the instructions in [Adding a monitor pod during gateway upgrade](#).

```
/apicup subsys set gwy monitor-image-tag="<new_monitor_version_number>"
```

Note that you must specify an updated value on the `monitor-image-tag`. The value must differ from the value that was originally used at deployment, as described in [Installing the Gateway subsystem into a Kubernetes environment](#). For example, if the original value was `2018.4.1.7`, do not use `2018.4.1.7`, even if the contents of the tag are different.

When you run `apicup subsys install` command again, `apicup` detects the changed value and restarts the monitor pod.

e. **Version 2018.4.1.9:** All gateway extensions and gateway script policies which were in place prior to the upgrade to Version 2018.4.1.9 are automatically moved from `local://` to `temporary://`. Therefore, any references to `local` in those extensions or policies must be changed to refer to `temporary`.

10. Apply the new Cassandra CRDs before upgrading the management subsystem.

a. Download the `cassandra-crds_lts_v2018.4.1.20.yaml` CRD from [IBM Fix Central](#).

b. Run the following command to renew the CRDs:

```
kubectl apply -f <CustomResourceDefinition.yaml>
```

Where `<CustomResourceDefinition.yaml>` is the same file name as the one created to define the CRDs. This renews the two required CRDs, `cassandraclusters.apic.ibm.com` and `cassandraclusterbackups.apic.ibm.com`.

11. Run `apicup subsys install` for each subsystem. Upgrade a single subsystem at a time and check the health status of each subsystem before upgrading the next subsystem. See [Checking cluster health on Kubernetes](#).

```
cd ./myProject
apicup subsys install <subsystem>
```

```
// apicup subsys install mgmt
// apicup subsys install analyt
// apicup subsys install ptl
// apicup subsys install gwy
```

12. **Version 2018.4.1.9 iFix1.0 and later:** After completion of the upgrade, verify that all tasks are running.

Due to a known limitation in versions prior to v2018.4.1.9 iFix1.0, some tasks may have stopped running. Complete the following steps:

a. Download the `apicops` utility from <https://github.com/ibm-apiconnect/apicops/releases>.

b. Run the following command to remove any pending tasks:

```
$ apicops task-queue:fix-stuck-tasks
```

c. Run the following command to verify that the returned list (task queue) is empty.

```
$ apicops task-queue:list-stuck-tasks
```

13. Upgrade Kubernetes or OpenShift if needed:

- Kubernetes: If the your version of Kubernetes is not supported by the version of API Connect that you upgraded to, obtain a supported version and install it. To review the list of supported versions of Kubernetes, follow the instructions in [IBM API Connect Version 2018 software product compatibility requirements](#).

- OpenShift: If you upgraded from 2018.4.1.19 or earlier, to 2018.4.1.20 or later, upgrade OpenShift now to the level supported by your new version of API Connect.

For example, if you upgraded from 2018.4.1.19 on OpenShift 4.6 to 2018.4.1.20, you must now upgrade OpenShift to 4.10.

14. If you upgraded the Portal, see [Verifying Portal upgrade](#).

15. If you want to enable high performance peering for a DataPower API Gateway, see [Enabling high performance peering for DataPower API Gateway on Kubernetes](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Adding a monitor pod during gateway upgrade

Version 2018.4.1.7 introduced a new Gateway monitor pod that is required during an upgrade.

### About this task

The Gateway monitor pod feature was introduced in Version 2018.4.1.7. The monitor pod is required on all Gateway deployments for Version 2018.4.1.7 and later. When upgrading from Version 2018.4.1.6 or earlier, you must install (add) a new monitor pod to your deployment. The procedure in this topic is for this upgrade scenario.

Note: If you have already deployed Version 2018.4.1.7 or later, and are upgrading to a newer version, do not use this procedure. In this case, your deployment includes an existing gateway monitor pod.

### Procedure

1. Download the distribution file.

The monitor pod is distributed in a separate tar file on IBM Fix Central, along with the other API Connect distribution files. For example, the file for Version 2018.4.1.7 is `dpm2018417.1ts.tar.gz`. For more information, see [First steps for installing API Connect: Upload files to registry](#).

2. Load the Kubernetes DataPower Monitor image to your local docker registry:

```
docker load -i dpm2018417.1ts.tar.gz
```

For these examples, assume the version number is 2018.4.1.7. The image is automatically tagged in the docker registry to

```
ibmcom/k8s-datapower-monitor:2018.4.1.7
```

3. Re-tag the image for the new registry with the registry host, image name, and tag in the following format: `<REGISTRY_HOST>/<IMAGE_NAME>:<TAG>`:

```
docker tag <existing REGISTRY_HOST>/<IMAGE_NAME>:<TAG>> <new REGISTRY_HOST>/<IMAGE_NAME>:<TAG>>
```

For example:

```
docker tag ibmcom/k8s-datapower-monitor:2018.4.1.7 MyRegistry/k8s-datapower-monitor:2018.4.1.7
```

The parameters are defined as follows:

- `<REGISTRY_HOST>/<IMAGE_NAME>` - Enter your registry host name and an image name, for example, *My Registry/k8s-datapower-monitor*. The `<REGISTRY_HOST>/<IMAGE_NAME>` matches the value entered for installation in the `apicup subsys set gwy monitor-image-repository` command.
  - `<TAG>` - Enter a tag for the image, for example, `2018.4.1.7`. The `<TAG>` value must match the value entered for the gateway image tag during installation using the `apicup subsys set gwy monitor-image-tag` command. You can look up required tag using the `./apicup version --images` command to list all images required by APICUP. The tag must match the tag for the Kubernetes DataPower Monitor. For example: `2018.4.1.7`.
4. Push the monitor pod image to the new registry:

```
docker push <REGISTRY_HOST>/<IMAGE_NAME>:<TAG>
```

For example:

```
docker push MyRegistry/k8s-datapower-monitor:2018.4.1.7
```

5. Use `apicup` to configure the monitor pod:

For example:

```
apicup subsys set gwy monitor-image-repository="ibmcom/k8s-datapower-monitor"
```

```
apicup subsys set gwy monitor-image-tag="2018.4.1.7"
```

When you run `apicup subsys install` command, `apicup` includes the monitor pod.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Verifying Portal upgrade

You can monitor the progress of existing Portal sites being upgraded to the new version.

### Procedure

---

1. After completing an upgrade of the Portal subsystem, there may be a delay while the existing sites are upgraded to the new platform version. Once all Portal pods have completed the upgrade, you can monitor the progress of the sites being upgraded using the following commands:
  - `apicup subsys exec portal list-sites sites` - Displays the status of the sites that are being upgraded to the new platform version. Any sites currently upgrading will be listed with an `UPGRADING` status. When a site is finished upgrading, it will have an `INSTALLED` status, with the new platform version listed.
  - `apicup subsys exec portal list-sites platforms` - Confirm that the new version of the platform is listed for all sites with `INSTALLED` status.
2. The installer may request that you change storage sizes during the upgrade. Unless your persistent storage solution supports manual resizing, do not change the size of the volumes. You can bypass the validation on volume sizes using the `--no-verify` option. The following storage size settings may be affected:

```
www-storage-size-gb  
backup-storage-size-gb  
db-storage-size-gb  
db-logs-storage-size-gb
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Troubleshooting the upgrade

Troubleshoot problems with the upgrade.

### Health check error for Cassandra pod

---

API Connect does not support resizing the storage capacity or modifying the storage class of the Cassandra database.

After completing the upgrade, if the health check of the management system returns an **Error**: for any component, and the problem persists, use the following steps to debug the cluster.

1. Verify that all upgrade jobs have completed. Upgrades can take some time, depending on the version. You can monitor the health check to ensure that all upgrade jobs and pods are no longer running. See [Checking cluster health on Kubernetes](#).
2. If upgrade pods are completed and all pods are up and running, verify the health status of the Cassandra pods. You might see a problem similar to the following:

```
./apicup subsys health-check <mgmt-subsystem>
```

```
Error: Problem checking cassandrapod(<namespace>.<cassandra-pod>): Expect pod image(<current-pod-image>) == <Expected-image>
```

The error described means that the Cassandra pod image is not up to date with expected image. If the error message persists, it means that the Cassandra operator failed to upgrade the Cassandra servers. In most cases, the failure occurs because `cassandra-volume-size-gb` or `storage-class` changed. To determine if either of these settings changed:

- a. Look for errors in the `cassandra-operator` logs. For example:

```
time="2019-06-17T15:30:56Z"
level=error msg="Error while processing work item:
Unable to process pt/r59a99aa884-apiconnect-cc:statefulset.
Giving up: StatefulSet.apps \"r59a99aa884-apiconnect-cc\" is invalid: spec:
Forbidden: updates to statefulset spec for fields other than 'replicas', 'template',
and 'updateStrategy' are forbidden."
```

- b. Compare the value for `cassandra-volume-size-gb` in `apiconnect-up.yml` with the actual Cassandra PersistentVolumeClaim (PVC) capacity. Run the following command to determine the PVC capacity:

```
kubectl get pvc -n <namespace> | grep -e 'apiconnect-cc' -e 'CAPACITY'
```

- c. Compare the value of `storage-class` in `apiconnect-up.yml` with actual Cassandra PVC storage. Run the following command to determine the `storage-class` value for the PVC attached to the Cassandra pod:

```
kubectl get pvc -n <namespace> | grep -e 'apiconnect-cc' -e 'STORAGECLASS'
```

3. **Workaround:** If necessary, use the following steps to upgrade the Cassandra servers:

- a. Ensure that the value of `cassandra-volume-size-gb` in `apiconnect-up.yml` matches the `apiconnect-cc` PVC claim capacity.
- b. Ensure that the value of `storage-class` in `apiconnect-up.yml` matches the `apiconnect-cc` PVC `storage-class`.
- c. If values don't match, revert back changes in `apiconnect-up.yml` so that they match the `apiconnect-cc` PVC capacity and `storage-class`.
- d. Update the management subsystem:

```
apicup subsys install <management-subsystem>
```

Cassandra servers will be automatically upgraded by the Cassandra operator.

- e. Allow sufficient time for the upgrade to complete, and then check the status of the cluster.

## Issues when installing Drupal 8 based custom modules or sub-themes into the Drupal 9 based Developer Portal

From IBM® API Connect 2018.4.1.17, the Developer Portal is based on the Drupal 9 content management system. If you want to install Drupal 8 custom modules or sub-themes into the Drupal 9 based Developer Portal, you must ensure that they are compatible with Drupal 9, including any custom code that they contain, and not using any deprecated APIs, for example. There are tools available for checking your custom code, such as [drupal check](#) on GitHub, which checks Drupal code for deprecations.

For example, any Developer Portal sites that contain modules or sub-themes that don't contain a Drupal 9 version declaration will fail to upgrade, and errors like the following output will be seen in the `admin` logs:

```
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: Checking theme: emeraldgreen
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '' found for emeraldgreen
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: Checking theme: rubyred
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '8.x' found for rubyred
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Found themes incompatible with
Drupal 9: emeraldgreen rubyred
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: /tmp/restore_site.355ec8 is NOT
Drupal 9 compatible
...
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_1
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '' found for custom_mod_1
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_2
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '8.x' found for custom_mod_2
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Found modules incompatible with
Drupal 9: emeraldgreen rubyred
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: site1.com is NOT Drupal 9
compatible
```

To fix version compatibility errors, all custom modules and sub-themes should declare a `core_version_requirement` key in their `*.info.yml` file that indicates Drupal 9 compatibility. For example:

```
name: Example module
type: module
description: Purely an example
core: 8.x
core_version_requirement: '^8 || ^9'
package: Example module
```

```
# Information added by Drupal.org packaging script on 2020-05-31
version: '8.x-1.3'
project: 'example_module'
datestamp: 1590905415
```

This example specifies that the module is compatible with all versions of Drupal 8 and 9. For more information, see [Let Drupal know about your module with an .info.yml file](#) on the drupal.org website.

If you have a backup of a site that you need to restore, and are getting the version compatibility error, but the module or theme \*.info.yml file cannot be changed easily, then you have two options. Either:

- Add an environment variable for the `www` pod of the `admin` container stating `SKIP_D9_COMPAT_CHECK: "true"`. However, if you choose this method, you must be positive that all of the custom modules and themes for your sites are Drupal 9 compatible, as otherwise the sites may end up inaccessible after the upgrade or restore. Create an extra values file to contain the environment variable, as follows:

```
apic-portal-www:
  admin:
    env:
      SKIP_D9_COMPAT_CHECK: "true"
```

Save the file as `d9compat.yaml`, and run the following command:

```
apicup subsys set <portal_subsystem_name> extra-values-file d9compat.yaml
```

Then, update the portal with the updated setting by running the following command:

```
apicup subsys install <portal_subsystem_name>
```

Or:

- Extract the site backup, edit the relevant files inside it, and then tar the backup file again. Note that this procedure will overwrite the original backup file, so ensure that you keep a separate copy of the original file before you start the extraction. For example:
  1. `mkdir /tmp/backup`
  2. `cd /tmp/backup`
  3. `tar xfz path_to_backup.tar.gz`
  4. Edit the custom module and theme files to make them Drupal 9 compatible, and add the correct `core_version_requirement` setting.
  5. `rm -f path_to_backup.tar.gz`
  6. `tar cfz path_to_backup.tar.gz`
  7. `cd /`
  8. `rm -rf /tmp/backup`

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Deleting the API Connect deployment in a Kubernetes runtime environment

To delete the Kubernetes deployment of API Connect, you delete the Helm charts, Custom Resource Definitions, the Persistent Volumes, and the namespace.

### About this task

To delete the API Connect deployment in a Kubernetes runtime environment, you will need the Kubernetes command-line tool, `kubectl`. For more information, see [kubectl](#).

### Procedure

Repeat the following steps for each namespace containing an API Connect subsystem:

1. List the Helm charts in your namespace by entering: `helm ls --namespace=<namespace>`. You will perform a delete for each chart. The charts will look similar to the following:
  - `dynamic-gateway-service-*`
  - `cassandra-operator-*`
  - `dynamic-gateway-*`
  - `apic-analytics-*`
  - `apiconnect-*`
  - `apic-portal-*`
2. Delete each Helm chart using the `--purge` option: `Helm delete --purge <chart-name>`. If the reclaim policy of a Persistent Volume is `Delete`, the PV is automatically deleted when the Helm chart is deleted.
3. List and delete the Custom Resource Definitions (CRDs). Enter `kubectl get crd` to list the CRDs. Delete the following API Connect CRDs by entering the following command: `kubectl delete crd <name>`:
  - `cassandraclusters.apic.ibm.com`
  - `cassandraclusterbackups.apic.ibm.com`
4. Check if there are remaining Persistent Volumes associated with API Connect by entering: `kubectl get pv`. If there are any remaining PV, delete them manually using the following command: `kubectl delete pv <name>`.
5. Delete the namespace if it is no longer needed. Ensure there are no other resources deployed in the namespace before deleting it. Enter the following command to delete the namespace: `kubectl delete namespace <name>`.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Maintaining a Kubernetes deployment

You can use utilities to complete maintenance tasks such as backup, restore, and certificate management on Kubernetes.

Note: When maintaining API Connect, do not use `kubectl exec` or `oc exec` commands to access API Connect pods unless advised by IBM.

- **[Backing up and restoring](#)**  
You can backup and restore API Connect subsystems.
- **[Disabling the Analytics subsystem on Kubernetes](#)**  
During maintenance of an API Connect cluster, you can shut down the Analytics subsystem by disabling the client, ingestion, and storage microservices so that those processes are not running and there is no way to reach them.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Backing up and restoring

You can backup and restore API Connect subsystems.

Note:

- Backups are intended for recovery of the Management, Portal, and Analytics subsystems onto the same deployment from which they were taken, or onto a new replacement installation in the same environment for disaster recovery. The same environment means the same network configuration and project directory as the original installation.
- You must back up both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.
- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- When restoring, the Gateway and all deployed subsystems (Management, Analytics, and Developer Portal) must be at the same version level.
- **[Backing up the management database in a Kubernetes environment](#)**  
Backups of the management database can be performed based upon a cron-like schedule or on-demand from the command line.
- **[Restoring the management database in a Kubernetes environment](#)**  
The management database can be restored as a complete restoration. Partial restorations are not supported.
- **[Backing up and restoring the Developer Portal in a Kubernetes environment](#)**  
How to backup and restore your Developer Portal service in your Kubernetes environment.
- **[Backing up and restoring the analytics database](#)**  
The analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required, for example, IBM Cloud Object Storage.
- **[Using APICUP to reconfigure](#)**  
You can use APICUP to change configuration of a subsystem after completion of initial installation.
- **[Configuring maximum size of client requests to the Management subsystem](#)**  
You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.
- **[Increasing memory allocation for Cassandra operator on OpenShift](#)**  
If the Cassandra operator pods restart due to out of memory errors, you can increase the memory allocation for the Cassandra operator.
- **[Setting rate limits for public APIs on the management service for a Kubernetes environment](#)**  
Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.
- **[Enabling high performance peering for DataPower API Gateway on Kubernetes](#)**  
Enabling high performance peering on DataPower API Gateway deployments optimizes API transaction performance.
- **[Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment](#)**  
In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.
- **[Monitoring and logging a Kubernetes deployment](#)**  
You can do health checks to determine program status, and can gather logs for use in troubleshooting.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Backing up the management database in a Kubernetes environment

Backups of the management database can be performed based upon a cron-like schedule or on-demand from the command line.

## About this task

Database backups can be used to restore the database for disaster recovery or for transferring data during an upgrade.

- For scheduled backups, see [Configuring scheduled backups](#)
- For on-demand backups, see [Performing on-demand backups](#)

We strongly recommend that you configure a backup schedule for your management database using the `cassandra-backup-schedule` setting during installation of the management subsystem. If you did not do so when you installed API Connect in your Kubernetes runtime environment, you have the option to perform an on-demand backup. We also recommend that you perform a backup (either scheduled or on-demand) of the management database prior to upgrading.

Both scheduled backups and on-demand backups require that the `cassandra-backup-x` settings be configured when installing the management subsystem. Automatic scheduled backups are performed according to the cron-like job configured by the `cassandra-backup-schedule` setting. On-demand backups also require the backup settings for protocol, host, etc., but are run on-demand from the command line.

Note:

- You must back up both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.
- The original project directory created with APICUP during the initial product installation (for example, myProject) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. A good practice is to back up the original project directory to a location from where it can always be retrieved.

## Procedure

### • Configuring scheduled backups

1. To configure scheduled backups, enter the `cassandra-backup-x` settings when installing the management subsystem as described in [Installing the Management subsystem into a Kubernetes environment](#). The `cassandra-backup-x` parameters are also described in the following table:

The parameters are as follows:

Parameter	Description
<code>cassandra-backup-protocol</code>	The backup protocol. Specify one of the following values: <ul style="list-style-type: none"> <li>• <code>sftp</code> - for secure file transfer protocol</li> <li>• <code>objstore</code> - for S3 compatible object storage</li> </ul> Note: <ul style="list-style-type: none"> <li>• For the management subsystem, IBM Cloud and Amazon Web Services (AWS) are supported S3 object store providers.</li> <li>• The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: <code>x509: certificate signed by unknown authority</code>.</li> </ul>
<code>cassandra-backup-path</code>	The full path to the directory where the backup files will be stored. This must point to a directory on the backup server. For object storage ( <code>objstore</code> ), the path can be set to the <code>bucket</code> value or the <code>bucket/subfolder</code> value.
<code>cassandra-backup-host</code>	The fully qualified domain name of the backup server. Ensure that the Kubernetes nodes can access this host. If using object store, enter <code>Endpoint/Region</code> . (The "/" character between the endpoint and region are required for this setting.)
<code>cassandra-backup-port</code>	The port for the protocol to connect to the <code>cassandra-backup-host</code> . The backup port is not required for object storage.
<code>cassandra-backup-schedule</code>	Cron like schedule for performing automatic backups. The format for the schedule is: <ul style="list-style-type: none"> <li>• <code>*****</code></li> <li>• <code>-----</code></li> <li>• <code>     </code></li> <li>• <code>     +-----</code> day of week (0 - 6) (Sunday=0)</li> <li>• <code>   +-----</code> month (1 - 12)</li> <li>• <code>  +-----</code> day of month (1 - 31)</li> <li>• <code> +-----</code> hour (0 - 23)</li> <li>• <code>+-----</code> min (0 - 59)</li> </ul> The backup schedule defaults to <code>0 0 * * *</code> . This means a backup is run every day at midnight and minute zero. The timezone for backups is UTC. <p>When you configure a host, if you do not specify a value for <code>cassandra-backup-schedule</code>, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed.</p> Note: Cassandra <b>repair</b> cron schedule is set to <code>00 1 * * 0,2,4,6</code> . This means the repair runs at 01:00 on Sunday, Tuesday, Thursday, and Saturday. By default, the Cassandra <b>backup</b> cron schedule should not run within one hour of the repair cron schedule. Please make sure to modify the current backup configuration as needed. If backups and repairs run at the same time, backup processes can fail intermittently.
<code>cassandra-backup-auth-user</code>	The username for the server specified in <code>cassandra-backup-host</code> . If using object store, this would be the S3 Secret Key ID.
<code>cassandra-backup-auth-pass</code>	The password for the server specified in <code>cassandra-backup-host</code> . If using object store, this would be the S3 Secret Access Key parameter. The password will be stored in Base64 encoded format. <p>For example:</p> <pre>apicup subsys set mgmt cassandra-backup-auth-pass '&lt;password&gt;'</pre> <p>Note that you cannot use the '=' sign to assign the password to <code>cassandra-backup-auth-pass</code>.</p>

For example:

```
cassandra-backup-protocol: sftp
cassandra-backup-host: mybackuphost.com
cassandra-backup-port: 22
cassandra-backup-path: /backups
cassandra-backup-schedule: 0 0 * * *
cassandra-backup-auth-user: myusername
cassandra-backup-auth-pass: mypassword
```

- These settings will be activated by the `apicup subsys install <SUBSYS_NAME>` command.
- To verify that automatic backups are in progress, you will see a pod labeled `<cassandra cluster name>-backup` at the scheduled time for the backup.
- When the scheduled backup is complete, the backup files are stored at the location specified by the `cassandra-backup-path` parameter. The file name varies depending upon the API Connect version that performed the backup, but the file name must be compatible with the version used for restoring the database. For details about the file name, see [Restoring the management database in a Kubernetes environment](#).
- List the backups by entering: `apicup subsys exec <SUBSYS_NAME> list-backups`. You can view a list of backups with the ID and Status in the output. Following is an example:

Cluster	Namespace	ID	Timestamp	Status
rf0c7310d07-apiconnect-cc	e2edemo	1537987501522014136	2018-09-26 18:45:01.522014136 +0000 UTC	Complete
rf0c7310d07-apiconnect-cc	e2edemo	1537920006787257385	2018-09-26 00:00:06.787257385 +0000 UTC	Complete

- #### Performing on-demand backups

- Configure the backup parameters. (The same parameters are required for on-demand backup that are required for a scheduled backup, but you will bypass the schedule.) If you did not enter the `cassandra-backup-x` parameters when you installed API Connect, you will need to enter them from the command line and re-install the management subsystem before performing an on-demand backup.
- After the backup parameters have been specified, run the `apicup subsys install <SUBSYS_NAME>` command to activate the new parameters. This step is not required if you specified these parameters during the initial installation.
- Enter the following command: `apicup subsys exec <SUBSYS_NAME> backup` where `SUBSYS_NAME` is the name of your management subsystem.
- When the back is completed, the backup files are stored at the location specified by the `cassandra-backup-path` parameter. The file name varies depending upon the API Connect version that performed the backup, but the file name must be compatible with the version used for restoring the database. For details about the file name for the backups, see [Restoring the management database in a Kubernetes environment](#).
- List the backups by entering: `apicup <subsys exec <SUBSYS_NAME> list-backups`. You can view a list of backups with the ID and Status in the output. Following is an example:

Cluster	Namespace	ID	Timestamp	Status
rf0c7310d07-apiconnect-cc	e2edemo	1537987501522014136	2018-09-26 18:45:01.522014136 +0000 UTC	Complete
rf0c7310d07-apiconnect-cc	e2edemo	1537920006787257385	2018-09-26 00:00:06.787257385 +0000 UTC	Complete

## Results

Use the ID generated for the backup files to restore the database from the backup. Usually the database is restored from a backup file after an upgrade is performed and to recover from a disaster. See [Restoring the management database in a Kubernetes environment](#) and [Upgrading API Connect in a Kubernetes environment](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Restoring the management database in a Kubernetes environment

The management database can be restored as a complete restoration. Partial restorations are not supported.

### Before you begin

Before you being restoring a management database, ensure your deployment and your process meets these requirements:

- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- Restoring the Management Service requires database downtime and is a destructive process that deletes current data and copies backup data. During the restoration process, external traffic must be stopped.
- In a Disaster Recovery scenario, do not log in to the administration UI or attempt to configure or change any settings prior to restoring the backup. Restore the backup immediately after installing the subsystem.
- To restore the management database, you must use the original project directory that was created with `apicup` during the initial product installation. You cannot restore the database without the initial project directory because it contains pertinent information about the cluster. The endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored system. Note that successful restoration depends on use of a *single apicup* project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.
- Map the DNS entries from the source cluster to the corresponding IP addresses on the target cluster. Record the DNS entries for each endpoint before starting the restore.
- When restoring the management database, the endpoints (on the new cluster which is the target for the restoration) have to be the same as those on the old cluster (the source of the backup). This includes all the endpoints for API Connect: `api-manager-ui`, `cloud-admin-ui`, `consumer-api`, `platform-api`; `api-gateway`, `api-gw-service`; `analytics-ingestion`, `analytics-client`; and `portal-admin`, `portal-www`.
- When restoring, the Gateway and all deployed subsystems (Management, Analytics, and Developer Portal) must be at the same version level.

### About this task

Follow the procedure on this page to restore your management database. You must complete the prerequisite steps before beginning the restore.

Note that in a disaster recovery scenario you must first re-establish the management subsystem. The procedure includes an optional first step for disaster recovery.

If you encounter errors, see [Troubleshooting restoration of management database](#). Note that the troubleshooting page includes [Overview of restore process for management database](#).

## Procedure

- If the restoration is for a disaster recovery scenario, complete this step to first install a new Management subsystem. If the restoration is *not* for a disaster recovery (meaning that you have a *running* Management subsystem to use for restoration), skip this step and go directly to Step 2.
  - Copy the project folder that corresponds to the backup files into a new location.
  - If, for the previous installation, you have redirected the configuration to an optional output folder using the `apicup subsys install mgmt --out=mgmt-out` command as explained in [Installing the Management subsystem into a Kubernetes environment](#), delete all output folders prior to starting the new installation.
  - (Optional) If the image registry location or the secret has changed, update the image registry and registry-secret for each subsystem, as follows:

- `apicup subsys set <SUB_SYS> registry <REPOSITORY>`

The location where you are running the image registry (for example, Artifactory). `<SUB_SYS>` is the name of the subsystem. `<REPOSITORY>` is the URL to the repository.

- `apicup subsys set <SUB_SYS> registry-secret <SECRET>`

Kubernetes secret with Docker credentials to authenticate with the image registry. The value for `registry-secret` must match the name of the secret created using the `kubectl create secret` command. The secret contains the Docker credentials for accessing the registry. `<SUB_SYS>` is the name of the subsystem. `<SECRET>` is the repository secret.

- Perform a fresh installation of the management subsystem using the following command:

```
apicup subsys install <SUB_SYS>
```

Important:

Do not make any other changes in the project directory nor run any other `apicup` operations before proceeding to the next step.

- Verify that your deployment meets the prerequisites for restoring a management database:
  - Verify that you are about to restore onto a deployment that has the same number of Cassandra pods as the deployment where the backup was created. For example, if the management service backup deployment had 3 Cassandra pods, the restore deployment must have 3 Cassandra pods. You cannot restore onto a deployment with fewer Cassandra pods because the Cassandra data is sharded across the pods. To successfully restore, first create the matching number of Cassandra pods.  
To view the number of pods, enter the `kubectl get pods` command.
  - Ensure that all Cassandra pods are on-line and running normally.
- Restoration of a management subsystem requires access to backup tar files. Obtain your backup files, as follows:
  - Enter `apicup subsys exec <MANAGEMENT_SUBSYS_NAME> list-backups`. The output lists the current backups in your namespace with Backup ID and status.

Cluster Status	Namespace	ID	Timestamp
rf0c7310d07-apiconnect-cc	e2edemo	1537987501522014136	2018-09-26 18:45:01.522014136 +0000 UTC Complete
rf0c7310d07-apiconnect-cc	e2edemo	1537920006787257385	2018-09-26 00:00:06.787257385 +0000 UTC Complete

The backup files are stored at the location specified by the `cassandra-backup-path` parameter.

Examine the backup filename to identify the backup ID for use with the restore command.

Table 1. Backup file naming convention

Backup file name	BackupID (for use with restore command)
<code>&lt;backupId&gt;-&lt;pod index&gt;-&lt;# of pods&gt;.tar.gz</code>	<code>[backupId]</code>
Example:	Example:
<code>1534954510365016356-0-3.tar.gz</code>	<code>1534954510365016356</code>

Note: **Disaster Recovery:** If you are restoring on a new deployment, you will not have any backups. You will have to find the `backupID` by going to your backup host and looking for the backup files from previous deployments.

- Confirm that you have a backup file for each Cassandra pod in your cluster. If you have  $n$  pods, you must have the same number of backup files.
- Optional but recommended:** Verify the integrity of the backup tar files.  
Ensure that the tar files are not corrupt. For example, on Linux:

```
tar -tzf <backup_file>
```

- Optional but recommended:** Determine whether your environment has sufficient space to perform the restore. You need enough free space such that the size of the backup file, when multiplied by four, does not exceed 85% of the available free space.  
For example, on Linux, you can use the following steps:

- Exec a bash terminal on the Cassandra pod:

```
kubectl exec -it <Cassandra-pod> --bash
```

- Paste the following script to calculate space available for restore:

```
# current available space
avail=$(df /var/db/ | awk 'NR==2{print $4}')

#space occupied by /var/db/data/
db_data=$(du -s /var/db/data/ | awk '{print$1}')

# Estimated available space after cleanup (avail + db_data) and a buffer of 15%
total_space_avail=$((($avail + $db_data) * 1024) * 85 / 100)
echo $total_space_avail
```

The value obtained in the above script is in bytes and must be calculated for every pod, and compared against  $4x$  the value, where  $x$  is the backup tar size of the corresponding backup file.

Each backup file is in format `<backup-id>-<ordinal-of-cassandra pod>-<number-of-cassandra-pods in cluster>.tar.gz`

In the example script above, if the backup tar size of `<backup-id>-0-3.tar.gz` is `15*1024*1024` bytes, the value for `$total_space_avail` in Cassandra `cc-0` pod must be around `60*1024*1024` bytes.

If free space is insufficient, create additional free space before starting the restore.

- Restore the management database by entering:

```
apicup subsys exec <MANAGEMENT_SUBSYS_NAME> restore <backupID>
```

The `restore` command will restore all backups from files with the same backupID. You must have the same number of management database (Cassandra) pods running as the number of backup files that match the backupID.

- Verify that the restore process completed successfully.

Ensure that the restore job is marked as completed. Note, however, that it is possible for the restore job to be marked complete, but the Cassandra restore is not complete.

The best way to ensure that the Cassandra restore is complete is to review the `CassandraRestoreStatus` field in the `CassandraClusters` Custom Resource. When the `CassandraRestoreStatus` is `completed`, the Cassandra database is successfully restored.

Example command flow to verify the restore:

- Examine the restore job and pod:

```
# kubectl get jobs | grep restore
restore-plnfs 0/1 71s 71s
```

```
# kubectl get pods | grep restore
restore-plnfs-hr2rh 0/2 Init:0/2 0 54s
```

- Since the status of the restore pod is in `Init:0/2`, the first init container (Container `restore`) is being executed. In this case, watch the `ClusterRestoreStatus` inside `CassandraCluster` (cc) Custom Resource to see the current status of the Cassandra restore process.

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: Running Retrieve checks on backup file 1583268283534609276-1-3.tar.gz for pod rdd94fb4a21-
apiconnect-cc-1
```

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: Running Retrieve checks on backup file 1583268283534609276-2-3.tar.gz for pod rdd94fb4a21-
apiconnect-cc-2
```

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: Restore prelim checks passed for rdd94fb4a21-apiconnect-cc-2
```

- When the restore process is complete, examine the restore pod and job status. Make sure `ClusterRestoreStatus` is marked as `completed`.

```
kubectl get jobs | grep restore
restore-plnfs 1/1 10m 7h17m
```

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: completed
```

If you encounter errors, see [Troubleshooting restoration of management database](#).

- Version 2018.4.1.9 iFix1.0 and later:** After completion of the restore, verify that all tasks are running. Complete the following steps:

- Download the `apicops` utility from <https://github.com/ibm-apiconnect/apicops/releases>.

- Run the following command to remove any pending tasks:

```
$ apicops task-queue:fix-stuck-tasks
```

- Run the following command to verify that the returned list (task queue) is empty.

```
$ apicops task-queue:list-stuck-tasks
```

- [Troubleshooting restoration of management database](#)

You can troubleshoot problems with restoring the management database.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Troubleshooting restoration of management database

You can troubleshoot problems with restoring the management database.

Review the information on this page to understand the steps you can take to troubleshoot a failed restore. Be sure to first read the [Overview of restore process for management database](#) to understand the logging and error reporting.

Note that for Version 2018.4.1.10 there is a known limitation with error reporting. See [Known limitation: failed restores not reporting properly](#).

- [Overview of restore process for management database](#)
- [Error: invalid backup host credentials](#)
- [Error: insufficient disk space](#)
- [Error: failure on preliminary backup checks on cc-1 and cc-2](#)
- [Known limitation: failed restores not reporting properly](#)
- [Frequently asked questions](#)

If you cannot resolve a failed restore, contact IBM Support for assistance.

## Overview of restore process for management database

The API Connect restore process is started by the command `apicup subsys exec <management_subsys> restore <backupID>`. The apicup installer starts a Kubernetes job named `restore-<id>`, which in turn starts a pod named `restore-<job-id>-<pod-id>`.

API Connect restore process

The management restoration pod consists of:

- `cassandra-restore` -- The main responsibility of this init container is to perform the Cassandra database restore. If this container encounters an error, the restoration job is Failed with pod status of `InitError (0/2)`.  
Note: For Version 2018.4.1.10 and earlier, this container is called `job-container`.
- `Cassandra-health-check` - An init container that verifies that the Cassandra health status is in a healthy state. .
- `Lur-upgrade-job` - This container checks for schema mismatches between restored data and the currently running installation. If necessary, the container performs a schema upgrade.
- `Apim-upgrade-job` - This container checks for schema mismatches between restored data and the currently running installation. If necessary, the container performs a schema upgrade. The container also resyncs all the gateway services.

The init containers start sequentially. The second init container starts only once the first init container has succeeded. Containers inside the pod start immediately after all the init containers in the pod are started. For more info, see the Kubernetes documentation: [Understanding pod status](#)

Cassandra restore process

The Cassandra restore process is performed by the init container `cassandra-restore`. Backups are required from each Cassandra pod. The container process flow is:

1. Perform preliminary retrieval checks.
2. Download the backup tar file onto the Cassandra container.
3. Verify the backup tar file integrity.
4. Stop the Cassandra process.
5. Perform the Cassandra restore.
6. Start the Cassandra process with restored data.

If any of the preliminary checks fail, error messages are returned. The error conditions must be fixed, and then the restore process can be run again.

Note that API Connect Version 2018.4.1.10 (and later) performs extensive preliminary checks prior to beginning a restore. Running the checks extends the time required to complete a restore. In particular, restoration of large backup files (larger than 5 GB) take longer.

Logging

Both init container and container logs are available during the restore process. To obtain logs from a restore pod:

```
kubectl logs <restore-pod> -n <namespace> -c <init container/container name>
```

The `apicup` command produces logs from all init and main containers sequentially as soon they finish, either successfully or with errors.

Cassandra restore logging

The logs for the init container are updated only upon completion (success or failure). To get accurate status information for the current state of the Cassandra restore process, review the `ClusterRestoreStatus` field in the `CassandraClusters` Custom Resource:

```
kubectl get cc -n <namespace> -o yaml | grep -A 2 ClusterRestoreStatus
```

## Error: invalid backup host credentials

Example output when this problem occurs:

```
./apicup subsys exec mgmt restore 158326828353460927

Cluster          Namespace      Backup Name      Backup Retrieval Timeout(hrs)  Status
rdd94fb4a21-apiconnect-cc  niharns1      1583268283534609276  24                               Started

Restore failed
Error: rpc error: code = Unknown desc =

**** [ Wed Mar  4 04:04:25 UTC 2020 ]prelimRetrieve 0: Preliminary Retrieve checks          FAILED ****
[ Wed Mar  4 04:04:25 UTC 2020 ] Preliminary retrieve checks failed on all 1 attempts.      ABORTING restore

Error: unable to get log stream for container cassandra-health-status, pod restore-hhrsc
-2slbm, job restore-hhrsc: container "cassandra-health-status" in pod "restore-hhrsc
-2slbm" is waiting to start: PodInitializing
```

ClusterRestoreStatus in Cassandra Clusters CR:

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: 'Restore Failed: Retrieve preliminary checks failed for rdd94fb4a21-apiconnect-cc-0'

kubectl get pods | grep restore
restore-hhrsc-2slbm          0/2    Init:Error  0          26m

kubectl get jobs | grep restore
restore-hhrsc                0/1          27m        27m
```

## Error: insufficient disk space

**Issue:** cc-0 prelim checks can reject restore process complaining about insufficient disk space.

**Workaround:** Increase the disk space (4X size of Cassandra backup tar file size) allocated to all Cassandra nodes on a fresh install and re-attempt restore. See [Freespace check](#).

## Error: failure on preliminary backup checks on cc-1 and cc-2

**Issue:** Failure on preliminary backup checks on cc-1 and cc-2 can leave the system in non-ready state

**Workaround:**

1. Always look at `ClusterRestoreStatus` in `CassandraClusters` Custom Resource for failed or completed Cassandra restore status, regardless of restore job status. In this case, the restore job is stuck on health status check, and Cassandra cc-0 will be in a non-ready state.
2. Execute the following command on each Cassandra pod sequentially starting with cc-0. Wait for the Cassandra pod to become ready (1/1) before executing on other Cassandra pods. If the Cassandra pod is already in ready state (1/1), you do not need to wait, just run the command.

```
kubect1 exec -it <cassandra-pod-X> -n <namespace>
-- sh -c 'rm -rf /var/db/.restore && rm -rf /var/db/restore/*'
```

In the above command the X in `<cassandra-pod-X>` stands for the numerical value (ordinal) of the Cassandra pod, such as (0,1,2).

3. Review the Cassandra operator logs to figure out why restore has failed and fix the problem.  
To see an example of this type of failure, review [Example 2: Corrupted backup tar file cc-1 not reporting properly](#).

## Known limitation: failed restores not reporting properly

**Issue:** Failure on preliminary backup checks on cc-0, such as a corrupt tar file or incomplete download of a backup tar file, can cause the restore job to complete, but the underlying `ClusterRestoreStatus` is marked as `Restore Failed`: `<Reason>`.

**Workaround:** Always check `ClusterRestoreStatus` in the `CassandraClusters` custom resource for failed or completed Cassandra restore status, regardless of restore job status. Consult the Cassandra operator logs to figure out why restore failed, and fix the problem.

See:

- [Example 1: Corrupted backup tar file cc-0 not reporting properly](#)
- [Example 2: Corrupted backup tar file cc-1 not reporting properly](#)

Example 1: Corrupted backup tar file cc-0 not reporting properly

In this example, restoration was started with `apicup`:

```
./apicup subsys exec restore 1583268283534609276
```

1. View the initial status of restore job and restore pod:

```
kubect1 get jobs | grep restore
restore-xs85r                0/1          38s          38s

kn get pods | grep restore
restore-xs85r-st554          0/2          Init:1/2     0            92s
```

2. Note that the restore completes, according to the job and pod status:

```
kubect1 get pods | grep restore
restore-xs85r-st554          0/2          Completed    0            3m43s

kubect1 get jobs | grep restore
restore-xs85r                1/1          2m51s        4m1s
```

3. Observe, however, that the `apicup` restore command output includes the following failure status:

```
./apicup subsys exec mgmt restore 1583268283534609276
Cluster      Namespace   Backup Name      Backup Retrieval Timeout(hrs)  Status
rdd94fb4a21-apiconnect-cc  niharns1     1583268283534609276  24                               Started

Cluster      Namespace   Backup Name      Status
rdd94fb4a21-apiconnect-cc  niharns1     1583268283534609276  Restore Failed: Backup retrieve checks failed
```

4. Check the value of `ClusterRestoreStatus` in the Custom Resource. Note that `ClusterRestoreStatus` is marked as `Restore Failed`.

```
kubect1 get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: 'Restore Failed: Backup retrieve checks failed'
```

5. Check the Cassandra operator pod logs and see errors:

```
time="2020-03-04T04:30:33Z" level=error msg="Restore Failed: Backup retrieve checks failed with an error: \n
Pod name: rdd94fb4a21-apiconnect-cc-0\n
Error: \n
gzip: stdin: not in gzip format\n
tar: Child returned status 1\n
tar: Error is not recoverable: exiting now\n
retrieveCheck 0: RetrieveCheck of backup file 1583268283534609276-0-3.tar.gz FAILED\n
**** [ Wed Mar  4 04:30:32 UTC 2020 ] retrieveCheck 0: Retrieve process END ****\n\n"
time="2020-03-04T04:30:33Z" level=info msg="Updating status to Restore Failed: Backup retrieve checks failed"
```

**Explanation:** Even though restore job says it completed, Cassandra restore never completed due to corrupt backup tar file. The restore job believes it reached completion, but in this case the error logging is incorrect. Therefore, you must check `ClusterRestoreStatus` in `CassandraCluster` Custom Resource to see if restore really completed. Note that `CassandraClusterRestore` status does not state exactly why restore failed, hence you must look at the Cassandra operator pod logs.

Table 1. Limitation with error reporting when Cassandra tar file for cc-0 is corrupted

Expected flow	Actual flow
1. Cassandra operator detects that cc-0 backup is corrupt	1. Cassandra operator detects that cc-0 backup is corrupt
2. Operator updates <code>ClusterRestoreStatus</code> as <code>Restore Failed</code>	2. Operator updates <code>ClusterRestoreStatus</code> as <code>Restore Failed</code>
3. Operator passes an error message back to restore init container (cassandra-restore).	3. Operator <i>does not</i> pass an error message back to restore init container (cassandra-restore)
4. <code>apicup</code> restore command line should exit with an error message on why restore init container (cassandra-restore) failed. Restore pod status should be <code>Init:Error</code> .	4. Restore pod moves forward and executes other init container and upgrade containers.
5. Restore job is marked as Failed	5. Restore pod is marked as completed

6. **Workaround:** The Cassandra cluster remains up and running as restore process failed internally, so you must review the Cassandra operator logs to figure out why exactly Cassandra restore failed. In this case, Cassandra restore failed due to corrupt backup tar file. Locate and use a non-corrupted Cassandra backup.

Example 2: Corrupted backup tar file cc-1 not reporting properly

In this example, restoration was started with `apicup`:

```
./apicup subsys exec restore 1583268283534609276
```

1. View the initial status of restore job and restore pod

```
kubectl get jobs | grep restore
restore-v7nvt 0/1 81s 81s

kubectl get pods | grep restore
restore-v7nvt-2jdzq 0/2 Init:0/2 0 101s
```

2. Continue to view pods, and observe that the restore pod is stuck.

The restore pod first init container (cassandra-restore), which performs the Cassandra restore, is marked as complete. The second init container is stuck waiting for the Cassandra cluster to become healthy.

```
kn get pods | grep restore
restore-v7nvt-2jdzq 0/2 Init:1/2 0 4m8s
```

The status `Init:1/2` means that first init container completed, but the process is waiting on second init container to finish.

3. Note that the output from the `apicup` restore command gives a status of `Restore Failed`:

```
./apicup subsys exec mgmt restore 1583268283534609276
Cluster          Namespace      Backup Name      Backup Retrieval Timeout(hrs)  Status
rdd94fb4a21-apiconnect-cc  niharns1      1583268283534609276  24                               Started

Cluster          Namespace      Backup Name      Status
rdd94fb4a21-apiconnect-cc  niharns1      1583268283534609276  Restore Failed: Backup retrieve checks failed
```

4. View the `ClusterRestoreStatus` in the Cassandra Cluster Custom Resource:

```
kn get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: 'Restore Failed: Backup retrieve checks failed'
```

5. View the Cassandra operator pod logs:

```
time="2020-03-04T05:04:18Z" level=error msg="Restore Failed: Backup retrieve checks failed with an error: \n Pod name: rdd94fb4a21-apiconnect-cc-1\n Error: \ngzip: stdin: not in gzip format\n tar: Child returned status 1\n tar: Error is not recoverable: exiting now\n retrieveCheck 0: RetrieveCheck of backup file 1583268283534609276-1-3.tar.gz FAILED\n **** [ Wed Mar 4 05:04:18 UTC 2020 ] retrieveCheck 0: Retrieve process END ****\n\n time="2020-03-04T05:04:18Z" level=info msg="Updating status to Restore Failed: Backup retrieve checks failed"
```

6. View the Cassandra pod status:

```
rdd94fb4a21-apiconnect-cc-0      0/1      Running      3      11h
rdd94fb4a21-apiconnect-cc-1      1/1      Running      2      11h
rdd94fb4a21-apiconnect-cc-2      1/1      Running      2      11h
```

**Explanation:** In this scenario, the restore process is stuck waiting for the Cassandra cluster to become healthy. Cassandra pod cc-0 is in a non-ready state. Due to a known limitation with error logging, the only way to accurately determine whether the restore is complete is to view `ClusterRestoreStatus` in `CassandraCluster` Custom Resource. Since `CassandraClusterRestore` status does not state exactly why the restore failed, you must look at Cassandra operator pod logs.

Table 2. Limitation with error reporting when corrupted Cassandra backup tar file cc-1 is corrupted

Expected flow	Actual flow
1. Cassandra operator detects that cc-1 backup is corrupt	1. Cassandra operator detects that cc-1 backup is corrupt
2. Operator updates <code>ClusterRestoreStatus</code> as <code>Restore Failed</code> .	2. Operator updates <code>ClusterRestoreStatus</code> as <code>Restore Failed</code> .
3. Operator cleans up the restore process content and makes sure that Cassandra cluster is healthy using the existing data.	3. Operator <i>does not</i> perform any cleanup and <i>does not</i> makes sure that the Cassandra cluster is in a healthy state
4. Operator passes an error message back to restore init container (cassandra-restore) to indicate that the restore has failed.	4. Operator <i>does not</i> pass an error message back to restore init container (cassandra-restore) to indicate that the restore has failed.

Expected flow	Actual flow
5. The <code>apicup</code> restore command line should exit with a proper error message on why restore init container (cassandra-restore) failed. The restore pod status should be <code>Init:Error</code> . The restore job should be marked as Failed.	5. Restore pod moves forward from the init container but becomes stuck on second init container.

7. **Workaround:**

- a. Since the Cassandra cluster is in a degraded state, and the Cassandra pod cc-0 is in a non-ready state (0/1), run the following command to bring the Cassandra cluster up and running.

```
kubect1 exec -it <cassandra-pod-X> -n <namespace> -- sh -c
'rm -rf /var/db/.restore && rm -rf /var/db/restore/*'
```

Note that you must run this command sequentially on all Cassandra pods, starting with cc-0. Make sure that the cc-x status is (1/1), before running this command on the next pod (cc-x+1).

- b. Review the Cassandra operator logs to determine why the Cassandra restore failed. In this scenario, since the Cassandra restore failed due to a corrupt backup tar file, the solution is to choose a non-corrupted Cassandra backup.

Note that this Cassandra restore issue applies not only specifically to a corrupted backup tar file, but also to any of the restore issues which may happen on Cassandra-x+1 pods (x is a numerical value starting with 0) and can leave previous Cassandra pods in a non-ready state.

## Frequently asked questions

Where can I find the status of the restore process?

See: [Cassandra restore logging](#)

In what cases can I re-run the restore process on existing installations?

The answer depends on which stage of the restore failed. If the restore process failed because of a corrupted tar file, you can re-initiate the restore process using a different backup ID.

In what cases I need to redeploy a whole new cluster before re-attempting a failed restore?

If the restore failed due to space allocation problems or any other reasons except corrupted backup tar, a complete new installation is needed. You must fix the problem reported by the restore process.

What action to take if I get the error message: Not enough space to download the tar file?

You must re-install the management subsystem, allocating sufficient disk space. Please look at system requirements section for recommended disk sizes.

What if the downloaded backup tar file is corrupted?

Use a different backup. Run backup tar integrity checks prior to attempting the restore.

If the backup tar integrity succeeds in your local system but restore process is failing, gather the required logs and contact IBM Support.

What if there is not enough space to perform restore using the downloaded backup tar file?

You must re-install the management subsystem, allocating sufficient disk space. See [Error: insufficient disk space](#).

What if the restore job finishes but I still don't see any restored data?

See [Known limitation: failed restores not reporting properly](#).

What if the restore process remains stuck on the health check status for a very long time?

This might be due to a known limitation. See [Example 2: Corrupted backup tar file cc-1 not reporting properly](#).

What if the restore process fails on Lur-upgrade-job and Apim-upgrade-job containers?

Run the restore process again. If the error persists, contact IBM Support.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Backing up and restoring the Developer Portal in a Kubernetes environment

How to backup and restore your Developer Portal service in your Kubernetes environment.

### About this task

It is strongly recommended that you configure the backup parameters for your portal service during installation. If you did not do so when you installed API Connect in your runtime environment, you must configure the backups for the Developer Portal before performing an upgrade. These backups can then be used to restore the Developer Portal if required. When your Developer Portal subsystem is running, you can also make on-demand backups by using the command line.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

These instructions cover the following backup and restore actions:

- [How to configure the location and timing of your backups](#)
- [How to run on-demand backups](#)
- [How to restore a Developer Portal service](#)

Note:

- The backup and restore procedures are the same for both Kubernetes and VMware environments.
- You must back up both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

- When restoring, the Gateway and all deployed subsystems (Management, Analytics, and Developer Portal) must be at the same version level.
- The backup secret is a Kubernetes secret that contains your username and password for your backup database (sftp/s3). Only password-based authentication is supported for sftp and s3, not authentication based on public certificates and private keys. Password-based authentication for s3 requires that you generate an access key and secret. For example:
  - IBM (Cloud Object Storage): [Service credentials](#).
  - AWS: [Managing access keys](#).

## Procedure

- How to configure the location and timing of your backups
  1. Open your API Connect installation project directory.
  2. Run the following commands to set the location and timing of your backups:

```
apicup subsys set pt1 site-backup-host mybackuphost.com
apicup subsys set pt1 site-backup-port 22
apicup subsys set pt1 site-backup-auth-user mybackupauthusername
apicup subsys set pt1 site-backup-auth-pass mybackupauthpassword
apicup subsys set pt1 site-backup-path /site-backups
apicup subsys set pt1 site-backup-protocol sftp
apicup subsys set pt1 site-backup-schedule "0 2 * * *"
```

The backup parameters are detailed in the following table.

Table 1. Portal backup parameters

Parameter	Description
<code>site-backup-host</code>	The fully qualified domain name of the backup server, in lowercase only. Ensure that the Kubernetes nodes can access this host. If using object storage, enter <i>Endpoint/Region</i> . (The / character between the endpoint and region is required for the object storage setting.)
<code>site-backup-port</code>	The port for the protocol to connect to the <code>site-backup-host</code> . Defaults to 22 if not explicitly set. The backup port is not required for object storage.
<code>site-backup-auth-user</code>	The user name for the server specified in <code>site-backup-host</code> . If using object storage, the user name is the S3 Secret Key ID.
<code>site-backup-auth-pass</code>	The password for the server specified in <code>site-backup-host</code> . If using object storage, the password is the S3 Secret Access Key parameter. The password is stored in Base64 encoded format, and must not be edited directly in the <code>apiconnect-up.yml</code> file.
<code>site-backup-path</code>	The full path to the directory where the backup files are stored. For object storage, the path can be set to the <i>bucket</i> value or the <i>bucket/subfolder</i> value.
<code>site-backup-protocol</code>	The protocol that is used to communicate with your remote backup endpoint. Specify one of the following values: <ul style="list-style-type: none"> <li>• <code>sftp</code> - for secure file transfer protocol</li> <li>• <code>objstore</code> - for S3 compatible object storage</li> </ul> The default protocol is <code>sftp</code> . Note: The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: <code>x509: certificate signed by unknown authority</code> .
<code>site-backup-schedule</code>	The schedule for how often automatic Portal backups are run. The format for the schedule is any valid cron string, as follows: <pre>* * * * * - - - - -                   +----- day of week (0 - 6) (Sunday=0)       +----- month (1 - 12)     +----- day of month (1 - 31)   +----- hour (0 - 23) +----- min (0 - 59)</pre> For example: <code>30 22 * * 1</code> performs backups at 10:30 pm on Mondays. The default backup schedule is <code>0 2 * * *</code> (runs every day at 2 am). The timezone for backups is UTC.

3. Optional: At any time you can view the current Portal subsystem values by running the following command:

```
apicup subsys get pt1
```

where `pt1` is the name that you assigned to your Portal service. The output from this command lists all of the subsystem settings, including backup, and indicates whether there are any errors. You must fix any errors before continuing.

4. Validate the installation with the new backup parameters by running the following command:

```
apicup subsys get pt1 --validate
```

where `pt1` is the name that you assigned to your Portal service. The output from this command lists all of the subsystem settings, including backup, and indicates whether the values are valid or invalid. You must correct any invalid values before continuing.

5. Activate the backup settings by running the following command:

```
apicup subsys install pt1
```

where `pt1` is the name that you assigned to your Portal service.

- How to run on-demand backups

You can make on-demand backups of your Developer Portal system, sites, and complete service, by running the following `exec` commands in your API Connect installation project directory.

- To backup the Portal system configuration (and not the sites), run the following command:

```
apicup subsys exec pt1 backup-system
```

- To backup a specific Portal site or all sites, run the following command:

```
apicup subsys exec pt1 backup-site arg
```

where `arg` is a specific site UUID or URL, or to backup all sites use the argument `installed`.

- To backup the entire Portal service (the system and all installed sites), run the following command:

```
apicup subsys exec pt1 backup
```

Where `pt1` is the name that you assigned to your Portal service.

Note: To restore a Developer Portal service, you need backups of both the Portal system and the installed sites.

- How to restore a Developer Portal service

You can restore your Developer Portal service by using the backups that exist on your remote server, by running the following `exec` commands in your API Connect installation project directory. Note that before you can run these commands, you must have configured your remote backup server details, and have valid backups of both the Portal system and the installed sites (see sections [How to configure the location and timing of your backups](#) and [How to run on-demand backups](#)).

Note:

- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- Restoration requires a functioning Developer Portal. In a disaster recovery scenario, you might need to reinstall the Developer Portal subsystem before you can restore the backed-up data. To reinstall, refer to [Installing the Developer Portal subsystem into a Kubernetes environment](#).
- To see what Portal system and site backups that you currently have on your remote backup server, run the following command. (This command may be useful when performing some of the following commands.)

```
apicup subsys exec pt1 list-backups remote
```

- To see what restore actions are performed when the `apicup subsys exec pt1 restore-all` command is run, you can use the following command:

```
apicup subsys exec pt1 restore-all dry backup_from
```

where `backup_from` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given.

Note: From IBM® API Connect Version 2018.4.1.17, the timestamp format changed to `YYYYMMDD.HHMMSS`. For Version 2018.4.1.16 and earlier, the timestamp format is `YYYY-MM-DD`

`HH:MM:SS`.

- To restore your Portal service, run the following command:

```
apicup subsys exec pt1 restore-all run backup_from
```

where `backup_from` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given. This command executes the portal restore process, which downloads the system backup and all of the site backups from the remote server, and installs them within the Portal stack. This process will then restore the system configuration from the found backup, and restore all of the sites.

Note: Note that if a backed up site is already installed on the current stack, then the site is reinstalled by using the backup (the site is overwritten by the backup).

If there are multiple sites to restore, then these sites are queued for restoring. You can track the restoration process within the Portal `www admin` logs.

- To view the list of installed and restoring sites, run the following command:

```
apicup subsys exec pt1 list-sites sites
```

Note that any sites that are pending restore and still in the queue do not appear in this list.

- To restore just the Portal system configuration, run the following command:

```
apicup subsys exec pt1 restore-system arg
```

where `arg` can be the system backup `tgz` file name, to restore the system by using the specified backup file, or use the argument `latest` to restore the system by using the latest backup file on the remote server. Note that if Portal system configuration information exists on the current stack, running this command will overwrite that configuration.

- To restore just the Portal sites, run the following command:

```
apicup subsys exec pt1 restore-site arg
```

where `arg` can be the site backup `tgz` file name or URL, to restore a particular site by using the specified backup file (or the latest backup file found if using a URL). Or you can use the argument `all` to restore all of the Portal sites that have backup files on the remote server. Note that if any of the backed up sites are already installed on the current stack, then they are reinstalled by using the backup (the sites are overwritten by the backup).

## What to do next

---

For a full list of the Developer Portal `exec` commands, see [List of the Developer Portal exec commands](#).

- [List of the Developer Portal exec commands](#)

You can use the `exec` commands to backup, restore, and list some of the environment details of your Developer Portal service.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## List of the Developer Portal `exec` commands

You can use the `exec` commands to backup, restore, and list some of the environment details of your Developer Portal service.

The following Developer Portal `exec` commands can be run in your API Connect installation project directory, where `pt1` is the name of your Portal service.

Tip: Running `exec` commands leaves completed jobs and pods on your subsystem. Therefore, it is recommended that you regularly delete those jobs and pods that have completed successfully, and whose logs are not required.

```

$ apicup subsys exec ptl backup-system
Backup the portal system to the remote server

$ apicup subsys exec ptl backup-site <arg>
Backup a portal site to the remote server.
valid args:
  site uuid/url - will backup that site only to the remote server
  installed    - will backup all installed sites to the remote server

$ apicup subsys exec ptl backup
Backup the portal system and all its sites to the remote server

$ apicup subsys exec ptl list-backups <arg>
List the portal backups either locally or on the remote server.
valid args:
  local    - will list backups present on the pod's filesystem
  remote   - will list backups on the remote server

$ apicup subsys exec ptl list-platforms
List the platforms that exist on the portal

$ apicup subsys exec ptl list-sites <arg>
List the installed portal sites
valid args:
  sites      - list only the sites
  platforms  - list the sites and their associated platform

$ apicup subsys exec ptl restore-system <arg>
Restore the portal system from the remote server
valid args:
  system backup-1234.tgz - restores the system from the given file which should exist on the pod's local filesystem or
the remote server
  latest                 - restores from latest system backup found from either local filesystem or remote server

$ apicup subsys exec ptl restore-site <arg>
Restore a portal site
valid args:
  site-1234.tgz - restore the site using this filename which should can be copied from the output of the list backups
command
  myportal.com  - find the latest backup for this URL (locally or remotely) and restore it.
  all           - restore all sites found on the remote server
NOTES:
If you specify a site TGZ / URL, the command runs restore_site with -f so overwrites any existing site
If you specify 'all', any installed sites will be reinstalled from the found backup

$ apicup subsys exec ptl restore-all <arg1> <arg2>
Restore the portal system and all backed up sites from the remote server
valid arg1:
  dry - executes a dry-run of the command, returning the actions that will be performed
  run - executes the command, restoring and replacing the system files and all sites. Any existing sites will be
reinstalled
valid arg2:
  now - use the latest backups available
  <TIMESTAMP> - in 'YYYYMMDD.HHMMSS' format, specify a timestamp to retrieve the backup from. The nearest backup,
searching backwards from this timestamp, will be used.

Note: IBM API Connect 2018.x was EOS after 30 April 2023. See support policy for details.
For a more recent version, see the IBM API Connect 10.0.5.x and later product documentation.

```

---

## Backing up and restoring the analytics database

The analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required, for example, IBM Cloud Object Storage.

### Before you begin

If you configure Analytics for offloading and your endpoint requires a particular certificate, add trust certificates to the Analytics subsystem before attempting to back up or restore the Analytics database. For information on adding certificates to Analytics for back-up and restore, see [Adding certificates for Analytics for back-up and restore](#).

Tip: The [Procedure](#) section includes examples that illustrate how the back-up and restore commands work.

### About this task

These commands apply to OVA, pure Kubernetes, and IBM Cloud Private (ICP) deployments. To back up and restore the analytics database, you will need S3 compatible object storage. Backups are created on an as-needed basis and cannot be automated in API Connect.

Important: All arguments are required. Replace an argument with empty quotes ("") to use the default setting.

Command	Values/Definition
---------	-------------------

Command	Values/Definition
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; create-s3-repo</pre>	<p>Create the S3 repository to store analytics backups. These settings are identical to those used when creating a repository in Elasticsearch. The arguments are:</p> <ul style="list-style-type: none"> <li>• REPO_NAME - Name of repository to be created.</li> <li>• REGION - The region where bucket is located. Defaults to US Standard.</li> <li>• BUCKET - The name of the bucket to be used for snapshots. Note: Analytics backup and restore supports virtual-host style bucket access, such as <code>bucket.s3-example.com</code>, but does not support path style bucket access such as <code>s3-example.com/bucket</code>.</li> <li>• ENDPOINT - The endpoint to the S3 API.</li> <li>• ACCESS_KEY - The access key to use for authentication.</li> <li>• SECRET_KEY - The secret key to use for authentication.</li> <li>• BASEPATH - The path name within the bucket where backup information is stored. The default is the root path. For S3 storage, you must include the port using the following format: <code>BASEPATH:PORT</code>.</li> <li>• COMPRESS_TRUE_FALSE - Default is true. Determines whether metadata files are stored in compressed format.</li> <li>• CHUNK_SIZE_GB - Default is 1GB. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB.</li> <li>• SERVER_SIDE_ENCRYPTION_TRUE_FALSE - Default is false. Determines whether files are encrypted. When set to true, files are encrypted on the server side using AES256.</li> </ul> <p>If the <code>create-s3-repo</code> command results in the following error, complete the steps in <a href="#">Adding certificates for Analytics for back-up and restore</a> to add the certificate to the Analytics subsystem and then run the command again:</p> <pre>PKIX path building failed: sun.security.provider.certpath.SunCertPathBuilderException: unable to find valid certification path to requested target</pre>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; list-repos</pre>	<p>List repositories for analytics backups. There are no arguments or defaults for the <code>list-repos</code> command.</p>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; delete-repo</pre>	<p>Delete specified analytics backup repository. The argument is:</p> <ul style="list-style-type: none"> <li>• REPO_NAME - Defaults to the existing repo if there is only one. The repository must be specified if there is more than one.</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li>• If only one repo exists: <code>apicup subsys exec &lt;ANALYTICS_SUBSYS&gt; delete-repo ""</code></li> <li>• If multiple repos exist: <code>apicup subsys exec &lt;ANALYTICS_SUBSYS&gt; delete-repo REPO_NAME</code></li> </ul>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; backup</pre>	<p>Perform a backup of analytics data on an as-needed basis.</p> <ul style="list-style-type: none"> <li>• INDICES - Default is <code>all</code> - All indices will be backed up. The INDICES arguments can consist of a series of index names, a single argument of comma-separated indices, or one or more keywords. Multiple keywords must be comma-separated. Values with whitespace must be enclosed in double-quotes. If no indices are specified, then all indices will be backed up. The keywords are mapped to indices or aliases in Elasticsearch. The keywords are as follows: <ul style="list-style-type: none"> <li>◦ <code>all</code> - Backup all data.</li> <li>◦ <code>apievents</code> - Backup all analytics data.</li> <li>◦ <code>ui</code> - Backup all UI visualizations and dashboards.</li> <li>◦ <code>config</code> - Backup all configuration information, such as retention period.</li> </ul> </li> <li>• BACKUP_NAME - Enter the name of the backup.</li> <li>• REPO_NAME - Defaults to the existing repo if there is only one. The repository must be specified if there is more than one.</li> <li>• IGNORE_UNAVAILABLE_TRUE_FALSE - Default is false. If false, the restore will fail if an index is missing. If true, missing indices will be skipped and the restore will continue.</li> </ul>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; list-backups</pre>	<p>List analytics backups per S3 repo. The argument is:</p> <ul style="list-style-type: none"> <li>• REPO_NAME - Defaults to the existing repo if there is only one. The repository must be specified if there is more than one.</li> </ul>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; details-backup</pre>	<p>Get details on specified analytics backup The arguments are:</p> <ul style="list-style-type: none"> <li>• BACKUP_NAME - Defaults to <code>backup-&lt;indices&gt;-&lt;time date&gt;</code> if not explicitly set. The name must be all lowercase. For example, if the backup command was run as <code>apicup subsys exec &lt;ANALYTICS_SUBSYS&gt; backup ui apievents</code> then the backup name would be <code>backup-ui-apievents-2018-10-10t16:04:25z</code>. If more than three indices are specified, the backup name is truncated to <code>backup-&lt;time date&gt;</code>.</li> <li>• REPO_NAME - Sets the name of the repository where the backups will be stored. Defaults to the existing repository if there is only one. The repository must be specified if there is more than one.</li> </ul>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; delete-backup</pre>	<p>Delete specified analytics backup The arguments are:</p> <ul style="list-style-type: none"> <li>• BACKUP_NAME - Enter the name of the backup to be deleted. You can view the names of backups using <code>apicup subsys exec &lt;ANALYTICS_SUBSYS&gt; list-backups</code>.</li> <li>• REPO_NAME - Defaults to the existing repository if there is only one. The repository must be specified if there is more than one.</li> </ul>

Command	Values/Definition
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; restore</pre>	<p>Restore analytics data</p> <ul style="list-style-type: none"> <li>INDICES - Default is <code>all</code> - All indices will be restored. The INDICES arguments can consist of a series of index names, a single argument of comma-separated indices, or one or more keywords. Multiple keywords must be comma-separated. Values with whitespace must be enclosed in double-quotes. If no indices are specified, then all indices will be backed up. The keywords are mapped to indices or aliases in Elasticsearch. The keywords are as follows: <ul style="list-style-type: none"> <li><code>all</code> - Restore all data.</li> <li><code>apievents</code> - Restore all analytics data.</li> <li><code>ui</code> - Restore all UI visualizations and dashboards.</li> <li><code>config</code> - Restore all configuration information, such as retention period.</li> </ul> </li> <li>BACKUP_NAME - Enter the name of the backup to be restored.</li> <li>REPO_NAME - Defaults to the existing repository if there is only one. The repository must be specified if there is more than one.</li> <li>IGNORE_UNAVAILABLE_TRUE_FALSE - Default is false. If false, the restore will fail if an index is missing. If true, missing indices will be skipped and the restore will continue.</li> <li>OVERRIDE_TRUE_FALSE - Default is false. If set to true, then the restore operation will override existing indices.</li> </ul>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; restore-status</pre>	<p>Displays analytics status for determining the progress of the restore process. Note: The <code>restore-status</code> command is available in Version 2018.4.1.7 or later.</p>

Attention: Naming conventions for indices and back ups follow the Elasticsearch rules:

- Lowercase only
- Cannot include \, /, \*, ?, ", <, >, |, ` (space character), ,, #
- Colons (:) are not supported in 7.0+ (indices prior to 7.0 could contain a colon)
- Cannot start with -, \_, +
- Cannot be . or ..
- 255 byte limit (multi-byte characters will reach the 255 limit sooner)

## Procedure

This section contains example commands with output. The name of the analytics subsystem in the examples is *analytics*.

- How to create a backup
  1. Create the S3 repository. The example creates a repository with the following values:
    - REPO\_NAME - myrepo
    - REGION - US
    - BUCKET - bucket
    - ENDPOINT - myrepo.s3repo.com
    - ACCESS\_KEY - access\_key
    - SECRET\_KEY - secret\_key
    - BASEPATH - my\_folder
    - COMPRESS\_TRUE\_FALSE - "" uses default of true
    - CHUNK\_SIZE\_GB - "" uses default of 1GB.
    - SERVER\_SIDE\_ENCRYPTION\_TRUE\_FALSE - "" sets to the default of false.

```
apicup subsys exec analytics create-s3-repo myrepo US bucket myrepo.s3repo.com access_key secret_key my_folder "" ""
""
OUTPUT:
Creating repository myrepo. List repos to see if creation completed, or check logs for errors.
```

Note:

With virtual host style repositories, the Analytics backup and restore process connects to the hostname formed by combining the values for `BUCKET` and `ENDPOINT`. For example, using the values given in this step, the host is `bucket.myrepo.s3repo.com`.

2. List the repositories. For example:

```
apicup subsys exec analytics list-repos
OUTPUT:
Name      Repo Type  Bucket   BasePath  Region  Endpoint                Chunk Size  Compress  Server Side
Encryption
myrepo    s3        bucket   my_folder US        myrepo.s3repo.com      1gb         true
```

3. Create a backup with the following values:
  - INDICES - all (or "" for the default of all)
  - BACKUP\_NAME - mybackup
  - REPO\_NAME - myrepo (use "" if only one repo exists)
  - IGNORE\_UNAVAILABLE\_TRUE\_FALSE - "" sets to the default of false.

```
apicup subsys exec analytics backup all mybackup myrepo ""
OUTPUT:
Successfully created backup mybackup.
```

4. List backups in the repo named *myrepo*.

```
apicup subsys exec analytics list-backups myrepo
OUTPUT:
Name      Start Time                End Time                State
mybackup  2019-02-20T17:05:56.415Z  2019-02-20T17:06:09.833Z  SUCCESS
```

5. Display details for a backup named *mybackup* in the repo named *myrepo*.

```
apicup subsys exec analytics details-backup mybackup myrepo
OUTPUT:
Backup Name: mybackup
State: SUCCESS
Failures:
Shards Failed: 0
Shards Successful: 13
Start Time: 2019-02-20T17:05:56.415Z
End Time: 2019-02-20T17:06:09.833Z
Version: 5.6.8
Indices: .export-status, apic-api-2019.02.19-1, apic-api-2019.02.20-000002, .apic-config, .kibana-6
```

6. Delete a backup named *mybackup* in the repo named *myrepo*.

```
apicup subsys exec analytics delete-backup mybackup myrepo
OUTPUT:
Deleting backup mybackup. List backups to see the status, or check logs for errors.
```

- How to restore a backup

Note: Restoration requires a functioning Analytics subsystem. In a disaster recovery scenario, you might need to install the Analytics subsystem before you can restore the backed-up data. To install, refer to [Installing the Analytics subsystem into a Kubernetes environment](#).

1. Restoring a backup

- INDICES - all (or "")
- BACKUP\_NAME - mybackup
- REPO\_NAME - myrepo (or "")
- IGNORE\_UNAVAILABLE\_TRUE\_FALSE - "" sets to the default of false.
- OVERRIDE\_TRUE\_FALSE - true

```
apicup subsys exec analytics restore all mybackup myrepo "" true
```

2. Check the status of the restore process. Enter the following command:

```
apicup subsys exec analytics restore-status
```

Note: The `restore-status` command is available in Version 2018.4.1.7 and later.

Following is example output:

Status	Active Primary Shards	Active Shards	Initializing Shards	Unassigned Shards
green	104	312	0	0

The restore process is successful when the status is green and there are no unassigned shards and no initializing shards. Note that the results are different if you are running in dev mode, or in standard mode with less than three nodes. For dev mode or standard mode with less than three nodes, the restore process will be finished when the initializing shards drops to 0. However, the status will remain yellow and unassigned shards will not drop to 0.

- Troubleshooting

Look for information in the `apicup` logs:

- Locate the analytics-operator pod with: `kubectl get pods`
- To view the logs, run: `kubectl logs <analytics-operator-pod>`

- [Adding certificates for Analytics for back-up and restore](#)

If you offload IBM API Connect Analytics data to an endpoint that is secured with a self-signed or private certificate, add the certificate to the Analytics subsystem to ensure connectivity with the endpoint during back-up and restore operations.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Adding certificates for Analytics for back-up and restore

If you offload IBM® API Connect Analytics data to an endpoint that is secured with a self-signed or private certificate, add the certificate to the Analytics subsystem to ensure connectivity with the endpoint during back-up and restore operations.

### About this task

If you connect to an endpoint without using the required self-signed or private certificate, the `create-s3-repo` command results in the following error:

```
PKIX path building failed: sun.security.provider.certpath.SunCertPathBuilderException: unable to find valid certification path to requested target
```

Resolve the error by adding the endpoint's certificate to the Analytics subsystem as explained in the following steps.

### Procedure

1. Obtain trust certificates that allow a client to connect securely to the offload endpoint.  
The certificate files should be PEM encoded. There will typically be one or two trust certificates required to complete the secure connection.
2. Create a separate file for each of the trust certificates, naming them cert1.pem and cert2.pem.
3. Verify that you can connect to the endpoint:
  - a. If you have multiple files, combine the certificates into a single file to use for validation by running the following command:

```
cat cert1.pem cert2.pem > certificates.pem
```

- b. Execute the following cURL command to connect to the endpoint using the certificates:

```
curl https://endpoint:port --cacert certificates.pem
```

A certificate verification failure indicates that the certificates obtained in step 1 failed to establish trust. Return to step 1 and try again. You cannot proceed to step 4 until the certificates are successfully verified.

- c. When the certificate verification is successful, proceed to step 4.
4. Create a Kubernetes secret to contain the certificates, and then apply it to the cluster where the Analytics subsystem runs.
- a. Log in to a server that has kubectl access to the Kubernetes cluster where API Connect Analytics is deployed.  
For OVA deployments, you must log in to one of the running Analytics VMs as a user with kubectl access.

- b. Encode each of the certificate files from step 2 in base64.

There are several ways to encode the file. If `cat` and `base64` are available, then you can run the following command to encode each file:

```
cat cert1.pem | base64 -w 0
```

Copy the output for each `cat` command so that you can paste it in the next step.

- c. Create a Kubernetes secret and add the certificate.

- i. Create a YAML file to contain the secret.

```
apiVersion: v1
kind: Secret
metadata:
  # Change value of name to be whatever you want the secret to be called
  name: analytics-br-cert
data:
  cert1.pem: output of base64 encoded cert1.pem
  cert2.pem: output of base64 encoded cert2.pem if required
```

- ii. In the file's `data` section, create a field for each certificate, and paste the corresponding encoded certificate as shown in the example. The value is a single line, so you do not need to enclose it in quotation marks.

- iii. Save the file.

- d. Update the cluster with the new certificate.

Run the following command to update the cluster:

```
kubectl apply -f analytics-br-cert.yaml -n your_namespace
```

where:

- `analytics-br-cert.yaml` is the secret's file name.
- `your_namespace` is the name of your deployment's namespace. The namespace is only needed for Kubernetes deployments.  
For OVA deployments, you can omit the entire `-n your_namespace` parameter from the command. By default, kubectl is already configured to match the namespace where your Analytics resources are deployed.

5. Update the Analytics subsystem so that it can use the new secrets.

- a. Create an `extra-values.yaml` file that specifies the names of your certificate and environment variables secret files.

Include the following lines in the `extra-values.yaml` file, making sure to use the name of your Kubernetes secret (the value of the `name` field in the `metadata` section of the secret, which might not match the file's name):

```
apic-analytics-storage:
  backupSecretCerts: analytics-br-cert
```

- b. Update the Analytics subsystem.

- i. Log in to the server where you run `apicup`, and navigate to the project directory.  
In Kubernetes deployments this is probably the same server that you used for step 1, but for OVA deployments it is a different server.
- ii. Run the following `apicup` commands to reinstall the Analytics subsystem using the configuration settings in the `extra-values.yaml` file.

```
apicup subsys set analytics extra-values-file=~/.extra-values.yaml
apicup subsys install analytics
```

6. Verify that the certificates were added in the storage logs.

Log in to the host node and use `sudo` to run the following command:

```
kubectl logs -n namespace analytics-storage-pod
```

For OVA deployments, you can omit the namespace parameter and value.

The following confirmation message displays when the pod starts up:

```
Adding /etc/velox/backup-certs/ca-analytics-backup.pem contents to the system keystore for backup and restore.
Certificate cert1.pem was added to keystore
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Using APICUP to reconfigure

You can use APICUP to change configuration of a subsystem after completion of initial installation.

The Install Assist utility (APICUP) is used to configure and complete initial installation of all subsystems, in both Kubernetes and VMware deployments. After initial installation, you can use the same `apicup` commands to reconfigure some of the settings from your existing deployment without having to completely reinstall the subsystem.

For example, if you did not configure optional features such as backup/restore or logging during initial installation, you can configure them later.

Note: Both Kubernetes and VMware deployments include subsystem settings that cannot be reconfigured without a complete redeployment. For example, for the Management Service these settings include hosts, endpoints, interfaces (`public-iface`, `traffic-iface`), IP ranges of the Kubernetes pod and the service networks (`k8s-pod-network`, `k8s-service-network`), and backup volume size `cassandra-volume-size-gb`. Before reconfiguring, review the installation instructions for your subsystem to determine which settings are optional during initial installation and thus able to be updated later. See the section [Installing and upgrading on Kubernetes](#).

For both initial installation and reconfiguration, you specify configuration values by using `apicup subsys set` commands, and then activate them with `apicup subsys install`.

```
apicup subsys set <subsystem_name> <parameter_name>=<parameter_value>
```

```
apicup subsys install <subsystem_name>
```

For example, the following commands configure backup for the management subsystem `mgmt`, either during initial install or after initial install:

```
apicup subsys set mgmt cassandra-backup-auth-user=MyUsername cassandra-backup-auth-pass=MyPassword
apicup subsys set mgmt cassandra-backup-host=<hostname>
apicup subsys set mgmt cassandra-backup-path=</backups>
apicup subsys set mgmt cassandra-backup-port=<22>
apicup subsys set mgmt cassandra-backup-protocol=<sftp, objstore>
apicup subsys set mgmt cassandra-backup-schedule=<"0 0 * * *">
apicup subsys set mgmt cassandra-max-memory-gb=16 cassandra-cluster-size=3
apicup subsys set mgmt cassandra-volume-size-gb=<50>
apicup subsys set mgmt create-crd=<true>
apicup subsys set mgmt external-cassandra-host=<hostname>
```

```
apicup subsys install mgmt
```

On initial installation, the APICUP utility installs a Helm chart along with configuration values contained in `apiconnect-up.yml`. On subsequent invocations of `apicup subsys install`, APICUP checks to see if a saved combination of Helm chart and configuration values exists. If it does, APICUP checks to see if the configuration values have been updated, and if so, then a Helm update is triggered. If the combination of Helm chart and values is unchanged, then the subsystem is not changed. In this way, you can reconfigure as needed without having to completely redeploy and reinstall the subsystem.

- [Converting installation mode](#)  
You can switch an API Connect installation between `dev` mode and `standard` mode.
- [Increasing the memory allocation for the management database](#)  
You can increase the maximum memory allocation for the management database in a running deployment.
- [Enabling Analytics ingestion-only on Kubernetes](#)  
Enable the ingestion-only configuration by redeploying the IBM® API Connect Analytics subsystem with the `ingestion-only` configuration setting.
- [Disabling Analytics ingestion-only on Kubernetes](#)  
Disable the ingestion-only configuration by redeploying the IBM API Connect Analytics subsystem with the `ingestion-only` value set to false.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Converting installation mode

You can switch an API Connect installation between `dev` mode and `standard` mode.

### About this task

The supported installation mode options are: `dev` and `standard`. Mode is set for each subsystem type: Management, Analytics, Developer Portal, Gateway Service.

- Development mode (`dev`) deploys a subsystem with the scale of one; a single node, non-HA subsystem. The recommended use for `dev` mode is for development and testing.  
Note: While it is possible to use `dev` mode installations in a production deployment, it is not recommended. The `dev` mode does not provide the failover resiliency nor the downtime guarantee that is needed to maintain high availability (HA) production deployments.
- The `standard` mode deploys in HA mode for a production environment. The `standard` mode is supported for installation of production environments that consist of three or more nodes. The `standard` mode is not supported for less than three nodes.
- If not explicitly set, the installation mode defaults to `dev` (development). To specify `standard` mode:

```
apicup subsys set [subsys-name] mode=standard
```

Note: Prior to Version 2018.4.1.4, the default mode was `standard`.

- If you installed in `standard` mode, but have less than three nodes, you can convert to `dev` mode. You must convert each subsystem.
- If you installed in `dev` mode, you can convert to `standard` mode. You must convert each subsystem.

Complete the following steps to determine your mode and, if necessary, convert the mode:

### Procedure

1. Review the output from the command: `apicup subsys get <subsystem_name>`.

For example, `apicup subsys get mgmt:`

- VMware (OVA) environment output:

```
Appliance settings
=====
Name                               Value                               Description
----                               -
.
.
mode                               standard
.
.
```

- Kubernetes output:

```
Kubernetes settings
=====
Name                               Value                               Errors
----                               -
.
.
mode                               standard
.
.
```

2. If you need to convert the mode, following the appropriate instructions:

- [Converting dev mode to standard mode on VMware](#)
- [Converting dev mode to standard mode on Kubernetes](#)
- [Converting standard mode to dev mode on VMware](#)
- [Converting standard mode to dev mode on Kubernetes](#)
- [Converting dev mode to standard mode on Kubernetes](#)  
You can convert your API Connect installation on Kubernetes from `dev` mode to `standard` mode.
- [Converting standard mode to dev mode on Kubernetes](#)  
You can convert your API Connect installation on Kubernetes from `standard` mode to `dev` mode.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Converting dev mode to standard mode on Kubernetes

You can convert your API Connect installation on Kubernetes from `dev` mode to `standard` mode.

### About this task

To review the installation modes, see [Converting installation mode](#).

Make sure the Kubernetes cluster where the subsystem is deployed has at least 3 nodes. .

### Procedure

1. Verify that the Kubernetes cluster where the subsystem is deployed has at least 3 nodes.  
Deploying a subsystem in `standard` mode on a cluster with less than 3 nodes is not supported.

2. For each subsystem in your deployment:

- a. Use `apicup` to convert to `standard` mode.

```
apicup subsys set <subsys> mode=standard
```

- b. Run the command:

```
apicup subsys install <subsys>
```

This command propagates the configuration change into the Helm charts that are deployed and updated by the `apicup` installer.

To review installation instructions for each subsystem on Kubernetes, see:

- [Installing the Management subsystem into a Kubernetes environment](#)
- [Installing the Analytics subsystem into a Kubernetes environment](#)
- [Installing the Developer Portal subsystem into a Kubernetes environment](#)

3. To verify your installation mode, use `apicup subsys get <subsystem_name>`.

For example, `apicup subsys get mgmt:`

```
Kubernetes settings
=====
```

Name	Value	Errors
mode	standard	

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Converting standard mode to dev mode on Kubernetes

You can convert your API Connect installation on Kubernetes from **standard** mode to **dev** mode.

### About this task

To review the installation modes, see [Converting installation mode](#).

### Procedure

Complete the following steps for each subsystem:

1. Use the following `apicup` command to convert to Dev mode:

```
# ./apicup subsys set [subsys-name] mode=dev
# ./apicup subsys install [subsys-name]
```

2. Select one of the following actions, based on your deployment:

- If your Kubernetes deployment has two or more nodes, you do not have to remove replicaset. Continue to step 3
- If your Kubernetes deployment has only one node, you must remove replicaset. Complete the following:
  - Find the Helm release name and namespace for the subsystem that you are switching to dev mode:

```
helm ls
```

Sample output:

NAME	REVISION	UPDATED	STATUS	CHART
NAMESPACE				
r04bac65d2f	1	Mon Feb 11 14:51:08 2019	DEPLOYED	dynamic-gateway-service-1.0.16
apiconnect

rf19e62b277	1	Mon Feb 11 14:50:03 2019	DEPLOYED	cassandra-operator-1.0.0
apiconnect				

- Use the following command to delete the replicaset for that release in its namespace:

```
kubectl delete rs -n <namespace> -l release=<release_name>
```

For example, using the previous sample output:

```
kubectl delete rs -n apiconnect -l release=rbcb2382b5e
```

3. To review your installation mode, use `apicup subsys get`

`<subsystem_name>`.

For example, `apicup subsys get mgmt`:

```
Kubernetes settings
=====
```

Name	Value	Errors
mode	dev	

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Increasing the memory allocation for the management database

You can increase the maximum memory allocation for the management database in a running deployment.

### Before you begin

---

When increasing the memory allocation, complete a manual backup of the management database and Portal subsystem just prior to changing the allocation. Note that this backup is in addition to any scheduled backups that you have configured. The manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured.

For details on creating a backup, see [Backing up the management database in a Kubernetes environment](#) and [Backing up and restoring the Developer Portal](#).

### About this task

---

Starting with API Connect version 2018.4.1.3, you can increase the maximum memory allocation for the management database in a running deployment. This procedure works for both Kubernetes and OVA environments. All the pods in the API Connect cluster must be up and running to increase the maximum memory value in a running deployment.

### Procedure

---

1. Ensure all pods are up and running using the `kubectl get pods` command.
2. Use the following `apicup` command to increase the maximum memory:

```
apicup subsys set <MANAGEMENT_SUBSYS_NAME> cassandra-max-memory-gb <new_value>
```

3. Reinstall the management subsystem to push the change to the cluster. This may take several minutes as each pod updates.

```
apicup subsys install <MANAGEMENT_SUBSYS_NAME>
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Enabling Analytics ingestion-only on Kubernetes

Enable the ingestion-only configuration by redeploying the IBM® API Connect Analytics subsystem with the `ingestion-only` configuration setting.

### Before you begin

---

Only complete this task if you want to offload all analytics data and disable the Analytics feature in the user interface. If you want to retain the data or allow users to access the Analytics user interface, skip this task and instead see [Configuring analytics offload for API Connect](#).

### About this task

---

If you choose to offload all analytics data to third-party services and have no need to retain the data in API Connect, you can configure the Analytics service with the ingestion-only setting. If you offload data and then separately disable the Analytics UI, the associated components are still deployed and require system resources. Configuring Analytics for ingestion-only removes unused Analytics components (such as analytics-storage and analytics-client) from the topology and only deploys the components required for offloading data (such as analytics-ingestion and analytics-mq-kafka). The reduced topology requires less CPU, memory, and storage.

### Procedure

---

1. Remove the Analytics service from your API Connect deployment by completing the following steps.
  - a. Unassociate the Analytics service from all gateway services as explained in step 7 in the topic, [Associating an analytics service with a gateway service](#).
  - b. Unregister the Analytics service from Cloud Manager.  
You can unregister the service from the Topology page: click the Options menu next to the service name and select Delete. For information on registering services, see [Registering an analytics service](#).
2. Create an extra values file to specify the URL of the offload endpoint where all analytics data will be routed.  
You can choose the name for the file, but you must use `.yaml` as the file-name extension. Format the file as shown in the following example, making sure to include required settings for the third-party system.

```
apic-analytics-ingestion:  
  outputOffload: |-  
    elasticsearch {  
      hosts => "http://offload_endpoint:port"  
      index => "api-call"  
    }  
  }
```

For information about configuring analytics offloading, see [Configuring analytics offload for API Connect](#).

3. Run the following `apicup` commands to reinstall the Analytics subsystem using the configuration settings in the extra values file:

```
apicup subsys set analyt ingestion-only=true
apicup subsys set analyt extra-values-file=extra-values.yaml
apicup subsys install analyt
```

4. Add the new Analytics service to your API Connect deployment by completing the following steps.
  - a. Register the new Analytics service with the Cloud Manager.

Attention: When you register an Analytics service that is configured for ingestion-only, you must use the ingestion endpoint and the ingestion TLS profile instead of the client endpoint and TLS profile.

For information on registering a service with the Cloud Manager, see [Registering an analytics service](#).
  - b. Associate the Analytics service with a gateway service as explained in [Associating an analytics service with a gateway service](#).

## Results

---

All analytics data is routed directly to the offloading endpoint, the Analytics UI is disabled, and no data is retained in API Connect.

In addition, the following Analytics configuration settings will not be validated or used when `ingestion-only` is set to enabled:

- `coordinating-max-memory-gb`
- `data-max-memory-gb`
- `data-storage-size-gb`
- `master-max-memory-gb`
- `master-storage-size-gb`
- `analytics-client`
- `es-storage-class`

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Disabling Analytics ingestion-only on Kubernetes

Disable the ingestion-only configuration by redeploying the IBM® API Connect Analytics subsystem with the `ingestion-only` value set to false.

### About this task

---

When you previously configured Analytics for ingestion-only, you deployed only a subset of the Analytics components. If you want to disable the ingestion-only setting, redeploy the subsystem to ensure that all components are available.

### Procedure

---

1. Remove the Analytics service from your API Connect deployment by completing the following steps.
  - a. Unassociate the Analytics service from all gateway services as explained in step 7 in the topic, [Associating an analytics service with a gateway service](#).
  - b. Unregister the Analytics service from Cloud Manager.

You can unregister the service from the Topology page: click the Options menu next to the service name and select Delete. For information on registering services, see [Registering an analytics service](#).
2. Generate the `analytics-client-ingress` certificate (if you initially created this certificate, it was removed when you deployed using the ingestion-only configuration).

For information, see [Working with certificates](#).
3. Run the following `apicup` commands to install the complete Analytics subsystem:

```
apicup subsys set analyt ingestion-only=false
apicup subsys install analyt
```
4. Add the new Analytics service to your API Connect deployment by completing the following steps.
  - a. Register the new Analytics service with the Cloud Manager.

For information on registering a service with the Cloud Manager, see [Registering an analytics service](#).
  - b. Associate the Analytics service with a gateway service as explained in [Associating an analytics service with a gateway service](#).

## Results

---

The Analytics subsystem is deployed with all components, the Analytics user interface is enabled, and the deployment is configured to route analytics data from the Gateway to API Connect, where it is stored. If you want to offload analytics data, configure offloading as explained in [Configuring analytics offload for API Connect](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring maximum size of client requests to the Management subsystem

You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.

## About this task

---

The default maximum size is 8 megabytes. You can increase this value.

Increasing the setting can be useful if you get errors when using the CLI to import a large API. Example error:

```
HTTP/1.1 413 Request Entity Too Large
```

## Procedure

---

1. Add an entry to an extra-values-file:

```
juhu:
  clientMaxBodySize: "12m"
```

Note that the default value is "8m".

For information on working with extra-values-files, see [Creating an extra values file in a Kubernetes environment](#)

2. Run `apicup` to update the settings in the deployed Management subsystem.

```
apicup subsys install <management-subsystem>
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Increasing memory allocation for Cassandra operator on OpenShift

If the Cassandra operator pods restart due to out of memory errors, you can increase the memory allocation for the Cassandra operator.

## About this task

---

On OpenShift 4.6, Cassandra operator pods can sometimes restart due to out of memory errors. The problem shows up as a number of **Restarts** for the Cassandra pod in the output from:

```
kubectl get pods -n <namespace>
```

You can see the out of memory errors in the output of `dmesg` on the worker node. For example:

```
[256264.442631] Memory cgroup out of memory: Killed process 1899490 (cop) total-vm:2427012kB, anon-rss:244376kB, file-
rss:23748kB, shmem-rss:0kB, UID:108
[256266.030417] oom_reaper: reaped process 1899490 (cop), now anon-rss:0kB, file-rss:0kB, shmem-rss:0kB
[256830.705886] cop invoked oom-killer: gfp_mask=0x6000c0 (GFP_KERNEL), nodemask=(null), order=0, oom_score_adj=-998
```

The problem has been seen on API Connect v2018.4.1.13 and later, running on OpenShift 4.6.9, with underlying Kubernetes 1.19 and Helm version 3.4.2.

To fix the problem:

## Procedure

---

1. Get the current deployment:

```
oc get deployment -n <namespace>
```

2. Edit the Cassandra deployment:

```
oc edit deployment <r9c835a18ba-cassandra-operator> -n <namespace>
```

3. Change the memory limits and memory requests value to **512Mb**:

```
resources:
  limits:
    cpu: 100m
    memory: 512Mi
  requests:
    cpu: 100m
    memory: 512Mi
```

4. Save the edits.
5. Verify that the Cassandra pod has been recreated. Check the output of:

```
kubectl get pods -n <namespace>
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

# Setting rate limits for public APIs on the management service for a Kubernetes environment

Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.

## Before you begin

---

Note: This article refers to third-party software that IBM does not control. As such, the software may change and this information may become outdated. These instructions assume you have a working Kubernetes environment with the kubectl command-line tool installed, and that you understand how to manage Kubernetes. For more information, see <https://kubernetes.io>.

## About this task

---

Rate limits can be set for public APIs on the management service. Rate limits on APIs help provide protection from DDoS (distributed denial of service) attacks. Without a rate limit, API calls from public APIs are unlimited.

The rate limit configuration requires that the header contains the actual client IP address. Any load balancer or proxy (for example, HAProxy) that is installed in front of the management service must be configured to pass the actual client IP address.

This procedure must be performed on a running API Connect deployment.

This feature is available in API Connect versions 2018.4.1.1 and higher.

Rate limits are calculated as requests per seconds per client.

## Procedure

---

- Configure the ingress-nginx-ingress-controller to pass the real client IP address:
  1. Set the `use-proxy-protocol` parameter to `true` by entering the following command:

```
kubectl edit ConfigMap -n kube-system ingress-nginx-ingress-controller
```

2. In the ConfigMap, set the following: `use-proxy-protocol: "true"`

- Set a rate limit:

1. Add the following entries to an extra-values-file:

```
juhu:
  rateLimitPerClient: 10
  limitRequestOption: "burst=10 nodelay"
```

In this example, the first option sets the rate to 10 requests per second (10r/s). The second option allows 10 requests boosted without delay within < 1 second. You can customize as needed.

The `rateLimitPerClient` property sets `rate`, and `limitRequestOption` sets `[burst=number] [nodelay | delay=number]` in the following nginx configuration:

```
limit_req_zone key zone=name:size rate=rate;
limit_req zone=name [burst=number] [nodelay | delay=number];
```

- Note that `zone` has been pre-defined and can't be configured. For details, see the nginx.org doc [Module ngx\\_http\\_limit\\_req\\_module](#).
- If you don't have an extra-values-file, you can create a new one. See [Creating an extra values file in a Kubernetes environment](#).

2. Run `apicup` to update the settings in the deployed Management subsystem.

```
apicup subsys install <management-subsystem>
```

Note: If the rate limit has been reached on the management subsystem, the client will get an HTTP error: **429 Too Many Requests**.

3. Validate that the juhu pod has restarted by listing the pods:

```
kubectl get pods -n <namespace> | grep juhu
```

4. Check the AGE column to ensure a new juhu pod has started.
5. If the older juhu pod is still running, delete it with the following command:

```
kubectl delete pods -n <namespace> <old-juhu-pod>
```

- Disable a rate limit:

1. Validate that the juhu pod has restarted by listing the pods:

```
kubectl get pods -n <namespace> | grep juhu
```

2. Check the AGE column to ensure a new juhu pod has started.
3. If the older juhu pod is still running, delete it with the following command:

```
kubectl delete pods -n <namespace> <old-juhu-pod>
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

# Enabling high performance peering for DataPower API Gateway on Kubernetes

Enabling high performance peering on DataPower API Gateway deployments optimizes API transaction performance.

## About this task

---

You can configure DataPower API Gateways to have dedicated `gateway-peering` objects for the API Connect Gateway Service, subscription data, and rate-limit data. By default, the gateway service is configured to share a single `gateway-peering` object for all three. In some scenarios, use of a single object can impact API performance. Enabling of high performance peering is highly recommended.

High performance peering is available in API Connect Version 2018.4.1.7 and later.

Use the procedure in this topic to reconfigure an existing API Connect deployment to enable high performance peering.

Important: Enabling high performance peering on an existing deployment requires an outage to API transaction processing during configuration.

- If you are upgrading the Gateway from Version 2018.4.1.6 to version 2018.4.1.7 or later, complete the upgrade first and then use the instructions in this topic to reconfigure peering. For upgrade instructions, see [Upgrading API Connect in a Kubernetes environment](#).
- If you are deploying DataPower API Connect externally to Kubernetes, such as part of a physical or virtual DataPower appliance, do not use this topic. Instead, follow the configuration instructions in [Sample configuration for multiple peering objects on gateway services external to Kubernetes](#)

It is important that all gateway instances are down at the same time, in order for dynamic reconfiguration to take place. In this case, dynamic reconfiguration is achieved by scaling down gateway services, using `apicup` to install, then scaling up the gateway services. To review the DataPower Gateway dynamic reconfiguration process, see [Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment](#).

## Procedure

---

1. Set the high performance peering option in the `apicup` gateway configuration.

```
apicup subsys set gwy enable-high-performance-peering="true"
```

You must run `apicup` in the same project directory as where the gateway was originally configured using `apicup`.

2. Obtain the name of the StatefulSet, and scale the cluster down to a single gateway.

```
kubectl get statefulset
kubectl scale statefulset r600e4a32ef-dynamic-gateway-service --replicas=1
```

3. Use `apicup` to redeploy the gateway pod.

```
apicup subsys install gwy
```

4. Optional: Log in to the DataPower CLI and use the `show gateway-peering-status` status to confirm that multiple `gateway-peering` objects have been configured.

Confirm that the status shows separate entries for API Connect Gateway Service (`gwd`), API Gateway rate limit (`rate-limit`), and API Gateway subscriptions (`subs`). For example:

```
idg# sw apiconnect
idg[apiconnect]# config
Global configuration mode
idg[apiconnect](config)# show gateway-peering-status
```

Address	Configuration name	Pending updates	Replication offset	Link status	Primary
192.168.0.127	gwd	0	0	ok	yes
192.168.0.127	rate-limit	0	0	ok	yes
192.168.0.127	subs	0	0	ok	yes

5. When the first gateway pod is marked ready, scale the StatefulSet to the original number of gateways. For example:

```
kubectl scale statefulset r600e4a32ef-dynamic-gateway-service --replicas=3
```

Be sure to scale up the same StatefulSet that you scaled down in Step 2.

6. Wait for management server heartbeat to detect that reconfiguration is required.

Heart beat processing usually detects the need for reconfiguration within 5 minutes, but the process may take a few more minutes to begin. When the `show api-collection` command returns data, the reconfiguration has begun. The length of time to required to reach completion depends on the number of catalogs, products, APIs, subscriptions, etc.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

# Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment

In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

If a Gateway service is not configured properly for resiliency and is restarted, the gateways in the Gateway service will lose the configuration from the Management server. Configuration data from the Management server is maintained on the gateway service according to the gateway peering configuration on the gateways.

---

## Preventing the loss of configuration data

For high availability in production environments, use a minimum of three gateways in the Gateway service.

---

## Forcing re-population of the configuration data

To repopulate the configuration data, complete the steps in the following section to trigger an outage-less DRR.

---

## Triggering an outage-less DRR

To force a Dynamic Reregistration and Reconfiguration across a peer group from within the gateway service without requiring a restart, complete the following steps using the CLI. This process flushes the primary peering object configured for the apic-gw-service. This task can only be performed with CLI, and requires the default admin ID for running the `diag` command.

1. Access the gateway service:

- For a virtual gateway, run the following command to access the DataPower CLI:

```
kubectl attach -it <pod_name>
```

- For a physical gateway, use `ssh` to connect to the gateway service.

2. Switch to the API Connect application:

```
switch <APIC_APP_DOMAIN>
```

3. Show the current gateway-peering-status:

```
show gateway-peering-status
```

4. If the server that you connected to is not primary for the apic-gw-service gateway-peering object, force this server to become primary:

```
config; gateway-peering-switch-primary <gateway-peering-name-for-apic-gw-service>;
```

5. Flush the apic-gw-service gateway-peering object:

```
diag; gateway-peering-flush <gateway-peering-name-for-apic-gw-service>; exit
```

When prompted, confirm the operation.

6. Disable and then re-enable the apic-gw-service object for every member of the gateway service:

```
config; apic-gw-service; admin-state disabled; exit  
apic-gw-service; admin-state enabled; exit; exit
```

7. Confirm that the apic-gw-service was flushed and is now waiting for gateway service registration:

Look in the debug log target for the apic-gw-service, located in `logtemp:///` and check for a message similar to the following example:

```
20200618T232339.332Z [0x88e000d7][apic-gw-service][notice]  
apic-gw-service(default): tid(2653): Waiting for gateway service registration.
```

The DRR will be triggered by the next arrival of a webhook event. Starting with API Connect Version 2018.4.1.2, the Management server sends a heartbeat to the gateway at five-minute intervals, prompting the gateway to check whether it has lost its configuration and if so, trigger a DRR. In Version 2018.4.1.8 and later, if the Management server has previously marked a Catalog or cloud as being unavailable for a particular gateway service, a successful heartbeat triggers synchronization for that Catalog or cloud on that gateway service.

8. If you attached to a virtual gateway, you can detach by pressing Ctrl+P and then pressing Ctrl+Q.

9. (Optional) Force a BAU webhook event to be sent from API Manager to trigger the DRR:

If you do not want to wait for the Management server to send a heartbeat, you can trigger the DRR manually by completing the following steps:

- a. Open the API Manager.
- b. Open the Catalog.
- c. Click Settings > Edit.
- d. Update the Summary field with some text so that it is modified.
- e. Click Save.

When the event is received, the DRR is initiated.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Monitoring and logging a Kubernetes deployment

You can do health checks to determine program status, and can gather logs for use in troubleshooting.

- [Checking cluster health on Kubernetes](#)  
You can use `apicup` to check the health of the API Connect clusters in your Kubernetes deployment.
- [Determining status of a cluster on Kubernetes](#)  
You can determine the health of an API Connect cluster on Kubernetes.
- [Obtaining simple health check data of Developer Portal sites by using a REST API call](#)  
Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.
- [Gathering logs for a Kubernetes environment](#)  
The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.
- [Changing logging levels](#)  
You can enable logging for entry and exit trace and for large payloads for `apim-v2` pods.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Checking cluster health on Kubernetes

You can use `apicup` to check the health of the API Connect clusters in your Kubernetes deployment.

Note: The `apicup` health check command is available on Version 2018.4.1.6 or later. For deployments on Version 2018.4.1.5 or earlier, use the instructions on [Determining status of a cluster on Kubernetes](#).

The `health-check` command checks a number of criteria to determine the health of their cluster. When all criteria are successfully met, the command displays no output, and exits with a status of 0. When one or more criteria are not met, the command stops processing and displays a message with the failure and exits with a status of 1.

The command takes no arguments. The only option is the `--verbose` flag. If `--verbose` is set the command prints all checks that were performed.

The `health-check` is run against the namespace that is specified in `apiconnect-up.yaml`.

The health check is run on the specified subsystem. For each expected Helm release, the command:

- Verifies that the deployed Chart version matches the `apicup` version.
- Validates that all Deployments, ReplicaSets, and DaemonSets are fulfilled.

Syntax:

Usage:

```
apicup subsys health-check <SUBSYS> [flags]
```

Flags:

```
-h, --help                help for health-check
--kubeconfig string      (optional) absolute path to the kubeconfig file (default "/Users/<username>/.kube/config")
-v, --verbose            Verbose output
```

Global Flags:

```
--accept-license  Accept the license for API Connect
--debug           Enable debug logging
```

Example usage, for a subsystem named `mgmt`:

```
../apicup subsys health-check mgmt
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Determining status of a cluster on Kubernetes

You can determine the health of an API Connect cluster on Kubernetes.

---

### About this task

At any time, you can review the status of the API Connect cluster. You should review the status before and after doing configuration tasks such as upgrading.

Note: For Version 2018.4.1.6 or later, you can also use `apicup subsys health-check`. See [Checking cluster health on Kubernetes](#)  
Do not use these instructions on VMware. See [Determining status of a cluster on VMware](#).

## Procedure

1. Check that the subsystem Helm release was successful.

The release names are generated off the subsystem chart plus namespace. First determine the release name for the subsystem by running `helm ls --namespace <namespace>`. Next use the following chart to determine which release corresponds to which subsystem.

Subsystem	Helm release
management	apiconnect-2.0.0, cassandra-operator-1.0.0
analytics	apic-analytics-2.0.0
portal	apic-portal-2.0.0

Example:

```
$ helm ls --namespace e2etest
NAME REVISION UPDATED STATUS CHART APP
VERSION NAMESPACE
r3b3275c7fb 1 Mon Apr 22 09:20:13 2019 DEPLOYED dynamic-gateway-service-1.0.23 1.0
demo-namespace
r7430a60641 1 Mon Apr 22 08:44:57 2019 DEPLOYED apiconnect-2.0.0
demo-namespace
r85ba975aee 1 Mon Apr 22 09:23:06 2019 DEPLOYED apic-portal-2.0.0
demo-namespace
re5c7f54039 1 Mon Apr 22 09:20:32 2019 DEPLOYED apic-analytics-2.0.0
demo-namespace
rf99c951215 1 Mon Apr 22 08:44:45 2019 DEPLOYED cassandra-operator-1.0.0 1.0.1
demo-namespace
```

In the previous example, the release types are as follows:

Value in NAME column	Release type
r7430a60641 and rf99c951215	Management
r85ba975aee	Portal
re5c7f54039	Analytics

If any release is not **DEPLOYED**, open a ticket with IBM Support, to obtain assistance with troubleshooting the release.

2. Check that the deployed charts are the correct version.

This check needs to be performed on only one node. See the previous steps to determine the Helm release name(s) for the subsystem type.

- Version 2018.4.1.4 or later  
Run the command `helm get [release-name] | grep productVersion | head -1`

```
# helm get values apiconnect | grep productVersion | head -1
productVersion: 2018.4.1.4
```

If the previous command returns `productVersion: ""`, the deployed charts are for a version prior to 2018.4.1.4. See the following instructions.

- Version 2018.4.1.3 or earlier
  - Management subsystem

- Run `helm get apiconnect | grep apiconnect/apim[: ] | head -1`. Compare output to the following table to determine chart `productVersion`:

Image output	Chart productVersion
image: "apiconnect/apim:2018.4.1-223-5e98505"	2018.4.1.0
image: "apiconnect/apim:2018.4.1-267-7151665"	2018.4.1.1
image: "apiconnect/apim:2018.4.1-339-0d1c113"	2018.4.1.2
image: "apiconnect/apim:2018.4.1-391-e1df735"	2018.4.1.3

- Run `helm get cassandra-operator | grep apiconnect/cassandra-operator[: ] | head -1`. Compare output to the following table to determine chart `productVersion`.

Image output	Chart productVersion
image: "image: apiconnect/cassandra-operator:2018-10-27-11-34-27-b30560eb3775c558f8438abb8e084ed97ca8a34f"	2018.4.1.0
image: "image: apiconnect/cassandra-operator:2018-11-13-14-39-43-cac5b0e471f011258f38b92c6959e4c30bc21b08"	2018.4.1.1
image: "image: apiconnect/cassandra-operator:2019-01-07-17-52-36-a571b8b69248e7afd5aac06ca5196ffeb8fd7875"	2018.4.1.2
image: "image: apiconnect/cassandra-operator:2019-02-19-01-57-00-77482ccb867d08277e9985a3a75cb86385720523"	2018.4.1.3

- Portal subsystem  
Run `helm get apic-portal | grep apiconnect/portal-web[: ] | head -1`. Compare output to the following table to determine chart `productVersion`.

Image output	Chart productVersion
image: apiconnect/portal-web:2018.4.1-385444eb87824c93e42c85412af8088eac8c7bb9-335	2018.4.1.0
image: apiconnect/portal-web:2018.4.1-ea9a86af8cf6f9e241f29f9a7ad860991e017d29-514	2018.4.1.1
image: apiconnect/portal-web:2018.4.1-8e3c67a1ec93f9eda7411286b75e19becaab0fb0-773	2018.4.1.2

Image output	Chart productVersion
image: apiconnect/portal-web:2018.4.1-31b0250446fd1660cc4622f44b7f8317391c536d-948	2018.4.1.3

- Analytics subsystem  
Run `helm get apic-analytics | grep apiconnect/analytics-client[:]`  
| `head -1`. Compare output to the following table to determine chart `productVersion`:

Image output	Chart productVersion
image: "apiconnect/analytics-client:2018-10-18-17-32-08-ba640482b2659c37905271d6a318fa0fc902aebd"	2018.4.1.0
image: "apiconnect/analytics-client:2018-11-21-11-19-56-ba640482b2659c37905271d6a318fa0fc902aebd"	2018.4.1.1
image: "apiconnect/analytics-client:2019-01-07-15-16-59-9f8c1b7bb4a8f9a0bf9529bab166f752821b62e4"	2018.4.1.2
image: "apiconnect/analytics-client:2019-02-12-12-52-40-700d61ffb1c2ff2c9860d6d75f1620fbceea64d6"	2018.4.1.3

3. Review the results of the previous step, and ensure that the product version matches the `apicup` version and the appliance version. If the chart version is wrong it is likely that either the wrong version of Install Assist was used for `apicup subsys install`, or an old `--plan-dir` was passed to the install command. Verify the correct version of `apicup` is being used and try to re-install by using `apicup subsy install`. It is safe to run the command multiple times.

4. Use `kubect1` to check the deployments and validate that the number of deployments matches for `DESIRED`, `CURRENT`, and `AVAILABLE`. If the numbers don't match, it is possible that one of the pods is still starting, or is having problems. Another possibility is that Kubernetes encountered problems trying to scale down an old replica set. Check for replica-sets that are for the same deployment and have a number count greater than 0 for `DESIRED`. Note that the replica-sets for a deployment start with the same name.

You can use `kubect1 get rs` to try to determine why the replica-set is not scaling down. For example, the following output shows a cluster in a non-healthy state.

```
# kubect1 get deployments
NAME                                DESIRED  CURRENT  UP-TO-DATE  AVAILABLE  AGE
apiconnect-a7s-proxy                3        3        3            1          2h
apiconnect-apim-v2                  3        3        3            3          2h
apiconnect-client-dl-srv            2        3        2            1          2h
apiconnect-juhu                     3        4        2            2          2h
apiconnect-ldap                     3        4        2            2          2h
apiconnect-lur-v2                   3        4        2            2          2h
apiconnect-ui                        2        3        2            1          2h
cassandra-operator-cassandra-operator 1        1        1            1          2h

# kubect1 get rs
NAME                                DESIRED  CURRENT  READY  AGE
apiconnect-a7s-proxy-56c9f975c      3        3        1      9m
apiconnect-apim-v2-55d77dff65       3        3        3      2h
apiconnect-client-dl-srv-56cfd98dd5  2        2        0      9m
apiconnect-client-dl-srv-6bc7d48477  1        1        1      2h
apiconnect-juhu-744db85f             2        2        0      9m
apiconnect-juhu-744f9cbc89           2        2        2      2h
apiconnect-ldap-6c855d4b             2        2        2      2h
apiconnect-ldap-d599cb954           2        2        0      9m
apiconnect-lur-v2-79556d69c          2        2        0      9m
apiconnect-lur-v2-7f97c7b8b5         2        2        2      2h
apiconnect-ui-69c8df97               2        2        0      9m
apiconnect-ui-84c97657c5             1        1        1      2h
cassandra-operator-cassandra-operator 1        1        1      2h
```

5. Check that the StatefulSets are fulfilled. For each subsystem run `kubect1 get sts -n <name-space>` and ensure that for each entry, the numerical values match for `DESIRED`, `CURRENT`, and `READY`.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Obtaining simple health check data of Developer Portal sites by using a REST API call

Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

### About this task

You can use the site health REST API to determine whether a particular Developer Portal site is running. The site health API returns the current system time of the site if both the database and web server are running. This API is fast and puts no load on the system, so it is ideal for use with load balancers to help them determine where to route traffic.

### Procedure

To call the site health REST API, append `/health` to the end of your Developer Portal site URL in your web browser, as follows:

`site_url/health`

Where `site_url` is the URL of the Developer Portal site that you want to check.

If both the database and web server of the site are running, the web browser returns the current system time. For example:

```
1511367695
```

If either the database or the web server of the site is not running, the web browser returns an error that the site can't be reached.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Gathering logs for a Kubernetes environment

The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.

### Before you begin

---

Review the log rotation recommendations in [Requirements for deploying IBM API Connect into a Kubernetes environment](#).

### About this task

---

When contacting IBM Support, several logs are required to assist in troubleshooting or diagnostics. The `generate_postmortem.sh` script gathers all the required logs using a single shell script. The `generate_postmortem.sh` script must be executed from the `apicup` project directory. You can download the script directly to the `apicup` project directory or set the environment variable `APICUP_PROJECT_PATH` by entering the following command: `export APICUP_PROJECT_PATH="/path/to/directory"`

Note: This article refers to third-party software and documentation that IBM does not control. As such, the software may change and this information may become outdated.

### Procedure

---

1. Install the `kubectl` command line interface for Kubernetes, if it is not already installed.
2. Configure `kubectl` to the Kubernetes cluster by entering the following commands:

```
rm -fr $HOME/.kube
mkdir -p $HOME/.kube
scp root@{kubernetes_master_host}:/etc/kubernetes/admin.conf $HOME/.kube/config
```

3. Install the correct version of `helm` and connect it to the Kubernetes cluster.

```
rm -fr $HOME/.helm
curl -s https://raw.githubusercontent.com/helm/helm/master/scripts/get | bash -s -- --version v2.8.2
helm init --client-only
```

4. Download the `generate_postmortem.sh` script. It will be downloaded to the `apicup` project directory. Enter the following command:

```
curl -o generate_postmortem.sh https://raw.githubusercontent.com/ibm-apiconnect/v2018-postmortem/master/generate_postmortem.sh
```

5. Add execute permissions to the `generate_postmortem.sh` script. Enter the following command:

```
chmod +x generate_postmortem.sh
```

6. Run the `postmortem` tool from the `apicup` project directory. Change directories to the `apicup` project directory, or set the environment variable `APICUP_PROJECT_PATH`. Enter the following command:

```
./generate_postmortem.sh
```

7. (Optional) Currently, log generation is supported for Gateway and Portal subsystems. Specify either `gateway` or `portal`, or all subsystems. Enter the following arguments:

```
All (generates logs for both Portal and Gateway subsystems): ./generate_postmortem.sh --diagnostic-all
Gateway: ./generate_postmortem.sh --diagnostic-gateway
Portal: ./generate_postmortem.sh --diagnostic-portal
```

8. (Optional) If there are errors when running the `generate_postmortem.sh` script, enter the following command:

```
./generate_postmortem.sh --debug &>debug.log
```

Note:

- Offboarding the logs to an external server is the recommended best practice for long term storage of log data.
- If the logs do not cover far enough back in time, or conversely if they are too large, adjust the log retention size. For further information, see: <https://docs.docker.com/config/containers/logging/json-file/>.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Changing logging levels

You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

### About this task

For apim-v2 pods in Version 2018.4.1.9 or later, the default logging settings do not include entry and exit trace and logging of large payloads.

Logging of large payloads is typically needed if you are logging `apim:webhookPayload` or other processes that log large variables.

You can also set the debug level without needing to restart the pods.

You can enable the settings through either the APIM deployment YAML file, the toolkit, or the REST APIs. Note, you must use the toolkit or REST API to set the debug level without restarting the pods.

### Procedure

- Updating the settings in the APIM deployment YAML file

Note: This action causes a pod restart.

- The DEBUG variable works the same as prior releases.

```
- env:
  - name: DEBUG
    value: audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:audit,bhendi:webhookAudit,bhendi:cassandra-
transactions,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*,apim:webhook:audit,apim:taskma
nager:info
```

To enable entry and exit trace, add `trace:*` to the start of the debug string:

```
- env:
  - name: DEBUG
    value: trace:*,audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:audit,bhendi:webhookAudit,bhendi:cassandra-
transactions,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*,apim:webhook:audit,apim:taskma
nager:info
```

- To enable large object logging:

```
- env:
  - name: VELOX_LOG_FULL_PAYLOAD
    value: "true"
```

- Updating the settings by using the toolkit

Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

```
apic log-spec:get
apic log-spec:update LOG_SPEC_FILE
```

Where the spec file contains:

```
{"specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}
```

- Updating the settings by using the REST API

Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

```
GET /cloud/api/log-spec
PUT /cloud/api/log-spec
```

For example, to set debug level and large objects logging:

```
curl -k https://172.16.140.212:3003/api/cloud/log-spec -X PUT -H "Authorization: Bearer $BEARER"
-H "Accept: application/json" -d '{"specification":
"apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}'
-H "Content-Type: application/json"
```

The command responds with:

```
{
  "specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error",
  "large_objects": true,
  "message": "Successfully changed the log specification on all apim-v2 pods. Success on IP(s): 172.16.140.212,
172.16.140.213"
}
```

Note: The response might include the following warning, which can be ignored:

```
WARNING: Could not change the log specification on all apim-v2 pods. Success on IP(s): 4.5.6.7 Failed on IP(s): 1.2.3.4
```

To view the REST APIs for logging, go to [API Connect REST APIs](#), and select IBM API Connect Platform - Cloud Management API 2.0.0 reference\_2\_Resource: Log Spec.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

# Disabling the Analytics subsystem on Kubernetes

During maintenance of an API Connect cluster, you can shut down the Analytics subsystem by disabling the client, ingestion, and storage microservices so that those processes are not running and there is no way to reach them.

## About this task

Disabling the Analytics subsystem stops the collection and storage of data as well as making the subsystem unavailable. When you disable Analytics, there will be no data in either the API Manager Dashboards or third-party offloads.

## Procedure

1. Back up your Analytics data as explained in [Backing up and restoring the analytics database](#).

2. Disable shard allocation for storage.

Disabling shard allocation is optional, but is recommended because it prevents new shards from being created for replication when a node is unavailable, and helps avoid corruption issues in full system restarts. Disable shard allocation for storage by running the following command:

```
kubectl -n namespace exec -it storage-master|shared_pod -- curl_es _cluster/settings -XPUT -d '{"persistent": {"cluster.routing.allocation.enable": "none"}}'
```

where:

- **namespace** is the namespace where the Analytics subsystem is installed.
- **storage-master|shared\_pod** is the name of any storage-master or storage-shared pod. You can get the name of your storage pods by running the following command and substituting in the namespace where Analytics is installed:

```
kubectl -n namespace get po
```

When you disable shard allocation, the response looks like the following example:

```
{"acknowledged": true, "persistent": {"cluster": {"routing": {"allocation": {"enable": "none"}}}}, "transient": {}}
```

3. Unassociate the Analytics service from all gateway services.

- a. In Cloud Manager, click  Topology.
- b. In the section for the Availability Zone that contains the Analytics service, locate the Gateway service that the Analytics service is associated with.
- c. Click  and select Unassociate analytics service.

All analytics collection will be disabled and there will be no data in either the API Manager Dashboards or third-party offloads. For more information, see [Associating an analytics service with a gateway service](#).

4. Unregister the Analytics service from Cloud Manager:

- a. In Cloud Manager, click  Topology.
- b. In the section for the Availability Zone that contains the Analytics service, locate the Analytics service and click Delete.

For more information, see [Registering an analytics service](#).

5. Perform a synced flush of storage.

Flushing the storage is optional, but is recommended because it helps to avoid losing the data that was not yet written to disk. This step flushes all current index operations synchronously and attempts to write everything that is in flux to disk. Perform a synced flush of storage by running the following command:

```
kubectl -n namespace exec -it storage-master|shared_pod -- curl_es _flush/synced -XPOST
```

When you flush storage, the response looks like the following example:

```
{"_shards": {"total": 33, "successful": 13, "failed": 0}, ".export-status": {"total": 1, "successful": 1, "failed": 0}, ".apic-config": {"total": 1, "successful": 1, "failed": 0}, ".kibana-6": {"total": 1, "successful": 1, "failed": 0}, "apic-api-2020.06.19-000002": {"total": 15, "successful": 5, "failed": 0}, "apic-api-2020.06.18-1": {"total": 15, "successful": 5, "failed": 0}}
```

The operation often fails, and it is safe to rerun it multiple times until it passes and there are all "failed" counts are zero. If it continues to fail after running multiple attempts over the span of a couple minutes, you can proceed to the next step.

6. Run the following two commands to configure analytics for ingestion-only:

```
$ apicup subsys set <analytics-subsystem-name> ingestion-only=true
```

```
$ apicup subsys install <analytics-subsystem-name>
```

7. Scale the analytics-ingestion deployment down to 0 replicas by completing the following steps.

- a. Get a list of all deployments so that you can find the name of the analytics-ingestion deployment:

```
$ kubectl get deployments -n <namespace>
```

- b. Scale the analytics-ingestion deployment down to 0 replicas:

```
$ kubectl scale deployment/<analytics-ingestion-deployment-name> --replicas=0 -n <namespace>
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## VMware

Use the instructions in this section to install, upgrade, and maintain API Connect on VMware.

- [Installing and upgrading on VMware](#)  
Use these instructions to install or upgrade a deployment of API Connect on VMware.
- [Maintaining a VMware deployment](#)  
You can use utilities to complete maintenance tasks such as backup, restore, and certificate management in a VMware environment.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Installing and upgrading on VMware

Use these instructions to install or upgrade a deployment of API Connect on VMware.

- [IBM API Connect Version 2018 software product compatibility requirements](#)  
Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.
- [Estimating internal storage space for Analytics](#)  
If you plan to store data locally in your IBM API Connect Analytics deployment, estimate disk space requirements.
- [Working with certificates](#)  
Use the `certs` command included in the APICUP installer to set and manage certificates for each subsystem. Default certificates are automatically applied, but defaults can be overridden by user-supplied custom certificates.
- [Tips and tricks for using APICUP](#)  
The APICUP installer in Install Assist contains built-in time saving functions.
- [Deploying to a VMware environment](#)  
The Install Assist tool provides a simplified installation for the OVA files into a VSphere environment.
- [Upgrading in a VMware environment](#)  
You can upgrade an existing deployment of API Connect on VMware to a newer version while retaining your data.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## IBM API Connect Version 2018 software product compatibility requirements

Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.

To generate an API Connect requirements report, complete the following steps:

1. Open the [Detailed system requirements for a specific product](#) page on the IBM Software Product Compatibility Reports site.
2. Search for the IBM API Connect product.
3. In the Search results list, select IBM API Connect.
4. From the Version list, select the required version.
5. Use the Filters to refine the contents of the requirements report.
6. Click Submit to generate your requirements report.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Estimating internal storage space for Analytics

If you plan to store data locally in your IBM® API Connect Analytics deployment, estimate disk space requirements.

This information applies only to Analytics deployments where the ingestion-only option is set to false (the default setting). The formula and guidelines are based on known information about how the Analytics service stores data, and cannot be directly applied to any other storage system.

Use the following guidelines to calculate a rough estimate of the amount disk space you need for storing stateful data in the API Connect Analytics microservices.

---

## Data storage: calculate how much data you want to store

---

This section applies if you have chosen a topology that uses the analytics-storage-data or analytics-storage-basic microservices.

The amount of disk space needed for storing analytics data is determined by the following factors:

Number of copies of the analytics data

Each copy of the analytics data must live on a separate node. The number of nodes in your deployment determines the number of copies of analytics data that is stored in your deployment. With the **Production** deployment profile, analytics data is replicated to three nodes (two replicas and one primary copy of the data) for storage. In the **Nonproduction** profile, you only need to store one copy of the data.

Number of copies of data:

```
Copies of data = [1 | 3]
```

Number of days that data is retained

By default, analytics data is retained for 90 days, but you can [modify the retention setting](#) as needed. Make sure you know how long you want to store the data before attempting to calculate required disk space.

Number of days that data is retained:

```
Data retention = [90 days | preferred length]
```

Amount of each type of data stored

The required storage space for each type of logging is highly dependent on your APIs and usage. For each API, you can [configure logging](#) for the API activity, header, and payload. You can also [customize the data](#) to add, redact, or remove fields, which also impacts the amount of data that you store.

To estimate storage needs, calculate the average size of each type of log. When calculating your estimates, remember that the header logging size is the sum of activity logging size and the average size of your headers. The payload logging size is the sum of the header logging size and the average size of your payloads. Typically the average size of an activity logged event is 600-1000 bytes depending on the uniqueness and complexity of your analytics data. This number is highly dependent on your APIs and your implementations. For a rough estimate, you can use an average of 800 bytes per activity logged event.

If you choose to add fields, calculate the average size of the new fields as well, and add that number to all types of log policies. If you choose to remove fields, you should not subtract this size from the log policies unless you are also removing headers and/or payloads.

Amount of each type of data that is stored:

```
Activity log bytes per call = [600-1000 bytes]
Header log bytes per call = Activity log bytes per call + Average size of headers
Payload log bytes per call = Header log bytes per call + Average size of payloads
```

Percentage of each type of data

Estimate the percentage of each type of log (activity, header, payload) for all API calls.

If you follow best practices of using only activity logging for production environments and using only payload logging for test environments, this number is easy to determine. If you use different log policies per API, and they depend on "success" or "error" factors, the percentage is more difficult to determine. Typically, if you do not use an all-or-nothing method for logging, error rates range from 3% to 25% with subsequent payload logging in test and production environments. However, this is entirely dependent on your use case and your APIs.

Percentage of each type of data that is stored:

```
% of Activity log = [0, 100 or other estimate]
% of Header log = [0, 100 or other estimate]
% of Payload log = [0, 100 or other estimate]
```

Estimated number of API calls per month

When planning your API Connect deployment, this number is helpful. When estimating analytics storage, this number is vital because it is directly correlated to how much storage you need for your deployment.

If you do not know the number of calls per month, but you do know the number of calls per second, use the following formula to convert it to calls per month:

```
Calls per month = Calls per second * 86400 seconds per day * 30 days per month
```

Number of API calls per month:

```
Calls per month = [any estimate]
```

## Calculating your disk space requirement

Estimate the disk space requirement for each storage node by completing following calculations.

Formula

```
Bytes per call = (% of Activity Log * Activity Log bytes per call) + (% of Header Log * Header Log bytes per call) + (% of
Payload Log * Payload Log bytes per call)
Calls per retention period = Calls per month * (Number of days retained / 30 days per month)
Storage for API calls = Calls per retention period * Bytes per call * Copies of data
Total storage = Storage for API calls + Overhead
Storage per node = Total storage / Nodes
```

Details

1. Bytes per call:

Estimate the number of bytes that are logged for a single copy of each API call. This can be calculated from the prerequisites of the percentage of each data type and the amount of each data type stored.

```
Bytes per call = (% of Activity Log * Activity Log bytes per call) + (% of Header Log * Header Log bytes per call) +
(% of Payload Log * Payload Log bytes per call)
```

2. Calls per retention period:

Calculate the anticipated number of API calls per retention period. This can be calculated from the prerequisites of the estimated calls per month and your desired data retention.

```
Calls per retention period = Calls per month * (Number of days retained / 30 days per month)
```

### 3. Storage for API Calls:

Calculate the storage needed for all copies of your api calls for your retention period. This can be calculated from steps 1 and 2, as well as the prerequisite of your total copies of your data.

**Storage for API calls = Calls per retention period \* Bytes per call \* Copies of data**

### 4. Total Storage:

Calculate the total storage you need by adding buffer space to the value from step 3. The Analytics service requires the some overhead space to complete its operations; for example, to contain system data and temporary debug header or payload logging. In addition, allowing extra space provides a buffer in case you underestimated the number of calls, or experience an unexpected increase.

There is no specific value for the buffer because it's based on your own situation. One approach is to use a value that brings the Storage for API calls result from step 3 up to the next round number. Make sure the rounding leaves you with a comfortable amount of additional space. For example, if the result from step 3 is 380 GB, then adding 20 GB to reach 400 GB is probably not sufficient and you should consider rounding to the a larger value such as 500 GB.

**Total storage = Storage for API calls + Buffer**

### 5. Storage per node:

Calculate the total storage amount required per storage node. The number of storage nodes is dependent on your deployment profile. For the **development** profile, use 1. For the **production** profile, it defaults to 3. If you manually scaled the analytics-storage-data or analytics-storage-basic microservices to be greater than 3, use your actual values.

**Storage per node = Total storage / Nodes**

Remember: This result is only an estimate. You should monitor the use of space over time and adjust storage as needed.

#### Example

Deployment information:

Copies of data = 3  
Data retention = 90 days  
Activity log bytes per call = 850 bytes  
Header log bytes per call = 15k bytes  
Payload log bytes per call = 30.5k bytes  
% of Activity log = 100%  
% of Header log = 0%  
% of Payload log = 0%  
Calls per month = 64 million

Formula:

Bytes per call = (% of Activity Log \* Activity Log bytes per call) + (% of Header Log \* Header Log bytes per call) + (% of Payload Log \* Payload Log bytes per call)  
Calls per retention period = Calls per month \* (Number of days retained / 30 days per month)  
Storage for API calls = Calls per retention period \* Bytes per call \* Copies of data  
Total storage = Storage for API calls + Overhead  
Storage per node = Total storage / Nodes

Details:

#### 1. Bytes per call = 850 bytes

**(100% of Activity Log \* 850 bytes) + (0% of Header Log \* 15k bytes) + (0% of Payload Log \* 30.5 bytes)**

#### 2. Calls per retention period = 192 million calls

**64 million calls per month \* (90 days retained / 30 days per month)**

#### 3. Storage for API calls = 489.6 GB

**192 million calls per period \* 850 bytes per call \* 3 copies of data**

#### 4. Total storage = 600 GB

**489.6GB storage + Buffer**

Since rounding to 500 GB only provides 10.4 GB of extra space, it's good practice to round to 600 GB instead.

#### 5. Storage per node = 200 GB

**600GB Total storage / 3 nodes**

In this example, the estimated disk needed on each node for analytics-storage-data and analytics-storage-basic microservices is 200GB.

## Master storage: estimate disk space needs

This section applies if you are planning a topology with the analytics-storage-master microservice enabled.

For the analytics-storage-master microservice, estimating the amount of disk space you need is much easier. For a production environment, set this value to 10GB. For a development environment, you can optionally reduce the value to 5GB.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Working with certificates

Use the `certs` command included in the APICUP installer to set and manage certificates for each subsystem. Default certificates are automatically applied, but defaults can be overridden by user-supplied custom certificates.

## About this task

Note: Use a single APICUP project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

- [Certificate management: Read This First](#)  
Requirements and best practices for managing API Connect certificates.
- [Setting and managing certificates](#)  
Default certificates are automatically applied, but defaults can be overridden by custom certificates.
- [Reference for certificates, commands, and validations](#)  
This section contains the reference information for certificates, commands for working with certificates, and validations.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Certificate management: Read This First

Requirements and best practices for managing API Connect certificates.

Important: Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged. For management purposes, API Connect certificates can be grouped by type (default, custom, and common) and by usage (public, public and user-facing, and internal). Understand each type and usage before you change any certificates.

- A default certificate is a private certificate that is uniquely generated by the installer for the current project directory, and will pass validation. Default certificates are automatically generated for each subsystem by the `apicup subsys install` command, unless the certificates were explicitly set by using the `apicup certs set` command. Note that the default certificates are self-signed, so they might not provide a level of trust suitable for external communication.
- For optimal trust levels, we recommend that you explicitly set all public and user-facing certificates by creating custom certificates.
- Some certificates are common across subsystems. Subsystems require the common certificates to allow them to register with the management subsystem. When installing any one subsystem, the common certificates are set for that subsystem and for all the other subsystems. If you use custom certificates for the common certificates, the custom certificates must be set prior to setting any other custom certificates.
- We do not recommend the explicit setting of internal certificates. The changing of internal certificates creates a risk of incompatibility with other internal certificates.

To review the usage (public, public and user-facing, or internal) of each certificate, see the following [Certificate management best practice](#) table.

Table 1. Certificate management best practice

Certificate usage	Certificate name	Best practice management
Public	<ul style="list-style-type: none"> <li>• apic-gw-service-ingress</li> </ul>	<p>For optimal trust levels, set these explicitly.</p> <p>If certificates are not explicitly set by using the <code>apicup certs set</code> command, then default self-signed certificates are automatically generated by <code>apicup subsys install</code>. Typically you usually want to customize them, to ensure a level of trust suitable for external communication.</p>
Public and User-facing	<ul style="list-style-type: none"> <li>• platform-api, api-manager-ui, cloud-admin-ui</li> <li>• consumer-api</li> <li>• portal-www-ingress</li> </ul>	<p>For optimal trust levels, set these explicitly.</p> <p>Recommended to be explicitly set as custom certificates because they are presented to an end user through a browser or Command Line Interface (CLI).</p>
Internal	<ul style="list-style-type: none"> <li>• root-ca, ingress-ca</li> <li>• mgmt-db-ca, mgmt-ca, service-server, service-client, db-server, db-client, service-plugin</li> <li>• portal-admin-ingress, portal-client, portal-ca, portal-db-ca, service-server, service-client, apim-client</li> <li>• analytics-client-ingress, analytics-ingestion-ingress, analytics-ingestion-client, analytics-client-client</li> <li>• analytics-ca, service-server, service-client</li> <li>• gw-ca, gateway-peering</li> </ul> <p>For VMware appliance deployments only: k8s-ca, appliance-client</p>	<p>Do not change. Accept the default certificates. It is possible to change these certificates (except ingress-ca) but is strongly discouraged because you risk creating incompatibilities that can block internal communications.</p> <p>Each intermediate cert (mgmt-db-ca, mgmt-ca, portal-ca, portal-db-ca, analytics-ca, gw-ca), is used to generate other internal certs. If, for example, you change an intermediate cert, the certs generated from it might not work with internal certs generated from other intermediate certs.</p> <p>Note that ingress-ca is auto-generated and cannot be set using the <code>apicup certs set</code> command.</p>

---

## Setting default certificates

Default certificates are automatically generated by APICUP when the subsystem is installed.

---

### About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see [Certificate management: Read This First](#). For details on each certificate, see [Certificate reference](#).
- Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Requirements for upgrading on VMware](#).

Default certificates are generated for each subsystem by the `apicup subsys install` command. If certificates are not explicitly set by using the `apicup certs set` command, then default certificates are automatically generated by APICUP. The default certificates are self-signed, so they might not provide a level of trust suitable for external communication.

---

## Procedure

1. Enter the settings for the subsystem by using `apicup subsys set <SUBSYS>` and validate the subsystem settings by using `apicup subsys get <SUBSYS> --validate`. The subsystem must pass validation before setting the certificates.
2. Install the subsystem by using the `apicup subsys install` command.
3. The default certificates are created for the subsystem. A default certificate is a private certificate that is uniquely generated by the installer for this project directory, they are self-signed and always pass validation.
4. List all certificates that are set for a subsystem by using the `apicup certs list` command.

```
apicup certs list -help

List all configured certificates

Usage:
  apicup certs list SUBSYS [flags]

Flags:
  -h, --help  help for list

Global Flags:
  --accept-license  Accept the license for API Connect
  --debug           Enable debug logging
```

Following is example output from the `apicup certs list` command:

```
Common certificates

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
 For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Setting custom certificates

Use the APICUP installer `certs` commands to set custom certificates.

### About this task

#### Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see [Certificate management: Read This First](#). For details on each certificate, see [Certificate reference](#).
- Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Requirements for upgrading on VMware](#).

The APICUP installer can be used to set certificates for each subsystem during installation. If certificates are not explicitly set by using the `apicup certs set` command, then default certificates are generated by APICUP. The default certificates are self-signed, so they might not provide a level of trust suitable for external communication.

#### Requirements for custom certificates:

- Extended Key Usage (EKU), either `serverAuth` or `clientAuth` depending upon the type of certificate. Certificates of type `Server` must have an Extended Key Usage with `serverAuth` purpose. Certificates of type `Client` must have an Extended Key Usage with `clientAuth` purpose.
- Subject Alternative Name (SAN) for the required hosts
- Any custom common certificates that are being used must be set prior to setting any custom certificates for a subsystem.

See [Certificate reference](#) to view the list of common certificates and to determine whether an EKU is needed for a certificate and which type of EKU (serverAuth or clientAuth).

Precedence order for TLS certificates for Management endpoints:

The Management subsystem has four public endpoints: *api-manager-ui*, *cloud-admin-ui*, *platform-api*, and *consumer-api*. Distinct TLS certificates can be set for each endpoint. However, if any two endpoints identical, only one TLS certificate will be effective. The order of precedence is: *api-manager-ui*, *cloud-admin-ui*, *platform-api*, *consumer-api*.

Following are examples for how precedence is determined for TLS certificates for endpoints:

- If all four endpoints are distinct, then all four TLS certificates will be effective for their respective endpoints.
- If all four endpoints are identical, then only the *api-manager-ui* TLS certificate will be effective for all endpoints, as it is first in the precedence order.
- If the *api-manager-ui*, *cloud-admin-ui*, and *platform-api* endpoints are the same, and *consumer-api* is a different endpoint, then the *api-manager-ui* TLS certificate will be effective for the *api-manager-ui/cloud-admin-ui/platform-api* endpoints, while the *consumer-api* TLS certificate will be effective for the *consumer-api* endpoint

Note: Once API Connect has been installed (meaning that the `apicup subsys install SUBSYS` command has been executed) with a given set of certificates, only the certificates for the public ingress endpoints (*portal-www*, *api-manager-ui*, *cloud-admin-ui*, *platform-api*, *consumer-api*) can be modified. The TLS certificates involved in mutual authentication (*portal-admin-ingress*, *portal-client*, *analytics-ingestion-ingress*, *analytics-ingestion-client*, *analytics-client-ingress*, and *analytics-client-client*) cannot be modified after the `install` command has been executed.

## Procedure

1. Set up and validate the subsystem. Enter the settings for the subsystem using `apicup subsys set <SUBSYS>` and validate the subsystem settings using `apicup subsys get <SUBSYS> --validate`. The subsystem must pass validation before setting the certificates.
2. Generate the custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (*platform-api-example*) with an EKU *serverAuth* and SAN using `openssl`:

```
openssl x509 -req -days 360 -in platform-api-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out platform-api-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nsubjectAltName=DNS:fqdn.myserver.com\nextendedKeyUsage=serverAuth")) -extensions SAN
```

where

- `DNS:fqdn.myserver.com` is the fully qualified domain name of the endpoint the certificate applies to. This matches the endpoints entered in the APICUP installer. See [Deploying the Management subsystem in a VMware environment](#)
- `platform-api-example.csr` is the file name for the certificate signing request

Following is an example for how to generate a certificate (*portal-client*) with an EKU *clientAuth* and SAN using `openssl`:

```
openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out portal-client-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

3. Once the certificate has been created, set the certificate by entering the following command:  
`apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE]`

If the certificate is signed by an intermediate CA, the `CA_File` argument must point to a file that concatenates the intermediate CA, followed by the root CA, in that order.

You can find definitions for commands at the following location: [Command reference](#)

If the certificate was generated with an EKU *serverAuth*, it must be assigned to a server certificate. If the certificate was generated with an EKU *clientAuth*, it must be assigned to a client certificate.

4. Repeat for additional custom certificates.
5. After setting the custom certificates, you can optionally generate the remaining default certificates prior to installation by entering the `apicup certs generate` command. The `generate` command generates any certificates that have not been set, so it will create default certificates for all remaining certificates. It will not overwrite any custom certificates you have set. You can review the certificates prior to installation.
6. List all certificates with `apicup certs list SUBSYS`. The results will include the generated default certificates and the custom certificates that you set.

Following is example output from the `apicup certs list` command:

```
list command:

Common certificates
=====
```

Name	Summary	Validation errors
----	-----	-----

service-server	CN: service-server SubjectKeyId: 6B:CD:BC:99:34:AF:50:D2:95:BF:0C:FD:82:94:E4:D7 AuthorityKeyId: 29:9C:F7:69:68:E4:1C:FC:D6:CE:83:26:3E:20:12:75	

7. Install the subsystem with the certificates using `apicup subsys install SUBSYS`. Any missing certificates will be generated. The installation will not proceed if there are any validation issues with the certificates. See [Validation reference](#).
8. Repeat for other subsystems.
9. If necessary, you can replace custom certificates after installation is complete. See [Replacing custom certificates](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Replacing custom certificates

Use the APICUP installer `certs` commands to replace existing certificates.

### About this task

**Important:**

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see [Certificate management: Read This First](#). For details on each certificate, see [Certificate reference](#).
- Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Requirements for upgrading on VMware](#).

The APICUP installer can be used to update certificates for each subsystem after installation.

Requirements for custom certificates:

- Extended Key Usage (EKU), either `serverAuth` or `clientAuth` depending upon the type of certificate. Certificates of type *Server* must have an Extended Key Usage with `serverAuth` purpose. Certificates of type *Client* must have an Extended Key Usage with `clientAuth` purpose.
- Subject Alternative Name (SAN) for the required hosts
- Any custom common certificates that are being used must be set prior to setting any custom certificates for a subsystem.

See [Certificate Reference](#) to view the list of common certificates and to determine whether an EKU is needed for a certificate and which type of EKU (`serverAuth` or `clientAuth`).

Precedence order for TLS certificates for Management endpoints:

The Management subsystem has four public endpoints: `api-manager-ui`, `cloud-admin-ui`, `platform-api`, and `consumer-api`. Distinct TLS certificates can be set for each endpoint. However, if any two endpoints identical, only one TLS certificate will be effective. The order of precedence is: `api-manager-ui`, `cloud-admin-ui`, `platform-api`, `consumer-api`.

Following are examples for how precedence is determined for TLS certificates for endpoints:

- If all four endpoints are distinct, then all four TLS certificates will be effective for their respective endpoints.
- If all four endpoints are identical, then only the api-manager-ui TLS certificate will be effective for all endpoints, as it is first in the precedence order.
- If the api-manager-ui, cloud-admin-ui, and platform-api endpoints are the same, and consumer-api is a different endpoint, then the api-manager-ui TLS certificate will be effective for the api-manager-ui/cloud-admin-ui/platform-api endpoints, while the consumer-api TLS certificate will be effective for the consumer-api endpoint

## Procedure

1. Generate the custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (platform-api-example) with an EKU serverAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in platform-api-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out platform-api-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nsubjectAltName=DNS:fqdn.myserver.com\nextendedKeyUsage=serverAuth")) -extensions SAN
```

where

- `DNS:fqdn.myserver.com` is the fully qualified domain name of the endpoint the certificate applies to. This matches the endpoints entered in the APICUP installer. See [Deploying the Management subsystem in a VMware environment](#).
- `platform-api-example.csr` is the file name for the certificate signing request

Following is an example for how to generate a certificate (portal-client) with an EKU clientAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out portal-client-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

2. Once the certificate has been created, set the certificate by entering the following command:

```
apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE]
```

You can find definitions for commands at the following location: [Command reference](#)

If the certificate was generated with an EKU serverAuth, it must be assigned to a server certificate. If the certificate was generated with an EKU clientAuth, it must be assigned to a client certificate.

3. Install the subsystem with the new certificate using `apicup subsys install SUBSYS`. Any missing certificates will be generated. The installation will not proceed if there are any validation issues with the certificates. See [Validation reference](#).
4. Repeat for other subsystems requiring new certificates.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Setting common certificates

Common certificates are set for one subsystem, but are applied to all subsystems. Use the APICUP installer `certs` commands to set the common certificates.

## About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see [Certificate management: Read This First](#). For details on each certificate, see [Certificate reference](#).
- Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Requirements for upgrading on VMware](#).

The common certificates are identical across subsystems. Subsystems require the common certificates to allow them to register with the management subsystem. When installing any one subsystem, the common certificates will be set for that subsystem and for all the other subsystems. If you are using custom certificates for the common certificates, they must be set prior to setting any custom certificates. See [Certificate reference](#) for a description of the common certificates.

Common certificates cannot be changed between subsystem installs. For example, you cannot set a common certificate for the management subsystem, install the management subsystem, then change a common certificate for the analytics subsystem, then install the analytics subsystem. This scenario will result in a failed installation because the common certificates are not identical.

## Procedure

Follow these steps to set custom common certificates. If using default certificates, the common certificates will be set for you. See [Setting default certificates](#).

1. Set up and validate all subsystems. Enter the settings for the subsystem using `apicup subsys set <SUBSYS>` and validate the subsystem settings using `apicup subsys get <SUBSYS> --validate`. The subsystem must pass validation before setting the certificates.
2. Generate a custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (platform-api) with an EKU serverAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in platform-api.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out platform-api-sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nsubjectAltName=DNS:ac-msntest.myserver.com,DNS:ac2-msntest.myserver.com\nextendedKeyUsage=serverAuth")) -extensions SAN
```

Following is an example for how to generate a certificate (portal-client) with an EKU clientAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in portal-client.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out portal-client-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

3. Once the certificate has been created and you have a `.pem` file, set the custom common certificates in one of your subsystems. After setting the custom certificates for one subsystem, they will take effect for all subsystems. The command is targeted at a specific subsystem, but the common certificates are copied to all subsystems regardless of which subsystem they are originally set in. Following is an example for setting the `portal-client` certificate:  
`apicup certs set mgmt portal-client myCertFile.pem myKeyFile.key myCAFile.crt`
4. Set the remaining certificates for each subsystem, default or custom. See [Setting default certificates](#) and [Setting common certificates](#).
5. List and validate the certificates for each subsystem. See [Validation reference](#).
6. Install each subsystem using `apicup subsys install SUBSYS`.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Setting the encryption-secret for the management database

Use the APICUP installer `certs` commands to set the encryption-secret for the management database.

### About this task

Note: Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Requirements for upgrading on VMware](#).

The encryption-secret is a secure random bytes password used for field level encryption in the management database. You can generate 128 random bytes using the following command in openssl:

```
openssl rand -out /path/to/secret/encryption-secret.bin 128
```

### Procedure

1. Enter the `apicup certs set SUBSYS CERT_NAME [KEY_FILE]` command and complete the following values:
  - SUBSYS - The subsystem for the `encryption-secret` is the name of your management subsystem, because it is used for field-level encryption for the management database.
  - CERT\_NAME - The certificate name is `encryption-secret`.
  - KEY\_FILE - Enter the file name for a secure random bytes string that is 128 bytes in length, for example `encryption-secret.bin`.
2. Set the remaining certificates if using custom certificates and install the management subsystem.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Clearing certificates

Certificates can be cleared in order to set new certificates.

### About this task

Note: Certificates are automatically copied during an upgrade (if the upgrade is initiated from the original project directory). For more information, see [Requirements for upgrading on VMware](#).

Existing certificates must be cleared in order to set new certificates. When using default certificates, new certificates are created only for those certificates that are not set. Some of the use cases for clearing certificates are: expired certificates and configuration changes. For example, if endpoints are changed, the existing certificates must be cleared and new certificates created.

### Procedure

1. Enter the `apicup certs set SUBSYS CERT_NAME --clear` command and complete the following values:
  - SUBSYS - The name of the subsystem
  - CERT\_NAME - The name of the certificate that you want to clear.

2. The certificate will be cleared and can be reset, either as a default or custom certificate.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Reference for certificates, commands, and validations

This section contains the reference information for certificates, commands for working with certificates, and validations.

- [Certificate reference](#)  
The Certificate reference provides a description of all the certificates required in API Connect.
- [Command reference](#)  
The APICUP installer includes the `certs` commands to set and manage certificates.
- [Validation reference](#)  
Certificates are validated using several parameters.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Certificate reference

The Certificate reference provides a description of all the certificates required in API Connect.

---

### Before you begin

APICUP sets default certificates for each subsystem during installation. The default certificates are self-signed so may not provide a level of trust suitable for external communication. Custom certificates can be set and managed following the steps described in [Setting custom certificates](#).

The Certificates reference topic lists all certificates that are set by the `apicup certs` commands. The default certificates can be used for the majority of these certificates. The certificates that are marked as *public and user-facing* are recommended to be explicitly set as custom certificates because they are presented to an end user through a browser or Command Line Interface (CLI).

The certificates that are described as *TLS certificate used by ingress* are also considered *public* in the sense that they interact with a client that sits outside of an API Connect cluster.

The remaining certificates are considered *internal* because they interact with internal components.

Certificates that are listed as *auto-generated* cannot be set using the `apicup certs set` command. For example, the common certificate `ingress-ca` is auto-generated and used as an intermediate CA for all default ingress certificates. If you set an ingress certificate as a custom certificate, you will need to configure an intermediate CA if desired.

Important:

When setting custom certificates, additional steps must be taken to provide an Extended Key Usage (EKU) serverAuth and ClientAuth and a Subject Alternative Name (SAN) for the required hosts. These certificates are generated automatically by the `apicup certs` command when using the default certificates.

- For custom certificates of type *server*, an additional extended key usage client authentication (EKU serverAuth) certificate is required.
- For custom certificates of type *client*, an additional extended key usage server authentication (EKU clientAuth) certificate is required.

---

## Procedure

1. **Common certificates** - The following certificates are common to all subsystems in a deployment. Subsystems require the common certificates to allow them to register with the management subsystem. The common certificates are identical across subsystems. When installing any one subsystem, the common certificates will be set for that subsystem and for all the other subsystems. Custom common certificates must be set prior to setting any custom subsystem certificates.

Common certificates cannot be changed between subsystem installs. For example, you cannot set a common certificate for the management subsystem, install the management subsystem, then change a common certificate for the analytics subsystem, then install the analytics subsystem. This scenario will result in a failed installation because the common certificates are not identical.

Table 1. Common certificates

Certificate name (value used in <code>apicup certs</code> )	Type	Usage	Requirements	Description
root-ca	CA	internal		CA certificate which forms the root of the certificate chain

Certificate name (value used in apicup certs)	Type	Usage	Requirements	Description
ingress-ca	CA	internal	signed by: root-ca	Auto-generated intermediate certificate used to generate certificates for subsystem ingress endpoints if not provided by user. The ingress-ca intermediate certificate cannot be set explicitly, it is always only generated. TLS certificates for the ingresses are not required to use ingress-ca as an intermediate certificate, but if a given ingress TLS certificate is left to be auto-generated then it will be signed by this ingress-ca.
mgmt-db-ca	CA	internal	signed by: root-ca	Intermediate CA certificate used to sign certificates used by Cassandra.
portal-client	Client	internal	Must be signed by the same authority as the one used for the matching ingress TLS certificate <b>portal-admin-ingress</b> .	Client certificate used by management subsystem to authenticate with the Portal admin endpoint. Requires EKU clientAuth.
analytics-client-client	Client	internal	Must be signed by the same authority as the one used for the matching ingress TLS certificate <b>analytics-client-ingress</b> .	Client certificate used by management subsystem to authenticate with analytics client endpoint. Requires EKU clientAuth.
analytics-ingestion-client	Client	internal	Must be signed by the same authority as the one used for the matching ingress TLS certificate <b>analytics-ingestion-ingress</b> .	Client certificate used by gateway subsystem to authenticate with analytics ingestion endpoint. Requires EKU clientAuth.

## 2. Management certificates

These certificates apply to a single Management subsystem.

The Management subsystem has four endpoints: *api-manager-ui*, *cloud-admin-ui*, *platform-api*, and *consumer-api*. Distinct TLS certificates can be set for each endpoint. However, if any two endpoints identical, only one TLS certificate will be effective. The order of precedence is: *api-manager-ui*, *cloud-admin-ui*, *platform-api*, *consumer-api*.

Following are examples for how precedence is determined for TLS certificates for endpoints:

- If all four endpoints are distinct, then all four TLS certificates will be effective for their respective endpoints.
- If all four endpoints are identical, then only the *api-manager-ui* TLS certificate will be effective for all endpoints, as it is first in the precedence order.
- If the *api-manager-ui*, *cloud-admin-ui*, and *platform-api* endpoints are the same, and *consumer-api* is a different endpoint, then the *api-manager-ui* TLS certificate will be effective for the *api-manager-ui/cloud-admin-ui/platform-api* endpoints, while the *consumer-api* TLS certificate will be effective for the *consumer-api* endpoint

The encryption-secret certificate is unique in that it is a secure random number. It is used to provide field level encryption in management (Cassandra) database. To set the encryption secret for the management database, use the following command: **apicup certs set SUBSYS CERT\_NAME**

[KEY\_FILE] For example: **apicup certs set mgmt1 encryption-secret /path/to/keyfile**. See [Setting the encryption-secret for the management database](#)

Table 2. Management certificates

Certificate name	Type	Usage	Requirements	Description
encryption-secret	secure random bytes		length: 128 bytes	Encryption secret used to do field level encryption in management (Cassandra) database
platform-api	Server	public and user-facing	The host names for which the certificate is valid must include the platform-api endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <i>store.acme.com</i> , the certificate can be one that is valid for host names matching <i>*.acme.com</i> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
consumer-api	Server	public and user-facing	The host names for which the certificate is valid must include the consumer-api endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <i>store.acme.com</i> , the certificate can be one that is valid for host names matching <i>*.acme.com</i> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
api-manager-ui	Server	public and user-facing	The host names for which the certificate is valid must include the api-manager-ui endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <i>store.acme.com</i> , the certificate can be one that is valid for host names matching <i>*.acme.com</i> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
cloud-admin-ui	Server	public and user-facing	The host names for which the certificate is valid must include the cloud-admin-ui endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <i>store.acme.com</i> , the certificate can be one that is valid for host names matching <i>*.acme.com</i> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
mgmt-ca	CA	internal	signed by: root-ca	Intermediate CA used to sign management subsystem certificates

Certificate name	Type	Usage	Requirements	Description
service-server	Server	internal	signed by: mgmt-ca Required hosts: <ul style="list-style-type: none"> <li>*.&lt;namespace&gt;</li> <li>*.&lt;namespace&gt;.svc</li> <li>*.&lt;namespace&gt;.svc.cluster.local</li> </ul>	Server certificates used by management services. Requires EKU serverAuth.
service-client	Client	internal	signed by: mgmt-ca	Client certificate used by management services. Requires EKU clientAuth.
db-server	Server	internal	signed by: mgmt-db-ca Required hosts: <ul style="list-style-type: none"> <li>*.&lt;namespace&gt;</li> <li>*.&lt;namespace&gt;.svc</li> <li>*.&lt;namespace&gt;.svc.cluster.local</li> </ul>	Server certificate used by management (Cassandra) database to communicate with other nodes. Requires EKU serverAuth.
db-client	Client	internal	signed by: mgmt-db-ca	Client certificate used by management services. Requires EKU clientAuth.
service-plugin	Client	internal	signed by: mgmt-ca	Client certificate used by plugin services to talk to management subsystem. Requires EKU clientAuth.
migration-client	Client		signed by: mgmt-ca	This certificate is deprecated and no longer used, and can be ignored.

### 3. Portal certificates

These certificates apply to a single portal subsystem.

Table 3. Portal certificates

Certificate name	Type	Usage	Requirements	Description
portal-admin-ingress	Server	internal	host must match admin endpoint	TLS certificate used by ingress. The <b>portal-client</b> common certificate must be set prior to setting the <b>portal-admin-ingress</b> certificate. Requires EKU serverAuth. The <b>portal-admin-ingress</b> TLS certificate does not have any specific requirement on the authority signing it. If the certificate is auto-generated, it is signed by the <b>ingress-ca</b> .
portal-www-ingress	Server	public and user-facing	host must match www endpoint	TLS certificate used by ingress. Requires EKU serverAuth.
portal-ca	CA	internal	signed by: root-ca	Intermediate CA used to sign portal subsystem certificates
portal-db-ca	CA	internal	signed by: portal-ca	Intermediate CA certificate used to sign certificates used by portal DB
service-server	Server	internal	signed by: portal-ca Required hosts: <ul style="list-style-type: none"> <li>*.&lt;namespace&gt;</li> <li>*.&lt;namespace&gt;.svc</li> <li>*.&lt;namespace&gt;.svc.cluster.local</li> </ul>	Server certificates used by portal services. Requires EKU serverAuth.
service-client	Client	internal	signed by: portal-ca	Client certificate used by portal services. Requires EKU clientAuth.
apim-client	Client	internal	signed by: portal-ca	Client certificate used by portal services to talk to management subsystem. Requires EKU clientAuth.

### 4. Analytics certificates

These certificates apply to a single analytics subsystem.

Table 4. Analytics certificates

Certificate name	Type	Usage	Requirements	Description
------------------	------	-------	--------------	-------------

Certificate name	Type	Usage	Requirements	Description
analytics-client-ingress	Server	internal	Required hosts: <ul style="list-style-type: none"> <li>client ingress endpoint</li> <li>*, &lt;namespace&gt;</li> <li>*, &lt;namespace&gt;.svc</li> <li>*, &lt;namespace&gt;.svc.cluster.local</li> </ul>	TLS certificate used by ingress. The <b>analytics-client-client</b> common certificate must be set prior to setting the <b>analytics-client-ingress</b> certificate. Requires EKU serverAuth. The <b>analytics-client-ingress</b> TLS certificate does not have any specific requirement on the authority signing it. If the certificate is auto-generated, it is signed by the <b>ingress-ca</b> .
analytics-ingestion-ingress	Server	internal	Required hosts: <ul style="list-style-type: none"> <li>ingestion ingress endpoint</li> <li>*, &lt;namespace&gt;</li> <li>*, &lt;namespace&gt;.svc</li> <li>*, &lt;namespace&gt;.svc.cluster.local</li> </ul>	TLS certificate used by ingress. The <b>analytics-ingestion-client</b> common certificate must be set prior to setting the <b>analytics-ingestion-ingress</b> certificate. Requires EKU serverAuth. The <b>analytics-ingestion-ingress</b> TLS certificate does not have any specific requirement on the authority signing it. If the certificate is auto-generated, it is signed by the <b>ingress-ca</b> .
analytics-ca	CA	internal	signed by: root-ca	Intermediate CA used to sign analytics subsystem certificates
service-server	Server	internal	signed by: analytics-ca Required hosts: <ul style="list-style-type: none"> <li>*, &lt;namespace&gt;</li> <li>*, &lt;namespace&gt;.svc</li> <li>*, &lt;namespace&gt;.svc.cluster.local</li> </ul>	Server certificates used by analytics services. Requires EKU serverAuth.
service-client	Client	internal	signed by: analytics-ca	Client certificate used by analytics services; requires EKU clientAuth.

#### 5. Gateway certificates

These certificates apply to a single gateway subsystem.

Table 5. Gateway certificates

Certificate name	Type	Usage	Requirements	Description
api-gateway-ingress	Server	public and user-facing	host must match api-gateway endpoint	TLS certificate used by ingress. Requires EKU serverAuth. (deprecated, see <b>Note</b> .)
apic-gw-service-ingress	Server	public	host must match apic-gw-service endpoint	TLS certificate used by ingress. Requires EKU serverAuth.
gw-ca	CA	internal	signed by: root-ca	Intermediate CA used to sign gateway subsystem certificates
gateway-peering	Server	internal	signed by: gw-ca	Server certificates used by gateway services. Requires EKU serverAuth.

Note: The **api-gateway-ingress** certificate is a legacy certificate which has been deprecated. It is no longer used to terminate TLS at the api-gateway endpoint. You configure a TLS profile for the termination of the api-gateway endpoint using the Cloud Manager API Invocation Endpoint and SNI settings when registering the gateway. The profiles used during configuration can be updated as needed. See [Registering a gateway service](#)

#### 6. OVA/Appliance certificates

These certificates apply only to an appliance in a VMware environment. The **k8s-ca** and **appliance-client** certificates are auto-generated and cannot be set as custom certificates. These are internal certificates used to set up the Kubernetes cluster in an OVA/Appliance.

Table 6. OVA/Appliance certificates

Certificate name	Type	Requirements	Description
k8s-ca	CA		Auto-generated CA certificate that forms the root of the certificate chain for the Appliance/Kubernetes cluster components
appliance-client	Client	signed by: k8s-ca	Auto-generated client certificate used to communicate with the Appliance API server. Requires EKU clientAuth.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.  
 For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Command reference

The APICUP installer includes the `certs` commands to set and manage certificates.

### About this task

The APICUP installer can be used to set certificates for each subsystem during installation. If certificates are not explicitly set using the `apicup certs set` command, then default certificates are generated by APICUP. We recommend that certificates be set at installation time only (or carried over from an upgrade). The default certificates are self-signed, so they may not be optimal for external communication.

For a description of the certificates that can be set, see [Certificate reference](#). We recommend that all public and user-facing certificates be explicitly set, including `portal-www-ingress` and `api-gateway-ingress`, and the four management endpoints (`platform-api`, `consumer-api`, `api-manager-ui`, and `cloud-admin-ui`). Following is the help reference for the `apicup certs set` command:

```
apicup certs set --help
Set or clear certificates and keys

Usage:
apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [KEY_FILE] [flags]

Flags:
--clear    Clear out a certificate or key entry
-h, --help help for set

Global Flags:
--accept-license Accept the license for API Connect
--debug         Enable debug logging
```

### Procedure

To set and clear certificates, complete the following steps:

1. Enter the `apicup certs set` command and complete the following values:

Table 1. `apicup certs set`

Command	Values	Result
<code>apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [KEY_FILE] [flags]</code>	Parameters are: <ul style="list-style-type: none"> <li>• SUBSYS - name of the subsystem to which the certificate applies</li> <li>• CERT_NAME - name of the certificate; see <a href="#">Certificate reference</a> for a list of certificates that can be set for each subsystem.</li> <li>• CERT_FILE - Path to the certificate file in PEM format.</li> <li>• KEY_FILE - Path to the private key file in PEM format.</li> <li>• CA_FILE - Path to the Certificate Authority (CA) file. The contents of the file may be the concatenation of an intermediate CA and the root CA (in that order). <b>Note:</b> When setting the <code>root-ca</code> certificate, omit the <code>CA_FILE</code> parameter.</li> </ul>	Applies the certificate when the subsystem is installed.
<code>apicup certs set SUBSYS CERT_NAME [KEY_FILE] [flags]</code>	<code>KEY_FILE</code> - The file containing the encryption-secret for field level encryption in the management database. Applies only to the management subsystem. The certificate name is <code>encryption-secret</code> . The type is secure random bytes with a length of 128 bytes. For example, <code>apicup certs set mgmt1 encryption-secret /path/to/encryption-secret.bin</code> . <b>Note:</b> Do not specify any of the <code>[CERT_FILE KEY_FILE CA_FILE]</code> parameters when setting the encryption-secret.	Applies the <code>encryption-secret</code> when the management subsystem is installed.
<code>flags</code> <ul style="list-style-type: none"> <li>• <code>--clear</code></li> <li>• <code>--help</code></li> </ul>	Flags are: <ul style="list-style-type: none"> <li>• <code>--clear</code> - Clears the specified certificate. For example, <code>apicup certs set mgmt1 encryption-secret --clear</code></li> <li>• <code>--help</code> - Displays help for the command.</li> </ul>	The specified certificate will be cleared. When making configuration changes such as changing endpoints, the corresponding certificate must be cleared so that a new certificate can be set.

2. The `apicup certs get` command retrieves a specific certificate for the specified subsystem.

```
apicup certs get --help
Get a certificate

Usage:
apicup certs get SUBSYS CERT_NAME [flags]

Flags:
-h, --help help for get
-o, --output string output to file or - (stdout) (default "-")
-t, --type string type of object to return: cert, key, ca (default "cert")

Global Flags:
--accept-license Accept the license for API Connect
--debug         Enable debug logging
```

Table 2. `apicup certs get`

Command	Values	Result
---------	--------	--------

Command	Values	Result
<code>apicup certs get SUBSYS CERT_NAME [flags]</code>	Parameters are: <ul style="list-style-type: none"> <li>SUBSYS - name of the subsystem to which the certificate applies</li> <li>CERT_NAME - name of the certificate to retrieve; see <a href="#">Certificate reference</a> for a list of certificates</li> </ul>	Returns the specified certificate for the specified subsystem.
<code>flags</code> <ul style="list-style-type: none"> <li><code>--output string</code></li> <li><code>--type string</code></li> <li><code>--help</code></li> </ul>	Flags are: <ul style="list-style-type: none"> <li><code>--output string</code> - Specify a file for the retrieved values, or specify "-" to send to stdout. Default is "-" to send to stdout. For example, <code>apicup certs get mgmt1 --output myCertsFile</code></li> <li><code>--type string</code> - Returns only the specified type. If not specified, the type is cert. For example, <code>apicup certs get mgmt1 --type ca</code></li> <li><code>--help</code> - Displays help for the command.</li> </ul>	<ul style="list-style-type: none"> <li>For <code>--output</code>: The specified certificate will be retrieved and sent to stdout or saved to the specified file</li> <li>For <code>--type</code>: Certificates will be retrieved that match the type specified.</li> </ul>

3. List all certificates that have been set for a subsystem using the `apicup certs list` command. You can list the certificates at any time to summarize the certificates that have been set.

```
apicup certs list -help
```

```
List all configured certificates
```

```
Usage:
```

```
apicup certs list SUBSYS [flags]
```

```
Flags:
```

```
-h, --help help for list
```

```
Global Flags:
```

```
--accept-license Accept the license for API Connect
--debug Enable debug logging
```

Table 3. apicup certs list

Command	Values	Result
<code>apicup certs list SUBSYS [flags]</code>	Parameters are: <ul style="list-style-type: none"> <li>SUBSYS - name of the subsystem for which you want to list certificates</li> </ul>	Returns a list of certificates that are configured for the subsystem.
<code>flags</code> <ul style="list-style-type: none"> <li><code>--help</code></li> </ul>	Flags are: <ul style="list-style-type: none"> <li><code>--help</code> - Displays help for the command.</li> </ul>	Help text is displayed.

Following is example output from the `apicup certs list` command:

```
Common certificates
```

```

4. The `apicup certs generate` command generates and sets default certificates. The `generate` command only generates and sets a certificate if it is not already set; it only sets the missing default certificates that have not been explicitly set using the `set` command. Execute the `generate` command before running the `apicup subsys install <SUBSYS>` command to confirm the certificates are correct before installing. It allows you to validate all certificates before performing the installation. The `generate` command is used as a tool to assist you when entering a combination of default and custom certificates. If you need to set specific certificates you can set them upfront (using `set`) and then generate the missing ones with default certificates. Or you can generate all certificates upfront and then override specific certificates to set custom certificates. Using `generate` helps to avoid validation errors during the installation procedure. Note that you must configure the subsystems and pass the `--validate` option before generating the default certificates.

```

apicup certs generate -help
Generate all unset certificates

```

```

Usage:
  apicup certs generate SUBSYS [flags]

```

```

Flags:
  -h, --help      help for generate
Global Flags:
  --accept-license  Accept the license for API Connect
  --debug           Enable debug logging

```

Table 4. apicup certs generate

Command	Values	Result
<code>apicup certs generate SUBSYS [flags]</code>	Parameters are: <ul style="list-style-type: none"> <li>SUBSYS - name of the subsystem for which you want to generate certificates</li> </ul>	Generates certificates that have not been set for the subsystem. Generates self-signed certificates.
<code>flags</code> <ul style="list-style-type: none"> <li><code>--help</code></li> </ul>	Flags are: <ul style="list-style-type: none"> <li><code>--help</code> - Displays help for the command.</li> </ul>	Help text is displayed.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Validation reference

Certificates are validated using several parameters.

The validations described in the following table are applied for all certificates, but are most helpful for custom certificates. For default certificates, the certificate validations will always pass, as the required elements are generated by APICUP. However, with custom certificates, some of the required elements may be missing or incorrect.

Validation	Messages	Error	See also/Action
Verify the certificate is set properly.	<code>certificate &lt;cert&gt; not set</code>	The certificate is not set.	
	<code>unable to load cert &lt;cert&gt;</code>	The certificate is set but cannot be read.	
Verify certificate key usage (Extended Key Usage).	<code>unable to verify cert &lt;cert&gt;: missing key usage &lt;n&gt;</code>	The certificate is missing the required key usage.	See <a href="#">Certificate reference</a> to see more information, including the type, for all certificates. See <a href="#">Setting custom certificates</a> for tips on how to generate the EKUs for custom certificates.
Verify the certificate signing CA. If available, the CA file is loaded. Then the certificate is verified against the provided CA file, including enforcement of Extended Key Usage.	<code>unable to parse CA to verify cert &lt;cert&gt;</code>	The CA file could not be parsed and loaded.	
	<code>unable to verify cert &lt;cert&gt;</code>	The certificate failed verification against the provided CA file.	One possible reason for receiving this error is that the correct EKU is missing. For a custom certificate, see <a href="#">Setting custom certificates</a> for information on generating EKUs.
Verify certificate hosts. The certificate must be valid for the hosts listed for the certificate in the Requirements column in the Certificates Reference.	<code>unable to verify cert &lt;cert&gt;: missing &lt;host&gt;</code>	The certificate is not valid for the required host.	See <a href="#">Certificate reference</a> for the required hosts.

Validation	Messages	Error	See also/Action
Verify that a certificate that is being used as a CA is actually a CA.	unable to verify cert <cert>: certificate is not a CA	The certificate is not a valid CA.	
Verify client certificate match. The portal-client, analytics-client-client, and analytics-ingestion-client certificates are verified against the CA of, respectively, portal-admin-ingress, analytics-client-ingress, and analytics-ingestion-ingress.	a CA certificate must be provided for this certificate	The CA certificate is missing for one of the portal-admin-ingress, analytics-client-ingress, and analytics-ingestion-ingress.	The common certificates portal-client, analytics-client-client, and analytics-ingestion-client must be set prior to setting any custom certificates.
	client cert cannot be verified against provided CA certificate	The verification failed.	

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Tips and tricks for using APICUP

The APICUP installer in Install Assist contains built-in time saving functions.

### Introduction

This section describes tips and techniques for working with the APICUP installation commands. The APICUP installer creates charts and secrets that are then managed by Helm.

- [Running Tiller with APICUP](#)
- [Entering multiple settings per command](#)
- [Entering multiple values](#)
- [Viewing the settings for a subsystem](#)
- [Validating the settings for a subsystem](#)
- [Output an installation plan](#)
- [Getting help for commands](#)
- [Getting help on a specific command](#)

### Running Tiller with APICUP

To run Tiller in a namespace:

```
export TILLER_NAMESPACE=apic
```

### Entering multiple settings per command

To configure multiple settings per command, enter a space between each setting and enter an equals sign (=) to configure the setting.

In the following examples, be sure to replace [spc] with an actual space.

**You can set multiple database parameters on one line:**

```
apicup subsys set mgmt cassandra-max-memory-gb=9[spc]cassandra-cluster-size=3[spc]cassandra-volume-size-gb=16[spc]cassandra-backup-protocol=sftp
```

**You can set all endpoints on one line:**

```
apicup subsys set mgmt platform-api=my.platform.com[spc]api-manager-ui=my.apim.com[spc]cloud-admin-ui=my.cloud.com[spc]consumer-api=my.consumer.com
```

### Entering multiple values

Separate multiple values for a key/value pair with commas.

```
apicup subsys set mgmt dns-servers=8.8.8.8,4.4.4.4 search-domains=a.com,b.com
```

### Viewing the settings for a subsystem

To view the current values that are set for a subsystem, enter the following command: `apicup subsys get <subsys_name>`. For example: `apicup subsys get mgmt` outputs the current values for the subsystem named `mgmt` and provides a description of each value. The output from the `get` command is organized into Kubernetes settings and Subsystem settings. Following is an example:

Figure 1. Output for the `get` command

```
Kubernetes settings
=====
```

```

Name          Value          Description
----          -
extra-values-file (Optional) Path to additional configuration yml file
ingress-type   ingress        Ingress type (use `route` for OpenShift)
mode           standard      mode
namespace      default       K8S namespace to install into
registry       Docker image registry to use
registry-secret Docker registry credentials secret
storage-class  -            K8S storage class for persistent storage

Subsystem settings
=====

Name          Value          Description
----          -
cassandra-backup-auth-pass (Optional) Server password for DB backups
cassandra-backup-auth-user (Optional) Server username for DB backups
cassandra-backup-host (Optional) FQDN for DB backups server
cassandra-backup-path (Optional) path for DB backups server
cassandra-backup-port (Optional) Server port for DB backups
cassandra-backup-protocol (Optional) Protocol for DB backups (sftp/ftp)
cassandra-backup-schedule (Optional) Cron schedule for DB backups
cassandra-cluster-size Size of DB cluster (min 3 for HA)
cassandra-max-memory-gb Memory limit for DB
cassandra-volume-size-gb Size of DB storage volume (not resizable)
create-crd     true          Create DB cluster CRDS (Required cluster admin privilege)
external-cassandra-host (Optional) Hostname of externally hosted DB

Endpoints
=====

Name          Value          Description
----          -
api-manager-ui FQDN of API manager UI endpoint
cloud-admin-ui FQDN of Cloud admin endpoint
consumer-api   FQDN of consumer API endpoint
platform-api   FQDN of platform API endpoint

Error: Subsystem validation failure. Run with --validate to see details

```

## Validating the settings for a subsystem

The values set for a subsystem can be validated for syntax by entering the `--validate` option for the `get` command: `apicup subsys get <subsys_name> --validate`. For example: `apicup subsys get mgmt --validate` validates the current values for the subsystem named `mgmt`. In the following example of the output for the `--validate` option, the check mark indicates a valid setting. The `x` indicates an invalid setting with an error message provided.

Figure 2. Output for the `--validate` option

```

Subsystem settings
=====

Name          Value          Description
----          -
cassandra-backup-auth-pass ✓
cassandra-backup-auth-user ✓
cassandra-backup-host ✓
cassandra-backup-path /backups ✓
cassandra-backup-port 22 ✓
cassandra-backup-protocol sftp ✓
cassandra-backup-schedule 0 0 * * * ✓
cassandra-cluster-size 1 ✓
cassandra-max-memory-gb 9 ✓
cassandra-volume-size-gb 50 ✓
create-crd true ✓
external-cassandra-host ✓

Endpoints
=====

Name          Value          Description
----          -
api-manager-ui x api-manager-ui is not a valid hostname
cloud-admin-ui x cloud-admin-ui is not a valid hostname
consumer-api x consumer-api is not a valid hostname
platform-api x platform-api is not a valid hostname

```

## Output an installation plan

Using APICUP, you can generate an installation plan and confirm it is correct prior to running the installation. You can then install the subsystem from the plan.

To output an installation plan, enter the following command:

```
apicup subsys install SUBSYS --out=install-plan
```

where `<install-plan>` is the name of the directory where the installation plan will be stored.

In the example, a directory named install-plan is created in the project directory. The myProject/install-plan directory contains the configuration parameters for the subsystem.

To install the subsystem from the install-plan, enter the following command from the project directory:

```
apicup subsys install SUBSYS --plan-dir=<full-path-to-plan-directory>
```

where <full-path-to-plan-directory> is the full qualified path to the plan directory.

Following are general rules for installing from the installation plan:

- Never edit the files in the output directory directly. Instead, if changes are needed, update the parameters using APICUP and generate a new plan.
- Always run APICUP commands from the original project directory created during the initial product installation. The project directory contains the apiconnect-up.yml file.
- You can generate the plan in any location, but the install command must be run from the project directory. Enter the full path to the plan as the argument to `--plan-dir` to perform an installation.

The plan must be current with the project and the certificates. If the plan is older than the last modification date of the project or certificates, you will receive an error message such as:

```
the project was modified since the plan was generated, regenerate plan or skip this check
with a --no-verify flag in the command
```

or

```
the certs were changed since the plan was generated, regenerate plan or skip this check with
a --no-verify flag in the command
```

## Getting help for commands

---

You can get help for all commands by entering: `apicup --help`. Following is an example of the output:

Figure 3. Help for Install Assist apicup commands

```
APIConnect Install Assist
Usage:
  apicup [command]

Available Commands:
  certs           Subsystem certificates
  completion      Generates bash or zsh completion scripts
  help            Help about any command
  hosts           Commands to configure subsystem hosts
  iface           Commands to configure hosts interfaces
  init            Create a new APIConnect UP project
  registry-upload Retag and upload images to custom registry
  server          Starts the APIConnect cluster operator
  subsys          Subsystem commands
  version         Get the APIConnect UP version

Flags:
  --accept-license  Accept the license for API Connect
  --debug           Enable debug logging
  -h, --help        help for apicup

Use "apicup [command] --help" for more information about a command.
```

## Getting help on a specific command

---

For help on a specific command, enter `--help` after the command. For example, `apicup subsys get mgmt --help` prints out the usage and flags for the `get` command. For example:

Figure 4. Help for get command

```
Get subsystem properties

Usage:
  apicup subsys get SUBSYS [flags]

Flags:
  --endpoints  List endpoints (default true)
  -h, --help   help for get
  --platform   List platform settings (default true)
  --subsystem  List subsystem settings (default true)
  --validate   Validate settings

Global Flags:
  --accept-license  Accept the license for API Connect
  --debug           Enable debug logging
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Deploying to a VMware environment

The Install Assist tool provides a simplified installation for the OVA files into a VSphere environment.

### About this task

---

The Install Assist tool contains the **APICUP** installation utility program, which provides an automated installation process for API Connect. This section contains the download and installation procedure.

- [Requirements for deploying on VMware](#)  
Ensure that your deployment uses supported versions of all software, and meets the firewall requirements.
- [Load balancer configuration in a VMware deployment](#)  
When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect OVA deployment.
- [Configuring remote logging for a VMware deployment](#)  
Appliance-based (OVA) deployments use Syslog for collecting logs. Logs must be collected for both running and terminated containers and processes. Logging collection is required for IBM Support to assist with troubleshooting.
- [First steps for deploying in a VMware environment](#)  
The first steps in deploying in a VMware environment are to obtain the API Connect distribution files and to create a project directory.
- [Deploying the Management subsystem in a VMware environment](#)  
You can create a virtual server by deploying the relevant IBM® API Connect OVA file on a VMware virtual server. Create all of the virtual servers that you want to use in your cloud.
- [Deploying the Analytics subsystem in a VMware environment](#)  
You can add analytics data collection by deploying the IBM API Connect Analytics OVA file on a VMware virtual server.
- [Deploying the Developer Portal in a VMware environment](#)  
You create a Developer Portal node by deploying the Developer Portal OVA template. After you deploy the Developer Portal OVA template, you can install the Developer Portal.
- [Access the Cloud Manager and begin API Connect Cloud Configuration](#)  
When all subsystems are deployed, use the admin account to access the Cloud Manager administrative console and begin configuration.
- [Configuring API Connect subsystems in a cluster on VMware](#)  
This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.
- [Installing the IBM License Metric Tool for VMware](#)  
The IBM License Metric Tool (ILMT) helps you assess if you are compliant with licensing requirements.
- [Adding a static route on a virtual machine](#)  
You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.
- [Configuring use of an external NTP server](#)  
You must configure an external NTP server for use by API Connect when deploying on a VMware virtual machine.
- [Deploying DataPower Gateway](#)  
API Connect uses IBM DataPower® Gateway to provide the gateway service.
- [Installing the toolkit](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Deployment overview for endpoints and certificates

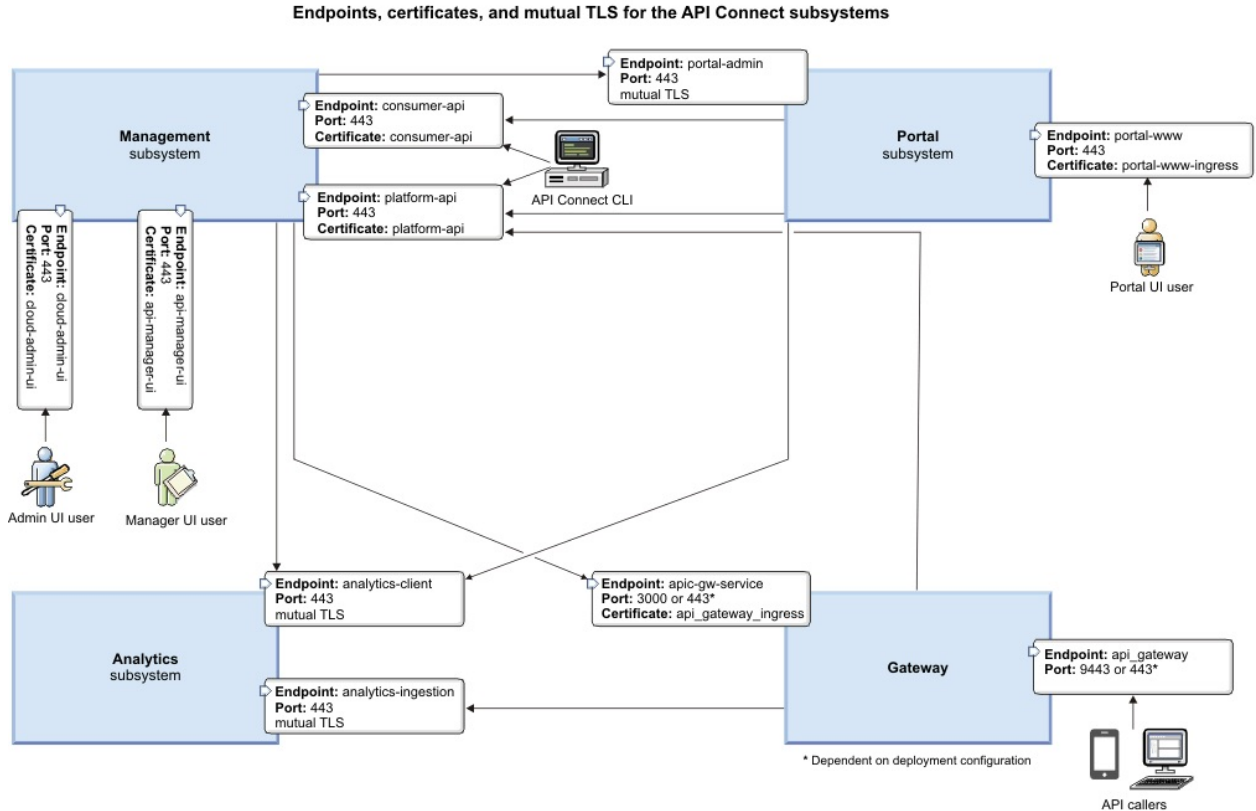

Refer to this diagram to view the connections and dataflow among the API Connect subsystems, including the endpoints and custom certificates, and the mutual TLS points.

### Introduction

---

When deploying API Connect, you will create one or more endpoints for the subsystems and then configure certificates or mutual TLS for most endpoints. [Figure 1](#) shows the endpoints for each subsystem by name, the name of the certificate that secures the endpoint, and whether mutual TLS is required. It also shows the ports consumed by the endpoints, which are standard for HTTP and HTTPS.

Figure 1. Deployment Overview diagram

## Configuring endpoints

The endpoints are configured by the Install Assist program using the APICUP installer. They are set for each subsystem. Endpoints are also entered when configuring the Topology for the Gateway, Portal, and Analytics subsystems in Cloud Manager.

For instructions on configuring endpoints and installing into an OVA environment, see [Deploying to a VMware environment](#).

Subsystem	Endpoints	Description	Certificates
Management	cloud-admin-ui	Configured using APICUP installer. Endpoint on the management server for communication with the Cloud Manager user interface.	cloud-admin-ui
	api-manager-ui	Configured using APICUP installer. API Manager URL endpoint on the management server for communication with the API Manager user interface.	api-manager-ui
	consumer-api	Configured using APICUP installer. Platform REST API endpoint for running consumer APIs on the management server.	consumer-api
	platform-api	Configured using APICUP installer. Platform REST API endpoint for running admin and provider APIs on the management server.	platform-api
Portal	portal-admin	Configured using APICUP installer. Corresponds to Management Endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS.	mutual TLS
	portal-www	Configured using APICUP installer. Portal Web site URL entered in Cloud Manager. Used publicly to access Portal.	portal-www-ingress
Analytics	analytics-client	Configured using APICUP installer. Corresponds to Management Endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS.	mutual TLS
	analytics-ingestion	Configured using APICUP installer. The analytics-ingestion endpoint is used by the Gateway service to push data to the Analytics service. Requires a TLS profile configured with mutual TLS.	mutual TLS
Gateway	apic-gw-service	Configured using APICUP installer. This is the endpoint the gateway uses for network communication. Enter this endpoint as the Management Endpoint entered in Cloud Manager.	apic-gw-service-ingress
	api-gateway	Configured using APICUP installer. This is the endpoint the gateway uses for API traffic. Enter this endpoint as the API Invocation Endpoint in Cloud Manager.	api-gateway-ingress

## Configuring certificates

The certificates are configured by the Install Assist program using the APICUP installer. The certificates for the endpoints are usually configured as custom certificates as described in [Setting custom certificates](#).

## Configuring mutual TLS

Mutual TLS is configured for TLS profiles in Cloud Manager. See [Creating a TLS Server Profile](#).

## Configuring a proxy

If a Developer Portal is deployed externally to the management server zone, it does not have access to the consumer and product APIs. You need to configure a proxy to enable communication. For more information, see [Configuring a proxy](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Firewall requirements on VMware

Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on VMware.

### Required Ports between zones

The following network diagram example helps to explain which ports must be configured in an API Connect network. Specific ports must be configured to enable the communication between the various zones, both public and private, in a network.

The ports specified in the diagram are default ports. Check your deployment to understand which communication, if any, is configured to use non-default ports.

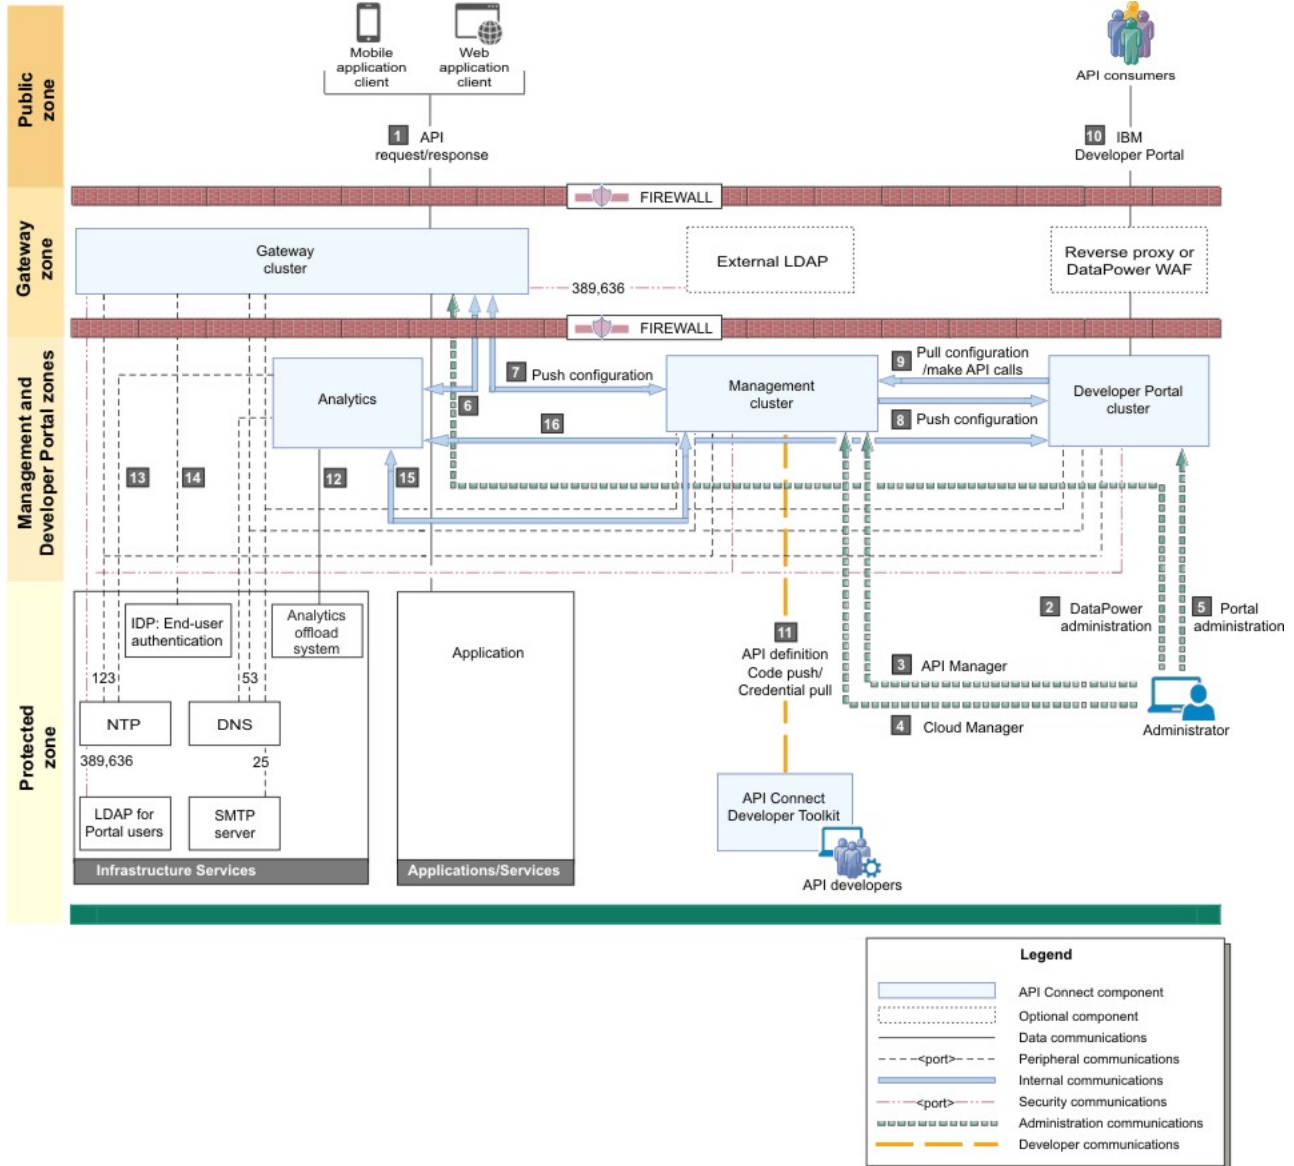

Table 1. Key for the network diagram example. The following table lists the port numbers with a usage description.

	Usage description	Default port number
1	API request/response – Users invoking the provided APIs.	443 HTTPS from Public zone to Gateway zone
2	DataPower® administration – Internal operators who are managing the Gateway servers.	22 SSH, 9090 HTTPS from Protected zone to Gateway zone
3	API Manager – Internal business users who are defining and monitoring APIs.	443 HTTPS from Protected zone to Management zone
4	Cloud Manager – Internal operators who are administering the Cloud.	22 SSH, 443 HTTPS from Protected zone to Management zone
5	Developer Portal administration – Internal operators who are managing the Portal servers.	22 SSH, 443 HTTPS from Protected zone to Management zone
6	Gateway servers post traffic to Analytics service.	443 HTTPS from Gateway servers to Analytics service
7	Push configuration – Management servers communicate bi-directionally with Gateway servers.	3000 or 443 (dependent on configuration) HTTPS Management servers to and from Gateway servers for webhook delivery
8	Push configuration/webhooks – Management servers push configuration and webhooks to the Developer Portal.	443 HTTPS Management servers to Developer Portal servers for webhook delivery
9	Pull configuration/make API calls – Developer Portal servers pull configuration and call REST APIs.	443 HTTPS from Developer Portal servers to Management servers within Management zone
10	Developer Portal – External developers who are accessing the Developer Portal.	443 HTTPS from Public zone to Developer Portal management zone. The reverse proxy/DataPower WAF for incoming web traffic to the Developer Portal cluster must be a transparent proxy - no modification of the portal URL, port, host name or path is allowed. For more information, see <a href="#">Configuring a proxy</a> .
11	Push API definition to Management server. Pick up credential for microservice code push.	443 HTTPS from Protected zone to Management zone
12	Analytics offload	Port will depend on type of plugin and protocol used for the offload. Some possible protocols are: HTTP, HTTPS, TCP, UDP, KAFKA
13	Analytics accesses NTP	Standard NTP
14	Analytics access DNS	Standard DNS
15	Management service queries Analytics service	443 HTTPS within Management zone
16	The Portal service invokes an API (GET) on the Analytics service to retrieve data.	443 HTTPS within Management zone

## Firewall port requirements on VMware

The following tables lists ports that must be open in both cluster and non-clustered deployments.

Note that clustered VMware environment deployments require additional ports. See [Firewall enabled ports for clustered OVA deployments](#)

Table 2. Firewall port requirements common to all subsystems

Subsystem	Ports and description
Ports that must be open on all API Connect subsystems	<p>The following ports must be open on the Management Server, Analytics, and Developer Portal subsystems, whether in a cluster or not.</p> <ul style="list-style-type: none"> <li>• 53 (outbound) DNS</li> <li>• 123 (outbound) NTP</li> <li>• 179 (inbound and outbound) BIRD routing daemon - VMware environments (OVA) deployments. Used for communication over TCP between servers either within the same subsystem or across different subsystems.</li> <li>• 443 (inbound and outbound) Used by all subsystems for communication with other subsystems</li> <li>• 2020 (inbound) status request. Used for communication over TCP between servers within the same subsystem.</li> <li>• 9177 (inbound and outbound) Member list (group membership) for API Connect <b>apic</b> daemon communication. Used for communication over both TCP and UDP, between servers within the same subsystem.</li> <li>• 9178 (inbound and outbound) API server, for API Connect <b>apic</b> daemon communication. Used for communication over TCP from between servers, both within the same subsystem and across different subsystems. Also used for communication between the <b>apicup</b> configuration utility and servers.</li> </ul>

Each subsystem uses ports in addition to the ports in [Table 2](#). See the following table.

Table 3. Additional firewall port requirements for each subsystem

Subsystem	Ports and description
-----------	-----------------------

Subsystem	Ports and description
Management Service	<p>Management Service uses the ports in <a href="#">Table 2</a> plus:</p> <ul style="list-style-type: none"> <li>22 remote backup server port (inbound, configurable) If backups are configured to use another port, ensure that the port is open. See <a href="#">Backing up the management subsystem in VMware environments</a>.</li> </ul> <p>Note: this port does not have to be open between the management server and the portal server.</p> <ul style="list-style-type: none"> <li>SMTP server port (outbound), typically 25</li> <li>161 (inbound) SNMP. Over UDP.</li> <li>LDAP server port (if using LDAP user registry), typically 389 (outbound)</li> <li>In a clustered deployment, the Management Services uses additional ports. See <a href="#">Firewall enabled ports for clustered OVA deployments</a>.</li> </ul>
Developer Portal	<p>The Developer Portal uses the ports listed in <a href="#">Table 2</a>, plus:</p> <ul style="list-style-type: none"> <li>22 - A remote backup server port (inbound, configurable) If backups are configured to use another port, ensure that the port is open. See <a href="#">Backing up and restoring the Developer Portal in a Kubernetes environment</a>.</li> </ul> <p>Note: this port does not have to be open between the management server and the portal server.</p> <ul style="list-style-type: none"> <li>In a clustered deployment, the Developer Portal uses additional ports. See <a href="#">Firewall enabled ports for clustered OVA deployments</a>.</li> </ul>
Analytics	<p>The Analytics subsystem uses the ports listed in <a href="#">Table 2</a>, plus:</p> <ul style="list-style-type: none"> <li>161 for SNMP is required for both non-clustered and clustered deployments. UDP, inbound only.</li> <li>In a non-clustered deployment, no additional ports are required.</li> <li>Analytics supports an optional configuration for offload of data. This configuration might require additional outbound ports to be open.</li> <li>In a clustered deployment, the Analytics subsystem uses additional ports. See <a href="#">Firewall enabled ports for clustered OVA deployments</a>.</li> </ul>
Gateway Server	<p>The Gateway Server uses these ports in both non-clustered and clustered deployments:</p> <ul style="list-style-type: none"> <li>161 (inbound) SNMP. UDP protocol. Not needed if SNMP not enabled.</li> <li>162 (outbound) SNMP traps</li> <li>3000 (inbound) Gateway Service local port (configurable)</li> <li>5550 (inbound) XML management port (configurable)</li> <li>5554 (inbound) REST management port (if enabled; configurable)</li> <li>9022 (inbound) Gateway SSH (if enabled; configurable)</li> <li>9090 (inbound) Web GUI console (if enabled; configurable)</li> <li>9443 (inbound) Gateway local port (configurable)</li> <li>In a clustered deployment, the Gateway Server uses additional ports. See <a href="#">Firewall enabled ports for clustered OVA deployments</a>.</li> </ul>

## Communications inside the Gateway cluster

There are a number of important points to note regarding the communications within the Gateway cluster.

- We advise that you use the same port for all Gateway servers within a cluster.
- Gateway servers communicate with each other to synchronize invocation counts.
- All Gateway servers in a Gateway cluster must be able to reach all of the other Gateway servers in the same Gateway cluster.
- Gateway servers in a Gateway cluster do not directly communicate with Gateway servers in a different Gateway cluster.
- All Gateway servers must be able to reach the management subsystem platform API endpoint, which was configured during the installation of your API Connect environment.

## Ethernet interface usage

To separate network traffic, you can use two or more Ethernet interfaces on the DataPower appliance on which a Gateway server is installed. For example, you can use one interface for internal IBM API Connect communications, and another for processing incoming API calls.

- [Firewall enabled ports for clustered OVA deployments](#)  
In a clustered OVA deployment of API Connect, specific ports must be configured for communication between members of each API Connect subsystem.
- [Load balancer ports for clustered OVA deployments](#)  
When you deploy a load balancer with a clustered deployment, in a VMware environment, you must ensure that the necessary ports are open.

## Related concepts

- [Firewall enabled ports for clustered OVA deployments](#)
- [Load balancer ports for clustered OVA deployments](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Firewall enabled ports for clustered OVA deployments

In a clustered OVA deployment of API Connect, specific ports must be configured for communication between members of each API Connect subsystem.

OVA deployments require the common ports listed in [Firewall requirements on Kubernetes](#). When the VMs are clustered, additional ports are used for communication between the members of the subsystems in the cluster.

All ports must be enabled inbound and outbound.

Table 1. Firewall enabled ports for clustered VMware environment deployments

Subsystem	Ports
Ports that must be open between all subsystem VMs	442, 2379, 2380, 6443, 6444, 9099, 10248, 10249, 10250, 10251, 10252, 10254, 10256, 10257, 10259 These are ports that must be open between all servers within a given subsystem. For example, from management server to management server, or from portal server to portal server, or from analytics server to analytics server. These ports are not used for communication between subsystems.  You might need additional TCP ports for Kubernetes-proxied services. The default range is 30000 – 32767. Since the ports in use can change dynamically, ensure that the default range is open.
Additional ports that must be open between Management Service VMs	7001, 7199, 8778, 9042
Additional ports that must be open between Developer Portal VMs	3009, 3010, 3306, 3307, 4443, 4444, 4567, 4568, 30865
Additional ports that must be open between Gateway Service VMs	16380, 16381, 26380, 26381
Additional ports that must be open between Analytics VMs	No additional ports are needed.

These internal ports are not used for communication between VMs. Ensure that they are open on the VM server locally.

Table 2. Internal ports reserved by API Connect

Subsystem	Ports
Reserved local ports on all subsystem VMs	8080, 30000:59999
Management Service VMs	2000, 2001, 3003, 3004, 3006, 3007, 8084, 8404, 8443
Portal Service VMs	3058, 3059, 3060, 3061
Analytics VMs	4443, 9200, 9300

Note: The ports should support IP-in-IP (protocol 4), per <https://docs.projectcalico.org/getting-started/kubernetes/requirements>.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Load balancer ports for clustered OVA deployments

When you deploy a load balancer with a clustered deployment, in a VMware environment, you must ensure that the necessary ports are open.

The load balancer needs port 443 for all API Connect subsystems (Management, Analytics, Developer Portal, DataPower Gateway).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Requirements for initial deployment on VMware

Review the requirements and considerations for deploying in a VMware environment.

### Deployment requirements on VMware

- Ensure you have supported software requirement versions. See [IBM API Connect Version 2018 software product compatibility requirements](#)
- Do not change the hardware version of the OVA during installation. Do not attempt to use an unsupported version, even if VMWare indicates compatibility with other versions. For example, when deploying IBM API Connect, the VMWare UI for the APIC OVAs might show information like:

Table 1.

Property	Value
Guest OS	Ubuntu Linux (64-bit)
Compatibility	ESXi 5.5 and later (VM version 10)
VMware Tools	Yes
CPUs	4
Memory	16 GB

Although the **Compatibility** field shows **ESXi 5.5 and later (VM version 10)**, API Connect supports only the versions listed in [IBM API Connect Version 2018 software product compatibility requirements](#). Do not change the VM version of the OVA. Ensure that the **Compatibility** field values are not changed, and remain **ESXi 5.5 and later (VM version 10)**.

Attempts to modify the VMware compatibility may typically result in failure to boot the OVA, as per <https://kb.vmware.com/s/article/52683>.

- Ensure that your operating system has one of the supported utilities for creating ISOs. The apicup installer uses **mkisofs** on Linux, and **hdiutil** on macOS. For Windows, you need software that creates ISO files using **mkisofs**, such as CDRTools. Verify that the utility you will use is located in a directory that is referenced by the PATH environment setting for your operating system. When creating the ISO, if you encounter the message **Error: unable to create config ISO for host**, verify that you have sufficient permissions to run the command.
- Verify you have access to [Passport Advantage®](#) to download the Install Assist package and the latest IBM API Connect packages for your operating system.

Package	IBM API Connect subsystem file
IBM API Connect® Management for VMWare	apiconnect-management.ova
IBM API Connect Analytics for VMWare	apiconnect-analytics.ova
IBM API Connect Developer Portal for VMWare	apiconnect-portal.ova

Important:

Use a single APICUP project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

The original project directory created with APICUP during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. A good practice is to back up the original project directory to a location from where it can always be retrieved.

- For each subsystem, gather the following networking settings, which you will need to supply during configuration:

Table 2.

Required information	Value for your system
IP address of the server	
IP address of the server	
Domain of the server	
IP addresses of the name servers	
IP address of the network gateway (not DataPower® gateway) for the server	
Name of the Ethernet interface	
VLAN	

Some virtualization environments require additional information when you create and configure virtual machines. For example, it might be necessary to assign a specific VLAN ID, Resource Pool, or Datastore. Please refer to information provided by your virtualization environment administrators.

## Configuration on VMware

- API Connect cannot be deployed on NFS.
- The timezone for API Connect pods is set to UTC. In API Connect deployments on VMware, the operating system timezone is also set to UTC. Do not change the timezone for the pods or the operating system.
- Ensure that the time settings match (within a few seconds) between the machine running **apicup** and the VMware **Host** clock. To verify the VMware host clock setting, see <https://kb.vmware.com/s/article/1003736>.

If the clocks are too different, the installation can fail because of invalid certificates due to time discrepancies.

- API Connect requires a dedicated IP range for deployment of the Kubernetes pod and Kubernetes service networks. These IP addresses cannot conflict with IP addresses used by other resources in your deployment, such as SMTP servers or user registries. The default values are 172.16.0.0/16 and 172.17.0.0/16, respectively. If a /16 subnet overlaps with existing IPs on the network, a CIDR as small as /22 is acceptable. If the default ranges conflict with other programs, you can modify the API Connect ranges during initial installation. Note that you cannot modify them once an appliance has been deployed. Follow the instructions for your subsystem if you want to modify either of the IP ranges.

- Only static IP addresses that are specified during the **apicup** project configuration before the installation of the OVAs are supported.
- Designated host names must have wildcard aliases or host aliases, which ensures that the different endpoints work together. For example, *\*.hostname.mycompany.com*.
- Kubernetes ingress limits the character set for DNS names to not support the underscore character "**\_**". This means you cannot specify underscores in domain names that are used as endpoints. For example, *my\_domain.bar.com* and *my.domain\_abc.com* are not supported for **<xxx>.<hostname>.<domainname>**, and will cause an error. For example:

```
Invalid value: "my_domain.bar.com": a DNS-1123 subdomain must consist of lowercase alphanumeric characters, '-' or '.', and must start and end with an alphanumeric character (e.g. 'example.com', regex used for validation is '[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)')
```

- Note that you cannot change host names or DNS names on a running cluster.
- **Version 2018.4.1.0 only:** Ensure that Reverse DNS lookup is configured for the host names and endpoints for each subsystem. Be sure that a ping of the subsystem host names and endpoints resolves to the corresponding IP address.

```
nslookup <ip_address>
ping <*.hostname.example.com>
```

Note: Reverse DNS lookup is not required for Version 2018.4.1.1 or later.

- For the management subsystem, the installer sets a default value of 9GB for **cassandra-max-memory-gb**. The minimum value for this setting is 9GB. The following table compares values for memory allocation for the management database:

Memory allocated to OVA node	Recommended cassandra-max-memory-gb	MAX_HEAP_SIZE (47% of cassandra-max-memory-gb value)
16GB	9GB (default)	4331m
32GB	16GB	7700m
64GB	24GB	11550m

- The allocation of memory by the JVM is more than just heap size, so where the previous table shows the maximum heap size can grow by up to 4331m, there is also more memory that can be requested by the JVM from the operating system. The ratio of 47% that is used in the table provides sufficient padding so that under

normal conditions the JVM should not request more than 9GB in total from the operating system. If the JVM did request more memory than the ratio padding allows, the limit in place on the Kubernetes pod would lead Kubernetes to kill the process/container so that it can be restarted, as per the design of setting memory limits on pods in Kubernetes.

- For Analytics, the installer specifies a default value of 16 GB for `es-max-memory-gb`. The minimum value for this setting is 12 GB.
- Decide the *mode* to use for the installation.

Table 3. Deployment modes

Mode	Description
<b>dev</b>	Development mode ( <b>dev</b> ) deploys a subsystem with the scale of one. Development mode is recommended for development, testing, and demonstration purposes.  <code>apicup subsys set mgmt mode=dev</code>  Do not use <b>dev</b> mode for production environments. Development mode does not provide high availability.
<b>standard</b>	Standard mode ( <b>standard</b> ) deploys in high availability mode for a production environment.  <code>apicup subsys set mgmt mode=standard</code>

Usage:

- Mode is set for each subsystem type: Management, Analytics, Developer Portal, and Gateway.
- If you do not specify the mode, a default mode is applied, as follows:
  - **Version 2018.4.1.4 and later:** **dev** mode
  - **Version 2018.4.1.3 and earlier:** **standard** mode
- Use of **standard** mode is supported only on installations with three or more nodes. Installations with less than three nodes must use **dev** mode. If you install in **standard** mode with only a single node, some pods can remain in a pending state. To avoid having pods remain pending, either install in **dev** mode or add additional nodes.
- For additional considerations for configuring clusters, see [Configuring API Connect subsystems in a cluster on VMware](#). Important: For best performance it is recommended that the network latency between any 2 nodes be as low as possible. Do not configure nodes from the same subsystem cluster across multiple data centers with a high latency network. A high latency network is one that experiences more than 30ms latency between nodes. For more information, see the [API Connect V2018 Whitepaper](#)
- Configure a remote server for logging. Follow these instructions: [Configuring remote logging for a VMware deployment](#). Pods are terminated during an upgrade, and the logs will be lost if not stored remotely.

## Passwords and certificates

- When creating configuration files for use in generating an ISO image for VMware, ensure that your working directories are secure. The VMware configuration requires an ISO image that contains a plain text password to be used to unlock the VMware data disk. This means that the API Connect project configuration file `apiconnect-up.yml`, and the `/user-data` directory for each host, contain the passwords you specified. This configuration information is used to create the ISO image that you combine with the `.ova` distribution files when deploying (unlocking) the VMware data disk.
- You can use `apicup` to specify an `ssh` keyfile that contains a public certificate for using `ssh` to log in to a virtual machine. Logging in through `ssh` is preferred because it is more secure than password-based login.
- Default certificates are generated for each subsystem by the `apicup subsys install` command. If certificates are not explicitly set using the `apicup certs set` command, then default certificates are automatically generated by `apicup`. The default certificates are self-signed, so they may not provide a level of trust suitable for external communication. See [Working with certificates](#).

## Setting and using a hashed default password

During configuration of the Management, Analytics, and Developer Portal subsystems, you create a password to use to log in to the management console for the first time. You must use a password hashing utility to hash the password. You then use `apicup` to assign this hashed password to the subsystem. These configuration steps ensure that the password is not stored in plain text on the data disk.

The syntax of the `apicup` command is:

```
apicup subsys set mgmt default-password='hashed_password'
```

Usage notes:

- The `default-password` is for the `apicadm` user account on the Appliance.
- The password for `apicadm` can be used **only** to log in through the VMware console. You cannot use it to `ssh` into the Appliance as an alternative to using the `ssh-keyfiles`. Interactive login for `ssh` is disabled.
- The `default-password` value configured is only used during initial installation (first boot) of each virtual appliance. Changing the value, then regenerating the ISO, and attaching the new ISO to the virtual appliance does not change the `apicadm` password.
- The `default-password` must be hashed. If it is plain text, you will not be able to log into the Appliance through the VMware console. When you use `apicup` to set or `get default-password`, `apicup` ensures that the hash type of the password is one of the following:
  - MD5
  - SHA1
  - SHA256
  - SHA512
  - BCRYPT
  - MD5-Crypt
- When using `apicup` to set a default password for a subsystem, be aware of syntax differences between operating systems. Windows requires double-quotes. Linux and OSX require single quotes.

Operating system	Command syntax
Linux or OSX	<code>apicup subsys set mgmt default-password='hashed_password'</code>
Windows	<code>apicup subsys set mgmt default-password="hashed_password"</code>

- You can use the `passwd` command (on the appliance) to change the `apicadm` password.
- When using the VMware Remote console to login to the appliance, be aware that the keyboard layout is English. This can cause a problems with hashed passwords, if you created the ISO on a system with a different keyboard layout and you used special characters or symbols. Passwords are hashed when you set the password that you enter to log into your Management appliance for the first time, and when you create hosts.

## DataPower Gateway for API Connect on VMware

- The Management server and Gateway firmware versions must match, for example, API Connect 2018.4.1.3 and DataPower 2018.4.1.3.
- Installation and configuration of DataPower Gateway on an appliance (physical or virtual) is completed after you install the API Connect subsystems. For the gateway service in a VMware environment, use the instructions in [Deploying DataPower Gateway](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Load balancer configuration in a VMware deployment

When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect OVA deployment.

### About this task

API Connect can be deployed on a single node cluster. In this case the ingress endpoints are host names for which the DNS resolution points to the single IP address of the corresponding node hosting a particular subsystem, and no load balancer is required. For high availability, it is recommended to have at least a three node cluster. With three nodes, the ingress endpoints cannot resolve to a single IP address. A load balancer should be placed in front of an API Connect subsystem to route traffic.

Because it is difficult to add nodes once endpoints are configured, a good practice is to configure a load balancer even for single node deployments. With the load balancer in place, you can easily add nodes when needed. Add the node to the list of servers pointed to by the load balancer to avoid changing the ingress endpoints defined during the installation of API Connect.

To support Mutual TLS communication between the API Connect subsystems, configure the load balancer with **SSL Passthrough** and **Layer 4** load balancing. In order for Mutual TLS to be performed directly by the API Connect subsystems, the load balancer should leave the packets unmodified, as is accomplished by Layer 4. Following is a description of the communication between the endpoints that are configured with Mutual TLS:

- API Manager (with the client certificate portal-client) communicates with the Portal Admin endpoint portal-admin (with the server certificate portal-admin-ingress)
- API Manager (with the client certificate analytics-client-client) communicates with the Analytics Client endpoint analytics-client (with the server certificate analytics-client-ingress)
- API Manager (with the client certificate analytics-ingestion-client) communicates with the Analytics Ingestion endpoint analytics-ingestion (with the server certificate analytics-ingestion-ingress)

Set endpoints to resolve to the load balancer

When configuring a load balancer in front of the API Connect subsystems, the ingress endpoints are set to host names that resolve to a load balancer, rather than to the host name of any specific node. For an overview of endpoints, see [Deployment overview for endpoints and certificates](#).

Use this example configuration as a guideline to determine the best way to configure the load balancer for your deployment.

## Procedure

### • Appliance deployment

In this example configuration, the API Connect Management, Portal, Analytics and Gateway subsystems are deployed as three node clusters in Standard mode. An HAProxy load balancer is used. The load balancer is configured with `ssl-passthrough` and with upstream selection based on SNI. DNS resolution is configured to resolve the endpoints to the IP address of the load balancer. If a single HAProxy node is used, then all endpoints must resolve to the IP address of the single HAProxy. The following example endpoints require DNS resolution for this example:

- `api-manager-ui.sample.example.com`
- `cloud-admin-ui.sample.example.com`
- `consumer-api.sample.example.com`
- `platform-api.sample.example.com`
- `admin.portal.sample.example.com`
- `web.portal.sample.example.com`
- `analytics.client.sample.example.com`
- `analytics.ingestion.sample.example.com`
- `api-gateway.sample.example.com`
- `apic-gw-service.sample.example.com`

Following is an example HAProxy configuration for one HAProxy node distributing traffic to Management and Portal clusters:

Note:

When you configure a load balancer in front of a Management subsystem, specify timeouts of at least 240 seconds. Note that large deployments might need larger values.

The default timeout is typically 50 or 60 seconds, which is not long enough to avoid **409**

**Conflict** or **504 Gateway Timeout** errors. The **409 Conflict** error can occur when the time needed to complete an operation is sufficiently long that a second request gets issued.

For example, to specify 240 seconds when using HAProxy as a load balancer, set `timeout client` and `timeout server` to `240000`.

```
# This sample HAProxy configuration file configures one HAProxy node to distribute traffic to
# Management, Portal, Analytics, and Gateway clusters. Another option is to configure one HAProxy
# node per cluster.
```

```

server gateway1 gateway2.sample.example.com:443 check
server gateway2 gateway3.sample.example.com:443 check

```

- The following diagram depicts a typical layout for a load balancer in front of three API Connect subsystems, with each subsystem containing three Appliance/OVA

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring remote logging for a VMware deployment

Appliance-based (OVA) deployments use Syslog for collecting logs. Logs must be collected for both running and terminated containers and processes. Logging collection is required for IBM Support to assist with troubleshooting.

### About this task

For appliance-based deployments using OVA, rsyslog is used to collect log files.

There are three options for collecting logs:

- Set the rsyslog configuration at boot up (this is the best practice in order to preserve settings when rebooting)
- Set the rsyslog configuration post-boot up
- Gather logs from a running system

For more information about rsyslog, see: <https://www.rsyslog.com/doc/v8-stable/configuration/index.html>

### Procedure

Log collection from the Syslog collectors is accomplished using the rsyslog module included in the cloudinit application. Cloud-init is an open source package used for injecting configurations during boot up. It is included with the appliance-based (OVA) installation. Cloud-init uses a configuration file, for example, config\_file.yaml, to configure logging and other customizations. The complete list of configuration customizations that can be made with cloud-init is documented in <https://cloudinit.readthedocs.io/en/latest/topics/modules.html>. Follow these steps to configure logging at boot up:

- Enter the rsyslog configuration in the config\_file.yaml file.
  - Following is an example of the options for rsyslog in config\_file.yaml:

```
rsyslog:
  remotes:
    syslog_server1: "192.168.1.1:514"
    syslog_server2: "10.0.4.1:601"
```

where:

- **remotes** are key pairs specifying the remote Syslog collectors from which you want to collect logs. Each key is the name for an rsyslog remote entry. Each value holds the remote IP address and port for the Syslog collector.
- **syslog\_serverX** are Syslog collectors (514 = TCP, 601=UDP)

Note:

A number of Appliance containers such as the **kube-apiserver** log by default to stderr, which is interpreted by rsyslog as a high severity message. To avoid having non-error log entries be presented as errors in rsyslog, it is recommend to configure a format that defaults the severity of the message to info level, and rely on further parsing of the log messages to highlight higher severity messages. Example configuration:

```
rsyslog:
  configs:
  - "*" * @192.168.1.187;myformat"
  - filename: 00-myformat.conf
    content: |
      template(name="myformat" type="string"
        string="<${myprio}> %TIMESTAMP::date-rfc3339% %HOSTNAME% %syslogtag% %msg::sp-if-no-1st-sp%%msg%")

      set $.myseverity = 6;
      set $.myprio = 20*8+$.myseverity;
```

where the logs would be forwarded to the server **192.168.1.187** using the format **myformat**. Further scanning of the log lines could be defined in the logging infrastructure to highlight the higher severity log entries by, for example, scanning for occurrences of **Error/Err/ERROR**.

- Enter the following command to configure log collection at boot up before starting installation:

```
apicup subsys set mgmt additional-cloud-init-file config_file.yaml
```

Refer to the rsyslog documentation for more information. See <https://www.rsyslog.com/doc/v8-stable/configuration/index.html>

- To collect logs post boot up, follow these steps:
  - ssh** into each VM and change directories to `etc/rsyslog.d`.
  - Create a new `.conf` file, for example, `<new>-cloud-config.conf`.
  - Restart rsyslog with the following command: **systemctl restart rsyslog**
- To gather logs from a running system, enter the following command:

```
sudo apic logs
```

The **apic logs** command collects the following information for the current VM:

- Logs for all containers (including terminated ones)
- Everything from **journalctl**
- All system service logs

The information is stored locally on the current VM. Entries are culled based upon age for a maximum size of 2 GB (compressed).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## First steps for deploying in a VMware environment

The first steps in deploying in a VMware environment are to obtain the API Connect distribution files and to create a project directory.

### Before you begin

- Review [Requirements for initial deployment on VMware](#).
- See also [Configuring API Connect subsystems in a cluster on VMware](#).

### About this task

In these First Steps, you will use Install Assist (**apicup**) to create a project directory that contains the configuration file **apiconnect-up.yaml**. When you configure the first subsystem, such as the Management Service, the subsystem configuration settings are placed in the file.

When you want to configure a second subsystem, it is important that you reuse the same project directory. This means that you only need to download Install Assist once, and create a project directory once. The configuration settings for the second subsystem are added to the existing **apiconnect-up.yaml**. In this way, the second subsystem, such as Developer Portal, can access the configuration information needed to interact with the first subsystem.

After completing these First Steps, follow the links to instructions for configuring your subsystem. You will specify configuration settings, create an ISO of the subsystem configuration, and then use VMware to deploy the distribution file (.ova file) for the subsystem with your ISO. Note that you create a separate ISO for each subsystem.

Installation and configuration of DataPower® Gateway on an appliance (physical or virtual) is completed after you install the API Connect subsystems. For the gateway service in a VMware environment, use the instructions in [Deploying DataPower Gateway](#).

Note: When maintaining API Connect, do not use **kubectl exec** commands to access API Connect pods unless advised by IBM.

Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

### Procedure

1. Download the latest IBM API Connect® package from [IBM Fix Central](#).

Package	IBM API Connect subsystem file
IBM API Connect Management for VMWare	apiconnect-management.ova and the Developer Toolkit
IBM API Connect Analytics for VMWare	apiconnect-analytics.ova
IBM API Connect Developer Portal for VMWare	apiconnect-portal.ova

Note that the IBM [Passport Advantage](#) site contains the API Connect LTS release, 2018.4.1.0, but not any packages that contain later Fix Packs. The Fix Pack distributions, such as 2018.4.1.5, contain the entire product. For a new installation, you do not need to first install the LTS version, 2018.4.1.0, or any of the fix packs (2018.4.1.x) prior to the latest one. For example, if you want to install 2018.4.1.5 as a new installation, you do not need to first install 2018.4.1.0, 2018.4.1.1, 2018.4.1.2, 2018.4.1.3 or 2018.4.1.4.

Note also that the Fix Pack page contains two copies of the files for each subsystem. One copy is for new installations and one is for upgrades of existing installations. For new installations, do not use files with names with the prefix `upgrade-`. Use the file names specified in the previous table. In addition, be aware that during upgrades, there are prerequisites to meet when moving between specific versions. For upgrades, do not use the procedures on this page. See [Upgrading in a VMware environment](#).

- Select one of the following actions:
  - If you are configuring your first subsystem, go to step [3](#).
  - If you have already configured a subsystem, go to step [7](#).
- Download the IBM API Connect Install Assist package for your operating system from [IBM Fix Central](#). It contains the `apicup` file, which simplifies installation of the API Connect components.
- OSX and Linux® only: Make the `apicup` file an executable file by entering the following command:

```
chmod +x apicup
```

- Set your path to the location of your `apicup` file.
  - For the OSX and Linux operating systems:

```
export PATH=$PATH:/Users/your_path/
```

- For the Windows operating system:

```
set PATH=c:\your_path;%PATH%
```

- Create a project called `myProject` and optionally copy the `apicup` executable into the project directory.
  - Create a project:

```
apicup init myProject
```

- Read and accept the license agreement.

- Optionally, copy the `apicup` executable into the `myProject` directory or folder created by the `apicup init` command.

Important:

Use a single APICUP project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

The original project directory created with APICUP during the initial product installation (for example, `myProject`) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. A good practice is to back up the original project directory to a location from where it can always be retrieved.

The `apiconnect-up.yml` file is created in that directory.

Important: The `apiconnect-up.yml` file must be in a secure and permanent location. The file contains password information and other information that is exposed in text format. Ensure that the project directory is secure.

- Continue with the configuration steps for your subsystem:
  - [Deploying the Management subsystem in a VMware environment](#)
  - [Deploying the Analytics subsystem in a VMware environment](#)
  - [Deploying the Developer Portal in a VMware environment](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Deploying the Management subsystem in a VMware environment

You can create a virtual server by deploying the relevant IBM® API Connect OVA file on a VMWare virtual server. Create all of the virtual servers that you want to use in your cloud.

### Before you begin

Before you deploy:

- Review the [Deployment requirements on VMware](#).
- Review the [Configuration on VMware](#).
- For information on deploying a cluster, see [Configuring API Connect subsystems in a cluster on VMware](#)
- If you are upgrading from a previous version, see [Upgrading in a VMware environment](#).

### About this task

You must deploy the API Connect OVA template to create each Management virtual server that you want in your cloud.

## Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in [First steps for deploying in a VMware environment](#).
2. Change to the project directory.

```
cd myProject
```

3. Create a management subsystem.

```
apicup subsys create mgmt management
```

Where:

- `mgmt` is the name of your management server that you are creating. You can assign it any name, as long as the identifier consists of lower case alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
- `management` indicates that you are creating a management microservice.

The API Connect Helm charts are deployed into the default namespace. You do not need to specify a namespace.

Tip: At any time, you can view the current management subsystem values in the `apiconnect-up.yml` by running the `apicup subsys get` command:

```
apicup subsys get mgmt
```

If you have not yet configured the subsystem, the command might return errors. Also, if you have not updated the value, a default value is listed, if there is one that is available.

After configuration is complete, you can view output similar to the following sample:

```
apicup subsys get mgmt
```

```
Appliance settings
```

```
=====
```

Name	Value	Description
-----	-----	-----
additional-cloud-init-file		(Optional) Path to additional cloud-init yml file
data-device	sdb	VM disk device (usually `sdb` for SCSI or `vdb` for VirtIO)
default-password	\$6\$rounds=4096\$imCJ9cfhFJ8X\$pbm19ClWzcYzHZFoQ6n7OnYCF/owQZiICpAtWazs/FUn/uE8uLD.9jwHE0AX4upFSqx/jf0ZmDbHPZ9bU1CY1	(Optional) Console login password for `apicadm` user
dns-servers	[1.2.136.11]	List of DNS servers
k8s-pod-network	172.16.0.0/16	(Optional) CIDR for pods within the appliance
k8s-service-network	172.17.0.0/16	(Optional) CIDR for services within the appliance
mode	standard	
public-iface	eth0	Device for API/UI traffic (Eg: eth0)
search-domain	[subnet1.example.com]	List for DNS search domains
ssh-keyfiles	[/home/vsphere/.ssh/id_rsa.pub]	List of SSH public keys files
traffic-iface	eth0	Device for cluster traffic (Eg: eth0)
license-version	Production	

```
Subsystem settings
```

```
=====
```

Name	Value	Description
-----	-----	-----
az-name	default-az	Availability Zone name
cassandra-backup-auth-pass		(Optional) Server password for DB backups
cassandra-backup-auth-user		(Optional) Server username for DB backups
cassandra-backup-host		(Optional) FQDN for DB backups server
cassandra-backup-path	/backups	(Optional) path for DB backups server
cassandra-backup-port	22	(Optional) Server port for DB backups
cassandra-backup-protocol	sftp	(Optional) Protocol for DB backups (sftp/ftp/objstore)
cassandra-backup-schedule	0 0 * * *	(Optional) Cron schedule for DB backups
cassandra-max-memory-gb	9	Memory limit for DB
cross-az-peers	[ ]	(Optional) IP addresses of nodes in other AZs

```
Endpoints
```

```
=====
```

Name	Value	Description
-----	-----	-----
api-manager-ui	api-manager-ui.testsrv0231.subnet1.example.com	FQDN of API manager UI endpoint
cloud-admin-ui	cloud-admin-ui.testsrv0231.subnet1.example.com	FQDN of Cloud admin endpoint
consumer-api	consumer-api.testsrv0231.subnet1.example.com	FQDN of consumer API endpoint
platform-api	platform-api.testsrv0231.subnet1.example.com	FQDN of platform API endpoint

4. For production environments, specify `mode=standard`.

```
apicup subsys set mgmt mode=standard
```

The `mode=standard` parameter indicates that you are deploying in high availability (HA) mode for a production environment. If the mode parameter is omitted, the subsystem deploys by default in `dev` mode, for use in development and testing. For more information, see [Requirements for initial deployment on VMware](#).

5. **Version 2018.4.1.10 or later:** Specify the license version you purchased.

```
apicup subsys set mgmt  
license-version=<license_type>
```

The `license_type` must be either **Production** or **Nonproduction**. If not specified, the default value is **Nonproduction**.

6. Optional: Configure scheduled backups of the subsystem. This step is optional but is recommended. Note that once you set up scheduled backups, you can also run backups on-demand. Refer to the instructions for scheduled backups in [Backing up the management subsystem in VMware environments](#).
7. Optional: Configure your logging.
  - Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.
  - a. Complete the procedure at [Configuring remote logging for a VMware deployment](#).
  - b. Enter the following command to create the log file:

```
apicup subsys set mgmt additional-cloud-init-file=config_file.yml
```

8. Enter the following commands to update the `apiconnect-up.yml` with the information for your environment:
  - a. Set your search domain. Multiple search domains should be separated by commas.

```
apicup subsys set mgmt search-domain=your_search_domain
```

Where `your_search_domain` is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is `mycompany.example.com`.

Ensure that the value for `your_search_domain` is resolved in the system's `/etc/resolv.conf` file to avoid "502" errors when accessing the Cloud Manager web site. For example:

```
# Generated by resolvconf
search your_search_domain ibm.com other.domain.com
```

- b. Set your domain name servers (DNS).
    - Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set mgmt dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
```

DNS entries may not be changed on a cluster after the initial installation.

- c. Use `apicup` to set your endpoints.
    - You can use wildcard aliases or host aliases with your endpoints.
    - Optionally, you can specify all endpoints with one `apicup` command. See [Tips and tricks for using APICUP](#).

Note: You cannot specify the underscore character "\_" in domain names that are used in endpoints. See [Configuration on VMware](#).

Table 1. Management subsystem endpoints

Setting	Endpoint host description
<code>platform-api</code>	Platform API endpoint. The host where your platform API calls are routed. <code>apicup subsys set mgmt platform-api=platform-api.hostname.domain</code>
<code>consumer-api</code>	Consumer API endpoint. The host where your consumer API calls are routed. <code>apicup subsys set mgmt consumer-api=consumer-api.hostname.domain</code>
<code>cloud-admin-ui</code>	Cloud admin user interface API endpoint. The host where your cloud administrator user-interface API calls are routed. <code>apicup subsys set mgmt cloud-admin-ui=cloud-admin-ui.hostname.domain</code>
<code>api-manager-ui</code>	API Manager user interface endpoint. The host where your API Manager API calls are routed. <code>apicup subsys set mgmt api-manager-ui=api-manager-ui.hostname.domain</code>

9. Set a Public key.

```
apicup subsys set mgmt ssh-keyfiles=path_to_public_ssh_keyfile
```

Setting this key enables you to use `ssh` with this key to log in to the virtual machine to check the status of the installation. You will perform this check in step [29](#) of these instructions.

10. Set the password that you enter to log into your Management appliance for the first time.
  - a. **Important:** Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).
  - b. If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the <code>mkpasswd</code> command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: <code>gem install mkpasswd</code> .
Windows, Red Hat	If necessary, a password hashing utility like OpenSSL.

- c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	<code>mkpasswd --method=sha-512 --rounds=4096 password</code>
Windows, Red Hat	For example, using OpenSSL: <code>openssl passwd -1 password</code> . Note that you might need to add your password hashing utility to your path; for example, in Windows: <code>set PATH=c:\cygwin64\bin;%PATH%</code>

- d. Set the hashed password for your subsystem:

```
apicup subsys set mgmt default-password='hashed_password'
```

11. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.
 

You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See [Configuration on VMware](#).

- a. Update the IP range for the Kubernetes pod

```
apicup subsys set mgmt k8s-pod-network='new_pod_range'
```

Where *new\_pod\_range* is the new value for the range.

- b. Update the IP range for Service networks.

```
apicup subsys set mgmt k8s-service-network='new_service_range'
```

Where *new\_service\_range* is the new value for the range.

12. Add your hosts.

```
apicup hosts create mgmt hostname.domainname hd_password
```

Where the following are true:

- *hostname.domainname* is the fully qualified name of the server where you are hosting your Management service, including the domain information.
- *hd\_password* is the password that the Linux Unified Key Setup uses to encrypt the storage for your Management service. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in `apiconnect-up.yml`.

Repeat this command for each host that you want to add.

Note:

- Host names and DNS entries may not be changed on a cluster after the initial installation.
- **Version 2018.4.1.0:** Ensure that Reverse DNS lookup configuration is configured for the host names.

```
nslookup <ip_address>
```

For **Version 2018.4.1.1 or later**, Reverse DNS lookup is not required.

13. Create your interfaces.

```
apicup iface create mgmt hostname.domainname physical_network_id host_ip_address/subnet_mask gateway_ip_address
```

Where *public\_iface\_id* is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where *x* is a number identifier.

The format is similar to this example: `apicup iface create mgmt myHostname.domain eth0`

```
192.0.2.10/255.255.255.0 192.0.2.1
```

14. Optional: Use `apicup` to view the configured hosts:

```
apicup hosts list mgmt
testsrv0231.subnet1.example.com
  Device  IP/Mask  Gateway
  eth0    1.2.152.231/255.255.254.0  1.2.152.1
```

Note: This command might return the following messages, which you can ignore:

```
* host is missing traffic interface
* host is missing public interface
```

15. Optional: Verify that the configuration settings are valid.

```
apicup subsys get mgmt --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

```
apicup subsys get mgmt --validate

16. Create your ISO file.

```
apicup subsys install mgmt --out mgmtplan-out
```

The `--out` parameter and value are required.

In this example, the ISO file is created in the `myProject/mgmtplan-out` directory.

If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
OSX and Linux	<code>export PATH=\$PATH:/Users/your_path/</code>
Windows	<code>set PATH="c:\Program Files (x86)\cdrtools";%PATH%</code>

17. Log into the VMware vSphere Web Client.
18. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
19. Right-click the directory and select Deploy OVF Template.
20. Complete the Deploy OVF Template wizard.
  - a. Select the `apiconnect-management.ova` template by navigating to the location where you downloaded the file from Passport Advantage®.
  - b. Enter a name and location for your file.
  - c. Select a resource for your template.
  - d. Review the details for your template.
  - e. Select the size of your configuration.
  - f. Select the storage settings.
  - g. Select the networks.
  - h. Customize the Template, if necessary.
  - i. Review the details to ensure that they are correct.
  - j. Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See [Requirements for initial deployment on VMware](#).

The template creation appears in your Recent Tasks list.

21. Select the Storage tab in the Navigator.
22. Navigate to your datastore.
23. Upload your ISO file.
  - a. Select the Navigate to the datastore file browser icon in the icon menu.
  - b. Select the Upload a file to the Datastore icon in the icon menu.
  - c. Navigate to the ISO file that you created in your project.

It is the `myProject/mgmtplan-out`
  - d. Upload the ISO file to the datastore.
24. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
25. Locate and select your virtual machine.
26. Select the Configure tab in the main window.
27. Select Edit....
  - a. On the Virtual Hardware tab, select CD/DVD Drive 1.
  - b. For the Client Device, select Datastore ISO File.
  - c. Find and select your datastore in the Datastores category.
  - d. Find and select your ISO file in the Contents category.
  - e. Select OK to commit your selection and exit the Select File window.
  - f. Ensure that the Connect At Power On check box is selected.

Tip:

- Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
- Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On

- g. Select OK to commit your selection and close the window.

28. Start the virtual machine by selecting the play button on the icon bar.

The installation might take several minutes to complete, depending on the availability of the system and the download speed.
29. Log in to the virtual machine by using an SSH tool to check the status of the installation:
  - a. Enter the following command to connect to `mgmt` using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of `apicadm`, which is the API Connect ID that has administrator privileges.

- b. Select Yes to continue connecting.

Your host names are automatically added to your list of hosts.

- c. Run the `apic status` command to verify that the installation completed and the system is running correctly.

Note that after installation completes, it can take several minutes for all servers to start. If you see the error message `Subsystems not running`, wait a few minutes, try the command again, and review the output in the `Status` column.

The command output for a correctly running Management system is similar to the following lines:

```
apicadm@testsys0181:~$ sudo apic status
```

```
INFO[0001] Log level: info
Cluster members:
```

```

30. Verify you can access the API Connect Cloud Manager. Enter the URL in your browser. The syntax is `https://<hostname.domain>/admin`. For example:

```
https://cloud-admin-ui.testsrv0231.subnet1.example.com/admin
```

The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See [Accessing the Cloud Manager user interface](#).

## What to do next

If you want to deploy an API Connect Analytics OVA file, continue with [Deploying the Analytics subsystem in a VMware environment](#).

If you want to deploy an API Connect Developer Portal OVA file, continue with [Deploying the Developer Portal in a VMware environment](#).

Identify the DataPower® appliances to be used as gateway servers in the API Connect cloud and obtain the IP addresses.

Define your API Connect configuration by using the API Connect cloud console. For more information, see [Defining the cloud](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Deploying the Analytics subsystem in a VMware environment

You can add analytics data collection by deploying the IBM® API Connect Analytics OVA file on a VMware virtual server.

### Before you begin

Before you deploy:

- Review the [Deployment requirements on VMware](#).
- Review the [Configuration on VMware](#).
- For information on deploying a cluster, see [Configuring API Connect subsystems in a cluster on VMware](#)
- If you are upgrading from a previous version, see [Upgrading in a VMware environment](#).

### About this task

You must deploy the API Connect OVA template to create each Analytics virtual server that you want in your cloud.

By default, the Analytics subsystem is configured to store data so that users can review it in the Analytics user interface. After deploying the subsystem, you can optionally configure it to offload some data to a third-party service for review and storage. Any data that is not offloaded remains accessible from the Analytics user interface.

If you want to offload all Analytics data, you can optionally install the subsystem with the ingestion-only configuration. In this scenario, unused Analytics components (such as `analytics-storage` and `analytics-client`) are omitted from the topology. Only the components that are required for offloading data are deployed. The reduced topology requires less CPU, memory, and storage.

If you do not configure ingestion-only during installation, you can enable it later as explained in [Enabling Analytics ingestion-only on VMware](#).

Settings that are required for the ingestion-only configuration are noted in the steps that follow.

Attention: You must deploy the API Connect OVA template to create each Analytics virtual server that you want in your cloud.

### Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in [First steps for deploying in a VMware environment](#).
2. Change to the project directory.

```
cd myProject
```

3. Create an analytics subsystem.

```
apicup subsys create analyt analytics
```

Where:

- `analyt` is the name of the analytics server that you are creating. You can assign it any name, as long as the identifier consists of lower case alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
- `analytics` indicates that you want it to create an Analytics microservice.

The `apiconnect-up.yml` file that is in that directory is updated to add the analytics-related entries.

Tip: At any time, you can view the current analytics subsystem values in the `apiconnect-up.yml` by running the `apicup get` command:

**apicup subsys get analyt**

If you have not updated the value, a default value is listed, if there is one that is available.  
Sample output from `apicup subsys get`, after configuration is completed:

```

apicup subsys get analyt
Appliance settings
=====

Name          Value          Description
----          -
additional-cloud-init-file yml file      (Optional) Path to additional cloud-init
data-device    sdb            VM disk device (usually `sdb` for SCSI or
`vdb` for VirtIO)
default-password $6$rounds=4096$imCJ9cfhFJ8X$pbmAl
9ClWzcYzHZFoQ6n7OnYCF/owQZIIcPAtWazs/FUN/
uE8uLD.9jwHE0AX4upFSqx/jf0ZmDbHPZ9bU1CY1 (Optional) Console login password for
`apicadm` user
dns-servers    [1.2.136.11]  List of DNS servers
k8s-pod-network 172.16.0.0/16 (Optional) CIDR for pods within the
appliance
k8s-service-network 172.17.0.0/16 (Optional) CIDR for services within the
appliance
mode           standard
public-iface   eth0           Device for API/UI traffic (Eg: eth0)
search-domain  [subnet1.example.com] List for DNS search domains
ssh-keyfiles   [/home/vsphere/.ssh/id_rsa.pub] List of SSH public keys files
traffic-iface  eth0           Device for cluster traffic (Eg: eth0)
license-version Production

Subsystem settings
=====

Name          Value          Description
----          -
es-max-memory-gb 16             Memory limit for elastic search

Endpoints
=====

Name          Value          Description
----          -
analytics-client a7s-client.testsrv0233.subnet1.example.com FQDN of Analytics client/UI endpoint
analytics-ingestion a7s-in.testsrv0233.subnet1.example.com FQDN of Analytics ingestion endpoint

```

4. For production environments, specify `mode=standard`.

```
apicup subsys set analyt mode=standard
```

The `mode=standard` parameter indicates that you are deploying in high availability (HA) mode for a production environment. If the mode parameter is omitted, the subsystem deploys by default in `dev` mode, for use in development and testing. For more information, see [Requirements for initial deployment on VMware](#).

5. **Version 2018.4.1.10 or later:** Specify the license version you purchased.

```
apicup subsys set analyt
license-version=<license_type>
```

The `license_type` must be either `Production` or `Nonproduction`. If not specified, the default value is `Nonproduction`.

6. Optional: Configure your logging.

Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.

- Complete the procedure at [Configuring remote logging for a VMware deployment](#).
- Enter the following command to create the log file:

```
apicup subsys set analyt additional-cloud-init-file=config_file.yml
```

7. Enter the following commands to update the `apiconnect-up.yml` with the information for your environment:

- Use `apicup` to set your endpoints.

You can use wildcard aliases or host aliases with your endpoints.

Optionally, you can specify all endpoints with one `apicup` command. See [Tips and tricks for using APICUP](#).

Note: You cannot specify the underscore character "\_" in domain names that are used in endpoints. See [Configuration on VMware](#).

The endpoints must be unique hostnames which both point to the IP address of the OVA (single node deployment), or to the IP of a load balancer configured in front of the OVA nodes. See examples in sample output in step [3](#).

Setting	Endpoint host description
analytics-ingestion	Your <i>unique_hostname</i> identifies the endpoint that enables the Gateway to push your analytics data. The values for the analytics-ingestion and analytics-client must be different. <code>apicup subsys set analyt analytics-ingestion=unique_hostname.domain</code>
analytics-client	Your <i>unique_hostname</i> identifies the endpoint that enables the Cloud Manager, API Manager, and Developer Portal to communicate with the Analytics subsystem. <code>apicup subsys set analyt analytics-client=unique_hostname.domain</code>
	This setting is not needed for the ingestion-only configuration.

- To configure the Analytics subsystem for ingestion-only, include the following command:

```
apicup subsys set analyt ingestion-only=true
```

- Set your search domain. Multiple search domains should be separated by commas.

```
apicup subsys set analyt search-domain=your_search_domain
```

Where *your\_search\_domain* is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is *mycompany.example.com*.

Ensure that the value for *your\_search\_domain* is resolved in the system's */etc/resolv.conf* file to avoid "502" errors when accessing the Cloud Manager web site. For example:

```
# Generated by resolvconf
search your_search_domain ibm.com other.domain.com
```

d. Set your domain name servers (DNS).

Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set analyt dns-servers=ip_address_of_dns_server
```

DNS entries may not be changed on a cluster after the initial installation.

8. Set a Public key.

```
apicup subsys set analyt ssh-keyfiles=path_to_public_ssh_keyfile
```

Setting this key enables you to use **ssh** with this key to log in to the virtual machine to check the status of the installation. You will perform this check in step 29 of these instructions.

9. You can set the password that you enter to log into your Analytics server for the first time.

a. **Important:** Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

b. If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the <b>mkpasswd</b> command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: <b>gem install mkpasswd</b> .
Windows, Red Hat	If necessary, a password hashing utility like OpenSSL.

c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	<b>mkpasswd --method=sha-512 --rounds=4096 password</b>
Windows, Red Hat	For example, using OpenSSL: <b>openssl passwd -1 password</b> . Note that you might need to add your password hashing utility to your path; for example, in Windows: <b>set PATH=c:\cygwin64\bin;%PATH%</b>

d. Set the hashed password for your subsystem:

```
apicup subsys set analyt default-password='hashed_password'
```

Notes:

- The password is hashed. If it is in plain text, you cannot log into the VMWare console.
- Note that the password can only be used to login through the VMware console. You cannot use it to SSH into the Appliance as an alternative to using the **ssh-keyfiles**.
- On Linux or OSX, use single quotes around *hashed\_password*. For Windows, use double quotes.
- If you are using a non-English keyboard, understand the limitations with using the remote VMware console. See [Requirements for initial deployment on VMware](#).

10. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.

You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See [Configuration on VMware](#).

a. Update the IP range for the Kubernetes pod

```
apicup subsys set analyt k8s-pod-network='new_pod_range'
```

Where *new\_pod\_range* is the new value for the range.

b. Update the IP range for Service networks.

```
apicup subsys set analyt k8s-service-network='new_service_range'
```

Where *new\_service\_range* is the new value for the range.

11. Add your hosts.

```
apicup hosts create analyt hostname.domainname hd_password
```

Where the following are true:

- *hostname.domainname* is the fully qualified name of the server where you are hosting your Analytics service, including the domain information.
- *hd\_password* is the password of the Linux Unified Key Setup uses to encrypt the storage for your Analytics service. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in **apiconnect-up.yml**.

Repeat this command for each host that you want to add.

Note:

- Host names and DNS entries may not be changed on a cluster after the initial installation.
- **Version 2018.4.1.0:** Ensure that Reverse DNS lookup configuration is configured for the host names.

```
nslookup <ip_address>
```

For **Version 2018.4.1.1 or later**, Reverse DNS lookup is not required.

12. Create your interfaces.

```
apicup iface create analyt hostname.domainname physical_network_id host_ip_address/subnet_mask gateway_ip_address
```

Where *public\_iface\_id* is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where `x` is a number identifier. The format is similar to this example: `apicup iface create analyt myHostname.domain eth0 192.0.2.1/255.255.1.1 192.0.2.1`

13. Optional: Use `apicup` to view the configured hosts:

```
apicup hosts list analyt
testsrv0233.subnet1.example.com
  Device IP/Mask Gateway
  eth0   1.2.152.233/255.255.254.0 1.2.152.1
```

14. Optional: Enable the message queue for analytics.

```
apicup subsys set analyt enable-message-queue=true
```

Options are `true` or `false`. The default is `false`. When set to true, the message queue will be activated and the analytics pipeline will be configured to use it. See [Configuring the analytics message queue](#).

You can enable the message queue later if you do not want to enable it during installation.

15. Verify that the configuration settings are valid.

```
apicup subsys get analyt --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

```
apicup subsys get analyt --validate
Appliance settings

----          -
es-max-memory-gb 16 ✓

Endpoints
=====
Name          Value
----          -
analytics-client a7s-client.testsrv0233.subnet1.example.co ✓
analytics-ingestion a7s-in.testsrv0233.subnet1.example.com ✓
```

Note: If you are installing the Analytics subsystem with the ingestion-only configuration, the following settings are not actually validated (because they are not used) but are marked as correct in the validation results:

- `analytics-client`
- `es-max-memory`

16. Create your ISO file.

```
apicup subsys install analyt --out analytplan-out
```

The `--out` parameter and value are required. In this example, the ISO file is created in the `myProject/analytplan-out/node-config` directory.

If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
OSX and Linux	<code>export PATH=\$PATH:/Users/your_path/</code>
Windows	<code>set PATH="c:\Program Files (x86)\cdrtools";%PATH%</code>

17. Log into the VMware vSphere Web Client.

18. Using the vSphere Navigator, navigate to the directory where you are deploying the OVA file.

19. Right-click the directory and select Deploy OVF Template.

20. Complete the Deploy OVF Template wizard.

- a. Select the apiconnect-analytics.ova template by navigating to the location where you downloaded the file from [Passport Advantage®](#).
- b. Enter a name and location for your file.
- c. Select a resource for your template.
- d. Review the details for your template.
- e. Select the size of your configuration.
- f. Select the storage settings.
- g. Select the networks.
- h. Customize the Template, if necessary.
- i. Review the details to ensure that they are correct.
- j. Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See [Requirements for initial deployment on VMware](#).

The template creation appears in your Recent Tasks list.

21. Select the Storage tab in the Navigator.
22. Navigate to your datastore.
23. Upload your ISO file.
  - a. Select the Navigate to the datastore file browser icon in the icon menu.
  - b. Select the Upload a file to the Datastore icon in the icon menu.
  - c. Navigate to the ISO file that you created in your project.  
It is the myProject/analytplan-out/node-config
  - d. Upload the ISO file to the datastore.
24. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
25. Locate and select your virtual machine.
26. Select the Configure tab in the main window.
27. Select Edit....
  - a. On the Virtual Hardware tab, select CD/DVD Drive 1.
  - b. For the Client Device, select Datastore ISO File.
  - c. Find and select your datastore in the Datastores category.
  - d. Find and select your ISO file in the Contents category.
  - e. Select OK to commit your selection and exit the Select File window.
  - f. Ensure that the Connect At Power On check box is selected.

Tip:

- Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
- Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On

- g. Select OK to commit your selection and close the window.

28. Start the virtual machine by selecting the play button on the icon bar.

The installation might take several minutes to complete, depending on the availability of the system and the download speed.

29. Log in to the virtual machine by using an SSH tool to check the status of the installation:

- a. Enter the following command to connect to *mgmt* using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

- b. Select Yes to continue connecting.  
Your host names are automatically added to your list of hosts.
- c. Run the **apic status** command to verify that the installation completed and the system is running correctly.  
The command output for a correctly running Analytics system is similar to the following lines:

```
#sudo apic status
INFO[0000] Log level: info

Cluster members:
- testsrv0233.subnet1.example.com (1.2.152.233)
  Type: BOOTSTRAP_MASTER

30. If you have now installed all subsystems, continue to [Access the Cloud Manager and begin API Connect Cloud Configuration](#).

## Results

An analytics installation starts the following Kubernetes pods:

- Full installation in **standard** mode:  
Table 1. Kubernetes pods in a full Analytics installation

Number	Pod
2	client
2	ingestion
2	mtls
1	operator
equal to the number of nodes	analytics-storage-basic

Note that for all pod types except analytics-storage-basic, there is only one of each pod when installed in **dev** mode. For analytics-storage-basic, the number of pods always matches the number of nodes in the subsystem, regardless of installation mode.

- Message queue deployment in **standard** mode: All of the pods shown in Table [Table 1](#), plus:

Table 2. Additional pods used for Message Queue deployments

Number	Pod
equal to the number of nodes	mq-kafka
equal to the number of nodes	mq-zookeeper

Note that the number of pods for mq-kafka and mq-zookeeper always match the number of nodes in the subsystem, regardless of installation mode.

- Ingestion-only installation in **standard** mode:

Table 3. Kubernetes pods in an ingestion-only Analytics installation

Number	Pods
2	ingestion
2	mtls

Note that in **dev** mode there is only one of each pod.

## What to do next

Identify the DataPower® appliances to be used as gateway servers in the API Connect cloud and obtain the IP addresses.

Define your API Connect configuration by using the API Connect cloud console. For more information, see [Defining the cloud](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Deploying the Developer Portal in a VMware environment

You create a Developer Portal node by deploying the Developer Portal OVA template. After you deploy the Developer Portal OVA template, you can install the Developer Portal.

## Before you begin

Before you deploy:

- Review the [Deployment requirements on VMware](#).
- Review the [Configuration on VMware](#).
- For information on deploying a cluster, see [Configuring API Connect subsystems in a cluster on VMware](#)
- If you are upgrading from a previous version, see [Upgrading in a VMware environment](#).

Note:

Ensure that your kernel or Kubernetes node has the value of its `inotify` watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a `non-ready` state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of `inotify` watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take `inotify` watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.

## About this task

You must deploy the Developer Portal OVA template to create each Developer Portal node that you want in your cloud. Each node has a separate CLI password account that is required to log in through a Secure Shell (SSH) to complete specific administrative actions for only that node.

Important deployment information for Developer Portal:

- You must deploy the Developer Portal OVA template by using a version of the VMware vSphere Client that supports the SHA-512 Cryptographic Hash Algorithm.
- The Developer Portal node is initially configured with a default password of `7iron-hide`, with the user name of `admin`. For security reasons, change the default password by completing one of the following actions:
  - During deployment, if the feature is available in your VMware instance, enter a new password. If you specify a password during deployment, the password for the Developer Portal command line interface (CLI) is modified. Use the new password when you log into the CLI. You cannot modify the admin user name for the CLI.
  - After deployment, log in to the CLI for each virtual appliance and run the command to change the default password for that specific node. The CLI command is `passwd`.

Note that this console uses a US keyboard configuration, in which the `@` symbol can be in a different place to other keyboard configurations. If you are not using a US keyboard, ensure that you typed the password correctly.

- Only static IP addresses that are specified during the `apicup` project configuration before the installation of the OVAs are supported.
- To enable effective high availability for your Portal service, you need a latency that is less than 50ms between all OVAs to avoid the risk of performance degradation. Servers with uniform specifications are required, as any write actions occur at the speed of the slowest OVA, as the write actions are synchronous across the cluster of OVAs. It is recommended that there are three servers in each cluster of OVAs for the high availability configuration. The three servers can be situated in the same data center, or across three data centers to ensure the best availability. However, you can configure high availability with two data centers.
- The backup secret is a Kubernetes secret that contains your username and password for your backup database (sftp/s3). Only password-based authentication is supported for sftp and s3, not authentication based on public certificates and private keys. Password-based authentication for s3 requires that you generate an access key and secret. For example:
  - IBM (Cloud Object Storage): [Service credentials](#).
  - AWS: [Managing access keys](#).

## Procedure

Note: The following steps apply to VMware only. Depending on the VMware version that you are using, some of the steps might vary. For example, you might not be able to change the user name and password during deployment.

1. Ensure that you obtained the distribution file and have a project directory, as described in [First steps for deploying in a VMware environment](#).
2. Change to the project directory.

```
cd myProject
```

3. Create a portal subsystem.

```
apicup subsys create port portal
```

Where:

- `port` is the name of the Developer Portal server that you are creating. You can assign it any name, as long as the identifier consists of lower case alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
- `portal` indicates that you want it to create a Developer Portal microservice.

The `apiconnect-up.yml` file that is in that directory is updated to add the portal-related entries.

Tip: At any time, you can view the current developer portal subsystem values in the `apiconnect-up.yml` by running the `apicup get` command:

```
apicup subsys get port
```

If you have not yet configured the subsystem, the command might return errors. Also, if you have not updated the value, a default value is listed, if there is one that is available.

After configuration is complete, you can view output similar to the following sample:

```
Appliance settings
```

```
=====
```

Name	Value	Description
-----	-----	-----
additional-cloud-init-file		(Optional) Path to additional cloud-init yml file

```

data-device          sdb                               VM disk device (usually `sdb` for SCSI
or `vdb` for VirtIO)
default-password    $6$rounds=4096$imCJ9cfhFJ8X$pbmAl9ClWzcYzHZFoQ6
                    n7OnYcf/owQZiCpAtWazs/FUn/uE8uLD.9jwHE0AX4upfSqx/jf0ZmDbHPZ9bUlCY1 (Optional) Console login password for
`apicadm` user
dns-servers         [1.2.136.11]                               List of DNS servers
k8s-pod-network    172.16.0.0/16                               (Optional) CIDR for pods within the
appliance
k8s-service-network 172.17.0.0/16                               (Optional) CIDR for services within the
appliance
mode                standard
public-iface        eth0                                           Device for API/UI traffic (Eg: eth0)
search-domain       [subnet1.example.com]                       List for DNS search domains
ssh-keyfiles        [/home/vsphere/.ssh/id_rsa.pub]             List of SSH public keys files
traffic-iface       eth0                                           Device for cluster traffic (Eg: eth0)
license-version     Production

```

**Subsystem settings**  
=====

Name	Value	Description
site-backup-auth-pass		(optional) Server password for portal backups
site-backup-auth-user		(optional) Server username for portal backups
site-backup-host		(optional) FQDN for portal backups server
site-backup-path	/site-backups	(optional) Path for portal backups
site-backup-port	22	(optional) port for portal backups server
site-backup-protocol	sftp	(Optional) Protocol for portal backups (sftp/objstore)
site-backup-schedule	0 2 * * *	(optional) Cron schedule for portal backups

**Endpoints**  
=====

Name	Value	Description
portal-admin	api.portal.apimdev0232.subnet1.example.com	FQDN of Portal admin endpoint
portal-www	portal.apimdev0232.subnet1.example.com	FQDN of Portal web endpoint

4. For production environments, specify `mode=standard`.

```
apicup subsys set port mode=standard
```

The `mode=standard` parameter indicates that you are deploying in high availability (HA) mode for a production environment. If the mode parameter is omitted, the subsystem deploys by default in `dev` mode, for use in development and testing. For more information, see [Requirements for initial deployment on VMware](#).

5. **Version 2018.4.1.10 or later:** Specify the license version you purchased.

```
apicup subsys set port
license-version=<license_type>
```

The `license_type` must be either `Production` or `Nonproduction`. If not specified, the default value is `Nonproduction`.

6. Optional: Configure scheduled backups of the subsystem. This step is optional but is recommended. Refer to the instructions in [Backing up and restoring the Developer Portal in a Kubernetes environment](#).
7. Optional: Configure your logging.

Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.

- Complete the procedure at [Configuring remote logging for a VMware deployment](#).
- Enter the following command to create the log file:

```
apicup subsys set port additional-cloud-init-file=config_file.yml
```

8. Enter the following commands to update the `apiconnect-up.yml` with the information for your environment:

- Use `apicup` to set your endpoints. You can use wildcard aliases or host aliases with your endpoints. Optionally, you can specify all endpoints with one `apicup` command. See [Tips and tricks for using APICUP](#).

Note: You cannot specify the underscore character "\_" in domain names that are used in endpoints. See [Configuration on VMware](#).

The endpoints must be unique hostnames which both point to the IP address of the OVA (single node deployment), or to the IP of a load balancer configured in front of the OVA nodes. See examples in the sample output in step 3.

Setting	Endpoint host description
portal-admin	This is the <i>unique_hostname</i> for communication between your Cloud Manager and API Manager, and your Developer Portal. The values for the portal-admin and portal-www must be different. <code>apicup subsys set port portal-admin=unique_hostname.domain</code>
portal-www	This is the <i>unique_hostname</i> for the Developer Portal Internet site that is created for the Developer Portal. Multiple portal-www endpoints may be configured, as described here: <a href="#">Defining multiple portal endpoints for a VMware environment</a> . <code>apicup subsys set port portal-www=unique_hostname.domain</code>

- Set your search domain. Multiple search domains should be separated by commas.

```
apicup subsys set port search-domain=your_search_domain
```

Where `your_search_domain` is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is `mycompany.example.com`.

Ensure that the value for `your_search_domain` is resolved in the system's `/etc/resolv.conf` file to avoid "502" errors when accessing the Cloud Manager web site. For example:

```
# Generated by resolvconf
search your_search_domain ibm.com other.domain.com
```

c. Set your domain name servers (DNS).

Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set port dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
```

DNS entries may not be changed on a cluster after the initial installation.

9. Set a Public key.

```
apicup subsys set port ssh-keyfiles=path_to_public_ssh_keyfile
```

Setting this key enables you to use `ssh` with this key to log in to the virtual machine to check the status of the installation. You will perform this check in step 29 of these instructions.

10. You can set a hashed password that you enter to log in to your Developer Portal server for the first time.

a. **Important:** Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

b. If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the <code>mkpasswd</code> command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: <code>gem install mkpasswd</code> .
Windows, Red Hat	If necessary, a password hashing utility like OpenSSL.

c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	<code>mkpasswd --method=sha-512 --rounds=4096 password</code>
Windows, Red Hat	For example, using OpenSSL: <code>openssl passwd -1 password</code> . Note that you might need to add your password hashing utility to your path; for example, in Windows: <code>set PATH=c:\cygwin64\bin;%PATH%</code>

d. Set the hashed password for your subsystem:

```
apicup subsys set port default-password="hashed_password"
```

Notes:

- The password is hashed. If it is in plain text, you cannot log into the VMWare console.
- Note that the password can only be used to login through the VMWare console. You cannot use it to SSH into the Appliance as an alternative to using the `ssh-keyfiles`.
- On Linux or OSX, use single quotes around `hashed_password`. For Windows, use double quotes.
- If you are using a non-English keyboard, understand the limitations with using the remote VMWare console. See [Requirements for initial deployment on VMWare](#).

11. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.

You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See [Configuration on VMWare](#).

a. Update the IP range for the Kubernetes pod

```
apicup subsys set port k8s-pod-network='new_pod_range'
```

Where `new_pod_range` is the new value for the range.

b. Update the IP range for Service networks.

```
apicup subsys set port k8s-service-network='new_service_range'
```

Where `new_service_range` is the new value for the range.

12. Add your hosts.

```
apicup hosts create port hostname.domainname hd_password
```

Where the following are true:

- `hostname.domainname` is the fully qualified name of the server where you are hosting your Developer Portal, including the domain information.
- `hd_password` is the password of the Linux Unified Key Setup used to encrypt the storage for your Developer Portal. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in `apiconnect-up.yml`. Repeat this command for each host that you want to add.

Note:

- Host names and DNS entries may not be changed on a cluster after the initial installation.
- **Version 2018.4.1.0:** Ensure that Reverse DNS lookup configuration is configured for the host names.

```
nslookup <ip_address>
```

For **Version 2018.4.1.1 or later**, Reverse DNS lookup is not required.

13. Create your interfaces.

```
apicup iface create port hostname.domainname physical_network_id host_ip_address/subnet_mask gateway_ip_address
```

Where `public_iface_id` is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where `x` is a number identifier. The format is similar to this example: `apicup iface create port myHostname.domain eth0 192.0.2.1/255.255.1.1 192.0.2.1`

- Optional: Use `apicup` to view the configured hosts:

```
apicup hosts list port
apimdev0232.hursley.ibm.com
Device IP/Mask Gateway
eth0 1.2.152.232/255.255.254.0 1.2.152.1
```

- Optional: Verify that the configuration settings are valid.

```
apicup subsys get port --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

```
apicup subsys get port --validate
Appliance settings

```

- Create your ISO file.

```
apicup subsys install port --out portplan-out
```

The `--out` parameter and value are required. In this example, the ISO file is created in the `myProject/portplan-out` directory.

If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
OSX and Linux	<code>export PATH=\$PATH:/Users/your_path/</code>
Windows	<code>set PATH="c:\Program Files (x86)\cdrtools";%PATH%</code>

- Log into the VMware vSphere Web Client.
- Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
- Right-click the directory and select Deploy OVF Template.
- Complete the Deploy OVF Template wizard.
  - Select the `apiconnect-portal.ova` template by navigating to the location where you downloaded the file from [Passport Advantage®](#).
  - Enter a name and location for your file.
  - Select a resource for your template.
  - Review the details for your template.
  - Select the size of your configuration.
  - Select the storage settings.

Note that the number of Central Processing Units, RAM, and size of disk that you need for the Developer Portal varies depending on the number of sites that are hosted and the number of concurrent users you expect your site to have:

Table 1. Developer Portal hardware requirements

Number of sites	Number of concurrent users	Number of CPUs	Amount of RAM (GB)	Data Disk Size (GB)++
-----------------	----------------------------	----------------	--------------------	-----------------------

Number of sites	Number of concurrent users	Number of CPUs	Amount of RAM (GB)	Data Disk Size (GB)++
1	1	2**	4	50
20	5	4	16	70
100	20	8	32	100
100	100	16	64	500

Important:

- ++The data disk size is extra to the main disk of the OVA. The main disk of the OVA is sized at 100GB, and should not be changed. Therefore, the total disk size of the OVA is 100GB plus the data disk size. The default data disk size is 100GB. If you want to select a different value, then you need to do this by using the OVF Tool, or the VMware GUI, before you power on the VM. Note that certain versions of the VMware GUI may not allow you to resize the data disk, and in this case you should use the OVF Tool.
- \*\*The requirement of 2 CPUs is suitable only for proof-of-concept work, and non-high availability deployments. For example, this configuration is suitable for the demo mode of the apicup installation, which is set by using the command `apicup subsys set port mode=dev`. Note that `standard` mode is set by default.
- It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a Portal site for every Catalog, for example Catalogs that are only for API Developers don't need a Portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services; see [Registering a Portal service](#).

- Select the networks.
- Customize the Template, if necessary.
  - Review the details to ensure that they are correct.
  - Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See [Requirements for initial deployment on VMware](#).

The template creation appears in your Recent Tasks list.

- Select the Storage tab in the Navigator.
- Navigate to your datastore.
- Upload your ISO file.
  - Select the Navigate to the datastore file browser icon in the icon menu.
  - Select the Upload a file to the Datastore icon in the icon menu.
  - Navigate to the ISO file that you created in your project. It is the `myProject/portplan-out`
  - Upload the ISO file to the datastore.
- Leave the datastore by selecting the VMs and Templates icon in the Navigator.
- Locate and select your virtual machine.
- Select the Configure tab in the main window.
- Select Edit....
  - On the Virtual Hardware tab, select CD/DVD Drive 1.
  - For the Client Device, select Datastore ISO File.
  - Find and select your datastore in the Datastores category.
  - Find and select your ISO file in the Contents category.
  - Select OK to commit your selection and exit the Select File window.
  - Ensure that the Connect At Power On check box is selected.

Tip:

- Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
- Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On

- Select OK to commit your selection and close the window.

- Start the virtual machine by selecting the play button on the icon bar.

The installation might take several minutes to complete, depending on the availability of the system and the download speed.

- Log in to the virtual machine by using an SSH tool to check the status of the installation:

- Enter the following command to connect to `mgmt` using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of `apicadm`, which is the API Connect ID that has administrator privileges.

- Select Yes to continue connecting. Your host names are automatically added to your list of hosts.
- Run the `apic status` command to verify that the installation completed and the system is running correctly. The command output for a correctly running Developer Portal system is similar to the following lines:

```
$ sudo apic status
INFO[0000] Log level: info
```

```

30. If you have now installed all subsystems, continue to [Access the Cloud Manager and begin API Connect Cloud Configuration](#).

## What to do next

If you want to deploy an API Connect Analytics OVA file, continue with [Deploying the Analytics subsystem in a VMware environment](#).

If you did not specify a new password during deployment in VMware, then after deployment, log in to the command-line interface (CLI) for each appliance and run the command `passwd` to change the password.

- [Defining multiple portal endpoints for a VMware environment](#)  
Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Defining multiple portal endpoints for a VMware environment

Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

### About this task

You can override the single endpoint definition for portal-www (and the associated portal-www-ingress TLS certificate), in order to support multiple portal-www endpoints.

For information about the endpoints for the Portal, see [Deploying the Developer Portal in a VMware environment](#).

Following are the example endpoints for configuring different sites served by the same Portal service, as configured in this task:

- `https://banking.example.com/loans`
- `https://insurance.example.com/vehicle`

These unique endpoints allow portal sites to be defined on the Portal service with different host names and domains. They replace endpoints that distinguish different sites by sub paths, as shown in the following examples:

- `https://www.example.com/banking/loans`
- `https://www.example.com/insurance/vehicle`

## Procedure

1. Create TLS secrets for each portal-www endpoint by generating certificates  
Following is an example for how to generate certificates for each portal-www endpoint using openssl:

```
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout banking-tls.key -out banking-tls.crt -subj
"/CN=banking.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout insurance-tls.key -out insurance-tls.crt -subj
"/CN=insurance.example.com"
```

2. Store the SSL certificates in a secret.

Copy the certificates to the Portal virtual machine as follows:

```
scp banking-tls.key banking-tls.crt insurance-tls.key insurance-tls.crt apicadm@<portal-vm-address>
```

Access the virtual machine using SSH and store the SSL certificates in a secret:

```
sudo kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls banking-tls --key banking-tls.key --cert banking-tls.crt
sudo kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls insurance-tls --key insurance-tls.key --cert insurance-tls.crt
```

3. Specify the portal-www endpoints in an extra values file.

Create an extra values file or append to your current one. Enter the name and secret for each endpoint as an ingress setting in the extra values file. (One extra values file is allowed.) For instructions on creating an extra-values-file, see [Creating an extra values file in a Kubernetes environment](#).

```
apic-portal-www:
  ingress:
    web:
      hosts:
        - name: banking.example.com
          secret: banking-tls
        - name: insurance.example.com
          secret: insurance-tls
```

4. Configure your Portal subsystem to load the extra values file with the following command:

```
apicup subsys set <portal-subsys> extra-values-file=<full-path-to-extra-values-file>
```

5. Install the portal subsystem with the new extra values file using `apicup subsys install portal-subsys`.

For more information on installing the Portal subsystem, see [Deploying the Developer Portal in a VMware environment](#).

6. If your deployment had existing Portal sites when you configured multiple endpoints, ensure that the Portal site URLs specified in the Manager UI Catalog settings page are consistent with the new endpoint URLs. Access the Catalog setting page, and review the URLs of those existing sites. Modify as appropriate.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Access the Cloud Manager and begin API Connect Cloud Configuration

When all subsystems are deployed, use the admin account to access the Cloud Manager administrative console and begin configuration.

### About this task

When you have deployed all required API Connect components, and all subsystems are running, complete the following:

### Procedure

1. If you have not previously accessed the Cloud Manager, verify you can access the API Connect Cloud Manager. Enter the URL in your browser.

The syntax is `https://<hostname.domain>/admin`. For example:

```
https://cloud-admin-ui.testsrv0231.subnet1.example.com/admin
```

The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See [Accessing the Cloud Manager user interface](#).

2. Define your API Connect configuration by using the API Connect Cloud Manager. See [Cloud Manager configuration checklist](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring API Connect subsystems in a cluster on VMware

This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.

### Before you begin

To create a cluster of hosts for each API Connect subsystem, use `apicup` to create a subsystem with all the required parameters, and to add as many hosts as needed to the configuration file. The configuration file is a `.yaml` file in the project directory.

For each host of a subsystem added in the `.yaml` file, a separate ISO file is created for the cluster member VM. Note that the ISO files for each VM must stay attached during the whole lifetime of the VM.

In an API Connect cluster in a VMware environment, the first three nodes are master nodes. Additional nodes are worker nodes.

Note: To add a new host to an existing cluster, you can create the host, regenerate the ISO and attach it to the new virtual machine, and it will automatically join the cluster.

To use these instructions, you should first review:

- [Requirements for initial deployment on VMware](#)
- [Load balancer configuration in a VMware deployment](#)
- [Deployment overview for endpoints and certificates](#)
- [Firewall requirements on VMware](#)
- [Firewall enabled ports for clustered OVA deployments](#)
- [API Connect 2018.4.1.x Whitepaper](#)

Important: For best performance it is recommended that the network latency between any 2 nodes be as low as possible. Do not configure nodes from the same subsystem cluster across multiple data centers with a high latency network. A high latency network is one that experiences more than 30ms latency between nodes. For more information, see the [API Connect V2018 Whitepaper](#)

## About this task

This page presents a concise step-by-step flow, with sample commands, for the configuration of each subsystem. As you step through the flow, you might want to refer back to the detailed configuration steps for each subsystem. The detailed instructions provide additional considerations for each step, and include optional configuration tasks for backups, logging, message queues (analytics), and password hashing. Each of the subsystem pages describe how to use the VMware console to deploy the ISOs that you create here.

Detailed configuration steps:

- [Deploying the Management subsystem in a VMware environment](#)
- [Deploying the Analytics subsystem in a VMware environment](#)
- [Deploying the Developer Portal in a VMware environment](#)

The example commands uses the following values for DNS server, internet gateway, host names and IP addresses:

Component	Host names and IP addresses
DNS Name Server	IP: 192.168.1.1
Internet gateway	IP: 192.168.1.2
Manager on VM1	Hostname: manager1.sample.example.com IP: 192.168.1.101
Manager on VM2	Hostname: manager2.sample.example.com IP: 192.168.1.102
Manager on VM3	Hostname: manager3.sample.example.com IP: 192.168.1.103
Analytics on VM4	Hostname: analytics1.sample.example.com IP: 192.168.1.104
Analytics on VM5	Hostname: analytics2.sample.example.com IP: 192.168.1.105
Analytics on VM6	Hostname: analytics3.sample.example.com IP: 192.168.1.106
Developer Portal on VM7	Hostname: portal1.sample.example.com IP: 192.168.1.107
Developer Portal on VM8	Hostname: portal2.sample.example.com IP: 192.168.1.108
Developer Portal on VM9	Hostname: portal3.sample.example.com IP: 192.168.1.109

## Procedure

1. Create the Management subsystems

a. Create the Management subsystem.

```
apicup subsys create mgmt management
```

b. Set install mode to **standard**.

```
apicup subsys set mgmt mode=standard
```

If you omit this step, the install mode defaults to **dev**, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

c. **Version 2018.4.1.10 or later:** Specify the license version you purchased.

```
apicup subsys set mgmt  
license-version=<license_type>
```

The *license\_type* must be either **Production** or **Nonproduction**. If not specified, the default value is **Nonproduction**.

d. Set management endpoints

Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
Management REST API URL	<code>apicup subsys set mgmt platform-api platform-api.sample.example.com</code>
Consumer (Portal) REST API URL	<code>apicup subsys set mgmt consumer-api consumer-api.sample.example.com</code>
Cloud Manager UI	<code>apicup subsys set mgmt cloud-admin-ui cloud-admin-ui.sample.example.com</code>
API Manager UI	<code>apicup subsys set mgmt api-manager-ui api-manager-ui.sample.example.com</code>

e. Set the search domain for the VM.

```
apicup subsys set mgmt search-domain sample.example.com
```

- f. Set the DNS Name Server for the VM to look up endpoints.

```
apicup subsys set mgmt dns-servers 192.168.1.1
```

- g. Set a Public Keyfile.

This is the public key of the user account that you want to use to **ssh** from, to the appliance.

```
apicup subsys set mgmt ssh-keyfiles "id_rsa.pub"
```

- h. Create the hosts for the subsystem.

You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the previous example with a strong password that meets your security requirements.

```
apicup hosts create mgmt manager1.sample.example.com password123
apicup hosts create mgmt manager2.sample.example.com password123
apicup hosts create mgmt manager3.sample.example.com password123
```

- i. Set the network interface. Note that the last parameter is the Internet Gateway.

```
apicup iface create mgmt manager1.sample.example.com eth0 192.168.1.101/255.255.255.0 192.168.1.2
apicup iface create mgmt manager2.sample.example.com eth0 192.168.1.102/255.255.255.0 192.168.1.2
apicup iface create mgmt manager3.sample.example.com eth0 192.168.1.103/255.255.255.0 192.168.1.2
```

- j. Set the network traffic interfaces.

```
apicup subsys set mgmt traffic-iface eth0
apicup subsys set mgmt public-iface eth0
```

- k. Verify the host configuration.

```
apicup hosts list mgmt
```

Note: This command might return the following messages, which you can ignore:

```
* host is missing traffic interface
* host is missing public interface
```

- l. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

```
apicup subsys set mgmt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

**Important:** Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

- m. Validate the installation.

```
apicup subsys get mgmt --validate
```

- n. Create an ISO file in a plan folder. For example, **mgmtplan-out**.

```
apicup subsys install mgmt --out mgmtplan-out
```

If you have multiple nodes listed for the hosts, when you run the **--out** command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

- o. To deploy the ISOs on VMware, see step [17](#) in [Deploying the Management subsystem in a VMware environment](#).

## 2. Create the analytics subsystems

- a. Create the subsystem:

```
apicup subsys create analyt analytics
```

- b. Specify **mode=standard**.

```
apicup subsys set analyt mode=standard
```

- c. **Version 2018.4.1.10 or later:** Specify the license version you purchased.

```
apicup subsys set analyt
license-version=<license_type>
```

The *license\_type* must be either **Production** or **Nonproduction**. If not specified, the default value is **Nonproduction**.

- d. Set analytics endpoints

Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
analytics-ingestion	<code>apicup subsys set analyt analytics-ingestion=analytics-ingestion.sample.example.com</code>
analytics-client	<code>apicup subsys set analyt analytics-client=analytics-client.sample.example.com</code>

- e. Set the search domain for the VM.

```
apicup subsys set analyt search-domain sample.example.com
```

- f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set analyt dns-servers 192.168.1.1
```

- g. Set a Public Keyfile.

This is the public key of the user account that you want to use to **ssh** from, to the appliance

```
apicup subsys set analyt ssh-keyfiles "id_rsa.pub"
```

- h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use `apicup` to set the hashed password for your subsystem:

```
apicup subsys set analyt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiU.8ctr0'
```

**Important:** Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

- i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the following password with a strong password that meets your security requirements.

```
apicup hosts create analyt analytics1.sample.example.com password123
apicup hosts create analyt analytics2.sample.example.com password123
apicup hosts create analyt analytics3.sample.example.com password123
```

- j. Set the network interface.

Note that the last parameter is the Internet Gateway.

```
apicup iface create analyt analytics1.sample.example.com eth0 192.168.1.104/255.255.255.0 192.168.1.2
apicup iface create analyt analytics2.sample.example.com eth0 192.168.1.105/255.255.255.0 192.168.1.2
apicup iface create analyt analytics3.sample.example.com eth0 192.168.1.106/255.255.255.0 192.168.1.2
```

- k. Check the host configuration for problems.

```
apicup hosts list analyt
```

- l. Validate the installation.

```
apicup subsys get analyt --validate
```

- m. Create an ISO file in a plan folder. For example, `analytplan-out`.

```
apicup subsys install analyt --out analytplan-out
```

If you have multiple nodes listed for the hosts, when you run the `--out` command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

- n. To deploy the ISOs, see step 17 in [Deploying the Analytics subsystem in a VMware environment](#)

### 3. Create the portal subsystems

- a. Create the portal.

```
apicup subsys create port portal
```

- b. For production environments, specify `mode=standard`.

```
apicup subsys set port mode=standard
```

If you omit this step, the install mode defaults to `dev`, which is for development and testing in non-HA environments only, and will not support three instances of the subsystem in one cluster.

- c. **Version 2018.4.1.10 or later:** Specify the license version you purchased.

```
apicup subsys set port
license-version=<license_type>
```

The `license_type` must be either `Production` or `Nonproduction`. If not specified, the default value is `Nonproduction`.

- d. Set the portal endpoints.

Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
portal-admin	<code>apicup subsys set port portal-admin=portal-admin.sample.example.com</code>
portal-www	<code>apicup subsys set port portal-www=portal-www.sample.example.com</code>

- e. Set the search domain for the VM.

```
apicup subsys set port search-domain sample.example.com
```

- f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set port dns-servers 192.168.1.1
```

- g. Set a Public Keyfile.

This is the public key of the user account that you want to use to `ssh` from, to the appliance

```
apicup subsys set port ssh-keyfiles "id_rsa.pub"
```

- h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use `apicup` to set the hashed password for your subsystem:

```
apicup subsys set port default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiU.8ctr0'
```

**Important:** Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

- i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses.

```
apicup hosts create port portal1.sample.example.com password123
apicup hosts create port portal2.sample.example.com password123
apicup hosts create port portal3.sample.example.com password123
```

Replace the example password in the previous example with a strong password that meets your security requirements.

- j. Set the network interface.

Note that the last parameter is the Internet Gateway.

```
apicup iface create port portal1.sample.example.com eth0 192.168.1.107/255.255.255.0 192.168.1.2
apicup iface create port portal2.sample.example.com eth0 192.168.1.108/255.255.255.0 192.168.1.2
apicup iface create port portal3.sample.example.com eth0 192.168.1.109/255.255.255.0 192.168.1.2
```

k. Check the host configuration for problems.

```
apicup hosts list port
```

l. Validate the installation.

```
apicup subsys get port --validate
```

m. Create an ISO file in a plan folder. For example, `portplan-out`.

```
apicup subsys install port --out portplan-out
```

If you have multiple nodes listed for the hosts, when you run the `--out` command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

n. To deploy the ISOs on VMware, see step [17](#) in [Deploying the Developer Portal in a VMware environment](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Installing the IBM License Metric Tool for VMware

The IBM® License Metric Tool (ILMT) helps you assess if you are compliant with licensing requirements.

### About this task

ILMT provides useful features for managing virtualized environments and measuring license utilization. ILMT discovers the software that is installed in your infrastructure, helps you to analyze the consumption data, and allows you to generate audit reports. Each report provides you with different information about your infrastructure, for example the computer groups, software installations, and the content of your software catalog.

By default, every ILMT audit report presents data from the previous 90 days. You can customize the type and amount of information displayed in a report by using filters, and save your personal settings for future use. You can also export the reports to .csv or .pdf format, and schedule report emails so that specified recipients are notified when important events occur.

For more information, see the [IBM License Metric Tool](#) documentation.

Note: These instructions cover ILMT installation for IBM API Connect deployments in a VMware environment, and apply to the Management, Developer Portal, and Analytics OVAs.

### Procedure

To download the BigFix Agent for the Ubuntu operating system, complete the following steps:

1. For example, starting from here: <http://support.bigfix.com/bes/release/>, follow the link to the latest release, for example: <http://support.bigfix.com/bes/release/9.5/patch11/>
2. In the Agent section of the table, click the Download link corresponding to the following release:
  - Operating System: Ubuntu
  - Version: 16
  - Architecture: x86\_64In this example, the direct download link would be: <http://software.bigfix.com/download/bes/95/BESAgent-9.5.11.191-ubuntu10.amd64.deb>

Upload the BigFix Agent package to each OVA server, as follows:

3. Upload the BigFix Agent .deb package to each running OVA server. Following is an example of the command for uploading the file that was downloaded in Step 2:

```
scp BESAgent-9.5.11.191-ubuntu10.amd64.deb apicadm@<OVA_Hostname>:~
```

The generic command is:

```
scp <BigFix_Agent_Package_File_Path> apicadm@<OVA_Hostname>:~
```

The BigFix Agent .deb package will be uploaded to `/home/apicadm`.

Install the BigFix client on each OVA server, as follows:

4. Log in, with a secure shell connection, to the server as the `apicadm` user.
5. Become root by entering `sudo -s`.
6. Follow the BigFix Agent installation instructions located here: [IBM Bigfix installation instructions Ubuntu](#) to install the .deb package.

### What to do next

Ensure that TCP/IP port 52311 is open on your firewall.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Adding a static route on a virtual machine

You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.

### About this task

---

Add commands to your additional `cloud-init` file. You can do this for the Management, Analytics, and Portal subsystems.

### Procedure

---

1. Specify an additional cloud-init file:

```
apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
```

2. Add lines to your cloud-init file.

Syntax:

```
bootcmd:  
- ip route add <destination>/<mask> via <gateway> dev eth<n>
```

Example:

```
bootcmd:  
- ip route add 172.27.218.0/24 via 172.27.218.1 dev eth1  
- ip route add 172.26.203.0/24 via 172.27.218.1 dev eth1
```

3. Regenerate the ISO file.

```
apicup subsys install <subsys> --out <plan-directory>
```

4. Restart the ISO, and ensure that the node(s) have this updated ISO attached at startup.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Configuring use of an external NTP server

You must configure an external NTP server for use by API Connect when deploying on a VMware virtual machine.

### About this task

---

Secure communication between API Connect subsystems relies on the system time being in sync on all hosts. For example, time stamps are checked to ensure that certificates are valid. When API Connect is deployed behind a firewall that blocks access to the internet, the API Connect subsystems cannot by default access a Network Time Protocol (NTP) server.

You can use an additional cloud-init file to manually specify an NTP server for use by the subsystems. Complete the following steps.

### Procedure

---

1. Create the cloud-init file extra values file, and enter the configuration details that you want to overwrite. For example:

```
ntp:  
  enabled: true  
  ntp_client: systemd-timesyncd  
  servers:  
    - time.google.com
```

2. Use `apicup` to specify the cloud-init file.

Syntax:

```
apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
```

Example:

```
apicup subsys set mgmt additional-cloud-init-file myCloudInitFile.yaml
```

3. Install the subsystem. Note that the output directory must be empty:

```
apicup subsys install mgmt --out mgmtplan-out
```

4. Deploy the VMware image (.ova) with the ISO file that is generated.

To review the deployment steps, see [Deploying the Management subsystem in a VMware environment](#).

5. Verify that the correct NTP server is being used:

```
journalctl -u systemd-timesyncd
```

Example output for the NTP server that was set in Step 1:

```
Nov 05 21:09:24 h-apicdev-4 systemd[1]: Starting Network Time Synchronization...
Nov 05 21:09:24 h-apicdev-4 systemd[1]: Started Network Time Synchronization.
Nov 05 21:09:24 h-apicdev-4 systemd-timesyncd[1697]: Synchronized to time server 216.239.35.8:123 (time.google.com).
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Deploying DataPower Gateway

API Connect uses IBM® DataPower® Gateway to provide the gateway service.

The instructions in this section describe how to deploy IBM DataPower Gateway from files obtained from [Passport Advantage®](#), and apply to the following API Connect scenarios:

- API Connect deployments for the VMware environment
- API Connect deployments for Kubernetes, with a DataPower Gateway in a *non-Kubernetes* environment.

For these scenarios, continue with [Installing DataPower Gateway](#).

Note: Do not use these instructions if you are deploying API Connect deployments for Kubernetes, with DataPower Gateway in a *Kubernetes* environment. In this case, you can use DataPower Gateway files that are packaged with API Connect, on the API Connect section of Fix Central, and configured by using the API Connect Install Assist (`apicup`) commands. Follow the instructions in [First steps for installing API Connect: Upload files to registry](#).

- [Installing DataPower Gateway](#)  
Install and configure IBM DataPower Gateway in a non-Kubernetes environment for use with API Connect.
- [Configuring DataPower Gateway for API Connect](#)  
You can configure the IBM DataPower Gateway to prepare for a registration with the API Connect Management server.
- [Sample configuration for multiple peering objects on gateway services external to Kubernetes](#)  
Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Installing DataPower Gateway

Install and configure IBM® DataPower® Gateway in a non-Kubernetes environment for use with API Connect.

### Before you begin

Do not use these instructions for either of the following deployment scenarios:

- Both API Connect and DataPower Gateway in a Kubernetes environment.  
In this scenario, use the instructions in [First steps for installing API Connect: Upload files to registry](#).
- An existing DataPower Gateway 2018.4.1.0 in a non-Kubernetes environment, and you want to install a newer Fix Pack, such as 2018.4.1.3.  
In this scenario, complete an *upgrade* rather than a new installation. See [Upgrading DataPower Gateway Service](#).

To review the installation and configuration scenarios, see [Deploying DataPower Gateway](#).

### About this task

These instructions apply for Version 2018.4.1.0 or later.

### Procedure

1. Ensure that DataPower Gateway firmware version you plan to install matches the API Connect Management server version. For example, DataPower 2018.4.1.6 and API Connect 2018.4.1.6. It is recommended that you use the latest version of each product, as viewable in the SPCR reports. See [IBM API Connect Version 2018 software product compatibility requirements](#).
2. Obtain your DataPower files from IBM [Passport Advantage®](#).  
Note that the DataPower files from [Passport Advantage](#) have entitled services for API Connect users.  
  
See also [Download the firmware image from Passport Advantage](#).
3. Follow the DataPower Gateway installation information:  
Note: Set the timezone to UTC on all DataPower installations for use with API Connect.

- For gateways on physical appliances, see [DataPower Gateway 2018.4.1.x Installation](#)
  - For virtual gateways, see [Virtual DataPower Gateways](#).
4. Continue with [Configuring DataPower Gateway for API Connect](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring DataPower Gateway for API Connect

You can configure the IBM® DataPower® Gateway to prepare for a registration with the API Connect Management server.

### About this task

API Connect and DataPower supports two different types of gateway configurations. The DataPower Gateway (v5 compatible) provides the same support as the gateway support that was available with API Connect version 5.x. The DataPower API Gateway is an enhanced gateway that is performance-focused. See [API Connect gateway types](#) for more information about the differences between the gateway types.

Continue with the instructions for the type of Gateway Service you are configuring:

- [Configuring DataPower API Gateway](#)  
You can configure the DataPower API Gateway to prepare for a registration with the API Connect Management server.
- [Configuring DataPower Gateway \(v5 compatible\)](#)  
You can configure the DataPower Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring DataPower API Gateway

You can configure the DataPower® API Gateway to prepare for a registration with the API Connect Management server.

### Before you begin

- These instructions are for DataPower Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower Gateway Service also in the Kubernetes environment. To review deployment scenarios, see [Deploying DataPower Gateway](#).
- Ensure you have installed the version of DataPower Gateway that matches the version of the API Connect Management server. See [Installing DataPower Gateway](#).
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See [Generating keys and certificates](#) in the DataPower Gateway IBM documentation for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower Gateway is set to UTC.

### About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects. The procedures for configuring the two types of gateways are very similar, so only one procedure is provided. Any specific differences are identified.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See [Gateway peering](#) for more information about configuring additional gateways for peering. See [Providing gateway service for API Connect](#) in the DataPower Gateways IBM Knowledge Center content for more details about the DataPower settings and procedures.

### Procedure

To configure a DataPower gateway to communicate with API Connect, complete the following steps:

**Note:** Use these instructions only for DataPower API Gateway . If you are configuring DataPower Gateway (v5 compatible) see [Configuring DataPower Gateway \(v5 compatible\)](#).

1. Open the DataPower WebGUI interface.  
Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Enable the XML management interface in the **default** domain, if required. The XML management interface is optional for DataPower API Gateway.
  - a. Search for **XML management interface** in the navigation search bar, and select it.
  - b. Set the Administrative state to enabled.
  - c. You can specify a different port number if you do not want to use the default of **5550**.
  - d. Select Apply to make the changes
  - e. Save changes to the default domain by selecting Save Configuration.
3. Create an application domain.  
This domain receives your traffic.

- a. Search for Application domain in the navigation search bar, and select it.
- b. Select Add to create the application domain.
- c. Enter a unique name for your domain.
- d. Ensure that enabled is selected for the Administrative state.
- e. Ensure that the default domain is listed in the Visible application domain list.
- f. Select Apply.
- g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
- h. Select Save changes and switch domains.
  - All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
  - i. Save changes to the domain by selecting Save Configuration.
4. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
  - See [Managing the NTP service](#).
5. Ensure that you have set a unique Appliance name (**System Identifier**) for each DataPower gateway. See [Initializing the DataPower Gateway](#).
6. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See [Generating keys and certificates](#) in the DataPower Gateway IBM documentation for instructions on how to create a crypto key with the DataPower tools.
7. Upload your private crypto key file to the domain.
  - a. Search for Crypto key in the navigation search bar, and select it.
  - b. Select Add to create a key object.
  - c. Create a unique name for the key object in the *Name* field.
  - d. Select Upload....
  - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
  - f. If you want to rename it, enter a new name for the file.
  - g. Select Upload to move it to the server in the cert:// folder.
  - h. Select Apply to save the changes.
8. Upload your crypto certificate file to the domain.
  - Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.
  - a. Search for Crypto certificate in the navigation search bar, and select it.
  - b. Select Add to create a certificate object.
  - c. Create a unique name for the certificate object in the *Name* field.
  - d. Select Upload....
  - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
  - f. If you want to rename it, enter a new name for the file.
  - g. Select Upload to move it to the server in the cert:// folder.
  - h. Select Apply to save the changes.
9. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
  - a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
  - b. Select Add.
  - c. Enter a name for your credential.
  - d. Ensure that the Administrative state has a value of enabled.
  - e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
  - f. In the Certificate field object, select the name of the certificate object that you created from the drop-down menu.
  - g. Select Apply to commit your changes.
10. Create your SSL Client profile.
  - a. Search for SSL Client profile in the navigation search bar, and select it.
  - b. Select Add to create a client profile.
  - c. Create a unique name for the profile in the *Name* field.
  - d. Select your Identification credential from the drop-down list.
  - e. Ensure that the value of *Validate server certificate* is set to off.
  - f. Select Apply to save the changes.
11. Create your SSL Server profile.
  - a. Search for SSL Server Profile in the navigation search bar, and select it.
  - b. Select Add to create a server profile.
  - c. Create a unique name for the profile in the *Name* field.
  - d. Select your Identification credential from the drop-down list.
  - e. Ensure that the value of *Request client authentication* is set to off.
  - f. Select Apply to save the changes.
12. For the DataPower API Gateway only: Define a configuration sequence.
  - The API Connect gateway service uses the configuration sequence to configure DataPower to implement the APIs that are defined in API Connect.
  - a. Search for Configuration sequence in the navigation search bar, and select it.
  - b. Select Add.
  - c. Enter a name for your configuration sequence.
    - The name **apic-config** is not allowed because it is already used internally.
  - d. Ensure that the Administrative state has a value of enabled.
  - e. Ensure that the value in the *Location profiles* field is set to local:///
    - This is the default value, so you might not need to change it.
  - f. Select the Access profile. See [Configuring the access profile for a configuration sequence](#) in the DataPower Gateway IBM Knowledge Center for instructions on how to create access profiles.
  - g. Change the value of the *Configuration execution interval* field to 3000.
    - The other fields can retain their default settings.
  - h. Select Apply to commit your changes.
13. Configure your gateway peering object for the API Connect Gateway Service.
  - This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.
  - a. Search for Gateway peering in the navigation search bar, and select it.
  - b. Select Add.
  - c. Enter a unique name for your gateway peering object.
  - d. Ensure that the Administrative state has a value of enabled.
  - e. Select a local address for the communications among the members of the peer group.
  - f. Select a local port for the communication.

- You can use the default value of 16380.
- g. Select a monitor port for the communication.  
You can use the default value of 26380.
  - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
  - i. Clear the Enable SSL checkbox. SSL is not needed for a single peer.
  - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
  - k. Select Apply to commit your changes.
14. Configure your gateway peering object for rate limit information.  
Note: Version 2018.4.1.7 or later is required.
- a. Search for Gateway peering in the navigation search bar, and select it.
  - b. Select Add.
  - c. Enter a unique name for your gateway peering object.
  - d. Ensure that the Administrative state has a value of enabled.
  - e. Select a local address for the communications among the members of the peer group.
  - f. Select a local port for the communication.  
Use a unique port, different than the ports used for communication by other gateway peering objects.
  - g. Select a monitor port for the communication.  
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
  - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
  - i. Clear the Enable SSL checkbox. SSL is not needed for a single peer.
  - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
  - k. Select Apply to commit your changes.
15. Configure your gateway peering object for subscription information.  
Note: Version 2018.4.1.7 or later is required.
- a. Search for Gateway peering in the navigation search bar, and select it.
  - b. Select Add.
  - c. Enter a unique name for your gateway peering object.
  - d. Ensure that the Administrative state has a value of enabled.
  - e. Select a local address for the communications among the members of the peer group.
  - f. Select a local port for the communication.  
Use a unique port, different than the ports used for communication by other gateway peering objects.
  - g. Select a monitor port for the communication.  
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
  - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
  - i. Clear the Enable SSL checkbox. SSL is not needed for a single peer.
  - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
  - k. Select Apply to commit your changes.
16. Configure the gateway peering manager.  
Note: Version 2018.4.1.7 or later is required.
- a. Search for Gateway Peering Manager in the navigation search bar, and select it.
  - b. Set the Administrative state to enabled.
  - c. In the pull-down menu next to API Connect Gateway Service, select the gateway peering object configured in Step [13](#) for the API Connect Gateway Service.
  - d. In the pull-down menu next to Rate Limit, select the gateway peering object configured in Step [14](#) for rate limit information.
  - e. In the pull-down menu next to Subscription, select the gateway peering object configured in Step [15](#) for subscription.
  - f. Select Apply to commit your changes.
17. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
- a. Search for API Connect Gateway service in the navigation search bar, and select it.
  - b. Ensure that the Administrative state is set to enabled.
  - c. In the *Local address* field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
  - d. Specify a value for Local Port. You can use the default port value of 3000, or specify a different port value.  
Note: The Local port specifies the port through which API Connect connects to manage the API Connect Gateway Service. Use this port when you configure a Gateway Service on API Connect. Beyond this port, the gateway service uses two additional consecutive ports after the defined local port to bind to a loopback address. Therefore, you must ensure that there are no conflicts on all three consecutive ports that start from the defined local port.
  - e. In the *SSL client* field drop-down list, select the name of the SSL client profile that you created.
  - f. In the *SSL server* field drop-down list, select the name of the SSL server profile that you created.
  - g. In the *API gateway address* field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
  - h. Use the default port value of 9443 for the API gateway port.  
If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
  - i. For DataPower API Gateway, set the Gateway Peering to **(none)**.  
When no gateway peering object is configured for the DataPower API Gateway, the peering configuration defined in the Gateway Peering Manager configuration is used.
  - j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.  
When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway. Clear it to enable a DataPower API Gateway.
18. Register the gateway service in the API Connect Cloud Manager console:
- a. Open the API Connect Cloud Manager console.
  - b. Navigate to Configure Topology.
  - c. Select Register Service.
  - d. Select DataPower API Gateway for the DataPower API Gateway.
  - e. Add a title, name, and summary for the gateway connection.
  - f. Optional: Configure the OAuth Shared Secret.  
This setting allows OAuth tokens to be shared across multiple gateway services.
  - g. Enter one of the following values in the *API Invocation Endpoint* field:
    - IP address of the load balancer for the API transactions
    - IP address or host name of one of the gateways
 For example: `https://192.0.2.0:9443/`
  - h. Enter the one of the following values in the *Management Endpoint* field:
    - IP address of the load balancer for the management server traffic set to port 3000
    - IP address or hostname of one of the gateways
 For example: `https://192.0.2.0:3000/`
19. Select the default TLS Client Profile

20. Optional: Configure Server Name Indication (SNI) profiles.  
SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring DataPower Gateway (v5 compatible)

You can configure the DataPower® Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

### Before you begin

- These instructions are for DataPower Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower Gateway Service also in the Kubernetes environment. To review deployment scenarios, see [Deploying DataPower Gateway](#).
- Ensure you have installed the version of DataPower Gateway that matches the version of the API Connect Management server. See [Installing DataPower Gateway](#).
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See [Generating keys and certificates](#) in the DataPower Gateway IBM documentation for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower Gateway is set to UTC.

### About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects. The procedures for configuring the two types of gateways are very similar, so only one procedure is provided. Any specific differences are identified.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See [Gateway peering](#) for more information about configuring additional gateways for peering. See [Providing gateway service for API Connect](#) in the DataPower Gateways IBM Knowledge Center content for more details about the DataPower settings and procedures.

### Procedure

To configure a DataPower gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower Gateway (v5 compatible). If you are configuring DataPower API Gateway, see [Configuring DataPower API Gateway](#).

1. Open the DataPower WebGUI interface.  
Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Enable the XML management interface in the **default** domain, if required. The XML management interface is required for DataPower Gateway (v5 compatible). The XML management interface is optional for DataPower API Gateway.
  - a. Search for **XML management interface** in the navigation search bar, and select it.
  - b. Set the Administrative state to enabled.
  - c. You can specify a different port number if you do not want to use the default of **5550**.
  - d. Select Apply to make the changes
  - e. Save changes to the default domain by selecting Save Configuration.
3. Create an application domain.  
This domain receives your traffic.
  - a. Search for Application domain in the navigation search bar, and select it.
  - b. Select Add to create the application domain.
  - c. Enter a unique name for your domain.
  - d. Ensure that enabled is selected for the Administrative state.
  - e. Ensure that the default domain is listed in the Visible application domain list.
  - f. Select Apply.
  - g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
  - h. Select Save changes and switch domains.  
All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
    - i. Save changes to the domain by selecting Save Configuration.
4. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.  
See [Managing the NTP service](#).
5. Ensure that you have set a unique Appliance name (**System Identifier**) for each DataPower gateway. See [Initializing the DataPower Gateway](#).
6. For the DataPower Gateway (v5 compatible) only: Enable statistics in the domain you created for **API Connect**.
  - a. Search for and select Statistics settings in the navigation search.
  - b. Select enabled for the Administrative state.
  - c. Select Apply.
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See [Generating keys and certificates](#) in the DataPower Gateway IBM documentation for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
  - a. Search for Crypto key in the navigation search bar, and select it.
  - b. Select Add to create a key object.
  - c. Create a unique name for the key object in the *Name* field.
  - d. Select Upload....
  - e. Browse for the key file (which must be a .pem or .p12 file) and select it.

- f. If you want to rename it, enter a new name for the file.
  - g. Select Upload to move it to the server in the `cert://` folder.
  - h. Select Apply to save the changes.
9. Upload your crypto certificate file to the domain.
- Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.
- a. Search for Crypto certificate in the navigation search bar, and select it.
  - b. Select Add to create a certificate object.
  - c. Create a unique name for the certificate object in the *Name* field.
  - d. Select Upload....
  - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
  - f. If you want to rename it, enter a new name for the file.
  - g. Select Upload to move it to the server in the `cert://` folder.
  - h. Select Apply to save the changes.
10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
- a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
  - b. Select Add.
  - c. Enter a name for your credential.
  - d. Ensure that the Administrative state has a value of enabled.
  - e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
  - f. In the Certificate field object, select the name of the certificate object that you created from the drop-down menu.
  - g. Select Apply to commit your changes.
11. Create your SSL Client profile.
- a. Search for SSL Client profile in the navigation search bar, and select it.
  - b. Select Add to create a client profile.
  - c. Create a unique name for the profile in the *Name* field.
  - d. Select your Identification credential from the drop-down list.
  - e. Ensure that the value of *Validate server certificate* is set to off.
  - f. Select Apply to save the changes.
12. Create your SSL Server profile.
- a. Search for SSL Server Profile in the navigation search bar, and select it.
  - b. Select Add to create a server profile.
  - c. Create a unique name for the profile in the *Name* field.
  - d. Select your Identification credential from the drop-down list.
  - e. Ensure that the value of *Request client authentication* is set to off.
  - f. Select Apply to save the changes.
13. Configure your gateway peering object for the API Connect Gateway Service.
- This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.
- a. Search for Gateway peering in the navigation search bar, and select it.
  - b. Select Add.
  - c. Enter a unique name for your gateway peering object.
  - d. Ensure that the Administrative state has a value of enabled.
  - e. Select a local address for the communications among the members of the peer group.
  - f. Select a local port for the communication.  
You can use the default value of 16380.
  - g. Select a monitor port for the communication.  
You can use the default value of 26380.
  - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
  - i. Clear the Enable SSL checkbox. SSL is not needed for a single peer.
  - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
  - k. Select Apply to commit your changes.
14. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
- a. Search for API Connect Gateway service in the navigation search bar, and select it.
  - b. Ensure that the Administrative state is set to enabled.
  - c. In the *Local address* field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
  - d. Use the default port value of 3000 for the Local port.
  - e. In the *SSL client* field drop-down list, select the name of the SSL client profile that you created.
  - f. In the *SSL server* field drop-down list, select the name of the SSL server profile that you created.
  - g. In the *API gateway address* field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
  - h. Use the default port value of 9443 for the API gateway port.  
If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
  - i. For DataPower Gateway (v5 compatible), select the gateway peering object that you created in Step [13](#).
  - j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.  
When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway.
15. Register the gateway service in the API Connect Cloud Manager console:
- a. Open the API Connect Cloud Manager console.
  - b. Navigate to Configure Topology.
  - c. Select Register Service.
  - d. Select DataPower Gateway (v5 compatible) for the gateway that was available in version 5.
  - e. Add a title, name, and summary for the gateway connection.
  - f. Optional: Configure the OAuth Shared Secret.  
This setting allows OAuth tokens to be shared across multiple gateway services.
  - g. Enter one of the following values in the *API Invocation Endpoint* field:
    - IP address of the load balancer for the API transactions
    - IP address or host name of one of the gateways
For example: `https://192.0.2.0:9443/`
  - h. Enter the one of the following values in the *Management Endpoint* field:
    - IP address of the load balancer for the management server traffic set to port 3000
    - IP address or hostname of one of the gateways
For example: `https://192.0.2.0:3000/`
16. Select the default TLS Client Profile

17. Optional: Configure Server Name Indication (SNI) profiles.

SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Sample configuration for multiple peering objects on gateway services external to Kubernetes

Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

- This reference shows how to configure API Connect domain configuration with gateway-peering configuration. To review domain configuration settings, see [Configuring DataPower Gateway for API Connect](#).
- This sample applies only to gateway services that are deployed external to Kubernetes, on either a physical or virtual appliance. This sample does not apply to gateway services that are deployed on Kubernetes.

The following examples show sample configuration for 3 different gateways, listed here with sample IP addresses of 1.1.1.1, 2.2.2.2, and 3.3.3.3. Note the following:

- The priority should be set differently on each of the three gateways. Set the lowest priority for the gateway that will run as primary.
- **persistence** should be set to **memory** for all configured peering objects.
- Optionally, add SSL configuration.

Configuration on gateway 1 (1.1.1.1)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

### About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer user interface.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer user interface.

You can download the toolkit compressed file in either of the following ways:

- From IBM Fix Central.
- From either the Cloud Manager or API Manager user interface.

The following table identifies the name of the compressed file that you need to download, depending on your chosen toolkit option and platform:

Table 1. Toolkit file names, by option and platform

Toolkit option	Mac OS X	Linux®	Windows
CLI	toolkit-mac.zip	toolkit-linux.tgz	toolkit-windows.zip
CLI + LoopBack + Designer	toolkit-loopback-designer-mac.zip	toolkit-loopback-designer-linux.tgz	toolkit-loopback-designer-windows.zip

## Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
  - To download the toolkit from IBM Fix Central, complete the following steps:
    - Open the [IBM Fix Central site](#) in your browser.
    - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
    - Select your installed 2018.x.y version from the Installed Version list, then click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
    - In the Text field, enter `toolkit`, then click Continue.
    - Select the required file, as identified in [Table 1](#).

- Note: When you download from IBM Fix Central, the release number is appended to the file name.
- Click Continue, then follow the instructions to complete the download operation.
  - To download the toolkit from either the Cloud Manager or API Manager user interface, complete the following steps:
    - Cloud Manager or API Manager user interface.
    - Select Help ( ? ) in the navigation.
    - Select Install API Connect CLI & API Designer.
    - Select CLI or CLI + LoopBack + Designer according to your preferred option.
    - Select your platform to download the toolkit compressed file.
    - Close the Install API Connect CLI & API Designer window.
2. Extract the contents of the toolkit compressed file to a folder of your choice.  
The contents of the file depend on the your chosen toolkit option and platform, as follows:

Table 2. Toolkit compressed file contents, by option and platform

Toolkit option	Mac OS X	Linux	Windows
CLI	apic-slim	apic-slim	apic-slim.exe
CLI + LoopBack + Designer	apic api_designer-mac.zip: contains the API Designer user interface application.	apic api_designer-linux	apic.exe api_designer-win.exe

The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.

The apic or apic.exe file is the CLI for IBM API Connect including LoopBack support.

Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.

The api\_designer-*platform* file is the API Designer user interface application for the specified platform.

3. Run the CLI.
- For the Mac OS X or Linux platforms, complete the following steps:
    - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
    - Make the CLI file an executable file by entering the following command:

```
chmod +x download_name
```

Where *download\_name* is the name of the toolkit file that you downloaded, either apic or apic-slim.

- Run CLI commands as follows:

```
./apic command_name_and_parameters
```

or

```
./apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

- For the Windows platform, complete the following steps:
  - Open a terminal window and navigate to the folder where you extracted the contents of the toolkit compressed file.
  - Run CLI commands as follows:

```
apic command_name_and_parameters
```

or

```
apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.

4. Launch the API Designer user interface by running the application from the location to which you extracted the contents of the toolkit compressed file.

Note:

- To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
  - In Windows File Explorer, navigate to the USER\_HOME\AppData\Local\Programs\api-designer folder.
  - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
- To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

## Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see [Developing your APIs and applications](#).

For information on using the toolkit CLI, see [Using the developer toolkit command-line tool](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Upgrading in a VMware environment

You can upgrade an existing deployment of API Connect on VMware to a newer version while retaining your data.

- [Requirements for upgrading on VMware](#)  
Before upgrading API Connect on VMware, ensure that your deployment meets all the upgrade requirements.
- [Upgrading API Connect subsystems in a VMware environment](#)  
Complete the following steps to upgrade API Connect subsystems.
- [Troubleshooting the API Connect upgrade on VMware](#)  
Troubleshoot your API Connect upgrade on VMware.
- [Upgrading DataPower Gateway Service](#)  
Use these instructions when upgrading DataPower Gateway Service in a non-Kubernetes environment, during upgrade of API Connect Version 2018.4.1.0 or later.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Requirements for upgrading on VMware

Before upgrading API Connect on VMware, ensure that your deployment meets all the upgrade requirements.

Restriction: A direct upgrade from any version of 2018 to API Connect 10.0.6.0 or later is not supported. You must upgrade to 10.0.5.x as an interim step before upgrading to 10.0.6.0.

The instructions for upgrading apply to the *latest* Fix Pack version. Ensure that you are upgrading to the latest Fix Pack version. For information on the available Fix Packs, see [What's New in the latest release](#).

Note: For more information if you are moving to v2018.4.1.10, see the Tech note at [IBM Support](#).

See the requirements for the version you are upgrading from:

- [Requirements for upgrading from v2018.4.1.8 or later on VMware](#)  
Review the requirements for upgrading from Version 2018.4.1.8 or later on VMware.
- [Requirements for upgrading from v2018.4.1.7 on VMware](#)  
Review the requirements for upgrading from Version 2018.4.1.7 on VMware.
- [Requirements for upgrading from v2018.4.1.5 or v2018.4.1.6 on VMware](#)  
Review the requirements for upgrading from Version 2018.4.1.5 or Version 2018.4.1.6 on VMware.
- [Requirements for upgrading from v2018.4.1.4 or earlier on VMware](#)  
Review the requirements for upgrading from Version 2018.4.1.4 or earlier on VMware.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Requirements for upgrading from v2018.4.1.8 or later on VMware

Review the requirements for upgrading from Version 2018.4.1.8 or later on VMware.

Restriction:

- A direct upgrade from any version of 2018 to API Connect 10.0.6.0 or later is not supported. You must upgrade to 10.0.5.x as an interim step before upgrading to 10.0.6.0.
- You cannot upgrade directly to FP24 from versions older than FP20; you must upgrade to FP20 first.
- Upgrading to FP20 from any version older than FP15 requires that you first upgrade to at least one version in the FP15-to-FP19 range.
- Before starting the upgrade, verify that API Connection deployment is fully operational. See [Checking cluster health on VMware](#).  
When upgrading to v2018.4.1.10 or later, this step is optional because a health check will be run automatically as part of the `apicup subsys install` command in [Upgrading API Connect subsystems in a VMware environment](#). Note that you might still want to run the health check when preparing for the upgrade, to ensure the health of the backup image you must create prior to running `apicup subsys install`.
- When upgrading from v2018.4.1.13 or later, use the following command to remove any previously used upgrade files:  

```
apic clean-upgrade-files
```
- When upgrading API Connect, complete a manual backup of the management database, Portal subsystem, and Analytics subsystem just prior to starting the upgrade. Note that this backup is in addition to any scheduled backups that you have configured. The manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured.

For details on creating a backup, see [Backing up the management subsystem in VMware environments](#), [Backing up and restoring the Developer Portal in a VMware environment](#) and [Backing up and restoring the analytics database](#).

- Ensure that port 9178 is open between the Analytics, Management, and Portal subsystems and the system running `apicup`.  
An i/o timeout error can occur if the firewall rejects traffic to the appliance. Make sure port 9178 is open and try again. Example error message:

```
apicup subsys install test-analytics upgrade_analytics_lts_v2018.4.1.5.tgz
INFO[0000] Preparing update
INFO[0010] Sending update packet to cluster (connected to testrv0192.subnet1.example.com)
Error: failed to install the subsystem: unable to open file send stream:
rpc error: code = Unavailable desc = all SubConns are in TransientFailure,
latest connection error: connection error:
desc = "transport: Error while dialing dial tcp 1.2.3.4:9178: i/o timeout"
```

- If not already set up, send your deployment logs to a remote server. The upgrade process terminates pods, and the logs will be lost if not stored remotely. To send your deployment logs to a remote server, see [Configuring remote logging for a VMware deployment](#).
- If you are upgrading any subsystem that has less than three nodes and was installed in **standard** mode, before you upgrade you must convert to **Dev** mode and remove replicaset. Conversion is necessary because **standard** mode is not supported on less than three nodes. See [Converting installation mode](#). To review installation modes, see [Requirements for initial deployment on VMware](#).
- Download the Install Assist (APICUP) installer from the same URL where you download your Fix Pack version. You must use the latest Install Assist package with the latest product version.
- The original project directory created with the APICUP installer during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. A good practice is to back up the original project directory to a location from which it can always be retrieved.
- If the upgrade is initiated from the original project directory, the certificates are automatically copied into the upgraded version. The original project directory contains the `apiconnect-up.yml` file. An upgrade using the same project directory as the one used for installation will transfer the `encryption-secret` and all other certificates for the project to the upgraded version.
- All external traffic to the management server must be blocked during the upgrade of the management subsystem. This restriction applies to traffic from all sources via the user interfaces (Cloud Manager, API Manager), CLI, and REST API. The Cloud Manager and API Manager UIs cannot be used during the upgrade of the management subsystem. The Developer Portal also cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the time.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Analytics, (3) Portal, (4) Gateway. Analytics and Portal may be switched between second or third, but Management must be upgraded first. Gateway must be upgraded after Management for the following reasons:
  - Upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
  - After a completed upgrade, the Management server and Gateway firmware versions must match, for example, APIC 2018.4.1.2 with DP 2018.4.1.2.
 Wait until the upgrade is finished on a subsystem before proceeding to the next one.
- Downgrading any of the IBM® API Connect subsystems to an earlier fix pack level is **not** supported.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Requirements for upgrading from v2018.4.1.7 on VMware

Review the requirements for upgrading from Version 2018.4.1.7 on VMware.

Restriction: A direct upgrade from any version of 2018 to API Connect 10.0.6.0 or later is not supported. You must upgrade to 10.0.5.x as an interim step before upgrading to 10.0.6.0.

- Before starting the upgrade, verify that API Connection deployment is fully operational. See [Checking cluster health on VMware](#). When upgrading to v2018.4.1.10 or later, this step is optional because a health check will be run automatically as part of the `apicup subsys install` command in [Upgrading API Connect subsystems in a VMware environment](#). Note that you might still want to run the health check when preparing for the upgrade, to ensure the health of the backup image you must create prior to running `apicup subsys install`.
- When upgrading API Connect, complete a manual backup of the management database, Portal subsystem, and Analytics subsystem just prior to starting the upgrade. Note that this backup is in addition to any scheduled backups that you have configured. The manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured.

For details on creating a backup, see [Backing up the management subsystem in VMware environments](#), [Backing up and restoring the Developer Portal in a VMware environment](#) and [Backing up and restoring the analytics database](#).

- The upgrade of the management server *from* Version 2018.4.1.7 or earlier may take longer than during previous fix pack upgrades. The extended time is due to underlying schema changes, and can be as long as several hours for long established deployments with a large amount of data, such as greater than 10 GB.

To reduce the amount of time required for the upgrade of the management database, use the `apicops` command to truncate the subscriber event table and remove unused snapshots:

```
apicops subscriber-queues:clear
apicops snapshots:clean-up
```

Use the latest release of the `apicops` command. Download it from <https://github.com/ibm-apiconnect/apicops/releases>.

- Ensure that port 9178 is open between the Analytics, Management, and Portal subsystems and the system running `apicup`. An i/o timeout error can occur if the firewall rejects traffic to the appliance. Make sure port 9178 is open and try again. Example error message:

```
apicup subsys install test-analytics upgrade_analytics_lts_v2018.4.1.5.tgz
INFO[0000] Preparing update
INFO[0010] Sending update packet to cluster (connected to testsrv0192.subnet1.example.com)
Error: failed to install the subsystem: unable to open file send stream:
rpc error: code = Unavailable desc = all SubConns are in TransientFailure,
latest connection error: connection error:
desc = "transport: Error while dialing dial tcp 1.2.3.4:9178: i/o timeout"
```

- If not already set up, send your deployment logs to a remote server. The upgrade process terminates pods, and the logs will be lost if not stored remotely. To send your deployment logs to a remote server, see [Configuring remote logging for a VMware deployment](#).
- If you are upgrading any subsystem that has less than three nodes and was installed in **standard** mode, before you upgrade you must convert to **Dev** mode and remove replicaset. Conversion is necessary because **standard** mode is not supported on less than three nodes. See [Converting installation mode](#). To review installation modes, see [Requirements for initial deployment on VMware](#).

- Download the Install Assist (APICUP) installer from the same URL where you download your Fix Pack version. You must use the latest Install Assist package with the latest product version.
- The original project directory created with the APICUP installer during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. A good practice is to back up the original project directory to a location from which it can always be retrieved.
- If the upgrade is initiated from the original project directory, the certificates are automatically copied into the upgraded version. The original project directory contains the `apiconnect-up.yml` file. An upgrade using the same project directory as the one used for installation will transfer the `encryption-secret` and all other certificates for the project to the upgraded version.
- All external traffic to the management server must be blocked during the upgrade of the management subsystem. This restriction applies to traffic from all sources via the user interfaces (Cloud Manager, API Manager), CLI, and REST API. The Cloud Manager and API Manager UIs cannot be used during the upgrade of the management subsystem. The Developer Portal also cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the time.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Analytics, (3) Portal, (4) Gateway. Analytics and Portal may be switched between second or third, but Management must be upgraded first. Gateway must be upgraded after Management for the following reasons:
  - Upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
  - After a completed upgrade, the Management server and Gateway firmware versions must match, for example, APIC 2018.4.1.2 with DP 2018.4.1.2.
 Wait until the upgrade is finished on a subsystem before proceeding to the next one.
- Downgrading any of the IBM® API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Requirements for upgrading from v2018.4.1.5 or v2018.4.1.6 on VMware

Review the requirements for upgrading from Version 2018.4.1.5 or Version 2018.4.1.6 on VMware.

Restriction: A direct upgrade from any version of 2018 to API Connect 10.0.6.0 or later is not supported. You must upgrade to 10.0.5.x as an interim step before upgrading to 10.0.6.0.

- Before starting the upgrade, verify that API Connection deployment is fully operational.
  - For Version 2018.4.1.6 or later, see [Checking cluster health on VMware](#).  
When upgrading *from* v2018.4.1.6 or later *to* v2018.4.1.10 or later, this step is optional because a health check will be run automatically as part of the `apicup subsys install` command in [Upgrading API Connect subsystems in a VMware environment](#). Note that you might still want to run the health check when preparing for the upgrade, to ensure the health of the backup image you must create prior to running `apicup subsys install`.
  - For Version 2018.4.1.5, see [Determining status of a cluster on VMware](#).
- When upgrading API Connect, complete a manual backup of the management database, Portal subsystem, and Analytics subsystem just prior to starting the upgrade. Note that this backup is in addition to any scheduled backups that you have configured. The manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured.

For details on creating a backup, see [Backing up the management subsystem in VMware environments](#), [Backing up and restoring the Developer Portal in a VMware environment](#) and [Backing up and restoring the analytics database](#).

- The upgrade of the management server *from* Version 2018.4.1.7 or earlier may take longer than during previous fix pack upgrades. The extended time is due to underlying schema changes, and can be as long as several hours for long established deployments with a large amount of data, such as greater than 10 GB.

To reduce the amount of time required for the upgrade of the management database, use the `apicops` command to truncate the subscriber event table and remove unused snapshots:

```
apicops subscriber-queues:clear
apicops snapshots:clean-up
```

Use the latest release of the `apicops` command. Download it from <https://github.com/ibm-apiconnect/apicops/releases>.

- When upgrading from Version 2018.4.1.5 or Version 2018.4.1.6, including any iFixes, obtain from Fix Central the Control Plane file that is required to upgrade the Kubernetes version to a supported version.

Version to upgrade from	Version to upgrade to	Control Plane file
2018.4.1.6	2018.4.1.9	<code>appliance-control-plane-1.14.1.tgz</code>
2018.4.1.5		

- Install the Control Plane file with each subsystem.
- `upgrade_management_lts_v2018.4.1.x.tgz` contains the required control-plane version(1.16.x)
- Note that Version 2018.4.1.10 the Control Plane artifact file is minor version 16 (major.minor.patch). Any version of the control plan matching the same minor version will work:

```
appliance-control-plane-1.16.[x].tgz
```

- You can install the Control Plane file and the upgrade file for the subsystem at the same time.  
For example, to upgrade the management subsystem from 2018.4.1.7 to 2018.4.1.10:

```
$ apicup subsys install management upgrade_management_lts_v2018.4.1.10.tgz appliance-control-plane-1.15.[x].tgz
```

For example, to upgrade the management subsystem from 2018.4.1.5-`ifix1.0` to 2018.4.1.10:

```
$ apicup subsys install management upgrade_management_lts_v2018.4.1.10.tgz appliance-control-plane-1.15.[x].tgz
appliance-control-plane-1.16.[x].tgz
```

- The ordering of files passed to `apicup subsys install` does not matter.
- If unsure of which files are required for upgrade, running `apicup subsys install` will interrogate the subsystem and error if any required files are missing. For example, upgrading from 2018.4.1.7 to 2018.4.1.10, but missing a control plane file:

```
$ apicup subsys install management upgrade_management_lts_v2018.4.1.10.tgz
Error: failed to install the subsystem: Unable to execute appliance plan: Missing minor version 16 in control plane
upgrade path
```

The error indicates that you also need to provide a control plane artifact that is minor version 16 (major.minor.patch). Any version of the control plan matching the same minor version will work.

Notes:

- Install the Control Plane file with each subsystem.
- For Version 2018.4.1.9, the Control Plane artifact file is minor version 14 (major.minor.patch). Any version of the control plan matching the same minor version will work:

```
appliance-control-plane-1.14.[x].tgz
```

- You can install the Control Plane file and the upgrade file for the subsystem at the same time. For example, to upgrade the management subsystem from 2018.4.1.5-`ifix1.0` to 2018.4.1.9:

```
$ apicup subsys install management upgrade_management_lts_v2018.4.1.9.tgz appliance-control-plane-1.14.[x].tgz
```

- The ordering of files passed to `apicup subsys install` does not matter.
- If unsure of which files are required for upgrade, running `apicup subsys install` will interrogate the subsystem and error if any required files are missing. For example, upgrading from 2018.4.1.5-`ifix1.0` to 2018.4.1.9, but missing a control plane file:

```
$ apicup subsys install management upgrade_management_lts_v2018.4.1.9.tgz
Error: failed to install the subsystem: Unable to execute appliance plan: Missing minor version 14 in control plane
upgrade path
```

The error indicates that you also need to provide a control plane artifact that is minor version 14 (major.minor.patch). Any version of the control plan matching the same minor version will work.

- Ensure that port 9178 is open between the Analytics, Management, and Portal subsystems and the system running `apicup`. An i/o timeout error can occur if the firewall rejects traffic to the appliance. Make sure port 9178 is open and try again. Example error message:

```
apicup subsys install test-analytics upgrade_analytics_lts_v2018.4.1.5.tgz
INFO[0000] Preparing update
INFO[0010] Sending update packet to cluster (connected to teststrv0192.subnet1.example.com)
Error: failed to install the subsystem: unable to open file send stream:
rpc error: code = Unavailable desc = all SubConns are in TransientFailure,
latest connection error: connection error:
desc = "transport: Error while dialing dial tcp 1.2.3.4:9178: i/o timeout"
```

- If not already set up, send your deployment logs to a remote server. The upgrade process terminates pods, and the logs will be lost if not stored remotely. To send your deployment logs to a remote server, see [Configuring remote logging for a VMware deployment](#).
- If you are upgrading any subsystem that has less than three nodes and was installed in `standard` mode, before you upgrade you must convert to `Dev` mode and remove replicaset. Conversion is necessary because `standard` mode is not supported on less than three nodes. See [Converting installation mode](#). To review installation modes, see [Requirements for initial deployment on VMware](#).
- Download the Install Assist (APICUP) installer from the same URL where you download your Fix Pack version. You must use the latest Install Assist package with the latest product version.
- The original project directory created with the APICUP installer during the initial product installation (for example, `myProject`) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. A good practice is to back up the original project directory to a location from which it can always be retrieved.
- If the upgrade is initiated from the original project directory, the certificates are automatically copied into the upgraded version. The original project directory contains the `apiconnect-up.yml` file. An upgrade using the same project directory as the one used for installation will transfer the `encryption-secret` and all other certificates for the project to the upgraded version.
- All external traffic to the management server must be blocked during the upgrade of the management subsystem. This restriction applies to traffic from all sources via the user interfaces (Cloud Manager, API Manager), CLI, and REST API. The Cloud Manager and API Manager UIs cannot be used during the upgrade of the management subsystem. The Developer Portal also cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the time.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Analytics, (3) Portal, (4) Gateway. Analytics and Portal may be switched between second or third, but Management must be upgraded first. Gateway must be upgraded after Management for the following reasons:
  - Upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
  - After a completed upgrade, the Management server and Gateway firmware versions must match, for example, APIC 2018.4.1.2 with DP 2018.4.1.2.
- Wait until the upgrade is finished on a subsystem before proceeding to the next one.
- Downgrading any of the IBM® API Connect subsystems to an earlier fix pack level is **not** supported.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Requirements for upgrading from v2018.4.1.4 or earlier on VMware

Review the requirements for upgrading from Version 2018.4.1.4 or earlier on VMware.

Restriction: A direct upgrade from any version of 2018 to API Connect 10.0.6.0 or later is not supported. You must upgrade to 10.0.5.x as an interim step before upgrading to 10.0.6.0.

- If you want to upgrade *from* an API Connect deployed version, 2018.4.1.4 or earlier *to* Version 2018.4.1.9 or later, you must first upgrade to Version 2018.4.1.5. You can then upgrade directly from Version 2018.4.1.5 to Version 2018.4.1.9 or later.

To upgrade *from* 2018.4.1.4 or earlier *to* 2018.4.1.5, you must upgrade the Fix Packs in the correct sequence. The sequence is required because Kubernetes imposes restrictions on skipping Kubernetes levels when upgrading. Complete the upgrade of all subsystems of one version before starting the upgrade to the next version. See the following table.

Deployed version	Required upgrade sequence
2018.4.1.0, 2018.4.1.1, or 2018.4.1.2	1. Version 2018.4.1.3 2. Version 2018.4.1.4 3. Version 2018.4.1.5
2018.4.1.3	1. Version 2018.4.1.4 2. Version 2018.4.1.5
2018.4.1.4	1. Version 2018.4.1.5

- Before starting the upgrade, verify that API Connection deployment is fully operational. On v2018.4.1.4 or earlier, see [Determining status of a cluster on VMware](#).
- When upgrading API Connect, complete a manual backup of the management database, Portal subsystem, and Analytics subsystem just prior to starting the upgrade. Note that this backup is in addition to any scheduled backups that you have configured. The manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured.

For details on creating a backup, see [Backing up the management subsystem in VMware environments](#), [Backing up and restoring the Developer Portal in a VMware environment](#) and [Backing up and restoring the analytics database](#).

- The upgrade of the management server *from* Version 2018.4.1.7 or earlier may take longer than during previous fix pack upgrades. The extended time is due to underlying schema changes, and can be as long as several hours for long established deployments with a large amount of data, such as greater than 10 GB.

To reduce the amount of time required for the upgrade of the management database, use the `apicops` command to truncate the subscriber event table and remove unused snapshots:

```
apicops subscriber-queues:clear
apicops snapshots:clean-up
```

Use the latest release of the `apicops` command. Download it from <https://github.com/ibm-apiconnect/apicops/releases>.

- Ensure that port 9178 is open between the Analytics, Management, and Portal subsystems and the system running `apicup`. An i/o timeout error can occur if the firewall rejects traffic to the appliance. Make sure port 9178 is open and try again. Example error message:

```
apicup subsys install test-analytics upgrade_analytics_lts_v2018.4.1.5.tgz
INFO[0000] Preparing update
INFO[0010] Sending update packet to cluster (connected to teststrv0192.subnet1.example.com)
Error: failed to install the subsystem: unable to open file send stream:
rpc error: code = Unavailable desc = all SubConns are in TransientFailure,
latest connection error: connection error:
desc = "transport: Error while dialing dial tcp 1.2.3.4:9178: i/o timeout"
```

- If not already set up, send your deployment logs to a remote server. The upgrade process terminates pods, and the logs will be lost if not stored remotely. To send your deployment logs to a remote server, see [Configuring remote logging for a VMware deployment](#).
- If you are upgrading any subsystem that has less than three nodes and was installed in `standard` mode, before you upgrade you must convert to `Dev` mode and remove replicaset. Conversion is necessary because `standard` mode is not supported on less than three nodes. See [Converting installation mode](#). To review installation modes, see [Requirements for initial deployment on VMware](#).
- When upgrading to Version 2018.4.1.4 or later from Version 2018.4.1.3 (or earlier), and your subsystem was installed in `standard` mode, be sure to specify `mode=standard` as a parameter to the `apicup subsys set` `[SUBSYSTEM-NAME]` command. For Version 2018.4.1.4, the default mode switched from `standard` to `dev`. If you do not specify the `mode` parameter for Version 2018.4.1.4, the installation will proceed in `dev` mode. This is a change in behavior from Version 2018.4.1.3 and earlier. For Version 2018.4.1.4, if you are deploying into a production environment, such as a cluster or high availability deployment, you should use `standard` mode:

```
apicup subsys set [SUBSYS-NAME] mode=standard
```

- In Version 2018.4.1.4 the default value for subsystem `mode` configuration has changed from `standard` to `dev`. If you explicitly specify (`set`) the `mode` value when configuring your subsystems, this change does not impact you. If you are unsure whether you specified it, set it on each Version 2018.4.1.4 subsystem with the following command: `apicup subsys set [SUBSYSTEM-NAME] mode=[desired mode]`. For Version 2018.4.1.4, if you are deploying into a production environment, such as a cluster or high availability deployment, you should use `standard` mode, so be sure to set it. For example:

To review installation modes, see [Converting installation mode](#).

- If you are upgrading to IBM® API Connect Version 2018.4.1.0, some default values from `apiconnect-up.yml` have changed and you might receive validation errors when you run the `apicup subsys get/install` command. To bypass the validation, you can add the `--no-verify` flag to the `apicup subsys install` commands.
- If you are upgrading from Version 2018.4.1.4 or earlier, ensure that your deployment has addressed all known security vulnerabilities with SSH. New installations of Version 2018.4.1.5 and later prevent use of weak SSH Message Authentication Code (MAC) and Key exchange algorithms (KexAlgorithms) with TCP over port 22. Use of weak algorithms can allow an attacker to recover the plain text message from the encrypted text. However, the upgrade to Version 2018.4.1.5 must necessarily retain your existing SSH configuration. If you have not yet addressed the security vulnerabilities with weak MACs and KexAlgorithms, manually update your configuration:

1. Add the following lines to `/etc/ssh/sshd_config`:

```
KexAlgorithms curve25519-sha256@libssh.org,diffie-hellman-group-exchange-sha256
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
```

2. Restart the SSH daemon:

```
sudo systemctl restart sshd
```

- If you are upgrading Analytics subsystem from Version 2018.4.1.3 or earlier, and you are upgrading an Analytics subsystem that has only *one* node, and was installed in `dev` mode, you must remove replicaset before you upgrade. Use `ssh` to access the VM, and use the following command:

```
sudo kubectl --kubeconfig /etc/kubernetes/admin.conf delete rs --all
```

For Version 2018.4.1.4 or later, when Analytics is installed in `dev` mode, you do not need to remove replicaset.

- If you are upgrading *from* Version 2018.4.1.0 to Version 2018.4.1.1, Version 2018.4.1.2 or Version 2018.4.1.3 in a multi-node OVA environment: When upgrading a multi-node cluster from Version 2018.4.1.0 only, create an update directory on each cluster member before running `apicup subsys install`:

Note: This step is not needed on Version 2018.4.1.1 or later.

```
$ sudo mkdir -p /var/lib/apiconnect/upgrades/
$ sudo chmod 700 /var/lib/apiconnect/upgrades/
$ sudo chown _apt /var/lib/apiconnect/upgrades/
```

If you do not precisely follow the previous instructions, the upgrade operation might fail, with errors similar to the following being written repeatedly to the log file on one of the nodes:

```
Dec 05 20:23:14 myhostname apic[5541]: time="2018-12-05T20:23:14Z" level=debug msg="podStage.Upgrade waiting for ip:1.2.3.4-kube-scheduler-xyzdev123 KUBE_SCHEDULER_POD(Running) gcr.io/google_containers/kube-scheduler-amd64:v1.10.6 => gcr.io/google_containers/kube-scheduler-amd64:v1.12.3"
```

To resolve this problem, run the following commands on each node:

```
$ sudo chmod 700 /var/lib/apiconnect/upgrades/
$ sudo apt-get update
$ sudo apt-get upgrade -y appliance-base (press enter in response to any prompts)
$ sudo systemctl restart appliance-manager
```

- **Troubleshooting tip:** After upgrading to 2018.4.1.4, if kubelet fails to start with the error `no space left on device`, run the following command on each virtual machine:

```
sudo sysctl -p /etc/sysctl.d/10-sysctl-appliance.conf
```

- **Troubleshooting tip:** If your Analytics subsystem does not start after upgrading to 2018.4.1.3, ensure that you removed ReplicaSets as described in [the requirement on this page for removing replicaset](#). If you removed the ReplicaSets and find that the Analytics pod still has replicas, such as version 2018.4.1.1 (running) and version 2018.4.1.3 (pending), delete the running pod with 2018.4.1.1, and the pending pod with the 2018.4.1.3 will start. This applies to both analytics-client and analytics-ingestion.

- Download the Install Assist (APICUP) installer from the same URL where you download your Fix Pack version. You must use the latest Install Assist package with the latest product version.
- The original project directory created with the APICUP installer during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. A good practice is to back up the original project directory to a location from which it can always be retrieved.
- If the upgrade is initiated from the original project directory, the certificates are automatically copied into the upgraded version. The original project directory contains the `apiconnect-up.yml` file. An upgrade using the same project directory as the one used for installation will transfer the `encryption-secret` and all other certificates for the project to the upgraded version.
- All external traffic to the management server must be blocked during the upgrade of the management subsystem. This restriction applies to traffic from all sources via the user interfaces (Cloud Manager, API Manager), CLI, and REST API. The Cloud Manager and API Manager UIs cannot be used during the upgrade of the management subsystem. The Developer Portal also cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the time.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Analytics, (3) Portal, (4) Gateway. Analytics and Portal may be switched between second or third, but Management must be upgraded first. Gateway must be upgraded after Management for the following reasons:
  - Upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
  - After a completed upgrade, the Management server and Gateway firmware versions must match, for example, APIC 2018.4.1.2 with DP 2018.4.1.2.
 Wait until the upgrade is finished on a subsystem before proceeding to the next one.
- Downgrading any of the IBM API Connect subsystems to an earlier fix pack level is **not** supported.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Upgrading API Connect subsystems in a VMware environment

Complete the following steps to upgrade API Connect subsystems.

### Before you begin

Restriction:

- You cannot upgrade directly to FP24 from versions older than FP20; you must upgrade to FP20 first.
- Upgrading to FP20 from any version older than FP15 requires that you first upgrade to at least one version in the FP15-to-FP19 range.
- Ensure that you have met the requirements for upgrading API Connect subsystems in a VMware environment. See [Requirements for upgrading on VMware](#).
- Ensure that you are upgrading to the *latest* Fix Pack version. These instructions apply to upgrading to the *latest* Fix Pack version. To access the Fix Packs, see the link in [What's New in the latest release](#).

## About this task

When you apply an upgrade, the new level of the subsystem overwrites the existing level. Your user configuration, APIs, Products, and subsystem configurations (Management, Analytics, and Developer Portal) are retained.

Note: **Upgrading to 2018.4.1.13 - iFix3.0 or later:** Permissions are added to the pre-supplied API Connect user roles as follows:

- A role that had the `Api-Drafts:View` permission, but not the `Api-Drafts:Manage` permission, has the `Product-Drafts:View` permission added if not already present.
- A role that has both the `Api-Drafts:View` and `Api-Drafts:Manage` permissions has the `Product-Drafts:View` and `Product-Drafts:Manage` permissions added if not already present.

The permission settings for custom roles are not changed.

For more information on user roles, and assigning permissions to roles, see [API Connect user roles](#) and [Creating custom roles](#).

## Procedure

1. Verify the API Connect deployment is healthy and fully operational:

Version to upgrade from	Instructions
v2018.4.1.6 or later	See <a href="#">Checking cluster health on VMware</a> When upgrading <i>from</i> v2018.4.1.6 or later <i>to</i> v2018.4.1.10 or later, this step is optional because a health check is run automatically as part of the <code>apicup subsys install</code> command in step 7. Note that you might still want to run the health check now, as preparation for the manual backup in step 2.
v2018.4.1.5 or earlier	See <a href="#">Determining status of a cluster on VMware</a>

2. Complete a manual backup of the API Connect subsystems. See [Backing up and restoring](#).

3. If necessary, prepare your management database for the upgrade:

Version to upgrade from	Instructions
v2018.4.1.8 or later	No preparation required. Skip this step, go directly to Step 4
v2018.4.1.7 or earlier	Due to schema changes, upgrade of the management database takes longer than previous upgrades. For long established deployments with a large amount of data, such as over 10 GB, upgrade can take as long as several hours. To reduce this time, use the <code>apicops</code> interface to truncate the subscriber event table and remove unused snapshots.  Download the latest release of the <code>apicops</code> interface from <a href="https://github.com/ibm-apiconnect/apicops/releases">https://github.com/ibm-apiconnect/apicops/releases</a> , and run the following commands:  <pre>apicops subscriber-queues:clear apicops snapshots:clean-up</pre>

4. Download the appropriate images from IBM® Fix Central.

To access the Fix Packs, see the link in [What's New in the latest release](#). On the Fix Pack page, select the version you want to install. When the version contents are displayed, access the files by clicking the link **Status: Available**.

The upgrade files are distributed in compressed tar format. The filename structure is:

```
upgrade_management_lts_<version>.tgz
upgrade_analytics_lts_<version>.tgz
upgrade_portal_lts_<version>.tgz
```

5. If necessary, download from the same Fix Pack page any Control Plane files that are needed.

Control Plane files provide support for specific Kubernetes versions. The file `upgrade_management_lts_<version>.tgz` contains the latest Control Plane file. An upgrade from the most recent API Connect version to the current version does not need a separate Control Plane file. However, when upgrading from older versions of API Connect, you must install one or more control plane files to ensure that all current Kubernetes versions are supported.

Consult the following table to see if your deployment needs one or more separate Control Plane files.

Note: If you want to upgrade to an older fix pack than the current release, see the Control Plane lists in [Control planes needed for upgrading to earlier fix packs](#).

Version to upgrade from	Instructions for upgrading to v2018.4.1.24
v2018.4.1.20 and iFixes	No control plane needed.
v2018.4.1.19 and iFixes v2018.4.1.18 was not released	Download: <ul style="list-style-type: none"> <li>• <code>appliance-control-plane-1.23.x.tgz</code></li> <li>• <code>appliance-control-plane-1.22.x.tgz</code></li> </ul>

<ul style="list-style-type: none"> <li>• v2018.4.1.6 and iFixes</li> <li>• v2018.4.1.5 and iFixes</li> </ul>	Download: <ul style="list-style-type: none"> <li>• <code>appliance-control-plane-1.23.x.tgz</code></li> <li>• <code>appliance-control-plane-1.22.x.tgz</code></li> <li>• <code>appliance-control-plane-1.21.x.tgz</code></li> <li>• <code>appliance-control-plane-1.20.x.tgz</code></li> <li>• <code>appliance-control-plane-1.19.x.tgz</code></li> <li>• <code>appliance-control-plane-1.18.x.tgz</code></li> <li>• <code>appliance-control-plane-1.17.x.tgz</code></li> <li>• <code>appliance-control-plane-1.16.x.tgz</code></li> <li>• <code>appliance-control-plane-1.15.x.tgz</code></li> <li>• <code>appliance-control-plane-1.14.x.tgz</code></li> </ul>

- Control Plane files are distributed on the same Fix Pack page as the API Connect distribution files.
- You will install the Control Plane files with each subsystem as part of Step 7.

6. Download the version of Install Assist (`apicup`) that matches your upgrade version of API Connect.

7. For each API Connect subsystem, in turn, run the `install` command. The syntax is:

```
apicup subsys install [SUBSYS-NAME] [path_to_subsystem_upgrade_tar_archive]
```

- When you run the `install`, the program sends the compressed tar file, which contains the upgrade images, to all cluster members. The compressed tar file is about 2 GB, and transfer can take some time. When the `install` command exits, the compressed tar file has arrived at each member. The upgrade process is now underway, and might continue for some time depending on factors such as the size of your deployment, your network speed, etc.
- If you downloaded Control Plane files in Step 5, install them at the same time as each subsystem. The syntax is:

```
apicup subsys install [SUBSYS-NAME] [path_to_subsystem_upgrade_tar_archive] [path_to_control_plane_file]
```

- You must install the Control Plane file and the upgrade file for the subsystem at the same time. You can install multiple Control Plane files with one `apicup subsys install` command. The ordering of files passed to `apicup subsys install` does not matter.
  - For example, to upgrade the management subsystem from 2018.4.1.7 to 2018.4.1.12:

```
$ apicup subsys install management upgrade_management_lts_v2018.4.1.10.tgz appliance-control-plane-1.15.[x].tgz
```

- For example, to upgrade the management subsystem from 2018.4.1.5-ifix1.0 to 2018.4.1.12:

```
$ apicup subsys install management upgrade_management_lts_v2018.4.1.10.tgz appliance-control-plane-1.15.[x].tgz appliance-control-plane-1.14.[x].tgz
```

- If unsure of which files are required for upgrade, running `apicup subsys install` interrogates the subsystem and returns an error if any required files are missing. For example, upgrading from 2018.4.1.7 to 2018.4.1.12, but missing a control plane file:

```
$ apicup subsys install management upgrade_management_lts_v2018.4.1.12.tgz
Error: failed to install the subsystem: Unable to execute appliance plan: Missing minor version 15 in control plane upgrade path
```

The error indicates that you also need to provide a Control Plane artifact that is *minor* version 15. Note that the Control Plane artifact file naming convention is *major.minor.patch*. Any *patch* version for the same *minor* version will work:

```
appliance-control-plane-1.15.[x].tgz
```

- The `apicup subsys install` command automatically runs `apicup health-check` prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade.
8. For each subsystem, verify that the upgrade was successful.
- Use `ssh` to access the appliance and run `sudo apic status`. Verify that the `Upgrade stage` property has the value `UPGRADE_DONE`. Note that after the upgrade completes, it can take several minutes for all servers to start. If you see the error message `Subsystems not running`, wait a few minutes, try the command again, and review the output in the `Status` column of the Pods Summary section. For example, here is output from an upgrade of the Analytics subsystem.

```
#sudo apic status
INFO[0000] Log level: info

Cluster members:
- testsrv0233.subnet1.example.com (1.2.152.233)

- To check the status of a cluster on v2018.4.1.6 or later, see [Checking cluster health on VMware](#).
- After completing an upgrade of the Portal subsystem, there may be a delay while the existing sites are upgraded to the new platform version. Once all Portal pods have been upgraded, run the following commands from your project directory. To see the progress of sites being upgraded to the new platform version, use the following commands:
  - `apicup subsys exec portal list-sites sites`  
Any sites currently upgrading will be listed as `UPGRADING`. Once all sites have finished upgrading they should have the `INSTALLED` status and the new platform version listed.
  - Once all sites are in `INSTALLED` state and have the new platform listed, run:  
`apicup subsys exec portal list-sites platforms`  
The new version of the platform should be the only platform listed.

Important: DO NOT reboot any of the virtual machines until ALL of the Portal sites are in `INSTALLED` state and there is only one platform returned, even if you're instructed to do so by the `apicup subsys health-check` during the upgrade process.

9. When the upgrade completes successfully, **ssh** into the appliance. If a message indicates that a reboot is necessary, reboot the virtual machine to complete the operating system upgrades.

10. **Version 2018.4.1.9 iFix1.0 and later:** After completion of the upgrade, verify that all tasks are running.

Due to a known limitation in versions prior to v2018.4.1.9 iFix1.0, some tasks may have stopped running. Complete the following steps:

- a. Download the **apicops** utility from <https://github.com/ibm-apiconnect/apicops/releases>.
- b. Run the following command to remove any pending tasks:

```
$ apicops task-queue:fix-stuck-tasks
```

- c. Run the following command to verify that the returned list (task queue) is empty.

```
$ apicops task-queue:list-stuck-tasks
```

11. If you upgraded the Analytics subsystem from Version 2018.4.1.9 (or earlier) to Version 2018.4.1.10 (or later), and you enabled the Analytics message queue, you must clean and restart the Analytics message queue and ingestion pods.

With root permissions, run the following script on a single Analytics OVA post upgrade.

```
#sudo su
#!/bin/bash
kubectl get pods --no-headers -o custom-columns=:metadata.name | grep zookeeper | while read POD ; do
  echo "-----Deleting zookeeper data for $POD"
  kubectl exec $POD -- rm -rf /var/lib/zookeeper/data
  kubectl exec $POD -- rm -rf /var/lib/zookeeper/log
  kubectl exec $POD -- rm /var/lib/zookeeper/zookeeper.entries
  kubectl exec $POD -- rm /var/lib/zookeeper/nodes.json
done
kubectl get pods --no-headers -o custom-columns=:metadata.name | grep zookeeper | while read POD ; do
  echo "-----Deleting pod"
  kubectl delete pod $POD --grace-period 0 --force &
done
sleep 120
kubectl get pods --no-headers -o custom-columns=:metadata.name | grep kafka | while read POD ; do
  echo "-----Deleting pod"
  kubectl delete pod $POD --grace-period 0 --force &
done
sleep 120
kubectl get pods --no-headers -o custom-columns=:metadata.name | grep ingestion | while read POD ; do
  echo "-----Deleting pod"
  kubectl delete pod $POD --grace-period 0 --force &
done
```

When the script completes, verify that the zookeeper pods are running:

```
kubectl get pods
```

If any of the zookeeper pods are not running, run the script again.

## What to do next

If you encounter problems with the cassandra or calico pods after completing the API Connect upgrade, see [Troubleshooting the API Connect upgrade on VMware](#) for suggested resolutions.

When you have successfully upgraded all of the API Connect subsystems, upgrade your DataPower Gateway Service. See [Upgrading DataPower Gateway Service](#).

- [Control planes needed for upgrading to earlier fix packs](#)

If you want to upgrade to an earlier fix pack than the current release, review this guide to determine which control planes you need.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Control planes needed for upgrading to earlier fix packs

If you want to upgrade to an earlier fix pack than the current release, review this guide to determine which control planes you need.

### Control planes for upgrading to 2018.4.1.24

Version to upgrade from	Instructions for upgrading to v2018.4.1.24
v2018.4.1.20 and iFixes Fix packs 21, 22, and 23 were not released.	No control plane needed.
v2018.4.1.19 and iFixes v2018.4.1.18 was not released	Download: <ul style="list-style-type: none"><li>• <code>appliance-control-plane-1.23.x.tgz</code></li></ul>
v2018.4.1.17 and iFixes	Download: <ul style="list-style-type: none"><li>• <code>appliance-control-plane-1.23.x.tgz</code></li><li>• <code>appliance-control-plane-1.22.x.tgz</code></li><li>• <code>appliance-control-plane-1.21.x.tgz</code></li></ul>

<ul style="list-style-type: none"> <li>v2018.4.1.6 and iFixes</li> <li>v2018.4.1.5 and iFixes</li> </ul>	Download: <ul style="list-style-type: none"> <li><code>appliance-control-plane-1.18.x.tgz</code></li> <li><code>appliance-control-plane-1.17.x.tgz</code></li> <li><code>appliance-control-plane-1.16.x.tgz</code></li> <li><code>appliance-control-plane-1.15.x.tgz</code></li> <li><code>appliance-control-plane-1.14.x.tgz</code></li> </ul>

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Troubleshooting the API Connect upgrade on VMware

Troubleshoot your API Connect upgrade on VMware.

Note: Do not install any extra software or run any commands on the VMs that are not documented in the IBM documentation or otherwise advised by IBM. When troubleshooting API Connect, do not use `kubectl exec` commands to access API Connect pods unless advised by IBM. Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

- [Restarting unhealthy cassandra pods](#)
- [Recreating a calico pod that is in the CrashLoopBackOff state](#)

---

### Restarting unhealthy cassandra pods

If you complete an upgrade and find that one or more of the cassandra pods (prefixed with `apiconnect-apiconnect-cc`) are not responding:

1. Run the following checks to verify that the pods require a restart:

- Check the status of the pods to see if they are marked as `Running` but not `Ready` as in:

```
apiconnect-apiconnect-cc-g4rhq 0/1 Running
```

- Check the `describe` of the pods for an event log with a warning similar to the following example:

```
Warning Unhealthy 2m6s (x177 over 38m) kubelet Readiness probe failed: Cassandra is either decommissioning or upgrading
```

2. Restart each pod by deleting it with the following command (which recreates the pod):

```
kubectl delete pod <pod_name>
```

Note: If there are multiple cassandra pods in this state, then delete them one at a time' wait until the previously deleted pod comes up and shows as `Running` in the `Ready` state before deleting the pod.

---

### Recreating a calico pod that is in the CrashLoopBackOff state

If you complete an upgrade and find that one or more of the calico pods are in the `CrashLoopBackOff` state, you can delete the pod to recreate it. Complete the following steps:

1. Get the names of the calico pods:

```
kubectl -n kube-system get pods | grep calico
```

2. Recreate each pod by deleting it with the following command:

```
kubectl -n kube-system delete pod <calico_pod_name>
```

- [Checking cluster health on VMware](#)  
You can use `apicup` to check the health of the API Connect clusters in your VMware deployment.
- [Determining status of a cluster on VMware](#)  
You can determine the health of an API Connect cluster on VMware
- [Obtaining simple health check data of Developer Portal sites by using a REST API call](#)  
Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.
- [Monitoring the network with SNMP](#)  
Presents a table of OID trees that you can poll using SNMP Get.
- [Gathering logs for a VMware environment](#)  
The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

# Upgrading DataPower Gateway Service

Use these instructions when upgrading DataPower Gateway Service in a non-Kubernetes environment, during upgrade of API Connect Version 2018.4.1.0 or later.

## Before you begin

---

Ensure you have completed the upgrade of the API Connect subsystems (Management service, Developer Portal, Analytics), before upgrading DataPower Gateway, for the following reasons:

- Upgrading the Management service before the DataPower Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
- The API Connect Management server and DataPower Gateway firmware versions must match once upgrade is complete. For example, APIC 2018.4.1.2 with DataPower 2018.4.1.2.

To review API Connect upgrade on VMware, see [Upgrading API Connect subsystems in a VMware environment](#).

## About this task

---

- The DataPower Gateway Service in a non-Kubernetes environment can be on either a physical appliance or in a virtual DataPower deployment.
- The upgrade of DataPower Gateway Service in a non-Kubernetes environment, for use in API Connect deployments in a VMware environment, does not use the API Connect Install Assist program (**apicup**).

Note: To upgrade the DataPower Gateway Service in a Kubernetes environment, do not use the following procedure. Instead, see [Upgrading API Connect in a Kubernetes environment](#).

## Procedure

---

1. When upgrading a high-availability cluster, ensure that you meet the requirements:

- Gateways must be updated one at a time.
- Before starting the upgrade, a single gateway must be running as primary for all gateway-peering definitions.
- When upgrading multiple gateways, the primary gateway must be upgraded last.

To determine which gateway is running as primary, use either the **show gateway-peering-status** command in the DataPower CLI, or use the Gateway Peering Status display in the WebGUI in the API Connect application domain. To move the primary to the DataPower on which you're currently working, you can issue the **gateway-peering-switch-primary <peering-object-name>** command.

2. Follow the upgrade instructions on the DataPower Gateway documentation. See [Installation operations](#).

Note: If upgrading a cluster (high-availability) deployment, ensure that you have identified which gateway is running a primary in gateway-peering definitions, and that you upgrade that gateway last.

3. **Version 2018.4.1.9 and later:** All gateway extensions and gateway script policies which were in place prior to the upgrade to Version 2018.4.1.9 are automatically moved from **local://** to **temporary://**. Therefore, any references to **local** in those extensions or policies must be changed to refer to **temporary**.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

# Maintaining a VMware deployment

You can use utilities to complete maintenance tasks such as backup, restore, and certificate management in a VMware environment.

Note: Do not install any extra software or run any commands on the VMs that are not documented in the IBM documentation or otherwise advised by IBM. When maintaining API Connect, do not use **kubectl exec** commands to access API Connect pods unless advised by IBM.

Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

- [Backing up and restoring](#)  
You can backup and restore API Connect subsystems.
- [Disabling the Analytics subsystem on VMware](#)  
Disable the Analytics subsystem by shutting down the VM that hosts it.
- [Using VM snapshots for infrastructure backup and disaster recovery](#)  
You can use VM snapshots to backup and restore the infrastructure used by API Connect on VMware, and also for infrastructure disaster recovery.
- [Using APICUP to reconfigure](#)  
You can use APICUP to change configuration of a subsystem after completion of initial installation.
- [Setting rate limits for public APIs on the management service for a VMware environment](#)  
Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.
- [Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment](#)  
In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.
- [Adding disk space to a VMware appliance](#)  
Increase disk space on the VMware appliance.

- [Running a filesystem check on a VMware root partition](#)  
You can run a filesystem check on the appliance root filesystem at boot time.
- [Managing an appliance data disk](#)  
You can use `apic` commands to manage appliance data disks in your VMware deployment.
- [Troubleshooting the API Connect upgrade on VMware](#)  
Troubleshoot your API Connect upgrade on VMware.
- [Changing logging levels](#)  
You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Backing up and restoring

You can backup and restore API Connect subsystems.

Note:

- Backups are intended for recovery of the Management, Portal, and Analytics subsystems onto the same deployment from which they were taken, or onto a new replacement installation in the same environment for disaster recovery. The same environment means the same network configuration and project directory as the original installation.
- You must back up both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.
- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- When restoring, the Gateway and all deployed subsystems (Management, Analytics, and Developer Portal) must be at the same version level.
- The API Connect backup and restore procedures back up all of the state required by API Connect but do not include the underlying infrastructure software or other internal state. In some scenarios, you may want to perform backups and disaster recovery at an infrastructure layer. You can do this by taking snapshots of the virtual machines or underlying storage volumes. See [Using VM snapshots for infrastructure backup and disaster recovery](#).
- [Backing up the management subsystem in VMware environments](#)  
Backups of the management database can be performed based upon a cron-like schedule or on-demand from the command line.
- [Restoring a management subsystem in a VMware environment](#)  
The management database can be restored as a complete restoration. Partial restorations are not supported.
- [Backing up and restoring the Developer Portal in a VMware environment](#)  
How to backup and restore your Developer Portal service in your VMware environment.
- [Backing up and restoring the analytics database](#)  
The analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required, for example, IBM Cloud Object Storage.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Backing up the management subsystem in VMware environments

Backups of the management database can be performed based upon a cron-like schedule or on-demand from the command line.

### Before you begin

---

The backup and restore feature is enhanced for API Connect Version 2018.4.1.

### About this task

---

Database backups can be used to restore the database for disaster recovery or for transferring data during an upgrade.

- For scheduled backups, see [Configuring scheduled backups](#)
- For on-demand backups, see [Performing on-demand backups](#)

We strongly recommend that you configure a backup schedule for your management database using the `cassandra-backup-schedule` setting during installation of the management subsystem. If you did not do so when you installed API Connect in your VMware runtime environment, you have the option to perform an on-demand backup. We also recommend that you perform a backup (either scheduled or on-demand) of the management database prior to upgrading.

There are two options for performing backups of the management database: scheduled backups and on-demand backups. Both options require the `cassandra-backup-x` settings to be configured when installing the management subsystem. Automatic scheduled backups are performed according to the cron-like job configured by the `cassandra-backup-schedule` setting. On-demand backups also require the backup settings, but are run on-demand from the command line.

Note: You must back up both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

## Procedure

---

• **Configuring scheduled backups**

1. To configure scheduled backups, enter the `cassandra-backup-x` settings when installing the management subsystem as described in [Deploying the Management subsystem in a VMware environment](#). The `cassandra-backup-x` parameters are also described in the following table:

The parameters are as follows:

Parameter	Description
<code>cassandra-backup-protocol</code>	The backup protocol. Specify one of the following values: <ul style="list-style-type: none"> <li>• <code>sftp</code> - for secure file transfer protocol</li> <li>• <code>objstore</code> - for S3 compatible object storage</li> </ul> Note: <ul style="list-style-type: none"> <li>• For the management subsystem, IBM Cloud and Amazon Web Services (AWS) are supported S3 object store providers.</li> <li>• The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: <code>x509: certificate signed by unknown authority</code>.</li> </ul>
<code>cassandra-backup-path</code>	The full path to the directory where the backup files will be stored. This must point to a directory on the backup server. For object storage ( <code>objstore</code> ), the path can be set to the <code>bucket</code> value or the <code>bucket/subfolder</code> value.
<code>cassandra-backup-host</code>	The fully qualified domain name of the backup server. Ensure that the Kubernetes nodes can access this host. If using object store, enter <code>Endpoint/Region</code> . (The <code>/</code> character between the endpoint and region are required for this setting.)
<code>cassandra-backup-port</code>	The port for the protocol to connect to the <code>cassandra-backup-host</code> . The backup port is not required for object storage.
<code>cassandra-backup-schedule</code>	Cron like schedule for performing automatic backups. The format for the schedule is: <ul style="list-style-type: none"> <li>• <code>*****</code></li> <li>• <code>-----</code></li> <li>• <code>     </code></li> <li>• <code>     +-----</code> day of week (0 - 6) (Sunday=0)</li> <li>• <code>   +-----</code> month (1 - 12)</li> <li>• <code>  +-----</code> day of month (1 - 31)</li> <li>• <code> +-----</code> hour (0 - 23)</li> <li>• <code>+-----</code> min (0 - 59)</li> </ul> The backup schedule defaults to <code>0 0 * * *</code> . This means a backup is run every day at midnight and minute zero. The timezone for backups is UTC.  When you configure a host, if you do not specify a value for <code>cassandra-backup-schedule</code> , the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed.  Note: Cassandra <code>repair</code> cron schedule is set to <code>00 1 * * 0,2,4,6</code> . This means the repair runs at 01:00 on Sunday, Tuesday, Thursday, and Saturday. By default, the Cassandra <code>backup</code> cron schedule should not run within one hour of the repair cron schedule. Please make sure to modify the current backup configuration as needed. If backups and repairs run at the same time, backup processes can fail intermittently.
<code>cassandra-backup-auth-user</code>	The username for the server specified in <code>cassandra-backup-host</code> . If using object store, this would be the S3 Secret Key ID.
<code>cassandra-backup-auth-pass</code>	The password for the server specified in <code>cassandra-backup-host</code> . If using object store, this would be the S3 Secret Access Key parameter. The password will be stored in Base64 encoded format. For example: <pre>apicup subsys set mgmt cassandra-backup-auth-pass '&lt;password&gt;'</pre> Note that you cannot use the <code>`</code> sign to assign the password to <code>cassandra-backup-auth-pass</code> .

For example:

```
cassandra-backup-protocol: sftp
cassandra-backup-host: mybackuphost.com
cassandra-backup-port: 22
cassandra-backup-path: /backups
cassandra-backup-schedule: 0 0 * * *
cassandra-backup-auth-user: myusername
cassandra-backup-auth-pass: mypassword
```

2. These settings will be activated by the `apicup subsys install <SUBSYS_NAME>` command.
3. To verify that automatic backups are in progress, you will see a pod labeled `<cassandra cluster name>-backup` at the scheduled time for the backup.
4. When the scheduled back is complete, the backup files are stored at the location specified by the `cassandra-backup-path` parameter. The file name varies depending upon the API Connect version that performed the backup, but the file name must be compatible with the version used for restoring the database. For details about the file name, see [Restoring a management subsystem in a VMware environment](#).
5. List the backups by entering: `apicup <subsys exec <SUBSYS_NAME> list-backups`. You can view a list of backups with the ID and Status in the output. Following is an example:

Cluster	Namespace	ID	Timestamp	Status
rf0c7310d07-apiconnect-cc	e2edemo	1537987501522014136	2018-09-26 18:45:01.522014136 +0000 UTC	Complete
rf0c7310d07-apiconnect-cc	e2edemo	1537920006787257385	2018-09-26 00:00:06.787257385 +0000 UTC	Complete

• **On-demand backups**

1. Configure the backup parameters. (The same parameters are required for on-demand backup that are required for a scheduled backup, but you will bypass the schedule.) If you did not enter the `cassandra-backup-x` parameters when you installed API Connect, you will need to enter them from the command line and re-install the management subsystem before performing an on-demand backup.
2. After the backup parameters have been specified, run the `apicup subsys install <SUBSYS_NAME>` command to activate the new parameters. This step is not required if you specified these parameters during the initial installation.
3. Enter the following command: `apicup subsys exec <SUBSYS_NAME> backup` where `SUBSYS_NAME` is the name of your management subsystem.
4. When the backup is completed, the backup files are stored at the location specified by the `cassandra-backup-path` parameter. The file name varies depending upon the API Connect version that performed the backup, but the file name must be compatible with the version used for restoring the database. For details about the file name for the backups, see [Restoring a management subsystem in a VMware environment](#).
5. List the backups by entering: `apicup <subsys exec <SUBSYS_NAME> list-backups`. You can view a list of backups with the ID and Status in the output. Following is an example:

Cluster	Namespace	ID	Timestamp	Status
rf0c7310d07-apiconnect-cc	e2edemo	1537987501522014136	2018-09-26 18:45:01.522014136 +0000 UTC	Complete
rf0c7310d07-apiconnect-cc	e2edemo	1537920006787257385	2018-09-26 00:00:06.787257385 +0000 UTC	Complete

## Results

Use the ID generated for the backup files to restore the database from the backup. Usually the database is restored from a backup file after an upgrade is performed and to recover from a disaster. See [Restoring a management subsystem in a VMware environment](#) and [Upgrading API Connect subsystems in a VMware environment](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Restoring a management subsystem in a VMware environment

The management database can be restored as a complete restoration. Partial restorations are not supported.

### Before you begin

- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- Restoring the Management Service requires database downtime and is a destructive process that deletes current data and copies backup data. During the restoration process, external traffic must be stopped.
- In a Disaster Recovery scenario, do not log in to the administration UI or attempt to configure or change any settings prior to restoring the backup. Restore the backup immediately after installing the subsystem.
- To restore the management database, you must use the original project directory that was created with `apicup` during the initial product installation. You cannot restore the database without the initial project directory because it contains pertinent information about the cluster. The endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored system. Successful restoration depends on use of a *single apicup* project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

Note: Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.

- Map the DNS entries from the source cluster to the corresponding IP addresses on the target cluster. Record the DNS entries for each endpoint before starting the restore.
- When restoring the management database, the endpoints (on the new cluster which is the target for the restoration) have to be the same as those on the old cluster (the source of the backup). This includes all the endpoints for API Connect: `api-manager-ui`, `cloud-admin-ui`, `consumer-api`, `platform-api`; `api-gateway`, `api-gw-service`; `analytics-ingestion`, `analytics-client`; and `portal-admin`, `portal-www`.
- When restoring, the Gateway and all deployed subsystems (Management, Analytics, and Developer Portal) must be at the same version level.

### About this task

Follow the procedure on this page to restore your management database. You must complete the prerequisite steps before beginning the restore.

Note that in a disaster recovery scenario you must first re-establish the management subsystem. The procedure includes an optional first step for disaster recovery.

If you encounter errors, see [Troubleshooting restoration of management database on VMware](#). Note that the troubleshooting page includes [Overview of restore process for management database](#).

### Procedure

1. If the restoration is for a disaster recovery scenario, complete this step to first install a new Management subsystem. If the restoration is *not* for a disaster recovery (meaning that you have a *running* Management subsystem to use for restoration), skip this step and go directly to Step 2.
  - a. Copy the project folder that corresponds to the backup files into a new location.
  - b. If, for the previous installation, you have redirected the configuration to an optional output folder using the `apicup subsys install mgmt --out=mgmt-out` command as explained in [Deploying the Management subsystem in a VMware environment](#), delete all output folders prior to starting the new installation.
  - c. Perform a fresh installation of the management subsystem using the following command:

```
apicup subsys install <SUB_SYS>
```

Important:

Do not make any other changes in the project directory nor run any other `apicup` operations before proceeding to the next step.

2. Verify that your deployment meets the prerequisites for restoring a management database:
  - a. You must restore onto a deployment that has the same number of OVA VM (nodes) as the deployment where the backup was created. For example, if the management service backup deployment had 3 OVA nodes, the restore deployment must have 3 OVA nodes. You cannot restore onto a deployment with fewer OVA nodes because the management service uses one Cassandra pod per node, and Cassandra data is sharded across the pods. To successfully restore, first create the matching number of OVA VM nodes. Note: Creation of multiple Cassandra pods on one management service OVA node is not supported.
  - b. Ensure that all Cassandra pods are on-line and running normally.
3. Restoration of a management subsystem requires access to backup tar files. Obtain your backup files, as follows:
  - a. Enter `apicup subsys exec <MANAGEMENT_SUBSYS_NAME> list-backups`. The output lists the current backups in your namespace with Backup ID and status.

Cluster	Namespace	ID	Timestamp
Status			

rf0c7310d07-apiconnect-cc	e2edemo	1537987501522014136	2018-09-26 18:45:01.522014136 +0000 UTC	Complete
rf0c7310d07-apiconnect-cc	e2edemo	1537920006787257385	2018-09-26 00:00:06.787257385 +0000 UTC	Complete

The backup files are stored at the location specified by the `cassandra-backup-path` parameter.

Examine the backup filename to identify the backup ID for use with the restore command.

Table 1. Backup file naming convention

Backup file name	BackupID (for use with restore command)
<backupId>-<pod index>-<# of pods>.tar.gz	[backupId]
Example:	Example:
1534954510365016356-0-3.tar.gz	1534954510365016356

Note: **Disaster Recovery:** If you are restoring on a new deployment, you will not have any backups. You will have to find the `backupID` by going to your backup host and looking for the backup files from previous deployments.

b. Confirm that you have a backup file for each Cassandra pod in your cluster. If you have  $n$  pods, you must have the same number of backup files.

c. **Optional but recommended:** Verify the integrity of the backup tar files.

Ensure that the tar files are not corrupt. For example, on Linux:

```
tar -tzf <backup_file>
```

d. **Optional but recommended:** Determine whether your environment has sufficient space to perform the restore. You need enough free space such that the size of the backup file, when multiplied by four, does not exceed 85% of the available free space.

For example, on Linux, you can use the following steps:

i. Exec a bash terminal on the Cassandra pod:

```
kubectl exec -it <Cassandra-pod> --bash
```

ii. Paste the following script to calculate space available for restore:

```
# current available space
avail=$(df /var/db/ | awk 'NR==2{print $4}')

#space occupied by /var/db/data/
db_data=$(du -s /var/db/data/ | awk '{print$1}')

# Estimated available space after cleanup (avail + db_data) and a buffer of 15%
total_space_avail=$((($avail + $db_data) * 1024) * 85 / 100)
echo $total_space_avail
```

The value obtained in the above script is in bytes and must be calculated for every pod, and compared against  $4x$  the value, where  $x$  is the backup tar size of the corresponding backup file.

Each backup file is in format `<backup-id>-<ordinal-of-cassandra pod>-<number-of-cassandra-pods in cluster>.tar.gz`

In the example script above, if the backup tar size of `<backup-id>-0-3.tar.gz` is  $15*1024*1024$  bytes, the value for `$total_space_avail` in Cassandra cc-0 pod must be around  $60*1024*1024$  bytes.

If free space is insufficient, create additional free space before starting the restore.

4. Restore the management database by entering:

```
apicup subsys exec <MANAGEMENT_SUBSYS_NAME> restore <backupID>
```

The `restore` command will restore all backups from files with the same backupID. You must have the same number of management database (Cassandra) pods running as the number of backup files that match the backupID.

5. Verify that the restore process completed successfully.

Ensure that the restore job is marked as completed. Note, however, that it is possible for the restore job to be marked complete, but the Cassandra restore is not complete.

The best way to ensure that the Cassandra restore is complete is to review the `CassandraRestoreStatus` field in the `CassandraClusters` Custom Resource. When the `CassandraRestoreStatus` is `completed`, the Cassandra database is successfully restored.

Example command flow to verify the restore:

a. Examine the restore job and pod:

```
# kubectl get jobs | grep restore
restore-plnfs 0/1 71s
```

```
# kubectl get pods | grep restore
restore-plnfs-hr2rh 0/2 Init:0/2 0 54s
```

b. Since the status of the restore pod is in `Init:0/2`, the first init container (Container restore) is being executed. In this case, watch the `ClusterRestoreStatus` inside `CassandraCluster` (cc) Custom Resource to see the current status of the Cassandra restore process.

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: Running Retrieve checks on backup file 1583268283534609276-1-3.tar.gz for pod rdd94fb4a21-apiconnect-cc-1
```

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: Running Retrieve checks on backup file 1583268283534609276-2-3.tar.gz for pod rdd94fb4a21-apiconnect-cc-2
```

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: Restore prelim checks passed for rdd94fb4a21-apiconnect-cc-2
```

c. When the restore process is complete, examine the restore pod and job status. Make sure `ClusterRestoreStatus` is marked as `completed`.

```
kubectl get jobs | grep restore
restore-plnfs 1/1 10m 7h17m
```

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: completed
```

If you encounter errors, see [Troubleshooting restoration of management database](#).

6. **Version 2018.4.1.9 iFix1.0 and later:** After completion of the restore, verify that all tasks are running. Complete the following steps:

- Download the `apicops` utility from <https://github.com/ibm-apiconnect/apicops/releases>.
- Run the following command to remove any pending tasks:

```
$ apicops task-queue:fix-stuck-tasks
```

- Run the following command to verify that the returned list (task queue) is empty.

```
$ apicops task-queue:list-stuck-tasks
```

- [Troubleshooting restoration of management database on VMware](#)

You can troubleshoot problems with restoring the management database.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Troubleshooting restoration of management database on VMware

You can troubleshoot problems with restoring the management database.

Review the information on this page to understand the steps you can take to troubleshoot a failed restore. Be sure to first read the [Overview of restore process for management database](#) to understand the logging and error reporting.

Note that for Version 2018.4.1.10 there is a known limitation with error reporting. See [Known limitation: failed restores not reporting properly](#).

- [Overview of restore process for management database](#)
- [Error: invalid backup host credentials](#)
- [Error: insufficient disk space](#)
- [Error: failure on preliminary backup checks on cc-1 and cc-2](#)
- [Known limitation: failed restores not reporting properly](#)
- [Frequently asked questions](#)

If you cannot resolve a failed restore, contact IBM Support for assistance.

## Overview of restore process for management database

The API Connect restore process is started by the command `apicup subsys exec <management_subsys> restore <backupID>`. The apicup installer starts a Kubernetes job named `restore-<id>`, which in turn starts a pod named `restore-<job-id>-<pod-id>`.

API Connect restore process

The management restoration pod consists of:

- `cassandra-restore --` The main responsibility of this init container is to perform the Cassandra database restore. If this container encounters an error, the restoration job is Failed with pod status of `InitError (0/2)`.  
Note: For Version 2018.4.1.10 and earlier, this container is called `job-container`.
- `Cassandra-health-check` - An init container that verifies that the Cassandra health status is in a healthy state. .
- `Lur-upgrade-job` - This container checks for schema mismatches between restored data and the currently running installation. If necessary, the container performs a schema upgrade.
- `Apim-upgrade-job` - This container checks for schema mismatches between restored data and the currently running installation. If necessary, the container performs a schema upgrade. The container also resyncs all the gateway services.

The init containers start sequentially. The second init container starts only once the first init container has succeeded. Containers inside the pod start immediately after all the init containers in the pod are started. For more info, see the Kubernetes documentation: [Understanding pod status](#)

Cassandra restore process

The Cassandra restore process is performed by the init container `<cassandra-restore>`. Backups are required from each Cassandra pod. The container process flow is:

1. Perform preliminary retrieval checks.
2. Download the backup tar file onto the Cassandra container.
3. Verify the backup tar file integrity.
4. Stop the Cassandra process.
5. Perform the Cassandra restore.
6. Start the Cassandra process with restored data.

If any of the preliminary checks fail, error messages are returned. The error conditions must be fixed, and then the restore process can be run again.

Note that API Connect Version 2018.4.1.10 (and later) performs extensive preliminary checks prior to beginning a restore. Running the checks extends the time required to complete a restore. In particular, restoration of large backup files (larger than 5 GB) take longer.

Logging

Both init container and container logs are available during the restore process. To obtain logs from a restore pod:

```
kubectl logs <restore-pod> -n <namespace> -c <init container/container name>
```

The `apicup` command produces logs from all init and main containers sequentially as soon they finish, either successfully or with errors.

#### Cassandra restore logging

The logs for the init container are updated only upon completion (success or failure). To get accurate status information for the current state of the Cassandra restore process, review the `ClusterRestoreStatus` field in the `CassandraClusters` Custom Resource:

```
kubectl get cc -n <namespace> -o yaml | grep -A 2 ClusterRestoreStatus
```

## Error: invalid backup host credentials

Example output when this problem occurs:

```
./apicup subsys exec mgmt restore 158326828353460927
```

```
Cluster      Namespace      Backup Name      Backup Retrieval Timeout(hrs)      Status
rdd94fb4a21-apiconnect-cc  niharns1      1583268283534609276      24      Started
```

Restore failed

```
Error: rpc error: code = Unknown desc =
Pod name: rdd94fb4a21-apiconnect-cc-0
```

Error:

```
ssh: Could not resolve hostname 9.30.251.186.xxx: Name or service not known
Couldn't read packet: Connection reset by peer
**** [ Wed Mar  4 04:04:25 UTC 2020 ]prelimRetrieve 0: Preliminary Retrieve checks      FAILED ****
[ Wed Mar  4 04:04:25 UTC 2020 ] Preliminary retrieve checks failed on all 1 attempts.      ABORTING restore
```

```
Error: unable to get log stream for container cassandra-health-status, pod restore-hhrsc
-2slbm, job restore-hhrsc: container "cassandra-health-status" in pod "restore-hhrsc
-2slbm" is waiting to start: PodInitializing
```

ClusterRestoreStatus in Cassandra Clusters CR:

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
```

```
ClusterRestoreStatus: 'Restore Failed: Retrieve preliminary checks failed for rdd94fb4a21-apiconnect-cc-0'
```

```
kubectl get pods | grep restore
```

```
restore-hhrsc-2slbm      0/2      Init:Error      0      26m
```

```
kubectl get jobs | grep restore
```

```
restore-hhrsc      0/1      27m      27m
```

## Error: insufficient disk space

**Issue:** cc-0 prelim checks can reject restore process complaining about insufficient disk space.

**Workaround:** Increase the disk space (4X size of Cassandra backup tar file size) allocated to all Cassandra nodes on a fresh install and re-attempt restore. See [Freespace check](#).

## Error: failure on preliminary backup checks on cc-1 and cc-2

**Issue:** Failure on preliminary backup checks on cc-1 and cc-2 can leave the system in non-ready state

**Workaround:**

1. Always look at `ClusterRestoreStatus` in `CassandraClusters` Custom Resource for failed or completed Cassandra restore status, regardless of restore job status. In this case, the restore job is stuck on health status check, and Cassandra cc-0 will be in a non-ready state.
2. Execute the following command on each Cassandra pod sequentially starting with cc-0. Wait for the Cassandra pod to become ready (1/1) before executing on other Cassandra pods. If the Cassandra pod is already in ready state (1/1), you do not need to wait, just run the command.

```
kubectl exec -it <cassandra-pod-X> -n <namespace>
-- sh -c 'rm -rf /var/db/.restore && rm -rf /var/db/restore/*'
```

In the above command the X in `<cassandra-pod-X>` stands for the numerical value (ordinal) of the Cassandra pod, such as (0,1,2).

3. Review the Cassandra operator logs to figure out why restore has failed and fix the problem.  
To see an example of this type of failure, review [Example 2: Corrupted backup tar file cc-1 not reporting properly](#).

## Known limitation: failed restores not reporting properly

**Issue:** Failure on preliminary backup checks on cc-0, such as a corrupt tar file or incomplete download of a backup tar file, can cause the restore job to complete, but the underlying `ClusterRestoreStatus` is marked as `Restore Failed`:  
<Reason>.

**Workaround:** Always check `ClusterRestoreStatus` in the `CassandraClusters` custom resource for failed or completed Cassandra restore status, regardless of restore job status. Consult the Cassandra operator logs to figure out why restore failed, and fix the problem.

See:

- [Example 1: Corrupted backup tar file cc-0 not reporting properly](#)
- [Example 2: Corrupted backup tar file cc-1 not reporting properly](#)

Example 1: Corrupted backup tar file cc-0 not reporting properly

In this example, restoration was started with `apicup`:

```
./apicup subsys exec restore 1583268283534609276
```

1. View the initial status of restore job and restore pod:

```
kubectl get jobs | grep restore
restore-xs85r          0/1          38s          38s

kn get pods | grep restore
restore-xs85r-st554    0/2          Init:1/2     0            92s
```

2. Note that the restore completes, according to the job and pod status:

```
kubectl get pods | grep restore
restore-xs85r-st554    0/2          Completed    0            3m43s

kubectl get jobs | grep restore
restore-xs85r          1/1          2m51s        4m1s
```

3. Observe, however, that the `apicup` restore command output includes the following failure status:

```
./apicup subsys exec mgmt restore 1583268283534609276
Cluster      Namespace   Backup Name      Backup Retrieval Timeout (hrs)  Status
rdd94fb4a21-apiconnect-cc niharns1    1583268283534609276 24                               Started

Cluster      Namespace   Backup Name      Status
rdd94fb4a21-apiconnect-cc niharns1    1583268283534609276 Restore Failed: Backup retrieve checks failed
```

4. Check the value of `ClusterRestoreStatus` in the Custom Resource. Note that `ClusterRestoreStatus` is marked as `Restore Failed`.

```
kubectl get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: 'Restore Failed: Backup retrieve checks failed'
```

5. Check the Cassandra operator pod logs and see errors:

```
time="2020-03-04T04:30:33Z" level=error msg="Restore Failed: Backup retrieve checks failed with an error: \n
Pod name: rdd94fb4a21-apiconnect-cc-0\n
Error: \n
gzip: stdin: not in gzip format\n
tar: Child returned status 1\n
tar: Error is not recoverable: exiting now\n
retrieveCheck 0: RetrieveCheck of backup file 1583268283534609276-0-3.tar.gz FAILED\n
**** [ Wed Mar 4 04:30:32 UTC 2020 ] retrieveCheck 0: Retrieve process END ****\n\n"
time="2020-03-04T04:30:33Z" level=info msg="Updating status to Restore Failed: Backup retrieve checks failed"
```

**Explanation:** Even though restore job says it completed, Cassandra restore never completed due to corrupt backup tar file. The restore job believes it reached completion, but in this case the error logging is incorrect. Therefore, you must check `ClusterRestoreStatus` in `CassandraCluster` Custom Resource to see if restore really completed. Note that `CassandraClusterRestore` status does not state exactly why restore failed, hence you must look at the Cassandra operator pod logs.

Table 1. Limitation with error reporting when Cassandra tar file for cc-0 is corrupted

Expected flow	Actual flow
1. Cassandra operator detects that cc-0 backup is corrupt	1. Cassandra operator detects that cc-0 backup is corrupt
2. Operator updates <code>ClusterRestoreStatus</code> as <code>Restore Failed</code>	2. Operator updates <code>ClusterRestoreStatus</code> as <code>Restore Failed</code>
3. Operator passes an error message back to restore init container (cassandra-restore).	3. Operator does <i>not</i> pass an error message back to restore init container (cassandra-restore)
4. <code>apicup</code> restore command line should exit with an error message on why restore init container (cassandra-restore) failed. Restore pod status should be <code>Init:Error</code> .	4. Restore pod moves forward and executes other init container and upgrade containers.
5. Restore job is marked as Failed	5. Restore pod is marked as completed

6. **Workaround:** The Cassandra cluster remains up and running as restore process failed internally, so you must review the Cassandra operator logs to figure out why exactly Cassandra restore failed. In this case, Cassandra restore failed due to corrupt backup tar file. Locate and use a non-corrupted Cassandra backup.

Example 2: Corrupted backup tar file cc-1 not reporting properly

In this example, restoration was started with `apicup`:

```
./apicup subsys exec restore 1583268283534609276
```

1. View the initial status of restore job and restore pod

```
kubectl get jobs | grep restore
restore-v7nvt 0/1 81s 81s

kubectl get pods | grep restore
restore-v7nvt-2jdzq 0/2 Init:0/2 0 101s
```

2. Continue to view pods, and observe that the restore pod is stuck.

The restore pod first init container (cassandra-restore), which performs the Cassandra restore, is marked as complete. The second init container is stuck waiting for the Cassandra cluster to become healthy.

```
kn get pods | grep restore
restore-v7nvt-2jdzq 0/2 Init:1/2 0 4m8s
```

The status `Init:1/2` means that first init container completed, but the process is waiting on second init container to finish.

3. Note that the output from the `apicup` restore command gives a status of `Restore Failed`:

```
./apicup subsys exec mgmt restore 1583268283534609276
Cluster      Namespace   Backup Name      Backup Retrieval Timeout (hrs)  Status
```

rdd94fb4a21-apiconnect-cc	niharns1	1583268283534609276	24	Started
Cluster	Namespace	Backup Name	Status	
rdd94fb4a21-apiconnect-cc	niharns1	1583268283534609276	Restore Failed: Backup retrieve checks failed	

4. View the `ClusterRestoreStatus` in the Cassandra Cluster Custom Resource:

```
kn get cc -o yaml | grep -A 1 ClusterRestoreStatus
ClusterRestoreStatus: 'Restore Failed: Backup retrieve checks failed'
```

5. View the Cassandra operator pod logs:

```
time="2020-03-04T05:04:18Z" level=error msg="Restore Failed: Backup retrieve checks failed with an error: \n
Pod name: rdd94fb4a21-apiconnect-cc-1\n
Error: \ngzip: stdin: not in gzip format\n
tar: Child returned status 1\n
tar: Error is not recoverable: exiting now\n
retrieveCheck 0: RetrieveCheck of backup file 1583268283534609276-1-3.tar.gz FAILED\n
**** [ Wed Mar  4 05:04:18 UTC 2020 ] retrieveCheck 0: Retrieve process END ****\n\n"
time="2020-03-04T05:04:18Z" level=info msg="Updating status to Restore Failed: Backup retrieve checks failed"
```

6. View the Cassandra pod status:

rdd94fb4a21-apiconnect-cc-0	0/1	Running	3	11h
rdd94fb4a21-apiconnect-cc-1	1/1	Running	2	11h
rdd94fb4a21-apiconnect-cc-2	1/1	Running	2	11h

**Explanation:** In this scenario, the restore process is stuck waiting for the Cassandra cluster to become healthy. Cassandra pod cc-0 is in a non-ready state. Due to a known limitation with error logging, the only way to accurately determine whether the restore is complete is to view `ClusterRestoreStatus` in `CassandraCluster` Custom Resource. Since `CassandraClusterRestore` status does not state exactly why the restore failed, you must look at Cassandra operator pod logs.

Table 2. Limitation with error reporting when corrupted Cassandra backup tar file cc-1 is corrupted

Expected flow	Actual flow
1. Cassandra operator detects that cc-1 backup is corrupt	1. Cassandra operator detects that cc-1 backup is corrupt
2. Operator updates <code>ClusterRestoreStatus</code> as <code>Restore Failed</code> .	2. Operator updates <code>ClusterRestoreStatus</code> as <code>Restore Failed</code> .
3. Operator cleans up the restore process content and makes sure that Cassandra cluster is healthy using the existing data.	3. Operator <i>does not</i> perform any cleanup and <i>does not</i> makes sure that the Cassandra cluster is in a healthy state
4. Operator passes an error message back to restore init container (cassandra-restore) to indicate that the restore has failed.	4. Operator <i>does not</i> pass an error message back to restore init container (cassandra-restore) to indicate that the restore has failed.
5. The <code>apicup</code> restore command line should exit with a proper error message on why restore init container (cassandra-restore) failed. The restore pod status should be <code>Init:Error</code> . The restore job should be marked as Failed.	5. Restore pod moves forward from the init container but becomes stuck on second init container.

7. **Workaround:**

- a. Since the Cassandra cluster is in a degraded state, and the Cassandra pod cc-0 is in a non-ready state (0/1), run the following command to bring the Cassandra cluster up and running.

```
kubectl exec -it <cassandra-pod-X> -n <namespace> -- sh -c
'rm -rf /var/db/.restore && rm -rf /var/db/restore/*'
```

Note that you must run this command sequentially on all Cassandra pods, starting with cc-0. Make sure that the cc-x status is (1/1), before running this command on the next pod (cc-x+1).

- b. Review the Cassandra operator logs to determine why the Cassandra restore failed. In this scenario, since the Cassandra restore failed due to a corrupt backup tar file, the solution is to choose a non-corrupted Cassandra backup.

Note that this Cassandra restore issue applies not only specifically to a corrupted backup tar file, but also to any of the restore issues which may happen on Cassandra-x+1 pods (x is a numerical value starting with 0) and can leave previous Cassandra pods in a non-ready state.

## Frequently asked questions

Where can I find the status of the restore process?

See: [Cassandra restore logging](#)

In what cases can I re-run the restore process on existing installations?

The answer depends on which stage of the restore failed. If the restore process failed because of a corrupted tar file, you can re-initiate the restore process using a different backup ID.

In what cases I need to redeploy a whole new cluster before re-attempting a failed restore?

If the restore failed due to space allocation problems or any other reasons except corrupted backup tar, a complete new installation is needed. You must fix the problem reported by the restore process.

What action to take if I get the error message: Not enough space to download the tar file?

You must re-install the management subsystem, allocating sufficient disk space. Please look at system requirements section for recommended disk sizes.

What if the downloaded backup tar file is corrupted?

Use a different backup. Run backup tar integrity checks prior to attempting the restore.

If the backup tar integrity succeeds in your local system but restore process is failing, gather the required logs and contact IBM Support.

What if there is not enough space to perform restore using the downloaded backup tar file?

You must re-install the management subsystem, allocating sufficient disk space. See [Error: insufficient disk space](#).

What if the restore job finishes but I still don't see any restored data?

See [Known limitation: failed restores not reporting properly](#).

What if the restore process remains stuck on the health check status for a very long time?

This might be due to a known limitation. See [Example 2: Corrupted backup tar file cc-1 not reporting properly](#).

What if the restore process fails on Lur-upgrade-job and Apim-upgrade-job containers?

Run the restore process again. If the error persists, contact IBM Support.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Backing up and restoring the Developer Portal in a VMware environment

How to backup and restore your Developer Portal service in your VMware environment.

### About this task

It is strongly recommended that you configure the backup parameters for your portal service during installation. If you did not do so when you installed API Connect in your runtime environment, you must configure the backups for the Developer Portal before performing an upgrade. These backups can then be used to restore the Developer Portal if required. When your Developer Portal subsystem is running, you can also make on-demand backups by using the command line.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

These instructions cover the following backup and restore actions:

- [How to configure the location and timing of your backups](#)
- [How to run on-demand backups](#)
- [How to restore a Developer Portal service](#)
- The backup secret is a Kubernetes secret that contains your username and password for your backup database (sftp/s3). Only password-based authentication is supported for sftp and s3, not authentication based on public certificates and private keys. Password-based authentication for s3 requires that you generate an access key and secret. For example:
  - IBM (Cloud Object Storage): [Service credentials](#).
  - AWS: [Managing access keys](#).

Note:

- The backup and restore procedures are the same for both Kubernetes and VMware environments.
- You must back up both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.
- When restoring, the Gateway and all deployed subsystems (Management, Analytics, and Developer Portal) must be at the same version level.

### Procedure

- How to configure the location and timing of your backups
  1. Open your API Connect installation project directory.
  2. Run the following commands to set the location and timing of your backups:

```
apicup subsys set ptl site-backup-host mybackuphost.com
apicup subsys set ptl site-backup-port 22
apicup subsys set ptl site-backup-auth-user mybackupauthusername
apicup subsys set ptl site-backup-auth-pass mybackupauthpassword
apicup subsys set ptl site-backup-path /site-backups
apicup subsys set ptl site-backup-protocol sftp
apicup subsys set ptl site-backup-schedule "0 2 * * *"
```

The backup parameters are detailed in the following table.

Table 1. Portal backup parameters

Parameter	Description
site-backup-host	The fully qualified domain name of the backup server, in lowercase only. Ensure that the Kubernetes nodes can access this host. If using object storage, enter <i>Endpoint/Region</i> . (The / character between the endpoint and region is required for the object storage setting.)
site-backup-port	The port for the protocol to connect to the <i>site-backup-host</i> . Defaults to 22 if not explicitly set. The backup port is not required for object storage.
site-backup-auth-user	The user name for the server specified in <i>site-backup-host</i> . If using object storage, the user name is the S3 Secret Key ID.
site-backup-auth-pass	The password for the server specified in <i>site-backup-host</i> . If using object storage, the password is the S3 Secret Access Key parameter. The password is stored in Base64 encoded format, and must not be edited directly in the apiconnect-up.yml file.
site-backup-path	The full path to the directory where the backup files are stored. For object storage, the path can be set to the <i>bucket</i> value or the <i>bucket/subfolder</i> value.

Parameter	Description
<code>site-backup-protocol</code>	The protocol that is used to communicate with your remote backup endpoint. Specify one of the following values: <ul style="list-style-type: none"> <li><code>sftp</code> - for secure file transfer protocol</li> <li><code>objstore</code> - for S3 compatible object storage</li> </ul> The default protocol is <code>sftp</code> . Note: The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: <code>x509: certificate signed by unknown authority</code> .
<code>site-backup-schedule</code>	The schedule for how often automatic Portal backups are run. The format for the schedule is any valid cron string, as follows: <pre> * * * * * - - - - -                   +----- day of week (0 - 6) (Sunday=0)       +----- month (1 - 12)     +----- day of month (1 - 31)   +----- hour (0 - 23) +----- min (0 - 59) </pre> For example: <code>30 22 * * 1</code> performs backups at 10:30 pm on Mondays. The default backup schedule is <code>0 2 * * *</code> (runs every day at 2 am). The timezone for backups is UTC.

3. Optional: At any time you can view the current Portal subsystem values by running the following command:

```
apicup subsys get pt1
```

where `pt1` is the name that you assigned to your Portal service. The output from this command lists all of the subsystem settings, including backup, and indicates whether there are any errors. You must fix any errors before continuing.

4. Activate the backup settings by running the following command:

```
apicup subsys install pt1
```

where `pt1` is the name that you assigned to your Portal service.

5. Validate the installation with the new backup parameters by running the following command:

```
apicup subsys get pt1 --validate
```

where `pt1` is the name that you assigned to your Portal service. The output from this command lists all of the subsystem settings, including backup, and indicates whether the values are valid or invalid. You must correct any invalid values before continuing.

- How to run on-demand backups

You can make on-demand backups of your Developer Portal system, sites, and complete service, by running the following `exec` commands in your API Connect installation project directory.

- To backup the Portal system configuration (and not the sites), run the following command:

```
apicup subsys exec pt1 backup-system
```

- To backup a specific Portal site or all sites, run the following command:

```
apicup subsys exec pt1 backup-site arg
```

where `arg` is a specific site UUID or URL, or to backup all sites use the argument `installed`.

- To backup the entire Portal service (the system and all installed sites), run the following command:

```
apicup subsys exec pt1 backup
```

Where `pt1` is the name that you assigned to your Portal service.

Note: To restore a Developer Portal service, you need backups of both the Portal system and the installed sites.

- How to restore a Developer Portal service

You can restore your Developer Portal service by using the backups that exist on your remote server, by running the following `exec` commands in your API Connect installation project directory. Note that before you can run these commands, you must have configured your remote backup server details, and have valid backups of both the Portal system and the installed sites (see sections [How to configure the location and timing of your backups](#) and [How to run on-demand backups](#)).

Note:

- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- Restoration requires a functioning Developer Portal. In a disaster recovery scenario, you might need to reinstall the Developer Portal subsystem before you can restore the backed-up data. To reinstall, refer to [Deploying the Developer Portal in a VMware environment](#).
- To see what Portal system and site backups that you currently have on your remote backup server, run the following command. (This command may be useful when performing some of the following commands.)

```
apicup subsys exec pt1 list-backups remote
```

- To see what restore actions are performed when the `apicup subsys exec pt1 restore-all` command is run, you can use the following command:

```
apicup subsys exec pt1 restore-all dry backup_from
```

where `backup_from` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given.

Note: From IBM® API Connect Version 2018.4.1.17, the timestamp format changed to `YYYYMMDD.HHMMSS`. For Version 2018.4.1.16 and earlier, the timestamp format is `YYYY-MM-DD`

`HH:MM:SS`.

- To restore your Portal service, run the following command:

```
apicup subsys exec pt1 restore-all run backup_from
```

where `backup_from` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given. This command executes the portal restore process,

which downloads the system backup and all of the site backups from the remote server, and installs them within the Portal stack. This process will then restore the system configuration from the found backup, and restore all of the sites. Note that if a backed up site is already installed on the current stack, then the site is reinstalled by using the backup (the site is overwritten by the backup). If there are multiple sites to restore, then these sites are queued for restoring. You can track the restoration process within the Portal **www admin** logs.

- o To view the list of installed and restoring sites, run the following command:

```
apicup subsys exec ptl list-sites sites
```

Note that any sites that are pending restore and still in the queue do not appear in this list.

- o To restore just the Portal system configuration, run the following command:

```
apicup subsys exec ptl restore-system arg
```

where **arg** can be the system backup **tgz** file name, to restore the system by using the specified backup file, or use the argument **latest** to restore the system by using the latest backup file on the remote server. Note that if Portal system configuration information exists on the current stack, running this command will overwrite that configuration.

- o To restore just the Portal sites, run the following command:

```
apicup subsys exec ptl restore-site arg
```

where **arg** can be the site backup **tgz** file name or URL, to restore a particular site by using the specified backup file (or the latest backup file found if using a URL). Or you can use the argument **all** to restore all of the Portal sites that have backup files on the remote server. Note that if any of the backed up sites are already installed on the current stack, then they are reinstalled by using the backup (the sites are overwritten by the backup).

## What to do next

---

For a full list of the Developer Portal **exec** commands, see [List of the Developer Portal exec commands](#).

- [List of the Developer Portal exec commands](#)

You can use the **exec** commands to backup, restore, and list some of the environment details of your Developer Portal service.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## List of the Developer Portal **exec** commands

You can use the **exec** commands to backup, restore, and list some of the environment details of your Developer Portal service.

The following Developer Portal **exec** commands can be run in your API Connect installation project directory, where **ptl** is the name of your Portal service.

Tip: Running **exec** commands leaves completed jobs and pods on your subsystem. Therefore, it is recommended that you regularly delete those jobs and pods that have completed successfully, and whose logs are not required.

```
$ apicup subsys exec ptl backup-system
Backup the portal system to the remote server
```

```
$ apicup subsys exec ptl backup-site <arg>
Backup a portal site to the remote server.
valid args:
  site uuid/url - will backup that site only to the remote server
  installed    - will backup all installed sites to the remote server
```

```
$ apicup subsys exec ptl backup
Backup the portal system and all its sites to the remote server
```

```
$ apicup subsys exec ptl list-backups <arg>
List the portal backups either locally or on the remote server.
valid args:
  local    - will list backups present on the pod's filesystem
  remote  - will list backups on the remote server
```

```
$ apicup subsys exec ptl list-platforms
List the platforms that exist on the portal
```

```
$ apicup subsys exec ptl list-sites <arg>
List the installed portal sites
valid args:
  sites      - list only the sites
  platforms  - list the sites and their associated platform
```

```
$ apicup subsys exec ptl restore-system <arg>
Restore the portal system from the remote server
valid args:
  system_backup-1234.tgz - restores the system from the given file which should exist on the pod's local filesystem or
the remote server
  latest                 - restores from latest system backup found from either local filesystem or remote server
```

```
$ apicup subsys exec ptl restore-site <arg>
Restore a portal site
valid args:
  site-1234.tgz - restore the site using this filename which should can be copied from the output of the list backups
command
  myportal.com  - find the latest backup for this URL (locally or remotely) and restore it.
```

```

    all - restore all sites found on the remote server
NOTES:
If you specify a site TGZ / URL, the command runs restore_site with -f so overwrites any existing site
If you specify 'all', any installed sites will be reinstalled from the found backup

$ apicup subsys exec ptl restore-all <arg1> <arg2>
Restore the portal system and all backed up sites from the remote server
valid arg1:
  dry - executes a dry-run of the command, returning the actions that will be performed
  run - executes the command, restoring and replacing the system files and all sites. Any existing sites will be
reinstalled
valid arg2:
  now - use the latest backups available
  <TIMESTAMP> - in 'YYYYMMDD.HHMMSS' format, specify a timestamp to retrieve the backup from. The nearest backup,
searching backwards from this timestamp, will be used.

```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Backing up and restoring the analytics database

The analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required, for example, IBM Cloud Object Storage.

### Before you begin

If you configure Analytics for offloading and your endpoint requires a particular certificate, add trust certificates to the Analytics subsystem before attempting to back up or restore the Analytics database. For information on adding certificates to Analytics for back-up and restore, see [Adding certificates for Analytics for back-up and restore on VMware](#).

Tip: The [Procedure](#) section includes examples that illustrate how the back-up and restore commands work.

### About this task

These commands apply to OVA, pure Kubernetes, and IBM Cloud Private (ICP) deployments. To back up and restore the analytics database, you will need S3 compatible object storage. Backups are created on an as-needed basis and cannot be automated in API Connect.

**Important:** All arguments are required. Replace an argument with empty quotes (" ") to use the default setting.

Command	Values/Definition
<pre> apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; create-s3-repo </pre>	<p>Create the S3 repository to store analytics backups. These settings are identical to those used when creating a repository in Elasticsearch. The arguments are:</p> <ul style="list-style-type: none"> <li>REPO_NAME - Name of repository to be created.</li> <li>REGION - The region where bucket is located. Defaults to US Standard.</li> <li>BUCKET - The name of the bucket to be used for snapshots. Note: Analytics backup and restore supports virtual-host style bucket access, such as <code>bucket.s3-example.com</code>, but does not support path style bucket access such as <code>s3-example.com/bucket</code>.</li> <li>ENDPOINT - The endpoint to the S3 API.</li> <li>ACCESS_KEY - The access key to use for authentication.</li> <li>SECRET_KEY - The secret key to use for authentication.</li> <li>BASEPATH - The path name within the bucket where backup information is stored. The default is the root path. For S3 storage, you must include the port using the following format: <code>BASEPATH:PORT</code>.</li> <li>COMPRESS_TRUE_FALSE - Default is true. Determines whether metadata files are stored in compressed format.</li> <li>CHUNK_SIZE_GB - Default is 1GB. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB.</li> <li>SERVER_SIDE_ENCRYPTION_TRUE_FALSE - Default is false. Determines whether files are encrypted. When set to true, files are encrypted on the server side using AES256.</li> </ul> <p>If the <code>create-s3-repo</code> command results in the following error, complete the steps in <a href="#">Adding certificates for Analytics for back-up and restore</a> to add the certificate to the Analytics subsystem and then run the command again:</p> <pre> PKIX path building failed: sun.security.provider.certpath.SunCertPathBuilderException: unable to find valid certification path to requested target </pre>
<pre> apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; list-repos </pre>	<p>List repositories for analytics backups. There are no arguments or defaults for the <code>list-repos</code> command.</p>
<pre> apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; delete-repo </pre>	<p>Delete specified analytics backup repository. The argument is:</p> <ul style="list-style-type: none"> <li>REPO_NAME - Defaults to the existing repo if there is only one. The repository must be specified if there is more than one.</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li>If only one repo exists: <code>apicup subsys exec &lt;ANALYTICS_SUBSYS&gt; delete-repo ""</code></li> <li>If multiple repos exist: <code>apicup subsys exec &lt;ANALYTICS_SUBSYS&gt; delete-repo REPO_NAME</code></li> </ul>

Command	Values/Definition
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; backup</pre>	<p>Perform a backup of analytics data on an as-needed basis.</p> <ul style="list-style-type: none"> <li>INDICES - Default is <b>all</b> - All indices will be backed up. The INDICES arguments can consist of a series of index names, a single argument of comma-separated indices, or one or more keywords. Multiple keywords must be comma-separated. Values with whitespace must be enclosed in double-quotes. If no indices are specified, then all indices will be backed up. The keywords are mapped to indices or aliases in Elasticsearch. The keywords are as follows: <ul style="list-style-type: none"> <li><b>all</b> - Backup all data.</li> <li><b>apievents</b> - Backup all analytics data.</li> <li><b>ui</b> - Backup all UI visualizations and dashboards.</li> <li><b>config</b> - Backup all configuration information, such as retention period.</li> </ul> </li> <li>BACKUP_NAME - Enter the name of the backup.</li> <li>REPO_NAME - Defaults to the existing repo if there is only one. The repository must be specified if there is more than one.</li> <li>IGNORE_UNAVAILABLE_TRUE_FALSE - Default is false. If false, the restore will fail if an index is missing. If true, missing indices will be skipped and the restore will continue.</li> </ul>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; list-backups</pre>	<p>List analytics backups per S3 repo.</p> <p>The argument is:</p> <ul style="list-style-type: none"> <li>REPO_NAME - Defaults to the existing repo if there is only one. The repository must be specified if there is more than one.</li> </ul>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; details-backup</pre>	<p>Get details on specified analytics backup</p> <p>The arguments are:</p> <ul style="list-style-type: none"> <li>BACKUP_NAME - Defaults to <b>backup-<i>&lt;indices&gt;-<i>&lt;time date&gt;</i></i></b> if not explicitly set. The name must be all lowercase. For example, if the backup command was run as <b>apicup subsys exec &lt;ANALYTICS_SUBSYS&gt; backup ui apievents</b> then the backup name would be <b>backup-ui-apievents-2018-10-10t16:04:25z</b>. If more than three indices are specified, the backup name is truncated to <b>backup-<i>&lt;time date&gt;</i></b>.</li> <li>REPO_NAME - Sets the name of the repository where the backups will be stored. Defaults to the existing repository if there is only one. The repository must be specified if there is more than one.</li> </ul>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; delete-backup</pre>	<p>Delete specified analytics backup</p> <p>The arguments are:</p> <ul style="list-style-type: none"> <li>BACKUP_NAME - Enter the name of the backup to be deleted. You can view the names of backups using <b>apicup subsys exec &lt;ANALYTICS_SUBSYS&gt; list-backups</b>.</li> <li>REPO_NAME - Defaults to the existing repository if there is only one. The repository must be specified if there is more than one.</li> </ul>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; restore</pre>	<p>Restore analytics data</p> <ul style="list-style-type: none"> <li>INDICES - Default is <b>all</b> - All indices will be restored. The INDICES arguments can consist of a series of index names, a single argument of comma-separated indices, or one or more keywords. Multiple keywords must be comma-separated. Values with whitespace must be enclosed in double-quotes. If no indices are specified, then all indices will be backed up. The keywords are mapped to indices or aliases in Elasticsearch. The keywords are as follows: <ul style="list-style-type: none"> <li><b>all</b> - Restore all data.</li> <li><b>apievents</b> - Restore all analytics data.</li> <li><b>ui</b> - Restore all UI visualizations and dashboards.</li> <li><b>config</b> - Restore all configuration information, such as retention period.</li> </ul> </li> <li>BACKUP_NAME - Enter the name of the backup to be restored.</li> <li>REPO_NAME - Defaults to the existing repository if there is only one. The repository must be specified if there is more than one.</li> <li>IGNORE_UNAVAILABLE_TRUE_FALSE - Default is false. If false, the restore will fail if an index is missing. If true, missing indices will be skipped and the restore will continue.</li> <li>OVERRIDE_TRUE_FALSE - Default is false. If set to true, then the restore operation will override existing indices.</li> </ul>
<pre>apicup subsys exec &lt;ANALYTICS_SUBSYS &gt; restore-status</pre>	<p>Displays analytics status for determining the progress of the restore process.</p> <p>Note: The <b>restore-status</b> command is available in Version 2018.4.1.7 or later.</p>

Attention: Naming conventions for indices and back ups follow the Elasticsearch rules:

- Lowercase only
- Cannot include \, /, \*, ?, ", <, >, |, ` (space character), ,, #
- Colons (:) are not supported in 7.0+ (indices prior to 7.0 could contain a colon)
- Cannot start with -, \_, +
- Cannot be . or ..
- 255 byte limit (multi-byte characters will reach the 255 limit sooner)

## Procedure

- How to create a backup
  1. Create the S3 repository. The example creates a repository with the following values:
    - REPO\_NAME - myrepo
    - REGION - US
    - BUCKET - bucket
    - ENDPOINT - myrepo.s3repo.com
    - ACCESS\_KEY - access\_key
    - SECRET\_KEY - secret\_key

- BASEPATH - my\_folder
- COMPRESS\_TRUE\_FALSE - "" uses default of true
- CHUNK\_SIZE\_GB - "" uses default of 1GB.
- SERVER\_SIDE\_ENCRYPTION\_TRUE\_FALSE - "" sets to the default of false.

```
apicup subsys exec analytics create-s3-repo myrepo US bucket myrepo.s3repo.com access_key secret_key my_folder "" ""
```

OUTPUT:

Creating repository myrepo. List repos to see if creation completed, or check logs for errors.

Note:

With virtual host style repositories, the Analytics backup and restore process connects to the hostname formed by combining the values for **BUCKET** and **ENDPOINT**. For example, using the values given in this step, the host is `bucket.myrepo.s3repo.com`.

2. List the repositories. For example:

```
apicup subsys exec analytics list-repos
```

OUTPUT:

Name	Repo Type	Bucket	BasePath	Region	Endpoint	Chunk Size	Compress	Server Side Encryption
myrepo	s3	bucket	my_folder	US	myrepo.s3repo.com	1gb	true	

3. Create a backup with the following values:

- INDICES - all (or "" for the default of all)
- BACKUP\_NAME - mybackup
- REPO\_NAME - myrepo (use "" if only one repo exists)
- IGNORE\_UNAVAILABLE\_TRUE\_FALSE - "" sets to the default of false.

```
apicup subsys exec analytics backup all mybackup myrepo ""
```

OUTPUT:

Successfully created backup mybackup.

4. List backups in the repo named *myrepo*.

```
apicup subsys exec analytics list-backups myrepo
```

OUTPUT:

Name	Start Time	End Time	State
mybackup	2019-02-20T17:05:56.415Z	2019-02-20T17:06:09.833Z	SUCCESS

5. Display details for a backup named *mybackup* in the repo named *myrepo*.

```
apicup subsys exec analytics details-backup mybackup myrepo
```

OUTPUT:

```
Backup Name: mybackup
State: SUCCESS
Failures:
Shards Failed: 0
Shards Successful: 13
Start Time: 2019-02-20T17:05:56.415Z
End Time: 2019-02-20T17:06:09.833Z
Version: 5.6.8
Indices: .export-status, apic-api-2019.02.19-1, apic-api-2019.02.20-000002, .apic-config, .kibana-6
```

6. Delete a backup named *mybackup* in the repo named *myrepo*.

```
apicup subsys exec analytics delete-backup mybackup myrepo
```

OUTPUT:

Deleting backup mybackup. List backups to see the status, or check logs for errors.

- How to restore a backup

Note: Restoration requires a functioning Analytics subsystem. In a disaster recovery scenario, you might need to deploy Analytics before you can restore the backed-up data. To install and deploy, refer to [Deploying the Analytics subsystem in a VMware environment](#).

1. Restoring a backup

- INDICES - all (or "")
- BACKUP\_NAME - mybackup
- REPO\_NAME - myrepo (or "")
- IGNORE\_UNAVAILABLE\_TRUE\_FALSE - "" sets to the default of false.
- OVERRIDE\_TRUE\_FALSE - true

```
apicup subsys exec analytics restore all mybackup myrepo "" true
```

2. Check the status of the restore process. Enter the following command:

```
apicup subsys exec analytics restore-status
```

Note: The `restore-status` command is available in Version 2018.4.1.7 and later.

Following is example output:

Status	Active Primary Shards	Active Shards	Initializing Shards	Unassigned Shards
green	104	312	0	0

The restore process is successful when the status is green and there are no unassigned shards and no initializing shards. Note that the results are different if you are running in dev mode, or in standard mode with less than three nodes. For dev mode or standard mode with less than three nodes, the restore process will be finished when the initializing shards drops to 0. However, the status will remain yellow and unassigned shards will not drop to 0.

- Troubleshooting

Look for information in the `apicup` logs.

- Access the VM using `ssh`

- Locate the analytics-operator pod with: `sudo kubectl --kubeconfig /etc/kubernetes/admin.conf get pods`
- To view the logs, run: `sudo kubectl --kubeconfig /etc/kubernetes/admin.conf <analytics-operator-pod>`
- [Adding certificates for Analytics for back-up and restore on VMware](#)  
If you offload IBM API Connect Analytics data to an endpoint that is secured with a self-signed or private certificate, add the certificate to the Analytics subsystem to ensure connectivity with the endpoint during back-up and restore operations.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Adding certificates for Analytics for back-up and restore on VMware

If you offload IBM® API Connect Analytics data to an endpoint that is secured with a self-signed or private certificate, add the certificate to the Analytics subsystem to ensure connectivity with the endpoint during back-up and restore operations.

### About this task

If you connect to an endpoint without using the required self-signed or private certificate, the `create-s3-repo` command results in the following error:

```
PKIX path building failed: sun.security.provider.certpath.SunCertPathBuilderException: unable to find valid certification path to requested target
```

Resolve the error by adding the endpoint's certificate to the Analytics subsystem as explained in the following steps.

### Procedure

1. Obtain trust certificates that allow a client to connect securely to the offload endpoint.  
The certificate files should be PEM encoded. There will typically be one or two trust certificates required to complete the secure connection.

2. Create a separate file for each of the trust certificates, naming them `cert1.pem` and `cert2.pem`.

3. Verify that you can connect to the endpoint:

- a. If you have multiple files, combine the certificates into a single file to use for validation by running the following command:

```
cat cert1.pem cert2.pem > certificates.pem
```

- b. Execute the following cURL command to connect to the endpoint using the certificates:

```
curl https://endpoint:port --cacert certificates.pem
```

A certificate verification failure indicates that the certificates obtained in step 1 failed to establish trust. Return to step 1 and try again. You cannot proceed to step 4 until the certificates are successfully verified.

- c. When the certificate verification is successful, proceed to step 4.

4. Create a Kubernetes secret to contain the certificates, and then apply it to the cluster where the Analytics subsystem runs.

- a. Log in to a server that has `kubectl` access to the Kubernetes cluster where API Connect Analytics is deployed.

For OVA deployments, you must log in to one of the running Analytics VMs as a user with `kubectl` access.

- b. Encode each of the certificate files from step 2 in base64.

There are several ways to encode the file. If `cat` and `base64` are available, then you can run the following command to encode each file:

```
cat cert1.pem | base64 -w 0
```

Copy the output for each `cat` command so that you can paste it in the next step.

- c. Create a Kubernetes secret and add the certificate.

- i. Create a YAML file to contain the secret.

```
apiVersion: v1
kind: Secret
metadata:
  # Change value of name to be whatever you want the secret to be called
  name: analytics-br-cert
data:
  cert1.pem: output of base64 encoded cert1.pem
  cert2.pem: output of base64 encoded cert2.pem if required
```

- ii. In the file's `data` section, create a field for each certificate, and paste the corresponding encoded certificate as shown in the example. The value is a single line, so you do not need to enclose it in quotation marks.

- iii. Save the file.

- d. Update the cluster with the new certificate.

Run the following command to update the cluster:

```
kubectl apply -f analytics-br-cert.yaml -n your_namespace
```

where:

- `analytics-br-cert.yaml` is the secret's file name.
- `your_namespace` is the name of your deployment's namespace. The namespace is only needed for Kubernetes deployments.

For OVA deployments, you can omit the entire `-n your_namespace` parameter from the command. By default, kubectl is already configured to match the namespace where your Analytics resources are deployed.

5. Update the Analytics subsystem so that it can use the new secrets.

- a. Create an `extra-values.yaml` file that specifies the names of your certificate and environment variables secret files.

Include the following lines in the `extra-values.yaml` file, making sure to use the name of your Kubernetes secret (the value of the `name` field in the `metadata` section of the secret, which might not match the file's name):

```
apic-analytics-storage:
  backupSecretCerts: analytics-br-cert
```

- b. Update the Analytics subsystem.

- i. Log in to the server where you run `apicup`, and navigate to the project directory.  
In Kubernetes deployments this is probably the same server that you used for step 1, but for OVA deployments it is a different server.
- ii. Run the following `apicup` commands to reinstall the Analytics subsystem using the configuration settings in the `extra-values.yaml` file.

```
apicup subsys set analytics extra-values-file=~/.extra-values.yaml
apicup subsys install analytics
```

6. Verify that the certificates were added in the storage logs.

Log in to the host node and use `sudo` to run the following command:

```
kubectl logs -n namespace analytics-storage-pod
```

For OVA deployments, you can omit the `namespace` parameter and value.

The following confirmation message displays when the pod starts up:

```
Adding /etc/velox/backup-certs/ca-analytics-backup.pem contents to the system keystore for backup and restore.
Certificate cert1.pem was added to keystore
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Disabling the Analytics subsystem on VMware

Disable the Analytics subsystem by shutting down the VM that hosts it.

---

### About this task

Disabling the Analytics subsystem stops the collection and storage of data as well as making the subsystem unavailable. When you disable Analytics, there will be no data in either the API Manager Dashboards or third-party offloads.

---

### Procedure

1. Back up your Analytics data as explained in [Backing up and restoring the analytics database](#).

2. Disable shard allocation for storage.

Disabling shard allocation is optional, but is recommended because it prevents new shards from being created for replication when a node is unavailable, and helps avoid corruption issues in full system restarts.

- a. Connect to the virtual machine as the API Connect administrator by completing the following steps:

- i. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```

- ii. When prompted, select Yes to continue connecting.

- iii. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

- b. Disable shard allocation for storage by running the following command:

```
kubectl -n namespace exec -it storage-master|shared_pod -- curl -s -XPUT -d '{"persistent": {"cluster.routing.allocation.enable": "none"}}'
```

where:

- `namespace` is the namespace where the Analytics subsystem is installed.
- `storage-master|shared_pod` is the name of any storage-master or storage-shared pod. You can get the name of your storage pods by running the following command and substituting in the namespace where Analytics is installed:

```
kubectl -n namespace get po
```

When you disable shard allocation, the response looks like the following example:

```
{"acknowledged": true, "persistent": {"cluster": {"routing": {"allocation": {"enable": "none"}}}}, "transient": {}}
```

Leave the connection open for the next step.

3. Perform a synced flush of storage.

Flushing the storage is optional, but is recommended because it helps to avoid losing the data that was not yet written to disk. This step flushes all current index operations synchronously and attempts to write everything that is in flux to disk. Perform a synced flush of storage by running the following command:

```
kubectl -n namespace exec -it storage-master|shared_pod -- curl -s -XPOST _flush/synced
```

When you flush storage, the response looks like the following example:

```
{ "_shards": {"total": 33, "successful": 13, "failed": 0}, ".export-status": {"total": 1, "successful": 1, "failed": 0}, ".apic-config": {"total": 1, "successful": 1, "failed": 0}, ".kibana-6": {"total": 1, "successful": 1, "failed": 0}, "apic-api-2020.06.19-000002": {"total": 15, "successful": 5, "failed": 0}, "apic-api-2020.06.18-1": {"total": 15, "successful": 5, "failed": 0}}
```

The operation often fails, and it is safe to rerun it multiple times until it passes and there are all "failed" counts are zero. If it continues to fail after running multiple attempts over the span of a couple minutes, you can proceed to the next step.

#### 4. Shut down the Analytics VMs.

You can shut down the VMs using one of the following methods:

- Use the VMware console
- `ssh` into the images and run the `shutdown` command

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Using VM snapshots for infrastructure backup and disaster recovery

You can use VM snapshots to backup and restore the infrastructure used by API Connect on VMware, and also for infrastructure disaster recovery.

Backup and restore procedures for the databases used by IBM API Connect on VMware are described in [Backing up and restoring](#). The procedures back up all of the state required by API Connect but do not include the underlying infrastructure software or other internal state.

In some scenarios, you may want to perform backups and disaster recovery at an infrastructure layer. You can do this by taking snapshots of the virtual machines or underlying storage volumes, providing that you follow the constraints described here.

Note that performing backups at the infrastructure layer differs from the standard approach in that not only is the database state backed up, but also the precise state of the software. This approach can be useful, for example, when testing upgrades of production systems.

- Requirements for taking a consistent backup of an API connect system at the infrastructure level
  - An API Connect system can be approximated by the following diagram:

Table 1. API Connect Installation

- The system comprises multiple Virtual Machine images which are running Kubernetes, multiple databases, with the API Connect micro services running on top. There is transactional communication between the virtual machines which is occurring at all levels of this stack. This communication occurs all the time, even if the system is seemingly idle.
- Within the system there are multiple stateful or database layers on the software that maintain a consistency protocol. For example `etcd` upon which Kubernetes is based uses the [Raft](#) consensus algorithm. These algorithms depend for consistency on the basic assertion that time flows forwards on all systems together. If one or more of the virtual machine's state where to move backwards relative to the others by even the smallest quantum of time then consistency would be lost and the system might behave badly.

Clearly, if Virtual Machine snapshots are taken across multiple virtual machines it is certain that these snapshots will not be taken at precisely the same time. The result will be a backup that contains a system state that contains data from snapshots taken at slightly different times. It is possible that such a backup system may be restored and may appear to work correctly but hidden deep within it there may be undetected inconsistencies that will cause strange unpredictable errors and inconsistencies later. These issues can be extremely difficult to diagnose.

It is also possible that you can test this procedure successfully multiple times and see no apparent problem occurring. Irrespective of the apparent success of tests, corruption can be occurring in the system state. For this reason, taking VM snapshots or clones of a running API Connect system is not supported.

- How to take a consistent backup of an API connect system at the infrastructure level
  - The only way to take a consistent backup of an API connect system using VM snapshots and clones is to shut down ALL of the virtual machines comprising the system before taking the snapshot or clone.
  - Once the virtual machines are stopped at the VM level, time is effectively frozen. Then a snapshot can be taken on all the VMs. A clone can be made from the snapshot taken on each VM. This set of clones represent a valid, consistent state that the API Connect system was in when it was shut down.
  - Once all of the snapshots and clones have been taken the original API Connect system can be restarted.
- Restoring an API Connect System from VM clones
  - The Cloned VMs represent a valid state of the original API Connect system. They will restart in exactly the same way as the original system restarted.
  - If the objective is to stand up another instance of the cloned API connect system for testing or DR purposes, the following must be true:
    - The original system and the cloned system must be isolated from one another. The clone will be using the same hostnames and IP addresses as the original and so must be stood up in a separate virtual machine hosting environment with Network Address Translation between itself and any network to which the original system is stood up.
    - The cloned system must be stood up in an identical environment in terms of its hardware, software and network.
- Disaster Recovery approaches using Disk Replication:

You can use APICUP to change configuration of a subsystem after completion of initial installation.

The Install Assist utility (APICUP) is used to configure and complete initial installation of all subsystems, in both Kubernetes and VMware deployments. After initial installation, you can use the same `apicup` commands to reconfigure some of the settings from your existing deployment without having to completely reinstall the subsystem.

For example, if you did not configure optional features such as backup/restore or logging during initial installation, you can configure them later.

Note: Both Kubernetes and VMware deployments include subsystem settings that cannot be reconfigured without a complete deployment. For example, for the Management Service these settings include hosts, endpoints, interfaces (`public-iface`, `traffic-iface`), IP ranges of the Kubernetes pod and the service networks (`k8s-pod-network`, `k8s-service-network`), and backup volume size `cassandra-volume-size-gb`. Before reconfiguring, review the installation instructions for your subsystem to determine which settings are optional during initial installation and thus able to be updated later. See the section [Installing and upgrading on Kubernetes](#).

For both initial installation and reconfiguration, you specify configuration values by using `apicup subsys set` commands, and then activate them with `apicup subsys install`.

```
apicup subsys set <subsystem_name> <parameter_name>=<parameter_value>
apicup subsys install <subsystem_name>
```

For example, the following commands configure backup for the management subsystem `mgmt`, either during initial install or after initial install:

```
apicup subsys set mgmt cassandra-backup-auth-user=MyUsername cassandra-backup-auth-pass=MyPassword
apicup subsys set mgmt cassandra-backup-host=<hostname>
apicup subsys set mgmt cassandra-backup-path=</backups>
apicup subsys set mgmt cassandra-backup-port=<22>
apicup subsys set mgmt cassandra-backup-protocol=<sftp, objstore>
apicup subsys set mgmt cassandra-backup-schedule=<"0 0 * * *">
apicup subsys set mgmt cassandra-max-memory-gb=16 cassandra-cluster-size=3
apicup subsys set mgmt cassandra-volume-size-gb=<50>
apicup subsys set mgmt create-crd=<true>
apicup subsys set mgmt external-cassandra-host=<hostname>

apicup subsys install mgmt
```

On initial installation, the APICUP utility installs a Helm chart along with configuration values contained in `apiconnect-up.yml`. On subsequent invocations of `apicup subsys install`, APICUP checks to see if a saved combination of Helm chart and configuration values exists. If it does, APICUP checks to see if the configuration values have been updated, and if so, then a Helm update is triggered. If the combination of Helm chart and values is unchanged, then the subsystem is not changed. In this way, you can reconfigure as needed without having to completely redeploy and reinstall the subsystem.

- [Converting installation mode](#)  
You can switch an API Connect installation between `dev` mode and `standard` mode.
- [Increasing the memory allocation for the management database](#)  
You can increase the maximum memory allocation for the management database in a running deployment.
- [Enabling Analytics ingestion-only on VMware](#)  
Enable the ingestion-only configuration by redeploying the IBM® API Connect Analytics subsystem with the `ingestion-only` configuration setting.
- [Disabling Analytics ingestion-only on VMware](#)  
Disable the ingestion-only configuration by redeploying the IBM API Connect Analytics subsystem with the `ingestion-only` value set to false.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Converting installation mode

You can switch an API Connect installation between `dev` mode and `standard` mode.

### About this task

The supported installation mode options are: `dev` and `standard`. Mode is set for each subsystem type: Management, Analytics, Developer Portal, Gateway Service.

- Development mode (`dev`) deploys a subsystem with the scale of one; a single node, non-HA subsystem. The recommended use for `dev` mode is for development and testing.  
Note: While it is possible to use `dev` mode installations in a production deployment, it is not recommended. The `dev` mode does not provide the failover resiliency nor the downtime guarantee that is needed to maintain high availability (HA) production deployments.
- The `standard` mode deploys in HA mode for a production environment. The `standard` mode is supported for installation of production environments that consist of three or more nodes. The `standard` mode is not supported for less than three nodes.
- If not explicitly set, the installation mode defaults to `dev` (development). To specify `standard` mode:

```
apicup subsys set [subsys-name] mode=standard
```

Note: Prior to version 2018.4.1.4, the default mode was `standard`.

- If you installed in `standard` mode, but have less than three nodes, you can convert to `dev` mode. You must convert each subsystem.
- If you installed in `dev` mode, you can convert to `standard` mode. You must convert each subsystem.

Complete the following steps to determine your mode and, if necessary, convert the mode:

---

## Procedure

1. Review the output from the command: `apicup subsys get`

`<subsystem_name>`.

For example, `apicup subsys get mgmt`:

- VMware (OVA) environment output:

```
Appliance settings
=====
Name                Value                Description
-----
.
.
mode                standard
.
.
```

- Kubernetes output:

```
Kubernetes settings
=====
Name                Value                Errors
-----
.
.
mode                standard
.
.
```

2. If you need to convert the mode, following the appropriate instructions:

- [Converting dev mode to standard mode on VMware](#)
- [Converting dev mode to standard mode on Kubernetes](#)
- [Converting standard mode to dev mode on VMware](#)
- [Converting standard mode to dev mode on Kubernetes](#)
- [Converting dev mode to standard mode on VMware](#)  
You can convert your API Connect installation on VMware from `dev` mode to `standard` mode.
- [Converting standard mode to dev mode on VMware](#)  
You can convert your API Connect installation on VMware from `standard` mode to `dev` mode.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Converting dev mode to standard mode on VMware

You can convert your API Connect installation on VMware from `dev` mode to `standard` mode.

### About this task

To review the installation modes, see [Converting installation mode](#).

### Procedure

1. Use `apicup` to convert to `standard` mode.

```
apicup subsys set <subsys> mode=standard
```

2. Create hosts and interfaces for two more nodes, to bring the total number of nodes to three.

a. Create hosts:

```
apicup hosts create mgmt hostname.domainname hd_password
```

To review host creation for your subsystem type, see:

- Step [12](#) in [Deploying the Management subsystem in a VMware environment](#)
- Step [11](#) in [Deploying the Analytics subsystem in a VMware environment](#)
- Step [12](#) in [Deploying the Developer Portal in a VMware environment](#)

b. Create interfaces. For example:

```
apicup iface create mgmt hostname.domainname physical_network_id host_ip_address/subnet_mask gateway_ip_address
```

To review interface creation for your subsystem type, see

- Step [13](#) in [Deploying the Management subsystem in a VMware environment](#)
- Step [12](#) in [Deploying the Analytics subsystem in a VMware environment](#)
- Step [13](#) in [Deploying the Developer Portal in a VMware environment](#)

3. Install the new plan in a new `<plan-dir>`, which will generate 3 ISOs.

```
apicup subsys install <subsys> --out <plan-dir>
```

4. Configure the 3 virtual machines to attach their respective ISOs at boot.  
Follow the steps in the installation instructions for your subsystem type:

- [Deploying the Management subsystem in a VMware environment](#)
- [Deploying the Analytics subsystem in a VMware environment](#)
- [Deploying the Developer Portal in a VMware environment](#)

5. Restart the first node, which initially was a **dev** node.
6. Start the second node.
7. Start the third node.
8. To review your installation mode, use `apicup subsys get <subsystem_name>`.  
For example, `apicup subsys get mgmt`:

```
Appliance settings
=====
Name                               Value                               Description
----                               -
.
.
mode                                standard
.
.
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Converting standard mode to dev mode on VMware

You can convert your API Connect installation on VMware from **standard** mode to **dev** mode.

### About this task

---

To review the installation modes, see [Converting installation mode](#).

### Procedure

---

For each subsystem in your deployment, complete the following steps:

1. Use the following `apicup` command to convert to Dev mode:

```
# ./apicup subsys set [subsys-name] mode=dev
# ./apicup subsys install [subsys-name]
```

2. Remove all replica sets. Use `ssh` to access the VM, and use the following command:

```
sudo kubectl --kubeconfig /etc/kubernetes/admin.conf delete rs --all
```

3. To review your installation mode, use `apicup subsys get <subsystem_name>`.

For example, `apicup subsys get mgmt`:

```
Appliance settings
=====
Name                               Value                               Description
----                               -
.
.
mode                                dev
.
.
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Increasing the memory allocation for the management database

You can increase the maximum memory allocation for the management database in a running deployment.

### Before you begin

---

When increasing the memory allocation, complete a manual backup of the management database and Portal subsystem just prior to changing the allocation. Note that this backup is in addition to any scheduled backups that you have configured. The manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured.

For details on creating a backup, see [Backing up the management subsystem in VMware environments](#) and [Backing up and restoring the Developer Portal in a VMware environment](#).

## About this task

Starting with API Connect version 2018.4.1.3, you can increase the maximum memory allocation for the management database in a running deployment. This procedure works for both Kubernetes and OVA environments. All the pods in the API Connect cluster must be up and running to increase the maximum memory value in a running deployment.

## Procedure

1. Ensure all pods are up and running using the `kubectl get pods` command.
2. Use the following `apicup` command to increase the maximum memory:

```
apicup subsys set <MANAGEMENT_SUBSYS_NAME> cassandra-max-memory-gb <new_value>
```

3. Reinstall the management subsystem to push the change to the cluster. This may take several minutes as each pod updates.

```
apicup subsys install <MANAGEMENT_SUBSYS_NAME>
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Enabling Analytics ingestion-only on VMware

Enable the ingestion-only configuration by redeploying the IBM® API Connect Analytics subsystem with the `ingestion-only` configuration setting.

## Before you begin

Only complete this task if you want to offload all analytics data and disable the Analytics feature in the user interface. If you want to retain the data or allow users to access the Analytics user interface, skip this task and instead see [Configuring analytics offload for API Connect](#).

## About this task

If you choose to offload all analytics data to third-party services and have no need to retain the data in API Connect, you can configure the Analytics service with the ingestion-only setting. If you offload data and then separately disable the Analytics UI, the associated components are still deployed and require system resources. Configuring Analytics for ingestion-only removes unused Analytics components (such as analytics-storage and analytics-client) from the topology and only deploys the components required for offloading data (such as analytics-ingestion and analytics-mq-kafka). The reduced topology requires less CPU, memory, and storage.

## Procedure

1. Remove the Analytics service from your API Connect deployment by completing the following steps.
  - a. Unassociate the Analytics service from all gateway services as explained in step 7 in the topic, [Associating an analytics service with a gateway service](#).
  - b. Unregister the Analytics service from Cloud Manager.  
You can unregister the service from the Topology page: click the Options menu next to the service name and select Delete. For information on registering services, see [Registering an analytics service](#).
2. Create an extra values file to specify the URL of the offload endpoint where all analytics data will be routed.  
You can choose the name for the file, but you must use `.yaml` as the file-name extension. Format the file as shown in the following example, making sure to include required settings for the third-party system.

```
apic-analytics-ingestion:
  outputOffload: |-
    elasticsearch {
      hosts => "http://offload_endpoint:port"
      index => "api-call"
    }
```

For information about configuring analytics offloading, see [Configuring analytics offload for API Connect](#).

3. Run the following `apicup` commands to reinstall the Analytics subsystem using the configuration settings in the extra values file:

```
apicup subsys set analyt ingestion-only=true
apicup subsys set analyt extra-values-file=extra-values.yaml
apicup subsys install analyt
```

4. Add the new Analytics service to your API Connect deployment by completing the following steps.
  - a. Register the new Analytics service with the Cloud Manager.  
Attention: When you register an Analytics service that is configured for ingestion-only, you must use the ingestion endpoint and the ingestion TLS profile instead of the client endpoint and TLS profile.  
For information on registering a service with the Cloud Manager, see [Registering an analytics service](#).

- b. Associate the Analytics service with a gateway service as explained in [Associating an analytics service with a gateway service](#).

## Results

---

All analytics data is routed directly to the offloading endpoint, the Analytics UI is disabled, and no data is retained in API Connect.

In addition, the following Analytics configuration settings will not be validated or used when `ingestion-only` is set to enabled:

- `coordinating-max-memory-gb`
- `data-max-memory-gb`
- `data-storage-size-gb`
- `master-max-memory-gb`
- `master-storage-size-gb`
- `analytics-client`
- `es-storage-class`

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Disabling Analytics ingestion-only on VMware

Disable the ingestion-only configuration by redeploying the IBM® API Connect Analytics subsystem with the `ingestion-only` value set to false.

### About this task

---

When you previously configured Analytics for ingestion-only, you deployed only a subset of the Analytics components. If you want to disable the ingestion-only setting, redeploy the subsystem to ensure that all components are available.

### Procedure

---

1. Remove the Analytics service from your API Connect deployment by completing the following steps.
  - a. Unassociate the Analytics service from all gateway services as explained in step 7 in the topic, [Associating an analytics service with a gateway service](#).
  - b. Unregister the Analytics service from Cloud Manager.  
You can unregister the service from the Topology page: click the Options menu next to the service name and select Delete. For information on registering services, see [Registering an analytics service](#).
2. Generate the `analytics-client-ingress` certificate (if you initially created this certificate, it was removed when you deployed using the ingestion-only configuration).  
For information, see [Working with certificates](#).
3. Run the following `apicup` commands to install the complete Analytics subsystem:

```
apicup subsys set analyt ingestion-only=false
apicup subsys install analyt
```
4. Add the new Analytics service to your API Connect deployment by completing the following steps.
  - a. Register the new Analytics service with the Cloud Manager.  
For information on registering a service with the Cloud Manager, see [Registering an analytics service](#).
  - b. Associate the Analytics service with a gateway service as explained in [Associating an analytics service with a gateway service](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Setting rate limits for public APIs on the management service for a VMware environment

Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.

### Before you begin

---

Note: This article refers to third-party software that IBM does not control. As such, the software may change and this information may become outdated. These instructions assume you have the kubectl command-line tool installed. For more information, see <https://kubernetes.io>.

### About this task

---

Rate limits can be set for public APIs on the management service. Rate limits on APIs help provide protection from DDoS (distributed denial of service) attacks. Without a rate limit, API calls from public APIs are unlimited.

The rate limit configuration requires that the header contains the actual client IP address. Any load balancer or proxy (for example, HAProxy) that is installed in front of the management service must be configured to pass the actual client IP address.

This procedure must be performed on a running API Connect deployment.

This feature is available in API Connect versions 2018.4.1.1 and higher.

Rate limits are calculated as requests per seconds per client.

## Procedure

---

- Set a rate limit:
  1. Add the following entries to an extra-values-file:

```
juhu:
  rateLimitPerClient: 10
  limitRequestOption: "burst=10 nodelay"
```

In this example, the first option sets the rate to 10 requests per second (10r/s). The second option allows 10 requests boosted without delay within < 1 second. You can customize as needed.

The `rateLimitPerClient` property sets `rate`, and `limitRequestOption` sets `[burst=number] [nodelay | delay=number]` in the following nginx configuration:

```
limit_req_zone key zone=name:size rate=rate;
limit_req zone=name [burst=number] [nodelay | delay=number];
```

- Note that `zone` has been pre-defined and can't be configured. For details, see the nginx.org doc [Module ngx\\_http\\_limit\\_req\\_module](#).
  - If you don't have an extra-values-file, you can create a new one. See [Creating an extra values file in a Kubernetes environment](#).
2. Run `apicup` to update the settings in the deployed Management subsystem.

```
apicup subsys install <management-subsystem>
```

Note: If the rate limit has been reached on the management subsystem, the client will get an HTTP error: **429 Too Many Requests**.

3. Validate that the juhu pod has restarted by listing the pods:

```
kubectl get pods -n <namespace> | grep juhu
```

4. Check the AGE column to ensure a new juhu pod has started.
5. If the older juhu pod is still running, delete it with the following command:

```
kubectl delete pods -n <namespace> <old-juhu-pod>
```

- Disable a rate limit:
    1. Validate that the juhu pod has restarted by listing the pods:
- ```
kubectl get pods -n <namespace> | grep juhu
```
2. Check the AGE column to ensure a new juhu pod has started.
  3. If the older juhu pod is still running, delete it with the following command:

```
kubectl delete pods -n <namespace> <old-juhu-pod>
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment

In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

If a Gateway service is not configured properly for resiliency and is restarted, the gateways in the Gateway service will lose the configuration from the Management server. Configuration data from the Management server is maintained on the gateway service according to the gateway peering configuration on the gateways.

## Preventing the loss of configuration data

---

For high availability in production environments, use a minimum of three gateways in the Gateway service. In non-production environments, if a single gateway is used, then availability can be improved by ensuring the persistence setting on the gateway peering configuration is set to `local://` or `RAID`; these settings apply to virtual and physical appliances only.

## Forcing re-population of the configuration data

---

To repopulate the configuration data, complete the steps in the following section to trigger an outage-less DRR.

## Triggering an outage-less DRR

---

To force a Dynamic Reregistration and Reconfiguration across a peer group from within the gateway service without requiring a restart, complete the following steps using the CLI. This process flushes the primary peering object configured for the apic-gw-service. This task can only be performed with CLI, and requires the default admin ID for running the `diag` command.

1. Use `ssh` to connect to gateway service.

2. Switch to the API Connect application:

```
switch <APIC_APP_DOMAIN>
```

3. Show the current gateway-peering-status:

```
show gateway-peering-status
```

4. If the server to which the ssh connection was made is not primary for the apic-gw-service gateway-peering object, force this server to become primary:

```
config; gateway-peering-switch-primary <gateway-peering-name-for-apic-gw-service>;
```

5. Flush the apic-gw-service gateway-peering object:

```
diag; gateway-peering-flush <gateway-peering-name-for-apic-gw-service>; exit
```

6. Disable and then re-enable the apic-gw-service object for every member of the gateway service:

```
config; apic-gw-service; admin-state disabled; exit
apic-gw-service; admin-state enabled; exit; exit
```

7. Confirm that the apic-gw-service was flushed and is now waiting for gateway service registration:

Look in the debug log target for the apic-gw-service, located in `logtemp:///` and check for a message similar to the following example:

```
20200618T232339.332Z [0x88e000d7][apic-gw-service][notice]
apic-gw-service(default): tid(2653): Waiting for gateway service registration.
```

The DRR will be triggered by the next arrival of a webhook event. Starting with API Connect Version 2018.4.1.2, the Management server sends a heartbeat to the gateway at five-minute intervals, prompting the gateway to check whether it has lost its configuration and if so, trigger a DRR. In Version 2018.4.1.8 and later, if the Management server has previously marked a Catalog or cloud as being unavailable for a particular gateway service, a successful heartbeat triggers synchronization for that Catalog or cloud on that gateway service.

8. (Optional) Force a BAU webhook event to be sent from API Manager to trigger the DRR:

If you do not want to wait for the Management server to send a heartbeat, you can trigger the DRR manually by completing the following steps:

- a. Open the API Manager.
- b. Open the Catalog.
- c. Click Settings > Edit.
- d. Update the Summary field with some text so that it is modified.
- e. Click Save.

When the event is received, the DRR is initiated.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Adding disk space to a VMware appliance

Increase disk space on the VMware appliance.

### About this task

---

For multi-node deployment of the appliance, only one VM at a time should have its disk space augmented. The subsystem should be in good health before proceeding to the next node. Health of the subsystem can be checked with `apicup subsys health-check <subsystem-name>`.

### Procedure

---

1. Shutdown the virtual machine, either by issuing a shutdown command as root from the VM, or by using the VMware console or command line interface. For example, use the VMware console user interface and click the red rectangle.
2. Use either the VMware console or command line interface to add a new device to the VM, of type Hard Disk and of the desired size to be added to the appliance. For example, on the VMware console:
  - a. Click Edit settings.
  - b. Click Add new device. From the drop-down menu, select Hard Disk.
  - c. Enter size in GB and click OK.
3. Use either the VMware console or the command line interface to power on the VM. As the VM starts it should detect the newly added disk and use it to augment the available capacity for the `/data/secure` mount point.

4. Optionally you may verify that a new disk `sdc` was added (or `sdd` if you already added one disk, and so on). Log in to the server and observe the new disk. For example:

```
root@apimdev1139:~# lsblk
NAME                                MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
sda                                  8:0    0  100G  0 disk
├─sda1                               8:1    0  99.9G  0 part  /
├─sda14                              8:14   0    4M    0 part
├─sda15                              8:15   0   106M  0 part  /boot/efi
sdb                                  8:16   0   250G  0 disk
├─apicconnect-data                 252:0   0   260G  0 lvm
├─apicSecureDisk                  252:1   0   260G  0 crypt /data/secure
sdc                                  8:32   0    10G  0 disk
├─apicconnect-data                 252:0   0   260G  0 lvm
├─apicSecureDisk                  252:1   0   260G  0 crypt /data/secure
sr0                                  11:0    1    44K  0 rom
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Running a filesystem check on a VMware root partition

You can run a filesystem check on the appliance root filesystem at boot time.

### About this task

If the appliance root filesystem is mounted read-only because it is corrupt, use the following steps to run `fsck` on root partition:

### Procedure

1. Access to the VMware console for the Appliance, and after causing it to reboot, make sure to bring up a console to the appliance (as needed to give focus to the window by clicking the mouse into it), and press the `Esc` key repeatedly.  
You will see a boot screen similar to the following:

```
GNU GRUB v2.02
.
.
- Ubuntu
- Advanced options for Ubuntu
.
.
Press Enter to boot the selected OS, 'e' to edit the commands
before booting or 'c' for a command-line
```

2. Press `e` to edit the commands before booting, and add the lines `fsck.mode=force` and `fsck.repair=yes`.  
For example, the boot screen contents resemble:

```
GNU GRUB v2.02
.
.
set params 'Ubuntu'
  fsck.mode=force
  fsck.repair=yes
.
.
Press Ctrl-x or F10 to boot
.
```

3. Press `F10` to boot.
4. The following command should show that `fsck` was run recently:

```
root@ip-230:~# sudo tune2fs -l /dev/sda1 | grep "Last checked"
Last checked:          Wed Jul  1 19:32:25 2020
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Managing an appliance data disk

You can use `apic` commands to manage appliance data disks in your VMware deployment.

The API Connect deployment on VMware uses 2 partitions. The first contains the base operating system, while the second is encrypted so that any customer data that is stored on disk uses the encrypted volume. Encryption is done with Linux Unified Key Setup (LUKS) disk encryption.

During installation of each API Connect subsystem, you specify a password `HD-PASSWD` when configuring the host:

```
apicup hosts create <SUBSYS> <HOSTNAME> <HD-PASSWD>
```

If you want to force a restart of processes, without requiring a full restart of the virtual machine, you can use the command `apic lock` to stop the Kubernetes node on the virtual machine and lock the secured storage. When you are ready to restart processes, you can use `apic unlock` to restart the Kubernetes node. The command `apic unlock` uses the password to unlock the partition so that files can be read from it and written to it. The unlock command also starts the `apic` daemon, also known as the `appliance-manager` service.

You can check that status of this service with:

```
sudo systemctl status appliance-manager
```

One `appliance-manager` daemon runs on each node, where it manages the Kubernetes cluster, processes update and upgrade requests, and gathers logs.

| apic command         | Description                                               |
|----------------------|-----------------------------------------------------------|
| <code>lock</code>    | Shut down appliance services and lock the secured storage |
| <code>logs</code>    | Retrieve logs from all nodes in the cluster               |
| <code>status</code>  | Report on cluster status                                  |
| <code>unlock</code>  | Unlock the secure storage and start the appliance         |
| <code>version</code> | Get the API Connect appliance base version                |

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Troubleshooting the API Connect upgrade on VMware

Troubleshoot your API Connect upgrade on VMware.

Note: Do not install any extra software or run any commands on the VMs that are not documented in the IBM documentation or otherwise advised by IBM. When troubleshooting API Connect, do not use `kubect1 exec` commands to access API Connect pods unless advised by IBM. Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

- [Restarting unhealthy cassandra pods](#)
- [Recreating a calico pod that is in the CrashLoopBackOff state](#)

---

## Restarting unhealthy cassandra pods

If you complete an upgrade and find that one or more of the cassandra pods (prefixed with `apiconnect-apiconnect-cc`) are not responding:

1. Run the following checks to verify that the pods require a restart:

- Check the status of the pods to see if they are marked as `Running` but not `Ready` as in:

```
apiconnect-apiconnect-cc-g4rhq 0/1 Running
```

- Check the `describe` of the pods for an event log with a warning similar to the following example:

```
Warning Unhealthy 2m6s (x177 over 38m) kubelet Readiness probe failed: Cassandra is either decommissioning or upgrading
```

2. Restart each pod by deleting it with the following command (which recreates the pod):

```
kubect1 delete pod <pod_name>
```

Note: If there are multiple cassandra pods in this state, then delete them one at a time' wait until the previously deleted pod comes up and shows as `Running` in the `Ready` state before deleting the pod.

---

## Recreating a calico pod that is in the CrashLoopBackOff state

If you complete an upgrade and find that one or more of the calico pods are in the `CrashLoopBackOff` state, you can delete the pod to recreate it. Complete the following steps:

1. Get the names of the calico pods:

```
kubect1 -n kube-system get pods | grep calico
```

2. Recreate each pod by deleting it with the following command:

```
kubect1 -n kube-system delete pod <calico_pod_name>
```

- [Checking cluster health on VMware](#)

You can use `apicup` to check the health of the API Connect clusters in your VMware deployment.

- [Determining status of a cluster on VMware](#)

You can determine the health of an API Connect cluster on VMware

- [Obtaining simple health check data of Developer Portal sites by using a REST API call](#)

Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

- [Monitoring the network with SNMP](#)  
Presents a table of OID trees that you can poll using SNMP Get.
- [Gathering logs for a VMware environment](#)  
The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Checking cluster health on VMware

You can use `apicup` to check the health of the API Connect clusters in your VMware deployment.

Note: The `apicup` health check command is available on Version 2018.4.1.6 or later. For deployments on Version 2018.4.1.5 or earlier, use the instructions on [Determining status of a cluster on VMware](#).

The `health-check` command checks a number of criteria to determine the health of their cluster. When all criteria are successfully met, the command displays no output, and exits with a status of 0. When one or more criteria are not met, the command stops processing and displays a message with the failure and exits with a status of 1.

The command takes no arguments. The only option is the `--verbose` flag. If `--verbose` is set the command prints all checks that were performed.

The `health-check` is run against the namespace that is specified in `apiconnect-up.yaml`.

The command verifies that for the specified subsystem:

- The `apicup` version matches the API Connect release version.
- All cluster members are running the same API Connect release version.
- All cluster members have a deployment status of `Done`.
- Docker is running.
- `kubelet` is running
- The installed subsystem matches the subsystem deployed to Helm.
- For each expected Helm release, the deployed Chart version matches the `apicup` version.
- All Kubernetes-defined nodes are running.
- The Kubernetes Control Plane pods are running:
  - `etcd/kube-apiserver`
  - `kube-system.kube-controller`
  - `kube-scheduler`
  - `kube-apiserver-proxy`
- The add-on Kubernetes Deployments are fulfilled:
  - `coredns`
  - `metrics-server`
  - `tiller-deploy`
- The add-on Kubernetes DaemonSets are fulfilled:
  - `calico-node`
  - `ngress-nginx-ingress-controller`
  - `kube-proxy`

Syntax:

Usage:

```
apicup subsys health-check <SUBSYS> [flags]
```

Flags:

```
-h, --help                help for health-check
--kubeconfig string      (optional) absolute path to the kubeconfig file (default "/Users/<username>/.kube/config")
-v, --verbose            Verbose output
```

Global Flags:

```
--accept-license        Accept the license for API Connect
--debug                 Enable debug logging
```

Example usage, for a subsystem named `mgmt`:

```
../apicup subsys health-check mgmt
```

Note:

- The command flag `--kubeconfig string` does not apply to deployments on VMware.
- In a multi-node OVA cluster, the `apicup subsys health-check` command does not return status information if a majority of the nodes are down. To obtain status information, start more nodes. Status is returned only when a quorum is achieved.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Determining status of a cluster on VMware

You can determine the health of an API Connect cluster on VMware

## About this task

At any time, you can review the status of the API Connect cluster. You should review the status before and after doing configuration tasks such as upgrading.

Note: For Version 2018.4.1.6 or later, you can also use `apicup subsys health-check`. See [Checking cluster health on VMware](#)  
Do not use these instructions on Kubernetes. See [Determining status of a cluster on Kubernetes](#).

## Procedure

1. Verify that the installer version matches your API Connect product version.
  - a. Check the `apicup` version. For example:

```
$/apicup version
APIConnect 2018.4.1.3
Installer 4.0.0
```

Note that for API Connect 2018.4.1.5, the Installer version is 5.0.0.

- b. On each appliance, run `apic version`:  
Example output:

```
INFO[0000] Log level: info
Appliance base 1.3.0
GitCommitSha:2018.4.1.2-11-g617cf1f
Packages:
- appliance-base:1.3.0
- appliance-runtime-1.3.0:1.0.0
- subsystem-management:2018.4.1.3
```

Verify the version number on the `subsystem` line. The previous example shows, for the management subsystem, version `2018.4.1.3` on the line `subsystem-management:2018.4.1.3`.

The Analytics subsystem displays as `subsystem-analytics`. The Developer Portal displays as `subsystem-portal`.

2. Ensure that all nodes have an installation status of **DONE**.  
Run `apic status`:

```
sudo -i
apic status
```

Ensure that the output for each node says:

```
Install stage: DONE
Upgrade stage: UPGRADE_DONE
```

If a node has recently been restarted, the install or upgrade stage might not show **DONE**. In this case, wait a few minutes for background processing to complete and view the status again.

Note that the status command always returns a value for `Upgrade stage`, even when an upgrade has not been attempted. In this scenario, the value might not be `UPGRADE_DONE`. This is normal and can be ignored.

Note: In a multi-node OVA cluster, the `apic status` command does not return status information if a majority of the nodes are down. To obtain status information, start more nodes. Status is returned only when a quorum is achieved.

3. Ensure that all Kubernetes nodes have a status of **READY**:

```
kubect1 get nodes
```

4. Verify that the subsystem Helm release was successful

The Helm release name(s) depend on the subsystem type you are checking. Subsystem type to helm release name:

| Subsystem  | Helm release                   |
|------------|--------------------------------|
| management | apiconnect, cassandra-operator |
| analytics  | apic-analytics                 |
| portal     | apic-portal                    |

Run `helm ls` to show the releases. Ensure that each release for each subsystem has a status of **DEPLOYED**:

```
# helm ls
NAME          REVISION    UPDATED              STATUS      CHART
NAMESPACE
apiconnect    1           Wed Apr 3 11:58:54 2019  DEPLOYED   apiconnect-2.0.0
default
cassandra-operator 1           Wed Apr 3 11:58:38 2019  DEPLOYED   cassandra-operator-1.0.0
default
```

If any release is not **DEPLOYED**, open a ticket with IBM Support, to obtain assistance with troubleshooting the release.

5. Check that the deployed charts are the correct version.

This check needs to be performed on only one node. See the previous steps to determine the Helm release name(s) for the subsystem type.

- Version 2018.4.1.4 or later  
Run the command `helm get [release-name] | grep productVersion | head -1`  

```
# helm get values apiconnect | grep productVersion | head -1
productVersion: 2018.4.1.4
```

If the previous command returns `productVersion: ""`, the deployed charts are for a version prior to 2018.4.1.4. See the following instructions.

- Version 2018.4.1.3 or earlier
  - Management subsystem

• Run `helm get apiconnect | grep apiconnect/apim[:] | head -1`. Compare output to the following table to determine chart `productVersion`:

| Image output                                  | Chart productVersion |
|-----------------------------------------------|----------------------|
| image: "apiconnect/apim:2018.4.1-223-5e98505" | 2018.4.1.0           |
| image: "apiconnect/apim:2018.4.1-267-7151665" | 2018.4.1.1           |
| image: "apiconnect/apim:2018.4.1-339-0d1c113" | 2018.4.1.2           |
| image: "apiconnect/apim:2018.4.1-391-e1df735" | 2018.4.1.3           |

• Run `helm get cassandra-operator | grep apiconnect/cassandra-operator[:] | head -1`. Compare output to the following table to determine chart `productVersion`.

| Image output                                                                                               | Chart productVersion |
|------------------------------------------------------------------------------------------------------------|----------------------|
| image: "image: apiconnect/cassandra-operator:2018-10-27-11-34-27-b30560eb3775c558f8438abb8e084ed97ca8a34f" | 2018.4.1.0           |

- Portal subsystem

Run `helm get apic-portal | grep apiconnect/portal-web[:] | head -1`. Compare output to the following table to determine chart `productVersion`.

| Image output                                                                       | Chart productVersion |
|------------------------------------------------------------------------------------|----------------------|
| image: apiconnect/portal-web:2018.4.1-385444eb87824c93e42c85412af8088eac8c7bb9-335 | 2018.4.1.0           |
| image: apiconnect/portal-web:2018.4.1-ea9a86af8cf6f9e241f29f9a7ad860991e017d29-514 | 2018.4.1.1           |
| image: apiconnect/portal-web:2018.4.1-8e3c67a1ec93f9eda7411286b75e19becaab0fb0-773 | 2018.4.1.2           |
| image: apiconnect/portal-web:2018.4.1-31b0250446fd1660cc4622f44b7f8317391c536d-948 | 2018.4.1.3           |

- Analytics subsystem

Run `helm get apic-analytics | grep apiconnect/analytics-client[:] | head -1`. Compare output to the following table to determine chart `productVersion`:

| Image output                                                                                     | Chart productVersion |
|--------------------------------------------------------------------------------------------------|----------------------|
| image: apiconnect/analytics-client:2018-10-18-17-32-08-ba640482b2659c37905271d6a318fa0fc902aebd" | 2018.4.1.0           |
| image: apiconnect/analytics-client:2018-11-21-11-19-56-ba640482b2659c37905271d6a318fa0fc902aebd" | 2018.4.1.1           |
| image: apiconnect/analytics-client:2019-01-07-15-16-59-9f8c1b7bb4a8f9a0bf9529bab166f752821b62e4" | 2018.4.1.2           |
| image: apiconnect/analytics-client:2019-02-12-12-52-40-700d61ffb1c2ff2c9860d6d75f1620fbceea64d6" | 2018.4.1.3           |

6. Review the results of the previous step, and ensure that the product version matches the `apicup` version and the appliance version.

If the chart version is wrong it is likely that either the wrong version of Install Assist was used for `apicup subsys install`, or an old `--plan-dir` was passed to the install command. Verify the correct version of `apicup` is being used and try to re-install by using `apicup subsy install`. It is safe to run the command multiple times.

7. Use `kubectl` to check the deployments and validate that the number of deployments matches for `DESIRED`, `CURRENT`, and `AVAILABLE`.

If the numbers don't match, it is possible that one of the pods is still starting, or is having problems. Another possibility is that Kubernetes encountered problems trying to scale down an old replica set. Check for replica-sets that are for the same deployment and have a number count greater than 0 for `DESIRED`. Note that the replica-sets for a deployment start with the same name.

You can use `kubectl get rs` to try to determine why the replica-set is not scaling down. For example, the following output shows a cluster in a non-healthy state.

```
# kubectl get deployments
NAME                                DESIRED  CURRENT  UP-TO-DATE  AVAILABLE  AGE
apiconnect-a7s-proxy                3         3         3             1           2h
apiconnect-apim-v2                  3         3         3             3           2h
apiconnect-client-dl-srv            2         3         2             1           2h
apiconnect-juhu                     3         4         2             2           2h
apiconnect-ldap                     3         4         2             2           2h
apiconnect-lur-v2                   3         4         2             2           2h
apiconnect-ui                       2         3         2             1           2h
cassandra-operator-cassandra-operator 1         1         1             1           2h

# kubectl get rs
NAME                                DESIRED  CURRENT  READY  AGE
apiconnect-a7s-proxy-56c9f975c      3         3         1       9m
apiconnect-apim-v2-55d77df65        3         3         3       2h
apiconnect-client-dl-srv-56cfd98dd5 2         2         0       9m
```

|                                                  |   |   |   |    |
|--------------------------------------------------|---|---|---|----|
| apiconnect-client-dl-srv-6bc7d48477              | 1 | 1 | 1 | 2h |
| apiconnect-juhu-744db85f                         | 2 | 2 | 0 | 9m |
| apiconnect-juhu-744f9cbc89                       | 2 | 2 | 2 | 2h |
| apiconnect-ldap-6c855d4b                         | 2 | 2 | 2 | 2h |
| apiconnect-ldap-d599cb954                        | 2 | 2 | 0 | 9m |
| apiconnect-lur-v2-79556d69c                      | 2 | 2 | 0 | 9m |
| apiconnect-lur-v2-7f97c7b8b5                     | 2 | 2 | 2 | 2h |
| apiconnect-ui-69c8df97                           | 2 | 2 | 0 | 9m |
| apiconnect-ui-84c97657c5                         | 1 | 1 | 1 | 2h |
| cassandra-operator-cassandra-operator-7c88b6b889 | 1 | 1 | 1 | 2h |

8. Verify that the DaemonSets are fulfilled.

For each subsystem run `kubectl get ds` and ensure that the values match for **DESIRED**, **CURRENT**, and **READY**.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Obtaining simple health check data of Developer Portal sites by using a REST API call

Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

### About this task

You can use the site health REST API to determine whether a particular Developer Portal site is running. The site health API returns the current system time of the site if both the database and web server are running. This API is fast and puts no load on the system, so it is ideal for use with load balancers to help them determine where to route traffic.

### Procedure

To call the site health REST API, append `/health` to the end of your Developer Portal site URL in your web browser, as follows:

`site_url/health`

Where `site_url` is the URL of the Developer Portal site that you want to check.

If both the database and web server of the site are running, the web browser returns the current system time. For example:

`1511367695`

If either the database or the web server of the site is not running, the web browser returns an error that the site can't be reached.

If you do get an error from the `/health` endpoint, refer to the [must gather logs page](#) and obtain the `portal-www web` logs, so that you can see more information on the error.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Monitoring the network with SNMP

Presents a table of OID trees that you can poll using SNMP Get.

Note:

- This information applies to API Connect deployments in VMware environments. It does not apply to Kubernetes deployments.
- Only SNMP v2 is supported.
- If the server has two or more network interfaces, the SNMP request is sent only to the first network interface.
- SNMP is enabled by default for all hosts in appliance versions 2018.2.x, 2018.3.x, 2018.4.1.0, 2018.4.1.1 and 2018.4.1.2
- SNMP is disabled by default for all hosts in all other appliance versions.

Simple Network Management Protocol (SNMP) collects information from network devices, such as servers, printers, hubs, switches, and routers on an Internet Protocol (IP). SNMP employs addresses for network devices using a hierarchical numbering system called Object Identifiers (OID). The following table provides OID addresses for polling in SNMP to monitor API Connect servers.

Each entry in the table represents many individual items. Use `snmpwalk` or another SNMP polling utility to see the complete list. You can poll the following OID trees:

Table 1.

| OID            | SNMP Name          | Notes |
|----------------|--------------------|-------|
| .1.3.6.1.2.1.1 | SNMPv2-MIB::system |       |
| .1.3.6.1.2.1.2 | IF-MIB::interfaces |       |
| .1.3.6.1.2.1.4 | IP-MIB::ip         |       |
| .1.3.6.1.2.1.5 | IP-MIB::icmp.      |       |
| .1.3.6.1.2.1.6 | TCP-MIB::tcp       |       |

| OID                  | SNMP Name                     | Notes                                                                                                                                                          |
|----------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| .1.3.6.1.2.1.7       | UDP-MIB::udp                  |                                                                                                                                                                |
| .1.3.6.1.2.1.11      | SNMPv2-MIB::snmp              |                                                                                                                                                                |
| .1.3.6.1.2.1.25.1    | HOST-RESOURCES-MIB::hrSystem  | Excluding .1.3.6.1.2.1.25.1.3 HOST-RESOURCES-MIB::hrSystemInitialLoadDevice<br>Excluding .1.3.6.1.2.1.25.1.4 HOST-RESOURCES-MIB::hrSystemInitialLoadParameters |
| .1.3.6.1.2.1.25.2    | HOST-RESOURCES-MIB::hrStorage |                                                                                                                                                                |
| .1.3.6.1.2.1.25.3    | HOST-RESOURCES-MIB::hrDevice  |                                                                                                                                                                |
| .1.3.6.1.4.1.2021.4  | UCD-SNMP-MIB::memory          |                                                                                                                                                                |
| .1.3.6.1.4.1.2021.10 | UCD-SNMP-MIB::laTable         | CPU Load Average                                                                                                                                               |
| .1.3.6.1.4.1.2021.11 | UCD-SNMP-MIB::systemStats     |                                                                                                                                                                |

## Enabling SNMP

Enable SNMP on each individual OVA node with the following commands from an OVA shell prompt as root:

```
systemctl start snmpd
systemctl enable snmpd
```

Sample output:

```
root@mgmt:~# systemctl start snmpd
root@mgmt:~# systemctl enable snmpd
snmpd.service is not a native service, redirecting to systemd-sysv-install
Executing /lib/systemd/systemd-sysv-install enable snmpd
insserv: warning: current start runlevel(s) (empty) of script `snmpd' overrides LSB defaults (2 3 4 5).
insserv: warning: current stop runlevel(s) (0 1 2 3 4 5 6) of script `snmpd' overrides LSB defaults (0 1 6).
```

## Disabling SNMP

Disable SNMP on each individual OVA node with the following commands from an OVA shell prompt as root:

```
systemctl stop snmpd
systemctl disable snmpd
```

Sample output:

```
root@mgmt:~# systemctl stop snmpd
root@mgmt:~# systemctl disable snmpd
snmpd.service is not a native service, redirecting to systemd-sysv-install
Executing /lib/systemd/systemd-sysv-install disable snmpd
insserv: warning: current start runlevel(s) (empty) of script `snmpd' overrides LSB defaults (2 3 4 5).
insserv: warning: current stop runlevel(s) (0 1 2 3 4 5 6) of script `snmpd' overrides LSB defaults (0 1 6).
```

## Checking SNMP status

Check whether SNMP is enabled on each individual OVA node with the following commands from an OVA shell prompt:

```
systemctl status snmpd
```

Sample output when SNMP is enabled and running:

```
apicadm@mgmt:~$ systemctl status snmpd
snmpd.service - LSB: SNMP agents
  Loaded: loaded (/etc/init.d/snmpd; bad; vendor preset: enabled)
  Active: active (running) since Wed 2019-02-06 03:53:02 UTC; 2 days ago
    Docs: man:systemd-sysv-generator(8)
   Tasks: 1
  Memory: 6.0M
     CPU: 3min 1.641s
  CGroup: /system.slice/snmpd.service
          └─1366 /usr/sbin/snmpd -Lsd -lf /dev/null -u snmp -g snmp -I -smux mteTrigger mteTriggerConf -p /run/snmpd.pid
...

```

Sample output when SNMP is stopped and disabled:

```
root@mgmt:~# systemctl status snmpd
snmpd.service - LSB: SNMP agents
  Loaded: loaded (/etc/init.d/snmpd; bad; vendor preset: enabled)
  Active: inactive (dead)
    Docs: man:systemd-sysv-generator(8)
...

```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Gathering logs for a VMware environment

The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.

## Before you begin

You can download the `generate_postmortem.sh` script directly to the OVA. If the OVA does not have internet access, first download the script to another machine and then transfer it to the OVA.

## About this task

When contacting IBM Support, several logs are required to assist in troubleshooting or diagnostics. The `generate_postmortem.sh` script gathers all the required logs using a single shell script.

## Procedure

1. Connect to the target appliance via SSH then switch to the `root user` with the following commands:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Download the `generate_postmortem.sh` script. Enter the following command:

```
curl -o generate_postmortem.sh https://raw.githubusercontent.com/ibm-apiconnect/v2018-
postmortem/master/generate_postmortem.sh
```

3. Add execute permissions to the `generate_postmortem.sh` script. Enter the following command:

```
chmod +x generate_postmortem.sh
```

4. Run the postmortem tool using the following command:

```
./generate_postmortem.sh --ova --pull-appliance-logs
```

5. (Optional) Currently, log generation is supported for Portal and Management subsystems. Specify either management or portal, or all subsystems. Enter the following arguments:

```
Portal: ./generate_postmortem.sh --ova --diagnostic-portal --pull-appliance-logs
Management: ./generate_postmortem.sh --ova --diagnostic-manager --pull-appliance-logs
```

6. (Optional) If there are errors when running the `generate_postmortem.sh` script, enter the following command:

```
./generate_postmortem.sh --ova --debug &>debug.log
```

Note: Offboarding the logs to an external server is the recommended best practice for long term storage of log data. See [Configuring remote logging for a VMware deployment](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Changing logging levels

You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

## About this task

For apim-v2 pods in Version 2018.4.1.9 or later, the default logging settings do not include entry and exit trace and logging of large payloads.

Logging of large payloads is typically needed if you are logging `apim:webhookPayload` or other processes that log large variables.

You can also set the debug level without needing to restart the pods.

You can enable the settings through either the APIM deployment YAML file, the toolkit, or the REST APIs. Note, you must use the toolkit or REST API to set the debug level without restarting the pods.

## Procedure

- Updating the settings in the APIM deployment YAML file

Note: This action causes a pod restart.

- The DEBUG variable works the same as prior releases.

```
- env:
  - name: DEBUG
    value: audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:audit,bhendi:webhookAudit,bhendi:cassandra-
transactions,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*,apim:webhook:audit,apim:taskma
nager:info
```

To enable entry and exit trace, add `trace:*` to the start of the debug string:

```
- env:
  - name: DEBUG
    value: trace:*,audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:audit,bhendi:webhookAudit,bhendi:cassandra-
```

```
transactions, apim:server, apim:error, apim:routes:*, apim:routesc:*, apim:oidc, apim:oidc:*, apim:webhook:audit, apim:taskmanager:info
```

- o To enable large object logging:

```
- env:  
  - name: VELOX_LOG_FULL_PAYLOAD  
    value: "true"
```

- Updating the settings by using the toolkit

Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

```
apic log-spec:get  
apic log-spec:update LOG_SPEC_FILE
```

Where the spec file contains:

```
{"specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}
```

- Updating the settings by using the REST API

Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

```
GET /cloud/api/log-spec  
PUT /cloud/api/log-spec
```

For example, to set debug level and large objects logging:

```
curl -k https://172.16.140.212:3003/api/cloud/log-spec -X PUT -H "Authorization: Bearer $BEARER"  
-H "Accept: application/json" -d '{"specification":  
"apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}'  
-H "Content-Type: application/json"
```

The command responds with:

```
{  
  "specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error",  
  "large_objects": true,  
  "message": "Successfully changed the log specification on all apim-v2 pods. Success on IP(s): 172.16.140.212,  
172.16.140.213"  
}
```

Note: The response might include the following warning, which can be ignored:

```
WARNING: Could not change the log specification on all apim-v2 pods. Success on IP(s): 4.5.6.7 Failed on IP(s): 1.2.3.4
```

To view the REST APIs for logging, go to [API Connect REST APIs](#), and select IBM API Connect Platform - Cloud Management API 2.0.0 reference\_>\_Resource: Log Spec.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## IBM Cloud Private

Use the instructions in this section to install, upgrade, and maintain API Connect on IBM Cloud Private.

- [Installing and upgrading on IBM Cloud Private](#)  
Use these instructions to install or upgrade a deployment of API Connect on IBM Cloud Private.
- [Backing up and restoring an IBM Cloud Private catalog deployment](#)  
You can back up and restore the API Connect Management subsystem and Portal subsystem on IBM Cloud Private.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

- [Deploying to an IBM Cloud Private environment](#)  
When you deploy IBM® API Connect to an IBM Cloud Private environment, you have the flexibility of accessing a cloud-based product and the added security of an on-premises product. Depending on the version of IBM Cloud Private, you can use the IBM Cloud Private catalog installation or the Install Assist installation method.
- [Installing the toolkit](#)
- [Upgrading with IBM Cloud Private Catalog](#)  
You can update an API Connect deployment with the IBM Cloud Private Catalog.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
 For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

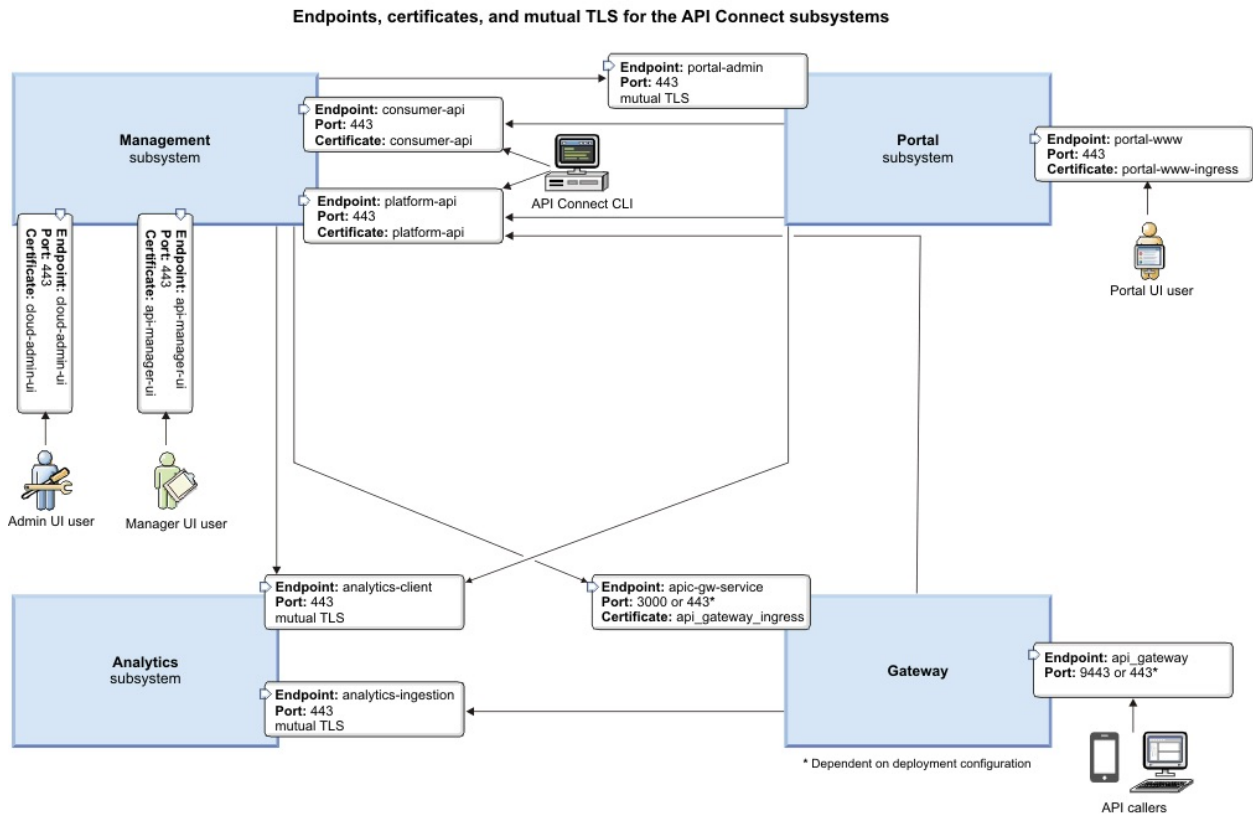

## Deployment overview for endpoints and certificates

Refer to this diagram to view the connections and dataflow among the API Connect subsystems, including the endpoints and custom certificates, and the mutual TLS points.

### Introduction

When deploying API Connect, you will create one or more endpoints for the subsystems and then configure certificates or mutual TLS for most endpoints. [Figure 1](#) shows the endpoints for each subsystem by name, the name of the certificate that secures the endpoint, and whether mutual TLS is required. It also shows the ports consumed by the endpoints, which are standard for HTTP and HTTPS.

Figure 1. Deployment Overview diagram

### Configuring endpoints

The endpoints are configured by the Install Assist program using the APICUP installer. They are set for each subsystem. Endpoints are also entered when configuring the Topology for the Gateway, Portal, and Analytics subsystems in Cloud Manager.

Instructions for installing into an IBM Cloud Private environment are here: [Deploying to an IBM Cloud Private environment](#).

| Subsystem  | Endpoints        | Description                                                                                                                                        | Certificates       |
|------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| Management | cloud-admin-ui   | Configured using APICUP installer. Endpoint on the management server for communication with the Cloud Manager user interface.                      | cloud-admin-ui     |
|            | api-manager-ui   | Configured using APICUP installer. API Manager URL endpoint on the management server for communication with the API Manager user interface.        | api-manager-ui     |
|            | consumer-api     | Configured using APICUP installer. Platform REST API endpoint for running consumer APIs on the management server.                                  | consumer-api       |
|            | platform-api     | Configured using APICUP installer. Platform REST API endpoint for running admin and provider APIs on the management server.                        | platform-api       |
| Portal     | portal-admin     | Configured using APICUP installer. Corresponds to Management Endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS. | mutual TLS         |
|            | portal-www       | Configured using APICUP installer. Portal Web site URL entered in Cloud Manager. Used publicly to access Portal.                                   | portal-www-ingress |
| Analytics  | analytics-client | Configured using APICUP installer. Corresponds to Management Endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS. | mutual TLS         |

| Subsystem | Endpoints           | Description                                                                                                                                                                                  | Certificates            |
|-----------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
|           | analytics-ingestion | Configured using APICUP installer. The analytics-ingestion endpoint is used by the Gateway service to push data to the Analytics service. Requires a TLS profile configured with mutual TLS. | mutual TLS              |
| Gateway   | apic-gw-service     | Configured using APICUP installer. This is the endpoint the gateway uses for network communication. Enter this endpoint as the Management Endpoint entered in Cloud Manager.                 | apic-gw-service-ingress |
|           | api-gateway         | Configured using APICUP installer. This is the endpoint the gateway uses for API traffic. Enter this endpoint as the API Invocation Endpoint in Cloud Manager.                               | api-gateway-ingress     |

## Configuring certificates

The certificates are configured by the Install Assist program using the APICUP installer. The certificates for the endpoints are usually configured as custom certificates as described in [Setting custom certificates](#).

## Configuring mutual TLS

Mutual TLS is configured for TLS profiles in Cloud Manager. See [Creating a TLS Server Profile](#).

## Configuring a proxy

If a Developer Portal is deployed externally to the management server zone, it does not have access to the consumer and product APIs. You need to configure a proxy to enable communication. For more information, see [Configuring a proxy](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Deploying to an IBM Cloud Private environment

When you deploy IBM® API Connect to an IBM Cloud Private environment, you have the flexibility of accessing a cloud-based product and the added security of an on-premises product. Depending on the version of IBM Cloud Private, you can use the IBM Cloud Private catalog installation or the Install Assist installation method.

- **Deploying with the IBM Cloud Private catalog**  
When you deploy IBM API Connect into the IBM Cloud Private Version 3.1.0 or later, you can use the IBM Cloud Private catalog deployment.
- **Deploying with the Install Assist tool**  
You can deploy IBM API Connect into any version of the IBM Cloud Private environment by using the Install Assist method.
- **Migrating an IBM Cloud Private catalog install to apicup**  
You can migrate an IBM Cloud Private installation that was done through the ICP catalog to an Install Assist (**apicup**) installation.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Deploying with the IBM Cloud Private catalog

When you deploy IBM® API Connect into the IBM Cloud Private Version 3.1.0 or later, you can use the IBM Cloud Private catalog deployment.

## Before you begin

This procedure lists the steps to install using the IBM Cloud Private catalog installation. If you want to install using the API Connect Install Assist method, see [Deploying with the Install Assist tool](#).

To install API Connect in the IBM Cloud Private environment by using the IBM Cloud Private catalog method, you must have the following items:

- The IBM Cloud Private environment installed on your server or servers. See [IBM® Cloud Private v3.1.0 documentation](#) in the IBM Cloud Private documentation for additional information about how to install IBM Cloud Private.
- The IBM Cloud Private CLI. See [Installing the IBM Cloud Private CLI](#).
- Access to IBM Fix Central so you can download the latest version of the following files that you have purchased:
  - IBM API Connect Enterprise Production V2018.x for IBM Cloud Private
  - IBM API Connect Professional Production V2018.x for IBM Cloud Private

These packages contain the files that are required for the installation, and the Helm chart for the product.
- Authentication to your IBM Cloud Private Docker registry. See [Configuring authentication for the Docker CLI](#) for the required steps.
- A configured Helm CLI. See [Setting up the Helm CLI](#) for the procedure.
- Ensure you have supported software requirement versions. See [IBM API Connect Version 2018 software product compatibility requirements](#).

Note: For installation and upgrade prerequisites, configuration instructions, and changes between releases, refer to the Helm chart README and Release Notes in the IBM Cloud Private catalog entry for API Connect.

## About this task

IBM Cloud Private provides an environment based on Kubernetes and Docker where you can host API Connect on a local cluster. Members with access to the cluster can use the service by subscribing to it.

Important: For a CP4I or ICP catalog installation, the certificate secret files are required to restore the database and to upgrade your deployment. These files are located in the operator pod. Both files should be exported as Kubernetes secrets and, along with the apiconnect-up.yml file, backed up to a secure and permanent location from where they can always be retrieved. See step 14 for more details.

## Procedure

1. Download and extract the zip file from IBM Fix Central that corresponds to the product that you purchased from [Passport Advantage®](#).

The package names are:

- IBM API Connect Enterprise Production V2018.x for IBM Cloud Private
- IBM API Connect Professional Production V2018.x for IBM Cloud Private

2. Log in to the CLI of your IBM Cloud Private cluster by entering the following command:

```
cloudctl login -a https://cluster_ip:8443 --skip-ssl-validation
```

Where *cluster\_ip* is the IP address or fully-qualified URL and port number of your IBM Cloud Private cluster environment.

3. Create a Helm TLS secret containing base64-encoded **ca.pem**, **cert.pem**, and **key.pem** artifacts.

For example, you can use the following command on a single line:

```
kubectl create secret generic helm-tls-secret \
  --from-file=cert.pem=$HOME/.helm/cert.pem \
  --from-file=ca.pem=$HOME/.helm/ca.pem \
  --from-file=key.pem=$HOME/.helm/key.pem \
  --namespace=<TARGET_NAMESPACE>
```

If you are deploying to the **default** namespace, the **--namespace** parameter is not needed. If you are deploying to any other namespace, you must specify **--namespace** or else the install will fail. The APIC operator pod reads secrets from the namespace it is deployed into.

4. Create a Docker registry secret.

This is a secret for an ICP registry where APIC build images are held.

```
kubectl create secret docker-registry <name> \
  --docker-server=registry \
  --docker-username=user \
  --docker-password=password \
  --namespace=TARGET_NAMESPACE
```

5. Log in to the cluster's Docker registry by entering the following command:

```
docker login cluster_ip:8500
```

6. Import the API Connect image archives into IBM Cloud Private by entering the following command for each image archive type that is not installed:

```
cloudctl catalog load-archive --archive image_archive_filename
```

Where *image\_archive\_filename* is one of the following file names, depending on which version of API Connect for IBM Cloud Private you purchased:

- ibm-apiconnect-ent.tgz
- ibm-apiconnect-pro.tgz

7. From the IBM Cloud Private management console, select Menu > Manage > Helm Repositories.

8. Select Sync Repositories.

The catalog is updated with the imported API Connect Helm chart.

9. Select the Catalog menu to view the list of Helm charts, and select your API Connect Helm chart.

Depending on which catalog you purchased, the Helm chart has one of the following names:

ibm-apiconnect-ent

This is the chart for the Enterprise edition.

ibm-apiconnect-pro

This is the chart for the Professional edition.

10. Select Configure to view and update the configuration settings for the Helm chart. Refer to the following table for endpoint mapping for the ICP Helm Chart:

| Endpoint created using APICUP installer | Endpoint created in ICP Helm chart with Helm CLI | Endpoint in the ICP UI       |
|-----------------------------------------|--------------------------------------------------|------------------------------|
| api-manager-ui                          | management.apiManagerUiEndpoint                  | Platform API Endpoint        |
| cloud-admin-ui                          | management.cloudAdminUiEndpoint                  | Cloud Admin UI Endpoint      |
| consumer-api                            | management.consumerApiEndpoint                   | Consumer API Endpoint        |
| platform-api                            | management.platformApiEndpoint                   | API Manager UI Endpoint      |
| portal-admin                            | portal.portalDirectorEndpoint                    | Portal Director Endpoint     |
| portal-www                              | portal.portalWebEndpoint                         | Portal Web Endpoint          |
| analytics-client                        | analytics.analyticsClientEndpoint                | Analytics Client Endpoint    |
| analytics-ingestion                     | analytics.analyticsIngestionEndpoint             | Analytics Ingestion Endpoint |
| api-gateway                             | gateway.apiGatewayEndpoint                       | API Gateway Endpoint         |
| apic-gw-service                         | gateway.gatewayServiceEndpoint                   | Gateway Service Endpoint     |

Important: Endpoints cannot change with upgrade or restore procedures.

11. Update the configuration values for the chart. Refer to the README file and the tool tips that are provided on the fields for additional information about the correct settings.

12. Perform the following actions to configure backup and restore credentials after installation or upgrade:

- a. Execute the following command:

```
kubectl edit apiconnectcluster release_name-apic-cluster --namespace release_namespace
```

- b. Ensure the following parameters are present and correct under the "settings" section of the Management subsystem specification:

The parameters are as follows:

| Parameter                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cassandra-backup-protocol</code>  | The backup protocol. Specify one of the following values: <ul style="list-style-type: none"> <li><code>sftp</code> - for secure file transfer protocol</li> <li><code>objstore</code> - for S3 compatible object storage</li> </ul> Note: <ul style="list-style-type: none"> <li>For the management subsystem, IBM Cloud and Amazon Web Services (AWS) are supported S3 object store providers.</li> <li>The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: <code>x509: certificate signed by unknown authority</code>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>cassandra-backup-path</code>      | The full path to the directory where the backup files will be stored. This must point to a directory on the backup server. For object storage ( <code>objstore</code> ), the path can be set to the <code>bucket</code> value or the <code>bucket/subfolder</code> value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>cassandra-backup-host</code>      | The fully qualified domain name of the backup server. Ensure that the Kubernetes nodes can access this host. If using object store, enter <code>Endpoint/Region</code> . (The <code>/</code> character between the endpoint and region are required for this setting.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>cassandra-backup-port</code>      | The port for the protocol to connect to the <code>cassandra-backup-host</code> . The backup port is not required for object storage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>cassandra-backup-schedule</code>  | Cron like schedule for performing automatic backups. The format for the schedule is: <ul style="list-style-type: none"> <li><code>*****</code></li> <li><code>-----</code></li> <li><code>     </code></li> <li><code>     +-----</code> day of week (0 - 6) (Sunday=0)</li> <li><code>   +-----</code> month (1 - 12)</li> <li><code>  +-----</code> day of month (1 - 31)</li> <li><code> +-----</code> hour (0 - 23)</li> <li><code>+-----</code> min (0 - 59)</li> </ul> The backup schedule defaults to <code>0 0 * * *</code> . This means a backup is run every day at midnight and minute zero. The timezone for backups is UTC.  When you configure a host, if you do not specify a value for <code>cassandra-backup-schedule</code> , the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed.  Note: Cassandra <code>repair</code> cron schedule is set to <code>00 1 * * 0,2,4,6</code> . This means the repair runs at 01:00 on Sunday, Tuesday, Thursday, and Saturday. By default, the Cassandra <code>backup</code> cron schedule should not run within one hour of the repair cron schedule. Please make sure to modify the current backup configuration as needed. If backups and repairs run at the same time, backup processes can fail intermittently. |
| <code>cassandra-backup-auth-user</code> | The username for the server specified in <code>cassandra-backup-host</code> . If using object store, this would be the S3 Secret Key ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>cassandra-backup-auth-pass</code> | The password for the server specified in <code>cassandra-backup-host</code> . If using object store, this would be the S3 Secret Access Key parameter. The password will be stored in Base64 encoded format. For example: <pre>apicup subsys set mgmt cassandra-backup-auth-pass '&lt;password&gt;'</pre> Note that you cannot use the <code>`</code> sign to assign the password to <code>cassandra-backup-auth-pass</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

For example:

```
cassandra-backup-protocol: sftp
cassandra-backup-host: mybackuphost.com
cassandra-backup-port: 22
cassandra-backup-path: /backups
cassandra-backup-schedule: 0 0 * * *
cassandra-backup-auth-user: myusername
cassandra-backup-auth-pass: mypassword
```

c. Ensure the following parameters are present and correct under the **settings** section of the Portal subsystem specification:

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>site-backup-host</code>      | The fully qualified domain name of the backup server, in lowercase only. Ensure that the Kubernetes nodes can access this host. If using object storage, enter <code>Endpoint/Region</code> . (The <code>/</code> character between the endpoint and region is required for the object storage setting.)                                                                                                                                                                                                                                                                                                                     |
| <code>site-backup-port</code>      | The port for the protocol to connect to the <code>site-backup-host</code> . Defaults to <code>22</code> if not explicitly set. The backup port is not required for object storage.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>site-backup-auth-user</code> | The user name for the server specified in <code>site-backup-host</code> . If using object storage, the user name is the S3 Secret Key ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>site-backup-auth-pass</code> | The password for the server specified in <code>site-backup-host</code> . If using object storage, the password is the S3 Secret Access Key parameter. The password is stored in Base64 encoded format, and must not be edited directly in the <code>apiconnect-up.yml</code> file.                                                                                                                                                                                                                                                                                                                                           |
| <code>site-backup-path</code>      | The full path to the directory where the backup files are stored. For object storage, the path can be set to the <code>bucket</code> value or the <code>bucket/subfolder</code> value.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>site-backup-protocol</code>  | The protocol that is used to communicate with your remote backup endpoint. Specify one of the following values: <ul style="list-style-type: none"> <li><code>sftp</code> - for secure file transfer protocol</li> <li><code>objstore</code> - for S3 compatible object storage</li> </ul> The default protocol is <code>sftp</code> . Note: The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: <code>x509: certificate signed by unknown authority</code> . |

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>site-backup-schedule</code> | <p>The schedule for how often automatic Portal backups are run. The format for the schedule is any valid cron string, as follows:</p> <pre>* * * * * - - - - -                   +----- day of week (0 - 6) (Sunday=0)       +----- month (1 - 12)     +----- day of month (1 - 31)   +----- hour (0 - 23) +----- min (0 - 59)</pre> <p>For example: <code>30 22 * * 1</code> performs backups at 10:30 pm on Mondays.<br/>The default backup schedule is <code>0 2 * * *</code> (runs every day at 2 am). The timezone for backups is UTC.</p> |

For example:

```
site-backup-host: mybackuphost.com
site-backup-port: 22
site-backup-auth-user: mybackupauthusername
site-backup-auth-pass: mybackupauthpassword
site-backup-path: /site-backups
site-backup-protocol: sftp
site-backup-schedule: "0 2 * * *"
```

d. Save the resource.

e. Wait for upgrade jobs to complete.

13. For DataPower Gateway version 2018.4.1.4 and higher, you may need to set the license version for use with the IBM License Metric Tool (ILMT). The license version must match the image that you are installing. If you are changing images, you may need to reset the license version to match your image. The options for the license version are: Developers, Production, and Non-Production. For more information about ILMT, see the [IBM License Metric Tool](#) documentation.

14. Export the certificates that are generated with Install Assist (`apicup`) by completing the following steps:

a. Get a shell to the `apiconnect-operator` pod by running the following command:

```
kubectl exec -it operator_pod_name -- /bin/bash
```

b. Generate the secrets by running the following command for each certificate:

```
kubectl create secret generic secret_name --from-file=apicup_secret_file -n namespace
```

15. Store the secrets from step 14, plus the `apiconnect-up.yml` file, in a secure and permanent location from where they can always be retrieved.

## What to do next

Continue your configuration by:

- Setting up the Cloud Manager, starting with [Accessing the cloud console user interface](#)
- To execute backup and restore commands, get a shell to the `apiconnect-operator` pod with

```
kubectl exec -it operator_pod_name -- /bin/bash
```

and then follow the instructions in the [Backing up and restoring](#) section.

Attention: Helm TLS certificates expire after 90 days. To refresh this certificate in the `apiconnect-operator` pod, delete the Helm TLS secret, follow steps 2 and 3 to regenerate the certificate and recreate the secret, and then restart the pod.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Deploying with the Install Assist tool

You can deploy IBM® API Connect into any version of the IBM Cloud Private environment by using the Install Assist method.

### Before you begin

This procedure lists the steps to install using the Install Assist tool. If you want to install using the IBM Cloud Private catalog method, see [Deploying with the IBM Cloud Private catalog](#).

To deploy API Connect in the IBM Cloud Private environment by using the IBM Cloud Private Install Assist method, you must have the following items:

- The IBM Cloud Private environment installed on your server or servers. See [IBM® Cloud Private v3.1.0 documentation](#) in the IBM Cloud Private documentation for additional information about how to install IBM Cloud Private.
- The IBM Cloud Private CLI. See [Installing the IBM Cloud Private CLI](#) in the IBM Cloud Private documentation for information about installing the CLI.
- Authentication to your IBM Cloud Private Docker registry. See [Configuring authentication for the Docker CLI](#) for the required steps.
- A configured Helm CLI. See [Setting up the Helm CLI](#) for the procedure.
- Ensure you have supported software requirement versions. See [IBM API Connect Version 2018 software product compatibility requirements](#).

### About this task

IBM Cloud Private provides an environment based on Kubernetes and Docker where you can host API Connect on a local cluster. Members with access to the cluster can use the service by subscribing to it.

## Procedure

1. Obtain the appropriate installation files described in [First steps for installing API Connect: Upload files to registry](#).
2. Login to the CLI of your IBM Cloud Private cluster by entering the following command:  
`cloudctl login -a https://<cluster_ip>:8443` where `cluster_ip` is the IP address or fully-qualified URL and port of your IBM Cloud Private cluster environment.
3. Login to the cluster's Docker registry by entering the following command: `docker login cluster_ip:8500`
4. Follow the registry upload steps described in [First steps for installing API Connect: Upload files to registry](#). Substitute `<cluster_ip>:8500/<namespace>` for `<registry_host>`.
5. For IBM Cloud Private versions 2.1.0.2, and later: Create a wrapper script named `helm` in your `usr/local/bin` directory that refers to your Helm CLI and appends `--tls` to the end of the Helm commands that are run by Install Assist.  
An example of this wrapper script follows:

```
#!/bin/bash
/usr/local/bin/helm $@ --tls
```

Note: The `HELM_HOME` environment variable must be set to the location where `ca.pem`, `cert.pem`, and `key.pem` were created in step 3 of [Deploying with the IBM Cloud Private catalog](#).

6. If installing on IBM Cloud Private version 3.1.1 or later, a PodSecurityPolicy must be bound to the target namespace(s) prior to installation. Choose either a predefined PodSecurityPolicy or have your cluster administrator set up a custom PodSecurityPolicy:

- Predefined PodSecurityPolicy name: `ibm-anyuid-hostpath-psp`
- Custom PodSecurityPolicy definition:

```
apiVersion: extensions/v1beta1
kind: PodSecurityPolicy
metadata:
  annotations:
    kubernetes.io/description: "This policy allows pods to run with
      any UID and GID and any volume, including the host path.
      WARNING: This policy allows hostPath volumes.
      Use with caution."
  name: ibm-anyuid-hostpath-psp
spec:
  allowPrivilegeEscalation: true
  fsGroup:
    rule: RunAsAny
  requiredDropCapabilities:
  - MKNOD
  allowedCapabilities:
  - SETPCAP
  - AUDIT_WRITE
  - CHOWN
  - NET_RAW
  - DAC_OVERRIDE
  - FOWNER
  - FSETID
  - KILL
  - SETUID
  - SETGID
  - NET_BIND_SERVICE
  - SYS_CHROOT
  - SETFCAP
  runAsUser:
    rule: RunAsAny
  seLinux:
    rule: RunAsAny
  supplementalGroups:
    rule: RunAsAny
  volumes:
  - '*'
```

- Custom Cluster Role for the custom PodSecurityPolicy:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  annotations:
    name: ibm-anyuid-hostpath-clusterrole
rules:
- apiGroups:
  - extensions
  resourceNames:
  - ibm-anyuid-hostpath-psp
  resources:
  - podsecuritypolicies
  verbs:
  - use
```

7. For DataPower Gateway version 2018.4.1.4 and higher, you may need to set the license version for use with the IBM License Metric Tool (ILMT). For a new installation, the license version must match the image that you are installing. If you are changing images or upgrading, you may need to reset the license version to match your image. For more information about ILMT, see the [IBM License Metric Tool](#) documentation.
  - a. To set the license, enter the following command when installing the Gateway subsystem: `apicup subsys set gwy license-version <license>` where `license` is one of `Developers`, `Production`, or `Nonproduction`.
8. Install API Connect using the instructions that are provided at [Deploying to a Kubernetes environment](#).

## What to do next

Continue your configuration by setting up the Cloud Manager, starting with [Accessing the cloud console user interface](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Migrating an IBM Cloud Private catalog install to apicup

You can migrate an IBM Cloud Private installation that was done through the ICP catalog to an Install Assist (**apicup**) installation.

### About this task

You can take migration steps and then complete an **apicup** installation. A sample migration script is provided at the end of this topic. The script shows how to do the migration tasks in Step 1 through Step 5 in the following procedure.

### Procedure

1. Create local directories for the **apicup** project and extra values.
2. Copy **apicup** files from operator pod to the local project directory.
3. Copy extra values from the operator pod to the local extra values directory.
4. Update **apiconnect-up.yml** extra values locations to reference the new extra values directory.
5. Scale apiconnect-operator StatefulSet to 0 replicas.
6. Run **apicup subsys list** to verify all subsystems are present and **apicup subsys get <subsystem name>** for any desired additional validation.
7. Follow [Deploying with the Install Assist tool](#) to upgrade.

Note: Depending on the values used for the current analytics and gateway subsystem installations, you may need to add **--no-verify true** to the **apicup subsys install** command.

8. When the subsystems have been successfully upgraded, delete *only the top-level ICP catalog helm release* with

```
helm delete --purge --no-hooks <icp catalog release name>
```

Important: You MUST specify **--no-hooks**. If you omit it, subsystems will be deleted.

Example migration script:

```
#!/bin/bash

APICONNECT_OPERATOR_POD=$(kubectl get pods | grep apiconnect-operator | awk '{print $1}')
APICONNECT_OPERATOR_STATEFULSET=$(kubectl get statefulsets | grep apiconnect-operator | awk '{print $1}')
PROJECT_DIRECTORY=$(pwd)/tmp-apiconnect-project
EXTRA_VALUES_DIRECTORY=$PROJECT_DIRECTORY/extra-values

# create project and extra values directories
mkdir $PROJECT_DIRECTORY

# create list of apicup files to copy
FILES=$(kubectl exec -it $APICONNECT_OPERATOR_POD ls | grep yml | tr -d '\r')

# copy apicup files
echo "copying apicup files to $PROJECT_DIRECTORY local project directory"
for f in $FILES; do
    kubectl cp $APICONNECT_OPERATOR_POD:/home/apic/$f $PROJECT_DIRECTORY/$f
done

# copy extra values
echo "copying extra values files to $EXTRA_VALUES_DIRECTORY"
kubectl exec $APICONNECT_OPERATOR_POD -- tar cf - "extra-values" | tar xf -
mv extra-values $PROJECT_DIRECTORY

# update location for extra values files
sed -i.bak "s#/home/apic/extra-values#$EXTRA_VALUES_DIRECTORY#g" $PROJECT_DIRECTORY/apiconnect-up.yml

# scale apiconnect-operator statefulset to 0 replicas to prevent it from making changes
kubectl scale --replicas=0 statefulset $APICONNECT_OPERATOR_STATEFULSET
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

### About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer user interface.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer user interface.

You can download the toolkit compressed file in either of the following ways:

- From IBM Fix Central.
- From either the Cloud Manager or API Manager user interface.

The following table identifies the name of the compressed file that you need to download, depending on your chosen toolkit option and platform:

Table 1. Toolkit file names, by option and platform

| Toolkit option            | Mac OS X                          | Linux®                              | Windows                               |
|---------------------------|-----------------------------------|-------------------------------------|---------------------------------------|
| CLI                       | toolkit-mac.zip                   | toolkit-linux.tgz                   | toolkit-windows.zip                   |
| CLI + LoopBack + Designer | toolkit-loopback-designer-mac.zip | toolkit-loopback-designer-linux.tgz | toolkit-loopback-designer-windows.zip |

## Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.

- To download the toolkit from IBM Fix Central, complete the following steps:
  - Open the [IBM Fix Central site](#) in your browser.
  - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
  - Select your installed 2018.x.y version from the Installed Version list, then click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
  - In the Text field, enter `toolkit`, then click Continue.
  - Select the required file, as identified in [Table 1](#).
  - Note: When you download from IBM Fix Central, the release number is appended to the file name.
  - Click Continue, then follow the instructions to complete the download operation.
- To download the toolkit from either the Cloud Manager or API Manager user interface, complete the following steps:
  - Cloud Manager or API Manager user interface.
  - Select Help ( ? ) in the navigation.
  - Select Install API Connect CLI & API Designer.
  - Select CLI or CLI + LoopBack + Designer according to your preferred option.
  - Select your platform to download the toolkit compressed file.
  - Close the Install API Connect CLI & API Designer window.

2. Extract the contents of the toolkit compressed file to a folder of your choice.

The contents of the file depend on the your chosen toolkit option and platform, as follows:

Table 2. Toolkit compressed file contents, by option and platform

| Toolkit option            | Mac OS X                                                                            | Linux                      | Windows                          |
|---------------------------|-------------------------------------------------------------------------------------|----------------------------|----------------------------------|
| CLI                       | apic-slim                                                                           | apic-slim                  | apic-slim.exe                    |
| CLI + LoopBack + Designer | apic<br>api_designer-mac.zip: contains the API Designer user interface application. | apic<br>api_designer-linux | apic.exe<br>api_designer-win.exe |

The `apic-slim` or `apic-slim.exe` file is the CLI for IBM API Connect.

The `apic` or `apic.exe` file is the CLI for IBM API Connect including LoopBack support.

Tip: If you are using the CLI option, then if you rename the `apic-slim` file to `apic`, or the `apic-slim.exe` file to `apic.exe`, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.

The `api_designer-platform` file is the API Designer user interface application for the specified platform.

3. Run the CLI.

- For the Mac OS X or Linux platforms, complete the following steps:
  - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
  - Make the CLI file an executable file by entering the following command:

```
chmod +x download_name
```

Where `download_name` is the name of the toolkit file that you downloaded, either `apic` or `apic-slim`.

- Run CLI commands as follows:

```
./apic command_name_and_parameters
```

or

```
./apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

- For the Windows platform, complete the following steps:
  - Open a terminal window and navigate to the folder where you extracted the contents of the toolkit compressed file.
  - Run CLI commands as follows:

```
apic command_name_and_parameters
```

or

```
apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.

4. Launch the API Designer user interface by running the application from the location to which you extracted the contents of the toolkit compressed file.

Note:

- To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
  - In Windows File Explorer, navigate to the USER\_HOME\AppData\Local\Programs\api-designer folder.
  - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
- To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

## Results

---

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see [Developing your APIs and applications](#).

For information on using the toolkit CLI, see [Using the developer toolkit command-line tool](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Upgrading with IBM Cloud Private Catalog

You can update an API Connect deployment with the IBM® Cloud Private Catalog.

Use the instructions for your version of API Connect

- You can upgrade API Connect Version 2018.3.7 to API Connect Version 2018.4.1 with the IBM Private Cloud Catalog. See [Upgrading Version 2018.3.7 with the IBM Private Cloud Catalog](#).
- You can upgrade from API Connect Version 2018.4.1 to a later version of API Connect with the IBM Cloud Private Catalog. See [Upgrading from Version 2018.4.1 with the IBM Cloud Private Catalog](#).
- [Upgrading from Version 2018.4.1 with the IBM Cloud Private Catalog](#)  
You can upgrade from API Connect Version 2018.4.1 to a later version of API Connect with the IBM Cloud Private Catalog.
- [Upgrading Version 2018.3.7 with the IBM Private Cloud Catalog](#)  
You can upgrade API Connect Version 2018.3.7 to API Connect Version 2018.4.1 with the IBM Private Cloud Catalog.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Upgrading from Version 2018.4.1 with the IBM Cloud Private Catalog

You can upgrade from API Connect Version 2018.4.1 to a later version of API Connect with the IBM Cloud Private Catalog.

### Before you begin

---

Warning: If you are upgrading from IBM® API Connect Version 2018.4.1.0 or 2018.4.1.1 to a later release and you want to retain existing analytics data, you must take an analytics backup before upgrade.

Note: For installation and upgrade prerequisites, configuration instructions, and changes between releases, refer to the Helm chart README and Release Notes in the IBM Cloud Private catalog entry for API Connect.

### Procedure

---

1. Export certificate secrets. To do so, get a shell to the `apiconnect-operator` pod with:

```
kubectl exec -it <operator pod name> -- /bin/bash
```

and run the following command for each .yml file in the working directory:

```
kubectl create secret generic <secret name> --from-file=<apicup secret file> -n <namespace>
```

2. Specify each secret name for its respective subsystem during upgrade. The common certificates secret should be specified in the `global` values configuration.  
3. Follow the upgrade procedures for a Kubernetes deployment. See [Upgrading API Connect in a Kubernetes environment](#).

### What to do next

---

For DataPower Gateway version 2018.4.1.4 and later releases, you may need to set the license version for use with the IBM License Metric Tool (ILMT). When using the default gateway image, the license version must match the image that you are installing. If you are changing images or upgrading, you may need to reset the license version to match your image. See [Deploying to an IBM Cloud Private environment](#). For more information about ILMT, see the [IBM License Metric Tool](#) documentation.

Warning: An IBM API Connect deployment that has been upgraded from Version 2018.4.1.0 or 2018.4.1.1 to a later release requires a new installation of the analytics subsystem. After upgrading, run the following commands to allow a new analytics subsystem release be installed:

```
kubectl delete deployments, statefulsets, secrets, jobs, pvc -l release=analytics_subsystem_release
helm delete --purge analytics_subsystem_release
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Upgrading Version 2018.3.7 with the IBM Private Cloud Catalog

You can upgrade API Connect Version 2018.3.7 to API Connect Version 2018.4.1 with the IBM Private Cloud Catalog.

### About this task

You must use the appropriate `apicup` commands to manage certificates and migrate them to `.yaml` files.

### Procedure

1. Download Install Assist (`apicup`) for API Connect v2018.3.7
2. Create a project with `apicup` called `<release_name> -apic-cluster`, where `<release_name>` is the name of the v2018.3.7 IBM Cloud Private Helm release, and set the endpoints to match those of the release.
3. For each certificate type of the installed release (common, analytics, gateway, management, and portal), write the contents of `kubectl get secret <cert_type>-generated-certs` to your local filesystem.
4. For each certificate type of the installed release, create a folder called `<cert_type>-generated-certs`, and for each data entry in each secret obtained in step 3, write the base64-decoded contents to a file whose name matches the entry's key. Copy the folder to the project directory created in step 2.
5. Download Install Assist for API Connect v2018.4.x.
6. Within the project directory create in step 2, run an Install Assist command, such as `apicup subsys get management`. This will migrate the certificates to `.yaml` files.
7. For each file generated in the previous step run:

```
kubectl create secret generic <secret name> --from-file=<apicup secret file> -n <namespace>
```
8. Specify each secret name for its respective subsystem during upgrade. The common certificates secret should be specified in the `global` values configuration.

### What to do next

When upgrading API Connect Version 2018.3.7 to Version 2018.4.1 or later, you should also upgrade DataPower to Version 2018.4.1.x. If you upgrade DataPower from v2018.3.x to v2018.4.x, you must resync the management configuration in order to reset DataPower. See [rapic\\_gw\\_reconfig\\_dyn.html#reference\\_pxx\\_nxf\\_5fb](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Backing up and restoring an IBM Cloud Private catalog deployment

You can back up and restore the API Connect Management subsystem and Portal subsystem on IBM Cloud Private.

Note:

- Backups are intended for recovery of the Management and Portal subsystems onto the same deployment from which they were taken, or onto a new replacement installation in the same environment for disaster recovery. The same environment means the same network configuration and project directory as the original installation. Backups are not designed as a means for migrating an API Connect deployment from one environment to another.
- You must back up both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.
- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- [Backing up and restoring the management database on IBM Cloud Private](#)  
You can back up and restore the API Connect management subsystem on IBM Cloud Private.
- [Backing up and restoring the Developer Portal on IBM Cloud Private](#)  
You can back up and restore the API Connect Developer Portal subsystem on IBM Cloud Private.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Backing up and restoring the management database on IBM Cloud Private

You can back up and restore the API Connect management subsystem on IBM Cloud Private.

### Before you begin

---

Ensure backup parameters are configured. See Step 12 in [Deploying with the IBM Cloud Private catalog](#).

### Procedure

---

- Backing up the management database
  1. Get a shell to the apiconnect-operator pod:

```
kubectl exec -it <operator pod name> -- /bin/bash
```
  2. Edit the `apiconnect-up.yml` file to ensure the backup parameters match that of the `apiconnectcluster` resource edited in Step 12 in [Deploying with the IBM Cloud Private catalog](#).
  3. To execute an on-demand backup for the management subsystem, run the following command:

```
apicup subsys exec management backup
```
- Restoring the management database
  1. To list management subsystem backups, run the following command:

```
apicup subsys exec management list-backups
```
  2. To restore a management subsystem backup, run the following command:

```
apicup subsys exec management restore <backupID>
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Backing up and restoring the Developer Portal on IBM Cloud Private

You can back up and restore the API Connect Developer Portal subsystem on IBM Cloud Private.

### Before you begin

---

Ensure backup parameters are configured. See Step 12 in [Deploying with the IBM Cloud Private catalog](#).

### Procedure

---

- Backing up the Developer Portal
  1. Get a shell to the apiconnect-operator pod:

```
kubectl exec -it <operator pod name> -- /bin/bash
```
  2. Edit the `apiconnect-up.yml` file to ensure the backup parameters match that of the `apiconnectcluster` resource edited in Step 12 in [Deploying with the IBM Cloud Private catalog](#).
  3. To execute an on-demand backup for the portal system configuration, run the following commands:
    - To backup the Portal system configuration (and not the sites), run the following command:

```
apicup subsys exec portal backup-system
```
    - To backup a specific Portal site or all sites, run the following command:

```
apicup subsys exec portal backup-site arg
```

where `arg` is a specific site UUID or URL, or to backup all sites use the argument `installed`.
    - To backup the entire Portal service (the system and all installed sites), run the following command:

```
apicup subsys exec portal backup
```
- Restoring the Developer Portal
  1. To list the portal subsystem system and site backups, run the following command:

```
apicup subsys exec portal list-backups remote
```
  2. To restore a Developer Portal subsystem backup, select from the following commands:
    - To restore your Portal subsystem, run the following command:

```
apicup subsys exec portal restore-all run backup_from
```

where `backup_from` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given. This command executes the portal restore

process, which downloads the system backup and all of the site backups from the remote server, and installs them within the Portal stack. This process will then restore the system configuration from the found backup, and restore all of the sites.

Note: From IBM API Connect Version 2018.4.1.17, the timestamp format changed to **YYYYMMDD.HHMMSS**. For Version 2018.4.1.16 and earlier, the timestamp format is **YYYY-MM-DD HH:MM:SS**.

- To restore just the Portal system configuration, run the following command:

```
apicup subsys exec portal restore-system arg
```

where **arg** can be the system backup tgz file name, to restore the system by using the specified backup file, or use the argument **latest** to restore the system by using the latest backup file on the remote server. Note that if Portal system configuration information exists on the current stack, running this command will overwrite that configuration.

- To restore just the Portal sites, run the following command:

```
apicup subsys exec portal restore-site arg
```

where **arg** can be the site backup tgz file name or URL, to restore a particular site by using the specified backup file (or the latest backup file found if using a URL). Or you can use the argument **all** to restore all of the Portal sites that have backup files on the remote server. Note that if any of the backed up sites are already installed on the current stack, then they are reinstalled by using the backup (the sites are overwritten by the backup).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## OpenShift

You can install API Connect on OpenShift.

- [Installing API Connect on OpenShift](#)  
Installing API Connect in an OpenShift environment is a Kubernetes installation with additional steps.
- [Disabling the Analytics subsystem on OpenShift](#)  
During maintenance of an API Connect cluster, you can shut down the Analytics subsystem by disabling the client, ingestion, and storage microservices so that those processes are not running and there is no way to reach them.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Installing API Connect on OpenShiftIBM®

Installing API Connect in an OpenShift environment is a Kubernetes installation with additional steps.

### Before you begin

Before starting the installation into an OpenShift runtime environment, consider the following information:

- During installation, OpenShift requires the **ingress-type** to be set to **route** for each subsystem, for example, **apicup subsys set SUB\_SYS ingress-type route**.
- If using an OpenShift registry, execute the **oc new-project apiconnect** command to create the apiconnect project prior to uploading the images using the **apicup registry-upload** command.
- SSH access must be disabled for the Gateway. Note that it is disabled by default.
- OpenShift routes do not redirect URLs for the api-manager-ui and cloud-admin-ui endpoints. To open the API Manager and Cloud Manager UIs in an OpenShift environment, the complete URLs for the API Manager and Cloud Manager UIs must be entered in the browser as follows:
  - API Manager user interface: **https://api\_manager\_ui\_endpoint/manager**
  - Cloud Manager user interface: **https://cloud\_admin\_ui\_endpoint/admin**
- On OpenShift, the API Connect management subsystem sets resource requests but does not set resource limits. Limits are not specified so that pods can request the necessary resources. If you choose to modify OpenShift to set resource limits, such as for CPU or memory, you must set the same value in the API Connect extra values YAML file. Ensure that the values in the YAML file match the values you set in OpenShift.  
Note: Setting of resource requests and limits on OpenShift is not supported for the API Connect Analytics subsystem.

### Procedure

1. Create namespaces or a namespace for API Connect. You can create separate namespaces for each subsystem, or place all subsystems in a single namespace. Following is an example for separate namespaces for each subsystem:

```
oc create ns apic-management
oc create ns apic-gateway
oc create ns apic-analytics
oc create ns apic-portal
```

Following is an example for one namespace containing all subsystems:

```
oc create ns apiconnect
```

Following is an example for Management, Portal and Analytics in a one namespace and Gateway in a separate namespace:

```
oc create ns apic-mpa
oc create ns apic-gateway
```

2. Create a registry secret in the namespace where the subsystems will be deployed.

```
oc apply -f <path-to-registry-secret>
```

This secret is referenced in the APICUP installer commands for each subsystem, for example:

```
apicup subsys set SUB_SYS
registry-secret=<registrySecret>
```

Refer to the installation instructions for each subsystem, for example, [Installing the Management subsystem into a Kubernetes environment](#).

3. Install and configure Tiller.

- a. Configure Tiller either globally on the cluster or scoped to a single namespace.

The following example configures Tiller globally on the cluster:

```
oc create ns tiller
export TILLER_NAMESPACE=tiller
oc process -f https://github.com/openshift/origin/raw/master/examples/helm/tiller-template.yaml -p
TILLER_NAMESPACE=${TILLER_NAMESPACE} -p HELM_VERSION=v2.10.0 | oc create -n "${TILLER_NAMESPACE}" -f -
oc create clusterrolebinding tiller-binding --clusterrole=cluster-admin --user=system:serviceaccount:tiller:tiller
```

The following example installs Tiller scoped to a single namespace, where `$(NAMESPACE)` is the namespace for API Connect or the namespace for a specific subsystem:

```
export TILLER_NAMESPACE=$(NAMESPACE)
oc process -f https://github.com/openshift/origin/raw/master/examples/helm/tiller-template.yaml -p
TILLER_NAMESPACE=${TILLER_NAMESPACE} -p HELM_VERSION=v2.10.0 | oc create -n "${TILLER_NAMESPACE}" -f -
oc create rolebinding $(NAMESPACE)-tiller-cluster-admin --clusterrole=cluster-admin --
serviceaccount=$(NAMESPACE):tiller --namespace=$(NAMESPACE)
```

Note: When Tiller is scoped to a single namespace, with OpenShift 4.3, the Tiller account might need additional permissions. Permissions must be updated when you see the following errors:

- Running `apicup subsys install mgmt --debug` returns:

```
no permissions to get CRDs
```

- Running `oc get crd` from the Tiller account returns:

```
Error from server (Forbidden):
customresourcedefinitions.apiextensions.k8s.io is forbidden:
User "system:serviceaccount:apiconnect:tiller" cannot list resource "customresourcedefinitions"
in API group "apiextensions.k8s.io" at the cluster scope
```

To resolve the problem, assign additional permissions to the Tiller account:

```
kind: ClusterRole
apiVersion: rbac.authorization.k8s.io/v1
metadata:
  name: helm-clusterrole
rules:
- apiGroups:
  - ""
  - rbac.authorization.k8s.io
  - roles.rbac.authorization.k8s.io
  - authorization.k8s.io
  - apiextensions.k8s.io
  resources:
  - "clusterroles"
  - "clusterrolebindings"
  - "customresourcedefinitions"
  verbs: ["create", "get", "escalate"]
- apiGroups: [""]
  resources: ["pods"]
  verbs: ["list", "get"]
```

---

```
kind: ClusterRoleBinding
apiVersion: rbac.authorization.k8s.io/v1
metadata:
  name: helm-clusterrolebinding
roleRef:
  kind: ClusterRole
  apiGroup: rbac.authorization.k8s.io
  name: helm-clusterrole
subjects:
- kind: ServiceAccount
  name: tiller
  namespace: {TILLER_APIC_NAMESPACE}
```

Replace `{TILLER_APIC_NAMESPACE}` with the namespace where both Tiller and API Connect are to be deployed.

- b. Update the deployment's Tiller YAML:

Update the YAML. Locate the following statement:

```
image: 'gcr.io/kubernetes-helm/tiller:v2.10.0'
```

And modify it to match the following example:

```
image: 'ghcr.io/helm/tiller:v2.10.0'
```

4. Assign Security Context Constraint (SCC) permissions to Service Accounts. The commands will vary depending upon the namespace configuration and permission level. Following are examples:

Attention: If you plan to install the Analytics subsystem so that data is stored locally (that is, `ingestion-only` is set to `false`, then you must install Analytics into a separate namespace where you can assign the `privileged` level of SCC access to it. See example 2 for more information.

**Example 1:** To assign anyuid access to all Service Accounts in a namespace, enter this command:

```
oc adm policy add-scc-to-group anyuid system:serviceaccounts:<namespace>
```

where `<namespace>` is the API Connect namespace, for example, `apiconnect`, that contains all four subsystems (Management, Gateway, Portal, Analytics). This command assigns anyuid permissions to all subsystems contained in the namespace. For a configuration with all four subsystems in one namespace, anyuid permissions are required because the Gateway requires anyuid.

Note: Use this approach when you install Analytics using the `ingestion-only` configuration.

**Example 2:** To assign anyuid access to the Management, Gateway, and Portal Service Accounts in one namespace, and assign privileged access to the Analytics Service Account in another namespace, enter the following commands:

```
#Assign anyuid access to the Management, Gateway, and Portal Service Accounts:
oc adm policy add-scc-to-group anyuid system:serviceaccounts:<namespace>
```

where `<namespace>` is the API Connect namespace (for example, `apiconnect`) that contains the Management, Gateway, and Portal subsystems. This command assigns anyuid permissions to all subsystems contained in the namespace, so be sure to set up a separate namespace for Analytics.

```
#Assign privileged access to the Analytics Service Account in a different namespace:
oc adm policy add-scc-to-group privileged system:serviceaccounts:<Analytics_namespace>
```

where `<Analytics_namespace>` is the namespace (for example, `analytics`) for the Analytics subsystem.

Note: Use this approach if you will install Analytics using with `ingestion-only` set to `false`. The privileged access level provides much greater access to resources in a namespace, and should only be used where necessary. Since only the Analytics subsystem requires this access level, you should assign the anyuid access level to the remaining subsystems (which requires them to be hosted in a different namespace).

**Example 3:** To assign non-root access to all Service Accounts except the Gateway, create a namespace that contains the Management, Portal and Analytics subsystems. Then create a namespace that contains only the Gateway subsystem. Enter these commands:

```
#Set nonroot permissions for all subsystems (Management, Portal, and Analytics) in the namespace
oc adm policy add-scc-to-group nonroot system:serviceaccounts:<namespace>
```

where `<namespace>` is the namespace that contains the Management, Portal and Analytics subsystems. This assigns nonroot permissions to all subsystems contained in the namespace.

```
#Set anyuid permission for the gateway subsystem
oc adm policy add-scc-to-group anyuid system:serviceaccounts:<namespace>
```

where `<namespace>` is the namespace that contains the gateway subsystem. This assigns anyuid permissions to the gateway.

5. For the DataPower® WebUI setup, depending on whether the default SCC which is installed as part of OpenShift has been modified, assign anyuid access to DAC\_OVERRIDE, SETUID, SETGID, and SYS\_CHGROOT. See the following examples.

**Example 1:** To assign anyuid access to DAC\_OVERRIDE for the gateway subsystem, enter this command:

```
oc adm policy add-scc-to-group anyuid system:dac_override:<namespace>
```

where `<namespace>` is the namespace that contains the gateway subsystem.

**Example 2:** To assign anyuid access to SETUID for the gateway subsystem, enter this command:

```
oc adm policy add-scc-to-group anyuid system:setuid:<namespace>
```

where `<namespace>` is the namespace that contains the gateway subsystem.

**Example 3:** To assign anyuid access to SETGID for the gateway subsystem, enter this command:

```
oc adm policy add-scc-to-group anyuid system:setgid:<namespace>
```

where `<namespace>` is the namespace that contains the gateway subsystem.

**Example 4:** To assign anyuid access to SYS\_CHGROOT for the gateway subsystem, enter this command:

```
oc adm policy add-scc-to-group anyuid system:sys_chgroot:<namespace>
```

where `<namespace>` is the namespace that contains the gateway subsystem.

Note: If you encounter problems assigning Security Context Constraints (SCC) in order to enable the WebUI for DataPower, see the recommendation to create a new SCC: [https://www.ibm.com/mysupport/s/question/0D50z00006RZGPB/apic-2018-gateway-service-error-when-enabling-datapower-web-ui?language=en\\_US](https://www.ibm.com/mysupport/s/question/0D50z00006RZGPB/apic-2018-gateway-service-error-when-enabling-datapower-web-ui?language=en_US).

6. Install the subsystems following the instructions for installing API Connect on Kubernetes. Set the `ingress-type` to `route` for each subsystem, for example, `apicup subsys set SUB_SYS ingress-type route`. See [Installing and upgrading on Kubernetes](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Disabling the Analytics subsystem on OpenShift

During maintenance of an API Connect cluster, you can shut down the Analytics subsystem by disabling the client, ingestion, and storage microservices so that those processes are not running and there is no way to reach them.

## About this task

Disabling the Analytics subsystem stops the collection and storage of data as well as making the subsystem unavailable. When you disable Analytics, there will be no data in either the API Manager Dashboards or third-party offloads.

## Procedure

1. Back up your Analytics data as explained in [Backing up and restoring the analytics database](#).

2. Disable shard allocation for storage.

Disabling shard allocation is optional, but is recommended because it prevents new shards from being created for replication when a node is unavailable, and helps avoid corruption issues in full system restarts. Disable shard allocation for storage by running the following command:

```
oc -n namespace exec -it storage-master|shared_pod -- curl_es _cluster/settings -XPUT -d '{"persistent":{"cluster.routing.allocation.enable":"none"}}'
```

where:

- `namespace` is the namespace where the Analytics subsystem is installed.
- `storage-master|shared_pod` is the name of any storage-master or storage-shared pod. You can get the name of your storage pods by running the following command and substituting in the namespace where Analytics is installed:

```
oc -n namespace get po
```

When you disable shard allocation, the response looks like the following example:

```
{"acknowledged":true,"persistent":{"cluster":{"routing":{"allocation":{"enable":"none"}}},"transient":{}}
```

3. Unassociate the Analytics service from all gateway services.

- a. In Cloud Manager, click  Topology.
- b. In the section for the Availability Zone that contains the Analytics service, locate the Gateway service that the Analytics service is associated with.
- c. Click  and select Unassociate analytics service.

All analytics collection will be disabled and there will be no data in either the API Manager Dashboards or third-party offloads. For more information, see [Associating an analytics service with a gateway service](#).

4. Unregister the Analytics service from Cloud Manager:

- a. In Cloud Manager, click  Topology.
- b. In the section for the Availability Zone that contains the Analytics service, locate the Analytics service and click Delete.

For more information, see [Registering an analytics service](#).

5. Perform a synced flush of storage.

Flushing the storage is optional, but is recommended because it helps to avoid losing the data that was not yet written to disk. This step flushes all current index operations synchronously and attempts to write everything that is in flux to disk. Perform a synced flush of storage by running the following command:

```
oc -n namespace exec -it storage-master|shared_pod -- curl_es _flush/synced -XPOST
```

When you flush storage, the response looks like the following example:

```
{"shards":{"total":33,"successful":13,"failed":0},"export-status":{"total":1,"successful":1,"failed":0},".apic-config":{"total":1,"successful":1,"failed":0},".kibana-6":{"total":1,"successful":1,"failed":0},"apic-api-2020.06.19-000002":{"total":15,"successful":5,"failed":0},"apic-api-2020.06.18-1":{"total":15,"successful":5,"failed":0}}
```

The operation often fails, and it is safe to rerun it multiple times until it passes and there are all "failed" counts are zero. If it continues to fail after running multiple attempts over the span of a couple minutes, you can proceed to the next step.

6. Run the following two commands to configure analytics for ingestion-only:

```
$ apicup subsys set <analytics-subsystem-name> ingestion-only=true
```

```
$ apicup subsys install <analytics-subsystem-name>
```

7. Scale the analytics-ingestion deployment down to 0 replicas by completing the following steps.

- a. Get a list of all deployments so that you can find the name of the analytics-ingestion deployment:

```
$ oc get deployments -n <namespace>
```

- b. Scale the analytics-ingestion deployment down to 0 replicas:

```
$ oc scale deployment/<analytics-ingestion-deployment-name> --replicas=0 -n <namespace>
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## IBM Cloud Pak for Integration

IBM API Connect provides the API management capability in IBM Cloud Pak for Integration.

## About this task

For information on deploying or upgrading API Connect as a component of Cloud Pak for Integration, see the *API management capability deployment* section in the [Cloud Pak for Integration documentation](#).

- [Backing up and restoring on Cloud Pak for Integration](#)  
Back up and restore API Management data in IBM Cloud Pak for Integration.
- [Disabling the Analytics subsystem on Cloud Pak for Integration](#)  
During maintenance of an API Connect cluster, you can shut down the Analytics subsystem by disabling the client, ingestion, and storage microservices so that those processes are not running and there is no way to reach them.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Backing up and restoring on Cloud Pak for Integration

Back up and restore API Management data in IBM Cloud Pak for Integration.

### About this task

If you deployed a version of the API Management capability in IBM Cloud Pak for Integration that uses API Connect V2018 FP13-ifix1, you can back up and restore your data.

Restriction: The following instructions apply only to API Connect V2018 FP13-ifix1.

- [CP4I: Backing up data in V2018 FP13-ifix1](#)
- [CP4I: Recovering the v2018 FP13-ifix1 deployment](#)  
Note: Although this topic discusses recovering the deployment after a disaster, it includes information on restoring backed up data (see steps 5 and later).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Disabling the Analytics subsystem on Cloud Pak for Integration

During maintenance of an API Connect cluster, you can shut down the Analytics subsystem by disabling the client, ingestion, and storage microservices so that those processes are not running and there is no way to reach them.

### About this task

Disabling the Analytics subsystem stops the collection and storage of data as well as making the subsystem unavailable. When you disable Analytics, there will be no data in either the API Manager Dashboards or third-party offloads.

## Procedure

1. Back up your Analytics data as explained in [Backing up and restoring the analytics database](#).
2. Disable shard allocation for storage.  
Disabling shard allocation is optional, but is recommended because it prevents new shards from being created for replication when a node is unavailable, and helps avoid corruption issues in full system restarts. Disable shard allocation for storage by running the following command:

```
oc -n namespace exec -it storage-master|shared_pod -- curl_es _cluster/settings -XPUT -d '{"persistent": {"cluster.routing.allocation.enable": "none"}}'
```

where:

- `namespace` is the namespace where the Analytics subsystem is installed.
- `storage-master|shared_pod` is the name of any storage-master or storage-shared pod. You can get the name of your storage pods by running the following command and substituting in the namespace where Analytics is installed:

```
oc -n namespace get po
```

When you disable shard allocation, the response looks like the following example:

```
{"acknowledged": true, "persistent": {"cluster": {"routing": {"allocation": {"enable": "none"}}}, "transient": {}}
```

3. Unassociate the Analytics service from all gateway services.

- a. In Cloud Manager, click  Topology.
- b. In the section for the Availability Zone that contains the Analytics service, locate the Gateway service that the Analytics service is associated with.
- c. Click  and select Unassociate analytics service.

All analytics collection will be disabled and there will be no data in either the API Manager Dashboards or third-party offloads. For more information, see [Associating an analytics service with a gateway service](#).

- Unregister the Analytics service from Cloud Manager:

- In Cloud Manager, click  Topology.
- In the section for the Availability Zone that contains the Analytics service, locate the Analytics service and click Delete.

For more information, see [Registering an analytics service](#).

- Perform a synced flush of storage.

Flushing the storage is optional, but is recommended because it helps to avoid losing the data that was not yet written to disk. This step flushes all current index operations synchronously and attempts to write everything that is in flux to disk. Perform a synced flush of storage by running the following command:

```
oc -n namespace exec -it storage-master|shared_pod -- curl -es _flush/synced -XPOST
```

When you flush storage, the response looks like the following example:

```
{ "_shards": {"total": 33, "successful": 13, "failed": 0}, ".export-status": {"total": 1, "successful": 1, "failed": 0}, ".apic-config": {"total": 1, "successful": 1, "failed": 0}, ".kibana-6": {"total": 1, "successful": 1, "failed": 0}, "apic-api-2020.06.19-000002": {"total": 15, "successful": 5, "failed": 0}, "apic-api-2020.06.18-1": {"total": 15, "successful": 5, "failed": 0}}
```

The operation often fails, and it is safe to rerun it multiple times until it passes and there are all "failed" counts are zero. If it continues to fail after running multiple attempts over the span of a couple minutes, you can proceed to the next step.

- Run the following two commands to configure analytics for ingestion-only:

```
$ apicup subsys set <analytics-subsystem-name> ingestion-only=true
```

```
$ apicup subsys install <analytics-subsystem-name>
```

- Scale the analytics-ingestion deployment down to 0 replicas by completing the following steps.

- Get a list of all deployments so that you can find the name of the analytics-ingestion deployment:

```
$ oc get deployments -n <namespace>
```

- Scale the analytics-ingestion deployment down to 0 replicas:

```
$ oc scale deployment/<analytics-ingestion-deployment-name> --replicas=0 -n <namespace>
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Migrating a Version 5 deployment

The current migration path from v5 is to API Connect v10. You can get more information about migrating to v10 here:

[https://www.ibm.com/support/knowledgecenter/SSMNEJ\\_v10/com.ibm.apic.install.doc/migrating.html](https://www.ibm.com/support/knowledgecenter/SSMNEJ_v10/com.ibm.apic.install.doc/migrating.html).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Using the API Connect operations command line interface

The IBM® API Connect v2018 **apicops** command line interface is targeted at Operations teams. It contains commands to check the health of the system and some commands to fix specific problems that might be encountered.

The **apicops** command line interface is in active development and the latest version is available to download from [Github.com](#). All suggestions, feedback, and bug reports are welcome - feel free to raise an issue in this repository. Please limit the issues to those specific to **apicops** itself - issues about API Connect cannot be accepted, they must be raised by using the normal IBM Support route.

Note: Support for **apicops** is for IBM API Connect v2018.4.1.6 and higher, only.

---

## Installing

Download the binary for your operating system from the latest release on [github.com](#) and rename it to be **apicops**. For more information, see [Releases - APIC Operations CLI](#).

Note: Linux and Mac variants require that you run **chmod +x** on the downloaded file before you can run it.

---

## Requirements

To run **apicops**, you need to have kubectl, or something that implements the same CLI as kubectl, such as oc (OpenShift client), installed locally. If you aren't using kubectl, then set the environment variable **APICOPS\_K8SCIENT** to the name of the Kubernetes client binary, such as oc.

If you are using the oc, then v4.1.x or higher is required, even if you are using v3.x of the OpenShift cluster.

Then, set the `KUBECONFIG` environment variable to point to your kubeconfig file and `apicops` picks it up from there.

```
$ export KUBECONFIG=/home/user/my.kubeconfig
$ apicops
```

If you are running inside an API Connect OVA file, then run `apicops` as root, `sudo -i`, and it automatically picks up the kubeconfig.

## Setting the target namespace

By default, the targeted namespace for the deployment is `default`. If your deployment uses an alternative namespace, then you need to set this value in the relevant context of your kubeconfig file. You can either edit your kubeconfig file, and add the namespace property with your value. Or, you can set the namespace for the current context by using the following command, where `<namespace>` is the value you want to use.

```
kubectl config set "contexts." `kubectl config current-context` ".namespace" <namespace>
```

You can view all contexts and their configured namespaces with the command:

```
kubectl config get-contexts
```

## Usage

```
$ apicops COMMAND
running command...
$ apicops (-v|--version|version)
apicops/0.1.46 linux-x64 node-v10.16.3
$ apicops --help [COMMAND]
USAGE
  $ apicops COMMAND
  ...
```

- [Identify Services State](#)

API Connect uses tasks to do actions such as synchronizing content between API Manager and the Gateways and Portals. When you are diagnosing some problems, it can be useful to determine what the state is of those tasks.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Identify Services State

API Connect uses tasks to do actions such as synchronizing content between API Manager and the Gateways and Portals. When you are diagnosing some problems, it can be useful to determine what the state is of those tasks.

Determining the state of the task can be done by using the `apicops`

`services:identify-state` command, which identifies the state of any gateway and portal services and returns any associated task IDs that are incomplete.

**USAGE**

```
$ apicops services:identify-state
```

**OPTIONS**

```
-e, --embellish  Output a table per service instead of single lines. In JSON mode beautify the JSON
-j, --json      Output as raw JSON instead of lines/tables
```

**ALIASES**

```
$ apicops iss
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring and managing your server environment

You configure and manage the servers that comprise your IBM® API Connect on-premises cloud by using the Cloud Manager user interface.

The Cloud Manager user interface is the part of IBM API Connect that enables a Cloud Administrator to define and manage the API Connect on-premises cloud.

You can use the Cloud Manager to define the API Connect cloud by performing the following tasks:

- Create Provider organizations and invite users to serve as the owner
- Create and manage user roles and role defaults
- Create availability zones for services
- Register the relevant servers that will provide the gateway, analytics, and portal services
- Associate an analytics service with a gateway to enable reports for API Events
- Configure resources for user authentication, TLS security, and OAuth providers and make the resources visible to all or selected provider organizations

- Connect to an existing SMTP mail server and edit templates for system-generated emails
- Set the default gateway service for catalogs
- [Activating your Cloud Manager user account](#)  
If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.
- [Accessing the Cloud Manager user interface](#)  
How to navigate to and log in to the Cloud Manager user interface.
- [Defining your topology](#)  
To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. The installation procedure provides initial configuration of an Availability Zone containing the Management service.
- [Managing authentication and security](#)  
Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.
- [Configuring the cloud settings](#)  
Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.
- [Administering provider organizations](#)  
Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.
- [Administering members and roles](#)  
Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.
- [Monitoring the cloud](#)  
API Connect generates events to monitor the status of your cloud.
- [Changing your Cloud Manager password and profile information](#)  
You can change your Cloud Manager password and update your profile information.
- [Resolving login problems by increasing HTTP header size](#)  
You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.
- [Extending the Gateway server behavior](#)  
To support your enterprise requirements, you can extend the Gateway servers within IBM API Connect to provide extra enforcement behavior.
- [Cloud Manager Tutorials](#)  
Tutorials for using the Cloud Manager user interface in IBM API Connect.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Activating your Cloud Manager user account

If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.

### Before you begin

A cloud administrator invited you to join API Connect .

### Procedure

1. Complete the following steps to activate your Cloud Manager account:

If the Identity Provider uses LDAP

An invitation email with an activation link is sent. Click the activation link, or paste it in a browser, to log in directly with your LDAP user credentials. Upon authentication, the API Connect user record is updated from the backend identity provider.

If the Identity Provider uses a local registry

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your first name, last name and password. Passwords must have a minimum of 8 characters and contain characters from at least three of the four following categories:

- Uppercase letters
- Lowercase letters
- Numbers
- Special characters (for example: ! # \$ %)

Note:

- The email address that you enter on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails.
- If you previously had an account that was removed, and you are being invited again, you must re-activate your account by using the Sign In option on the page, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail.

If the Identity Provider uses an authentication URL

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your credentials, which then become your user name and password. Upon authentication, the API Connect user record is updated from the backend identity provider.

If multiple user registries are available for selection on the sign up page, then make sure that the correct registry for your Cloud Manager account is selected. You might need to ask your administrator which user registry is appropriate for your account.

For information on configuring user registries and making them available for Cloud Manager login, see [User registries overview](#) and [Selecting user registries for Cloud Manager and API Manager](#).

2. Click Sign up to complete your registration, then click Sign in to open the Cloud Manager login page.

---

## Results

You have created your API Connect administrator account.

---

## What to do next

Log in to the Cloud Manager user interface and, depending on your role, start to manage the cloud topology, and work with provider organizations and cloud resources. To access the Cloud Manager login page in the future, use the following URL:

`https://host/admin`

where *host* is the fully qualified host name or IP address of the Management server.

# Accessing the Cloud Manager user interface

How to navigate to and log in to the Cloud Manager user interface.

---

## Before you begin

To open the Cloud Manager user interface, enter the URL for the <cloud-admin-ui> endpoint entered during installation, followed by `/admin`. The <cloud-admin-ui> endpoint is configured in the Management subsystem using the following command: `apicup subsys set mgmt cloud-admin-ui <endpoint>`.

The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address.

---

## Procedure

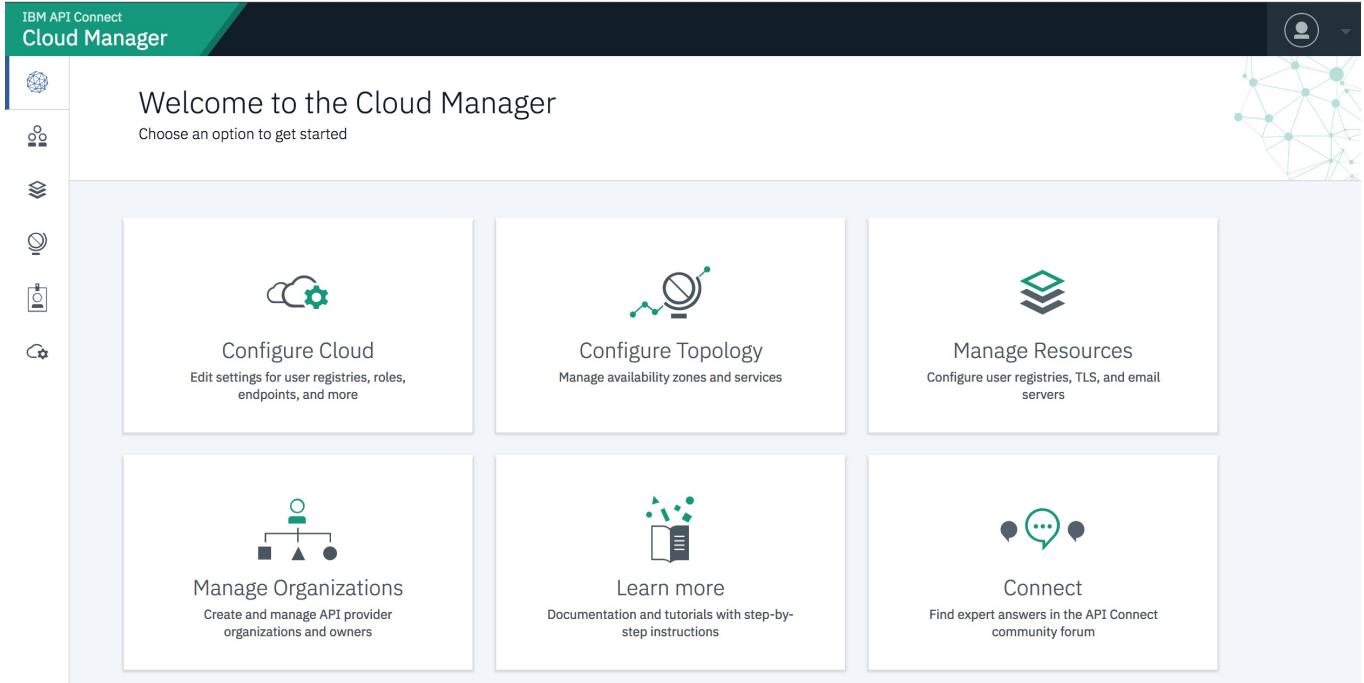

1. Open a browser and enter the URL for the cloud-admin-ui endpoint followed by `/admin`. Note that this is secure connection using HTTPS, for example:  
`https://<cloud-admin-ui>/admin`.
2. Enter the Cloud Administrator user name and password. If you are logging in for the first time, enter `admin` for the user name and `7iron-hide` for the password. Otherwise, enter `admin` for the user name and `<your password>` for the password.
3. If your cloud contains multiple user registries, as configured on the Settings\_>User Registries screen, then choose the user registry that contains your login credentials. You may need to ask your administrator which user registry is appropriate for your account.
4. Click Sign In.  
Important: The first time that you access the cloud console, you must, for security reasons, enter a new password and your email address. If you forget your password and request a password reset, the notification email is sent to this email address. The email is sent by the email server configured in the **Notifications** section of the cloud **Settings**.

---

## Results

The Cloud Manager user interface opens to the home page, as shown in the following screen capture:

## What to do next

Configure the email server so you can reset your password if needed and send other notifications. See [Tutorial: Configuring the Cloud](#).

Configure your topology by registering services. See [Tutorial: Configuring the Cloud](#).

Create a Provider Organization. See [Tutorial: Creating a Provider Organization](#).

## Related tasks

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

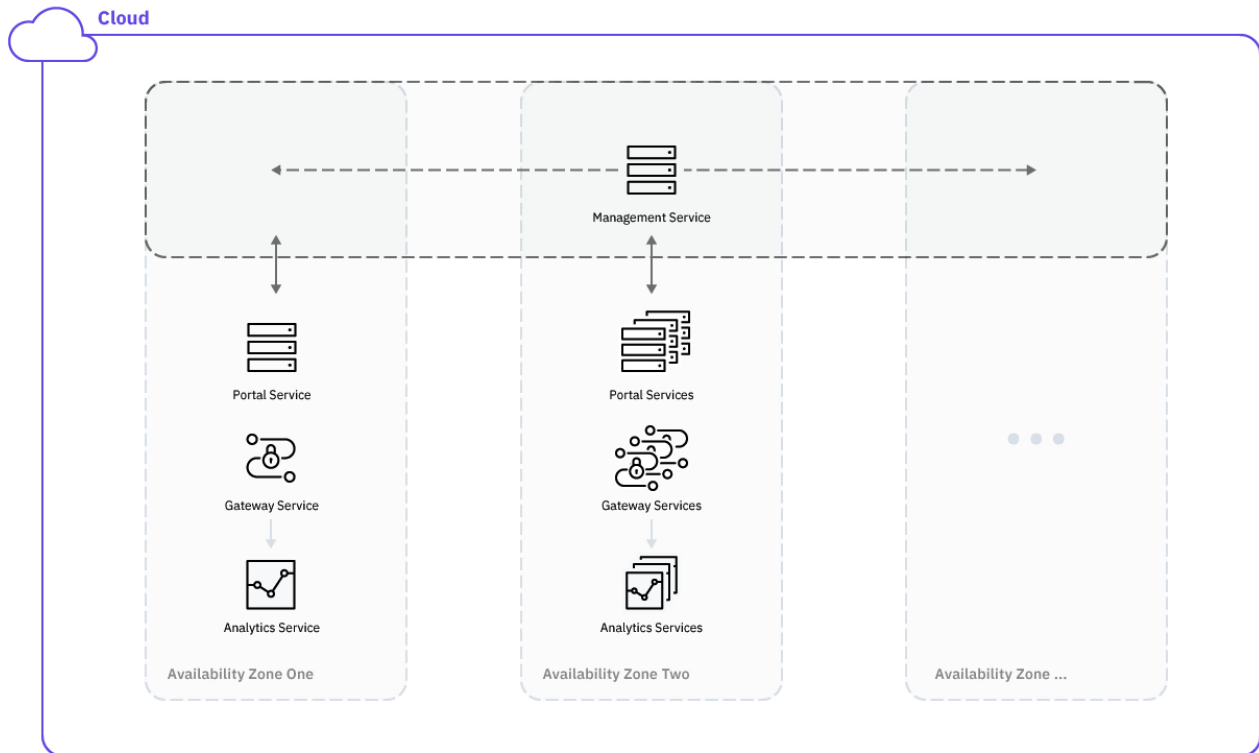

## Defining your topology

To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. The installation procedure provides initial configuration of an Availability Zone containing the Management service.

## About this task

The Cloud Manager topology consists of Availability Zones that contain the API Connect services (management, gateway, analytics and portal services). Availability Zones can contain one or more gateway services, analytics service, and portal service, but there is one management service that spans all Availability Zones. When configuring your Availability Zones and Services, the recommended practice is that the gateway, analytics, and portal services do not communicate across Availability Zones. Only the management service can span across Availability Zones.

The following diagram illustrates the topology for services and Availability Zones in an API Connect network:

One of the following roles is required to register and manage services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Following are the tasks involved in defining the API Connect topology:

- Create one or more Availability Zones.
- Register one or more Gateway, Analytics, and Portal services in each Availability Zone
- Associate an Analytics service with each Gateway service
- Set the visibility for the services

There are two types of deployment scenarios:

1. Appliance-based deployment using .ova files on Virtual Machines
2. Container-based deployment using Docker and Kubernetes clusters

The configuration of the Management service will differ depending upon the deployment scenario. For both, a Management service is added to the Default Availability Zone by the installation utility.

Once the cloud is defined and an email server has been configured, you invite other users to access API Manager to create APIs. You expose these APIs to the development community through the Developer Portal user interface.

To define the API Connect cloud, complete the following tasks:

- **Configuring the Management service**  
A Management service is configured in the Default Availability Zone by the installation script. For an appliance-based deployment on VMs, additional Management services may be configured using the .ova file. For a container-based deployment, only one Management service is configured for the cloud.
- **Creating an Availability Zone**  
An Availability Zone is a logical or physical set of data centers containing one or more API Connect services. Availability Zones provide redundancy and failover in the event of network issues. The Default Availability Zone is created during installation; it includes a Management service.
- **Registering a gateway service**  
A gateway service is required to handle incoming traffic for APIs.
- **Registering an analytics service**  
Configure at least one analytics service in your API Connect on-premises cloud. The analytics service is always associated with a gateway service, from which it collects API event data.
- **Registering a portal service**  
Define one or more portal services in your API Connect on-premises cloud.
- **Associating an analytics service with a gateway service**  
To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.
- **Setting visibility for a service**  
The visibility setting determines which provider organizations can access a service.

## Related concepts

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring the Management service

A Management service is configured in the Default Availability Zone by the installation script. For an appliance-based deployment on VMs, additional Management services may be configured using the .ova file. For a container-based deployment, only one Management service is configured for the cloud.

## Before you begin

---

You must complete the following tasks:

- Run the Install Assist installation program to configure the Default Availability Zone that contains the Management service. See [Installing API Connect into a Kubernetes environment](#) and [Deploying the Management OVA file](#).

## About this task

---

The Management service is added to your cloud by the installation script. It will be added to the Default Availability Zone. You cannot add or configure Management services using the Cloud Manager user interface.

The Management service is handled differently depending on the deployment option:

- Appliance-based deployment: API Connect Services are deployed on VMs using an .ova configuration file. Multiple Management services may be deployed, but each Availability Zone can have only one Management service.
- Container-based deployment: Services are deployed in Docker containers and managed in Kubernetes clusters. One Management service is deployed for the entire cloud using the installation script.

## Results

---

One or more Management services are configured.

## What to do next

---

Complete the following task:

- [Registering a gateway service](#)

## Related tasks

---

- [Creating an Availability Zone](#)
- [Registering a gateway service](#)
- [Registering an analytics service](#)
- [Registering a portal service](#)
- [Associating an analytics service with a gateway service](#)
- [Setting visibility for a service](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Creating an Availability Zone

An Availability Zone is a logical or physical set of data centers containing one or more API Connect services. Availability Zones provide redundancy and failover in the event of network issues. The Default Availability Zone is created during installation; it includes a Management service.

## Before you begin

---

You must complete the following task:

- Run Install Assist to configure the Default Availability Zone that contains the Management service. See [Installing API Connect into a Kubernetes environment](#) or [Deploying the Management OVA file](#).

## About this task

Availability zones organize API Connect operations based upon your business needs. Availability zones are sets of logical or physical data centers containing one or more API Connect services. Multiple availability zones in your cloud provide redundancy and fail over in the event of network issues. Availability zones can be organized by region, for global separation, or for physical or logical separation of data centers.

The Default Availability Zone is created during the installation process. It contains the Management service that was configured by Install Assist. You register one or more gateway, analytics, and portal services in the availability zones to configure your API Connect cloud topology.

Note: For appliance-based deployments, additional management services may be added (one per availability zone) using the installation script. However, for container-based deployments using Docker and Kubernetes, only one management service is allowed. No additional management services can be added if you are using container-based deployment.

When you create an availability zone, you should provide a descriptive title; a name is generated automatically for internal identification. For example:

Table 1. Example availability zones

| Title                          | Name                           |
|--------------------------------|--------------------------------|
| US Availability Zone           | us-availability-zone           |
| Hampshire Availability Zone    | hampshire-availability-zone    |
| Newport Availability Zone      | newport-availability-zone      |
| London South Availability Zone | london-south-availability-zone |

One of the following roles is required to add and manage Availability Zones:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

## Procedure

Follow these steps to add one or more additional Availability Zones to your on-premises cloud:

1. In the Cloud Manager, click  Topology.
2. You will see the current Availability Zones configured in your cloud. The Default Availability Zone is created by the installation script, and includes the Management service. To add another Availability Zone, choose Create Availability Zone.
3. Enter the following values:

| Field              | Description                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------|
| Title (required)   | Enter a descriptive title for the availability zone. This title will display on the screen. |
| Name (required)    | This field is auto-populated by the system and used as the internal field name.             |
| Summary (optional) | Enter a brief description.                                                                  |

4. Click Create to complete the operation.

## Results

The availability zone will be added on the Services page. You can now add gateway, analytics, and portal services to the availability zone.

## Related tasks

- [Registering a gateway service](#)
- [Registering an analytics service](#)
- [Registering a portal service](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Registering a gateway service

A gateway service is required to handle incoming traffic for APIs.

## Before you begin

Before registering a Gateway service in Cloud Manager, the DataPower® API Connect Gateway Service has to either be installed as a subsystem in your Kubernetes cluster or enabled on the DataPower appliance. For a Kubernetes environment, see [Installing the Gateway subsystem into a Kubernetes environment](#). For appliances, see [Configuring API Connect Gateway Service](#) for more information.

Also complete the following task:

- [Configuring the Management service](#)

## About this task

A Gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting.

One of the following roles is required to register and manage a gateway services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Note: You can also register, and manage, gateway services by using the developer toolkit CLI; for details, see [apic gateway-services](#).

## Procedure

Complete the following steps to configure a Gateway service for your cloud:

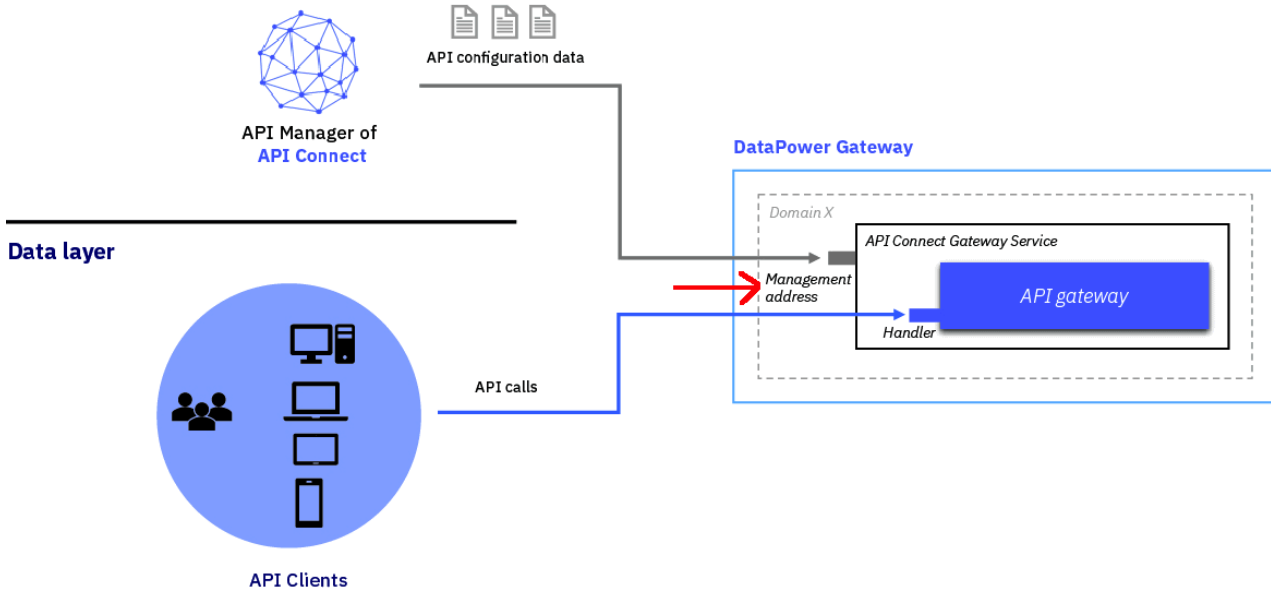

1. In the Cloud Manager, click  Topology.
2. From the Availability Zone that will contain the Gateway service, select Register Service.
3. On the Configure Service page, select DataPower Gateway as the service type. Select the Gateway type that you want to create, either DataPower Gateway (v5 compatible) or DataPower API Gateway. For a description of the gateway types, see [API Connect gateway types](#)
4. Enter the values to configure the Gateway service. You will need to obtain the endpoints from your deployment configuration. For a Kubernetes environment, the endpoints are configured by the following values in the apicup installation script. For an appliance, the endpoint is configured in DataPower.

| Field                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)                                                           | Enter a descriptive title for the gateway service. This title will be displayed on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Name (required)                                                            | This field is auto-populated by the system and used as the internal field name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Summary (optional)                                                         | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Management Endpoint:</b><br>Endpoint (required)                         | Enter the API Connect Gateway Service endpoint. <ul style="list-style-type: none"> <li>• For a Kubernetes environment, the Management Endpoint is the endpoint entered for the command <code>set gwy apic-gw-service</code>. See <a href="#">Installing the Gateway subsystem into a Kubernetes environment</a> for more information.</li> <li>• For an appliance, the Management Endpoint is the <i>Management address</i> to the API Connect Gateway Service shown in the <a href="#">gateway service connection diagram</a>. For one gateway, this takes the form <code>http://&lt;ip-address-for-gateway&gt;:3000</code>. For multiple gateways, it would be the address:port of the load balancer</li> </ul> |
| <b>Management Endpoint:</b><br>TLS Client Profile (optional)               | Specify the TLS Client profile to use when contacting the gateway through the management endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>API Invocation Endpoint and SNI:</b> API Endpoint Base (required)       | Enter the base portion of the URL that maps to the base portion of the URL for incoming API traffic. It is a public FQDN with additional paths that are specific to your API calls. For example: <code>https://api.mycompany.com</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>API Invocation Endpoint and SNI:</b> Server Name Indication - Host Name | For supporting Server Name Indication (SNI) at the API Endpoint Base. The default hostname of '*' is required to allow all hosts. Enter other host names as needed. Wild card format is supported. The SNI capability enables you to serve multiple TLS secure host names through the same Gateway service, using the same IP address and port, without requiring them to use the same TLS profile.<br>Note: To allow requests from clients that don't support SNI, you <b>must</b> include a host name value of '*'.                                                                                                                                                                                             |
| <b>API Invocation Endpoint and SNI:</b> TLS Server Profile                 | The TLS server profile that supports the given hostname for SNI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| OAuth Shared Secret (optional)                                             | For sites using native OAuth providers, enter the shared secret that will be used by all API calls going through the gateway.<br>Note: The specified shared secret must be 64 characters (64 bytes) in length, prefixed with <code>0x</code> , and must consist only of hexadecimal characters. For example: <code>0xa354282f227c10250511ae9c9e8c7ed9f4f1bd0d7c04cb6d5bd178f8c62296e3</code>                                                                                                                                                                                                                                                                                                                      |

The following diagram illustrates the gateway service connection:

---

## Management layer

5. When you are finished, click Save.

---

## Results

The Gateway service is added to the appropriate Availability Zone for your cloud.

---

## What to do next

If you want to change the TLS Profile from Cloud Manager, for SNI Mapping of API Invocation endpoint, it is automatically changed in the associated Gateway. You do not need to do a removal or re-registration of the Gateway service.

Add additional gateway services. Add one or more analytics services. Add one or more portal services. Associate the gateway service with an analytics service. Set the visibility for the gateway.

---

---

---

## Registering an analytics service

Configure at least one analytics service in your API Connect on-premises cloud. The analytics service is always associated with a gateway service, from which it collects API event data.

---

## Before you begin

You must complete the following tasks:

- [Creating an Availability Zone](#)
- [Registering a gateway service](#)

---

## About this task

The Analytics service collects API event data from the Gateway service. In Cloud Manager, you configure the Analytics service and then associate it with one or more Gateways. You can have multiple Gateways associated with a single Analytics service, but each Gateway can be associated with only one Analytics service. Using the Analytics service, you can filter, sort, and aggregate the API event data and view the results on a dashboard. One of the following roles is required to register and manage analytic services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

## Procedure

Complete the following steps to configure the Analytics services for your cloud:

1. In the Cloud Manager, click  Topology.
2. In the Availability Zone that will contain the Analytics service, select Register Services > Analytics.
3. Enter the values to configure the Analytics service:

| Field                            | Description                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)                 | Enter a descriptive title for the Analytics service. This title will display on the screen.                                                                                                                                                                                                                                                        |
| Name (required)                  | This field is auto-populated by the system and used as the internal field name.                                                                                                                                                                                                                                                                    |
| Summary (optional)               | Enter a brief description.                                                                                                                                                                                                                                                                                                                         |
| Endpoint (required)              | Enter the fully-qualified domain name. If configured during installation using the Install Assist utility, it is the <code>apicup subsys set analytics analytics-client</code> value.<br>If you are using the ingestion-only configuration for Analytics, the client endpoint is not used. Instead, provide the TLS endpoint URL for this setting. |
| TLS Client Profile (required)    | Select the TLS Client Profile that will be used to communicate with the analytics service. The Client Profile applies to the Endpoint.                                                                                                                                                                                                             |
| Advanced Analytics Configuration | Configure advanced parameters in Kibana.                                                                                                                                                                                                                                                                                                           |

4. Click Save to complete the operation.

## Results

The Analytics service is added to your cloud settings.

## What to do next

Associate the Analytics service one or more Gateway services. For more information, see [Associating an analytics service with a gateway service](#).

## Related tasks

- [Registering a gateway service](#)
- [Registering a portal service](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Registering a portal service

Define one or more portal services in your API Connect on-premises cloud.

## Before you begin

You must complete the following tasks:

- [Creating an Availability Zone](#)
- [Registering a gateway service](#)
- [Configuring an email server for notifications](#)
- [Setting up notifications](#)
- [Setting up notifications](#)

Note:

When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the `portal-ww` pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully.  
To disable the endpoint check, complete one of the following updates depending on your platform:

On Kubernetes

Add the following section to the Portal custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

On VMware

In your `apicup` project, create a file called `ptl-extra-values.yaml` (or edit the file if one already exists), and add the following section:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

Run the following commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>
apicup subsys install <ptl_subsys>
```

## About this task

Each Availability Zone contains one or more Portal services. The Portal service provides a developer portal used by application developers to discover APIs and onboard consumers. An email server must be configured and set as the email server for the cloud before registering a portal service. One of the following roles is required to register and manage Portal services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Important: It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a Portal site for every Catalog, for example Catalogs that are only for API Developers don't need a Portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services.

## Procedure

Complete the following steps to configure the Portal services for your cloud:

1. In the Cloud Manager, click  Topology.
2. In the Availability Zone that will contain the Portal service, select Register Services > Portal.
3. Enter the values to configure the Portal service.

| Field                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)                                          | Enter a descriptive title for the portal service. This title will display on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Name (required)                                           | This field is auto-populated by the system and used as the internal field name.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Summary (optional)                                        | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Management Endpoint:</b> Endpoint (required)           | Enter the IP address, fully-qualified host name, service, or ingress name. Used for communication with API Manager. If configured during installation using the Install Assist utility, it is the <code>apicup subsys set portal portal-admin</code> value.                                                                                                                                                                                                                                                            |
| <b>Management Endpoint:</b> TLS Client Profile (optional) | Select the TLS Client Profile that will be used to communicate with the portal service. The profile applies to the Management Endpoint.                                                                                                                                                                                                                                                                                                                                                                                |
| Portal Website URL (required)                             | The URL that will be used for public access to the portal. If configured during installation using the Install Assist utility, it is the <code>apicup subsys set portal portal-www &lt;portal&gt;.&lt;hostname&gt;.&lt;domainname&gt;</code> value. Multiple <code>portal-www</code> endpoints may be configured, as described here in these topics: <a href="#">Defining multiple portal endpoints for a Kubernetes environment</a> and <a href="#">Defining multiple portal endpoints for a VMware environment</a> . |

4. When you are finished, click Save.

## Results

The Portal service is configured in your cloud and can be used to publish APIs.

## Associating an analytics service with a gateway service

To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.

---

### Before you begin

You must complete the following tasks:

- Run Install Assist to configure the Default Availability Zone that contains the Management service.
- Register a gateway service and an analytics service.

---

### About this task

Each gateway service is associated with an analytics service. Each gateway service can be associated with only one analytics service (a one-one relationship), however, each analytics service can be associated with one or more gateway services (a one-many relationship). The associated analytics service collects API event data from the gateway service.

In order to associate an analytics service with a gateway, you must first configure at least one analytics service and one gateway service.

One of the following roles is required to associate an analytics service with a gateway service:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Follow these steps to associate an analytics service with a gateway service:

---

### Procedure

1. In the Cloud Manager, click  Topology.
2. In the section for the Availability Zone you want to work on, locate the Gateway service that requires an Analytics service in the SERVICE column.
3. Locate the ASSOCIATED ANALYTICS SERVICE column.
4. If an Analytics service has been configured, the Associate Analytics service link is enabled for each Gateway service. Click Associate Analytics Service in the same row as the Gateway service that requires an Analytics service.
5. In Associate Analytics Service, you will see the name of the Gateway service and a list of Analytics services that have been configured in your cloud.
6. Select the Analytics service to associate with the Gateway service by adding a checkmark, then click Associate.
7. To remove the associated Analytics service, select Unassociate analytics service from the actions menu. Note that when there is no Analytics service associated with a Gateway service, all analytics collection will be disabled and there will be no data in either the API Manager Dashboards or third-party offloads.

---

### Results

The Analytics service is associated with a Gateway service and will collect API event data for that Gateway.

---

---

---

## Setting visibility for a service

The visibility setting determines which provider organizations can access a service.

---

### Before you begin

You must complete the following tasks:

- Run Install Assist to configure the Default Availability Zone that contains the Management service
- Create additional availability zones if needed, see [Creating an Availability Zone](#)
- Register at least one gateway service, see [Registering a gateway service](#)
- Register other services

## About this task

---

The visibility setting controls which provider organizations can use a service. The default visibility setting is Public.

One of the following roles is required to set the visibility for services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

## Procedure

---

Follow these steps to set the visibility for the services in your on-premises cloud:

1. In the Cloud Manager, click  Topology.
2. From the list of Services, choose Set visibility from the actions menu next to the name of the service that requires the visibility setting.
3. Select the visibility setting for the service. The options are:
  - Private - the service is not visible and cannot be used by any provider organization
  - Public - the service is visible and can be used by all provider organizations
  - Custom - the service is visible only to the provider organizations designated by you
4. For Custom visibility, select the provider organizations that will be able to use the service.
5. Click Make visible to complete the operation.

## Results

---

For Private, the service cannot be used by any provider organizations. For Public, the service can be used by all provider organizations. For Custom, the service can be used by the provider organizations that you designate.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Managing authentication and security

---

Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.

As Cloud Administrator or Topology Administrator (or with a custom role that contains the `Settings:Manage` permission), you can configure the following authentication and security mechanisms:

- User registries to authenticate users of Cloud Manager and API Manager and of your Catalogs and APIs.
- OAuth providers to provide protection for APIs.
- TLS profiles to secure transmission of data through the Gateway to external web sites and among web servers.

The following topics describe how to configure user registries, OAuth providers, and TLS profiles:

- [User registries overview](#)  
API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.
- [TLS profiles overview](#)  
API Connect supports TLS Profiles for securing data transmission over HTTPS.
- [OAuth Provider overview](#)  
API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

---

---

## User registries overview

API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.

---

## Introduction to user registries

A user registry holds unique user account credentials, primarily usernames and passwords, which are accessed during authentication for logging into Cloud Manager, API Manager, the Developer Portal, and also for calling APIs (if the API is configured to use Basic Authentication in the Security Definition). The Cloud Administrator configures user registries to ensure that all users are successful at logging in.

User registries also provide security when calling APIs. For information on configuring Security Definitions for APIs, see [Creating a basic authentication security definition](#).

User registries are configured as Resources. Once the user registry has been configured as a resource in Resources > User registries, the next step is indicate the active user registries for your cloud in Cloud Settings > User registries. The user registry must be made active in your cloud in order to make it available for authentication. When a user logs into Cloud Manager or API Manager, the specified user registry is queried for credentials to confirm the user's identity.

In Cloud Manager and API Manager, a registry cannot be changed after a user is invited to be the owner of a provider organization, even if the invitation is not yet accepted.

User registries in API Connect serve the following primary functions:

- To authenticate a user at login time based upon username and password.
- To store basic profile information such as first name, last name, and email address.
- To provide secure access to Catalogs.
- To provide Basic Authentication for APIs when called by an application.

In order to log in to Cloud Manager, API Manager, the Developer Portal, or access a catalog, a user must have valid credentials (username and password) stored in a user registry that is configured in API Connect.

The Security Definition for an API can be configured to require a username and password, called the Basic Authentication method. With Basic Authentication, the username and password are included in the HTTP authorization header, and the credentials are verified through user registry.

User registries that are configured in Cloud Manager have the following characteristics:

- They are available to Cloud Manager, API Manager, the Developer Portal, and for Basic Authentication for APIs.
- They are available to provider organizations, as determined by the visibility setting.
- They can be edited and deleted only in Cloud Manager.

User registries that are configured in API Manager have the following characteristics:

- They are available to the Developer Portal (for Catalogs) and for Basic Authentication for APIs.
- They are available only to the Provider Organization that created them.

---

## User registries supported by API Connect

API Connect integrates with several types of user registries to accommodate all security solutions. You can use your corporate LDAP registry, an Authentication URL, or an LUR to provide secure access to Cloud Manager, API Manager, the Developer Portal, and APIs. API Connect includes two internal databases that serve as local user registries, or LURs. The Providers LUR supports credentials for Provider organizations and the Admin LUR supports credentials for the Administrator organization. Multiple registries may be configured.

The following user registry types can serve as a resource in API Connect:

- Local user registry (LUR) - An internal database of usernames and passwords stored on the local server. Contains the Admin user account which may not be modified or deleted.
- LDAP - A user registry definition that points to an existing corporate LDAP directory. May be set up as case-sensitive.
- Authentication URL - Accesses a URL that points to a service for validating user credentials.
- OpenID Connect (OIDC).
- [Configuring an Authentication URL user registry](#)  
An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.
- [Configuring an LDAP user registry in the Cloud Manager](#)  
You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.
- [Configuring a Local User Registry](#)  
A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.
- [Configuring an OIDC user registry](#)  
Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.
- [Setting visibility for a user registry](#)  
The visibility setting determines which provider organizations can access a resource, for example, user registries.
- [Deleting a user registry](#)  
As the Cloud Manager administrator, you can delete user registries.
- [Removing a user from a user registry](#)  
As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

## Configuring an Authentication URL user registry

An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.

### About this task

This topic describes how to configure a new Authentication URL user registry as a Resource in your cloud. After the user registry is configured, you must select it for use in your cloud in Settings > User Registries. See [Selecting user registries for Cloud Manager and API Manager](#).

One of the following roles is required to configure user registries.:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note: When a user is presented with the form for completing their API Connect user registration, which fields are pre-populated depends on which fields are returned in the response from the Authentication URL identity provider. If any of the following fields are returned, they will be pre-populated in the registration form:

- `username`
- `email`
- `first_name`
- `last_name`

If the `username` field is not returned, the registration form displays the user name that was provided by the user. The pre-population capability requires that the response from the Authentication URL identity provider satisfies the following conditions:

- The `Content-Type` must be `application/json`.
- The response body format must be JSON.

A sample response is as follows:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache
```

```
{
  "username": "myuser",
  "email": "myuser@example.com",
  "first_name": "My",
  "last_name": "User"
}
```

### Procedure

1. In the Cloud Manager, click .
2. Select User Registries to see the list of current user registries in your cloud.
3. Click Create in the User Registries section.
4. Select Authentication URL User Registry and enter the following parameters:

| Field                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)              | Enter a descriptive name to use on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Name (required)               | The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see <a href="#">apic user-registries</a> .                                                                                                                                                                                                                                                                                                                                                                         |
| Summary (optional)            | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Display Name (required)       | The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see <a href="#">Accessing the Cloud Manager user interface</a> , <a href="#">Accessing the API Manager user interface</a> , and <a href="#">Activating your API Manager user account</a> .<br>Note: The Developer Portal uses the <b>Title</b> of the User Registries when rendering them at the login page, rather than the <b>Display Name</b> . |
| URL (required)                | Enter the URL for the authentication service. When establishing authentication, API Connect makes a GET call to the URL. The call includes the user name and password it has collected from the user in its authorization header. Either <code>200 OK</code> or <code>401 Unauthorized</code> will be returned.                                                                                                                                                                                                                                     |
| TLS Client Profile (optional) | Select a TLS Client Profile to allow secure authentication with a specific web server.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Case sensitive | <p>To ensure proper handling of user name capitalization, you <b>must</b> ensure that your case-sensitivity setting here matches the setting on your backend Authentication URL server:</p> <ul style="list-style-type: none"> <li>• <b>Only</b> select Case sensitive if your backend server supports case-sensitivity.</li> <li>• <b>Do not</b> select Case sensitive if your backend server does not support case-sensitivity.</li> </ul> <p>Note:</p> <p>The Developer Portal does not support case sensitive usernames.</p> <p>Note: After at least one user has been onboarded into the registry, you cannot change this setting.</p> |

5. Click Save.

## Results

The Authentication URL user registry is saved and is available to be selected as a user registry for Cloud Manager or API Manager by selecting it in Settings > User Registries. It can also be used for Basic Authentication in the Security Definition for an API.

# Configuring an LDAP user registry in the Cloud Manager

You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

## Before you begin

To configure an LDAP user registry as a shared resource in the Cloud Manager, the LDAP directory must be created for use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, to authenticate users to the Cloud Manager and the API Manager, or for securing a Catalog to authenticate Developer Portal users.

Important: If you are using an LDAP registry to secure APIs, note the following limitations:

- Authentication methods Compose DN and Compose UPN are not supported with the DataPower® API Gateway.
- The STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported with an LDAP user registry

One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

## About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used across the Cloud Manager, the API Manager, and the Developer Portal components in your environment.

This topic describes how to configure a shared LDAP user registry that is available to all of the provider organizations in your API Connect environment. If you want to create an organization-specific registry, see [Creating an LDAP user registry in API Manager](#) for more information. Note also that the visibility of a user registry is set to **shared** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see [Setting visibility for a user registry](#).

Note:

- If you configure your LDAP user registry to be writable (by selecting the User Managed checkbox on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create and manage LDAP user registries by using the developer toolkit CLI (see [Using the CLI to configure a shared LDAP user registry](#)), and by using the API Connect REST APIs (see the [API Connect REST API documentation](#)).

You create an LDAP user registry by configuring a set of properties in the Cloud Manager UI. If you want to enable writable LDAP, you must complete the Attribute Mapping section by selecting the User Managed checkbox, and providing the mapping of your source LDAP attribute names to the target API Connect values. You can also change a registry to be read-only again by clearing the User Managed checkbox. After configuring the user registry, you must set it as active in Settings > User Registries. To make the registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions.

For general information about authenticating with LDAP, see [LDAP authentication](#).

## Procedure

Follow these steps to configure a new LDAP user registry as a shared resource in the Cloud Manager UI.

1. In the Cloud Manager, click  Resources.
2. Click Create in the User Registries section.
3. Select LDAP User Registry for the user registry type, and enter the following information:

| Field                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title                                  | Enter a descriptive name to display on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Name                                   | The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see <a href="#">apic user-registries</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Display Name (required)                | The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see <a href="#">Accessing the Cloud Manager user interface</a> , <a href="#">Accessing the API Manager user interface</a> , and <a href="#">Activating your API Manager user account</a> .<br><br>Note: The Developer Portal uses the <b>Title</b> of the User Registries when rendering them at the login page, rather than the <b>Display Name</b> .                                                               |
| Summary (optional)                     | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Address                                | Enter the IP address or host name of the LDAP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Port                                   | Enter the Port number that API Connect can use to communicate with the LDAP registry. For example, 389.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Select a TLS Client Profile (optional) | Select the TLS Client Profile the LDAP server requires.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Select an LDAP protocol version        | Select the version number for the LDAP protocol that you are using.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Case-sensitivity                       | To ensure proper handling of user name capitalization, you <b>must</b> ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: <ul style="list-style-type: none"> <li>• <b>Only</b> select Case sensitive if your backend LDAP server supports case-sensitivity.</li> <li>• Do <b>not</b> select Case sensitive if your backend LDAP server does not support case-sensitivity.</li> </ul> Note:<br>The Developer Portal does not support case sensitive usernames.<br><br>Note: After at least one user has been onboarded into the registry, you cannot change this setting. |

4. Click Next and enter the authentication information, which will vary depending on the selected Authentication Method. The choices are:
  - Compose DN - Select this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, Compose DN is not supported with the DataPower API Gateway.
  - Compose UPN - Select this format if your LDAP directory supports binding with User Principal Names such as `john@acme.com`. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, Compose UPN is not supported with the DataPower API Gateway.
  - Search DN - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For all of the authentication methods:

If you are creating an LDAP registry to authenticate users of an API, you can specify an LDAP authorization group to restrict API access. To be able to call an API that is secured by the LDAP registry, a user must successfully authenticate with their LDAP user ID and password **and** they must be a member of the specified authorization group. The authorization group can be a Static Group or Dynamic Group. A static group is one in which the individual members of the group are explicitly listed. A dynamic group is one which is defined according to the set of attributes that the group members share in common.

5. For authentication method Compose DN, enter the following:

| Field                               | Description                                                                                                                                                                             |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bind Method                         | Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind. |
| Admin DN                            | For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example <code>cn=admin,dc=company,dc=com</code> .              |
| Admin Password                      | For Authenticated Bind, enter the user password for the Admin DN.                                                                                                                       |
| Prefix                              | Specify the prefix to the DN. For example (uid=).                                                                                                                                       |
| Suffix                              | Specify the suffix to the DN. For example ).                                                                                                                                            |
| Base DN (optional)                  | Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN.                                                                              |
| Use group authentication (optional) | Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.                                         |

6. For authentication method Compose UPN, enter the following:

| Field       | Description                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bind Method | Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind. |

| Field                               | Description                                                                                                                                                                |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Admin DN                            | For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example <code>cn=admin,dc=company,dc=com</code> . |
| Admin Password                      | For Authenticated Bind, enter the user password for the Admin DN.                                                                                                          |
| Suffix                              | Enter the domain part of the user principal name. For example, <code>@acme.com</code> .                                                                                    |
| Use group authentication (optional) | Enter the Filter condition for the group.                                                                                                                                  |

7. For authentication method Search DN, enter the following:

| Field                               | Description                                                                                                                                                                             |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bind Method                         | Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind. |
| Admin DN                            | For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example <code>cn=admin,dc=company,dc=com</code> .              |
| Admin Password                      | For Authenticated Bind, enter the user password for the Admin DN.                                                                                                                       |
| Prefix                              | Specify the prefix to the DN. For example <code>(uid=</code> .                                                                                                                          |
| Suffix                              | Specify the suffix to the DN. For example <code>)</code> .                                                                                                                              |
| Base DN (optional)                  | Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN.                                                                              |
| Use group authentication (optional) | Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.                                         |

8. Optional: Click Test configuration to test the settings for your LDAP user registry. Enter valid credentials to ensure that you can access the LDAP database.

9. Optional: If you want to make your LDAP user registry writable, select the User Managed checkbox in the Attribute Mapping section, and provide the mapping of your source LDAP attribute names to the target API Connect values. Click Add to add each name/value pair, specified as follows:

- LDAP ATTRIBUTE NAME - is the name of the source LDAP attribute.
- API CONNECT VALUE - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in [ ] with the value that the user supplies when signing up.

The default user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`, as shown in the following example:

| LDAP ATTRIBUTE NAME       | API CONNECT VALUE                                      |
|---------------------------|--------------------------------------------------------|
| <code>dn</code>           | <code>uid=[username],ou=users,dc=company,dc=com</code> |
| <code>cn</code>           | <code>[first_name] [last_name]</code>                  |
| <code>sn</code>           | <code>[last_name]</code>                               |
| <code>mail</code>         | <code>[email]</code>                                   |
| <code>userPassword</code> | <code>[password]</code>                                |

You must ensure that you enter the correct attribute mapping values for your LDAP configuration, to enable API Connect to access the LDAP database. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.

10. Click Create.

Your new LDAP registry is shown in the list of User Registries on the Resources page.

## What to do next

To make the LDAP registry available for user authentication in the Cloud Manager and the API Manager, you must set it as active in the Settings > User Registries section. See [Selecting user registries for Cloud Manager and API Manager](#) for more information.

If you want to make the LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see [Creating and configuring Catalogs](#).

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see [Creating a basic authentication security definition](#).
- To use for authentication in the User Security configuration for a native OAuth provider, see [Configuring user security for a native OAuth provider](#).
- [Using the CLI to configure a shared LDAP user registry](#)  
You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

---

## Using the CLI to configure a shared LDAP user registry

You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

---

### Before you begin

To configure an LDAP user registry as a resource in the Cloud Manager, the LDAP directory must be created and available to use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for authenticating users to the Cloud Manager, the API Manager, and the Developer Portal.

Important: If you are using an LDAP registry to secure APIs, note the following limitations:

- Authentication methods `compose_dn` and `compose_upn` is not supported with the DataPower® API Gateway.
- The STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported with an LDAP user registry

One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

---

### About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for onboarding and authenticating Developer Portal users, while a shared LDAP user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure a shared LDAP user registry. If you want to create an organization-specific registry, see [Using the CLI to create an organization-specific LDAP user registry](#) for more information. Note also that the visibility of a user registry is set to `shared` by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see [Setting visibility for a user registry](#).

Note:

- If the LDAP user registry is configured as writable (by enabling the `user-managed` property on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create LDAP user registries by using the Cloud Manager UI (see [Configuring an LDAP user registry in the Cloud Manager](#)), and by using the API Connect REST APIs (see the [API Connect REST API documentation](#)).

You configure an LDAP user registry by first defining the registry details in a configuration file. You then use a developer toolkit CLI command to create the registry, passing the configuration file as a parameter. Finally, to make the registry available for user authentication, you need to configure the registry in the management server, or in the appropriate Catalog, or both, depending on your requirements. To secure APIs with an LDAP registry, you must configure security definitions. You can use the following instructions to create a writable or a read-only LDAP user registry.

For general information about authenticating with LDAP, see [LDAP authentication](#).

---

### Logging in to the management server CLI

Before you can define the LDAP user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

For full details of the login command, see [Logging in to a management server](#).

For more information about how to use the CLI, see [Installing the toolkit](#), and [Overview of the command-line tool](#).

---

### Defining your LDAP configuration

You define the configuration of your LDAP user registry in an `ldap_config_file.yaml` file, as shown in the following example. Note that the actual contents of your YAML file will vary depending on the authentication method of your LDAP server, and this is explained in the following tables.

```
name: registry_name
title: "display_title"
integration url: LDAP_integration_url
user_managed: true_or_false
user_registry_managed: false
case_sensitive: true_or_false
identity_providers:
- name: provider_name
  title: provider_title
endpoint:
  endpoint: "ldap_server_url_and_port"
configuration:
  authentication method: authentication_method
  authenticated_bind: "true_or_false"
  admin_dn: "admin_dn"
```

```

admin_password: admin_password
search_dn_base: "search_dn_base"
search_dn_scope: search_dn_scope
search_dn_filter_prefix: prefix
search_dn_filter_suffix: suffix
attribute_mapping:
  dn: "distinguished_name"
  cn: "common_name"
  sn: "last_name"
  mail: "email_address"
  userPassword: "password"

```

The registry properties that are common to each authentication method are described in the following table:

| Property                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>name</b>                  | The name of the registry. This name is used in CLI commands.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>title</b>                 | A descriptive name to display in a graphical user interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>integration_url</b>       | The LDAP integration URL in your API Connect configuration. You can determine the LDAP integration URL by using the following CLI command:<br><code>apic integrations:list --server mgmt_endpoint_url --subcollection user-registry</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>user_managed</b>          | Determines whether your user registry is writable or not. Must be set to <b>true</b> for writable LDAP. You can change this setting to <b>false</b> if you don't want the registry to be writable; see the Switching your LDAP registry between writable and read-only section at the end of this topic for details. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.                                                                                                                                                                                                                                                                                                                |
| <b>user_registry_managed</b> | Must be set to <b>false</b> for LDAP. Determines whether API Connect manages your user registry. Only LUR registries are managed by API Connect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>case_sensitive</b>        | Determines whether your user registry is case-sensitive. Valid values are: <ul style="list-style-type: none"> <li>• <b>true</b></li> <li>• <b>false</b></li> </ul> <p>To ensure proper handling of user name capitalization, you <b>must</b> ensure that your case-sensitivity setting here matches the setting on your backend LDAP server:</p> <ul style="list-style-type: none"> <li>• <b>Only</b> set <b>case_sensitive</b> to <b>true</b> if your backend LDAP server supports case-sensitivity.</li> <li>• Set <b>case_sensitive</b> to <b>false</b> if your backend LDAP server does not support case-sensitivity.</li> </ul> <p>Note: After at least one user has been onboarded into the registry, you cannot change this setting.</p> |
| <b>identity_providers</b>    | An array containing the details of your LDAP server, where: <ul style="list-style-type: none"> <li>• <b>name</b> - is the name of the LDAP server and is the name that is used in CLI commands</li> <li>• <b>title</b> - is the display name of the LDAP server</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>endpoint</b>              | The endpoint of your LDAP server, made up of the url and port, for example:<br><code>"ldap://server.com:389"</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>tls_profile</b>           | Optionally set the TLS Client Profile that the LDAP server requires.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>protocol_version</b>      | Optionally set the version number for the LDAP protocol that you are using. Valid values are: <ul style="list-style-type: none"> <li>• 2</li> <li>• 3</li> </ul> <p>Defaults to 3 if not explicitly set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

The properties in the configuration section will vary depending on the selected authentication method. The three authentication methods are:

- **compose\_dn** - Set this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, **compose\_dn** is not supported with the DataPower API Gateway.
- **compose\_upn** - Set this format if your LDAP directory supports binding with User Principal Names such as `john@acme.com`. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, **compose\_upn** is not supported with the DataPower API Gateway.
- **search\_dn** - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DN of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For authentication method **compose\_dn**, set the following configuration properties:

| Properties                   | Description                                                                                                                                                                                                                                                                                                                    |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>authentication_method</b> | <b>compose_dn</b>                                                                                                                                                                                                                                                                                                              |
| <b>authenticated_bind</b>    | The bind method. Valid values are: <ul style="list-style-type: none"> <li>• <b>"true"</b> - authenticated bind</li> <li>• <b>"false"</b> - anonymous bind</li> </ul> <p>If specific permissions are not needed to search the registry, select <b>"false"</b>. If specific permissions are necessary, select <b>"true"</b>.</p> |
| <b>admin_dn</b>              | If <b>authenticated_bind</b> is set to <b>"true"</b> , enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example:<br><code>"cn=admin,dc=company,dc=com"</code>                                                                                                             |
| <b>admin_password</b>        | If <b>authenticated_bind</b> is set to <b>"true"</b> , enter the user password for the <b>admin_dn</b> .                                                                                                                                                                                                                       |
| <b>search_dn_base</b>        | Optionally set a base DN, for example:<br><code>"dc=company,dc=com"</code>                                                                                                                                                                                                                                                     |
| <b>bind_prefix</b>           | Set the prefix to the DN, for example:<br><code>(uid=</code>                                                                                                                                                                                                                                                                   |

| Properties               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bind_suffix</b>       | Set the suffix to the DN, for example:<br>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>attribute_mapping</b> | <p>If <b>user_managed</b> is set to <b>true</b>, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:</p> <pre>ldap_registry_attribute_name: "apic_ldap_attribute_value"</pre> <p>Where:</p> <ul style="list-style-type: none"> <li><code>ldap_registry_attribute_name</code> - is the name of the source LDAP attribute</li> <li><code>apic_ldap_attribute_value</code> - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in [ ] with the value that the user supplies when signing up.</li> </ul> <p>The user profile properties that API Connect requires during user registration are <b>username</b>, <b>first_name</b>, <b>last_name</b>, <b>email</b>, and <b>password</b>. The following extract shows an example of an attribute mapping:</p> <pre>attribute_mapping: dn: "uid=[username],ou=users,dc=company,dc=com" cn: "[first_name] [last_name]" sn: "[last_name]" mail: "[email]" userPassword: "[password]"</pre> |

For authentication method **compose\_upn**, set the following configuration properties:

| Properties                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <code>search_dn_scope</code>         | Optionally set the search DN scope. The scope determines which part of the directory information tree is examined. Possible values are: <ul style="list-style-type: none"> <li><code>base</code></li> <li><code>one</code></li> <li><code>sub</code></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>search_dn_filter_prefix</code> | Set the prefix to the DN, for example:<br>(uid=                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>search_dn_filter_suffix</code> | Set the suffix to the DN, for example:<br>)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>attribute_mapping</code>       | <p>If <code>user_managed</code> is set to <code>true</code>, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:</p> <pre>ldap_registry_attribute_name: "apic_ldap_attribute_value"</pre> <p>Where:</p> <ul style="list-style-type: none"> <li><code>ldap_registry_attribute_name</code> - is the name of the source LDAP attribute</li> <li><code>apic_ldap_attribute_value</code> - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in [ ] with the value that the user supplies when signing up.</li> </ul> <p>The user profile properties that API Connect requires during user registration are <code>username</code>, <code>first_name</code>, <code>last_name</code>, <code>email</code>, and <code>password</code>. The following extract shows an example of an attribute mapping:</p> <pre>attribute_mapping: dn: "uid=[username],ou=users,dc=company,dc=com" cn: "[first_name] [last_name]" sn: "[last_name]" mail: "[email]" userPassword: "[password]"</pre> |

Save your `ldap_config_file.yaml` so it can be accessed by the `user-registries:create` command in the following section. See the [Example](#) section for an example configuration file.

## Creating your LDAP user registry

To create your shared LDAP user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin ldap_config_file.yaml
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL.
- `--org admin` means that the registry will be created in the admin organization, which is required for a user registry to be shared.
- `ldap_config_file` is the name of the YAML file that defines the configuration of your LDAP user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The `registry_name` is derived from the `name` property in the configuration YAML file. The `registry_url` is the URL with which the registry resource can be accessed. Your shared LDAP user registry is now created; see the following sections for instructions on how to make the registry available to users.

## Configuring your LDAP registry for Cloud Manager or API Manager login

If you want to make your LDAP registry available for authenticating Cloud Manager and API Manager users, you must configure it on the management server.

- Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

- Determine what the current user registries are, because you will need to confirm these as well as add your new LDAP registry:

```
apic user-registry-settings:get --server mgmt_endpoint_url --output -
```

This command outputs a list of all the current user registries in your environment, similar to the following example:

```
type: user_registry_setting
api_version: 2.0.0
name: user-registry-setting
admin_user_registry_default_url: >-
  https://server.com/api/user-registries/xxxxx/xxxxx-1234
admin_user_registry_urls:
- >-
  https://server.com/api/user-registries/xxxxx/xxxxx-1234
provider_user_registry_default_url: >-
  https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
provider_user_registry_urls:
- >-
  https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
created_at: '2019-09-30T12:22:19.467Z'
updated_at: '2019-10-17T10:05:37.867Z'
url: 'https://server.com/api/cloud/settings/user-registries'
```

- Enter the following command to update your user registries (the terminating hyphen character means that the command takes input from the command line):

```
apic user-registry-settings:update --server mgmt_endpoint_url -
```

The following message is output:

```
Reading USER_REGISTRY_SETTING_FILE arg from stdin
```

4. If you want to make your LDAP registry available for authenticating Cloud Manager users, enter the following data, followed by a new line:

```
admin_user_registry_urls:
- >-
  current_admin_user_registry_urls
- new_ldap_user_registry_url
```

where:

- `current_admin_user_registry_urls` are the current admin user registry URLs, as listed in Step 2 in the `admin_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
- `new_ldap_user_registry_url` is the URL of your new LDAP user registry, as determined in Step 1.

5. If you want to make your LDAP registry available for authenticating API Manager users, enter the following data, followed by a new line:

```
provider_user_registry_urls:
- >-
  current_provider_user_registry_urls
- new_ldap_user_registry_url
```

where:

- `current_provider_user_registry_urls` are the current provider organization user registry URLs, as listed in Step 2 in the `provider_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
- `new_ldap_user_registry_url` is the URL of your new LDAP user registry, as determined in Step 1.

6. Press **CTRL D** to terminate the input. A confirmation message is output, for example:

```
user-registry-setting https://server.com/api/cloud/settings/user-registries
```

where `server.com` is your management server endpoint.

## Configuring your LDAP registry in a Catalog

If you want to make your LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

2. Log in to the management server as a member of a provider organization by entering the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

For full details of the `apic login` command, see [Logging in to a management server](#).

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
```

where `catalog_name` is the value of the `name` property of the required Catalog. The command returns:

```
Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
```

4. Enter the following data, followed by a new line:

```
user_registry_url: ldap_registry_url
```

where `ldap_registry_url` is the URL of your LDAP registry, obtained in step 1.

5. Press **CTRL D** to terminate the input.

## Switching your LDAP registry between writable and read-only

After an LDAP user registry has been created, it can be switched between writable and read-only by updating the `user_managed` property in the registry configuration. Complete the following steps.

1. Determine the name or ID of the LDAP user registry that you want to update, by running the following command (or you can use the summary from the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

The command returns a list of all the user registries on that server, shown by name followed by their registry URL. The registry ID is located at the end of the URL, for example `https://company.com/api/user-registries/x-x-x-x-x-x/registry_id`.

2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic user-registries:update --server mgmt_endpoint_url --org admin registry_name_or_id -
```

where `registry_name_or_id` is the name or ID of the LDAP user registry that you want to update (as determined in the previous step). The command returns:

```
Reading USER_REGISTRY_FILE arg from stdin
```

3. Enter the following data, followed by a new line:

```
user_managed: true_or_false
```

where `true` makes the registry writable, and `false` makes the registry read-only.

4. Press **CTRL D** to terminate the input.

Note that if you are changing your registry from read-only to writable, you must also set the `attribute_mapping` configuration, as described in the previous registry property tables.

## Using an LDAP user registry to secure APIs

---

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see [Creating a basic authentication security definition](#).
- To use for authentication in the User Security configuration for a native OAuth provider, see [Configuring user security for a native OAuth provider](#).

For details of all the `apic user-registries` and `apic configured-catalog-user-registries` commands, see [apic user-registries](#) and [apic configured-catalog-user-registries](#).

## Example

---

The following example shows a configuration file that uses the Search DN authentication method for setting up writable LDAP:

```
name: sdn-ldap
title: "SDN LDAP User Registry"
integration_url: https://mycompany.com/api/cloud/integrations/user-registry/xxx-xxx-xxx
user_managed: true
user_registry_managed: false
case_sensitive: false
identity_providers:
  - name: ldap
    title: "SDN LDAP Identity Provider"
endpoint:
  endpoint: "ldap://mycompany.com:389"
configuration:
  authentication_method: search_dn
  authenticated_bind: "true"
  admin_dn: "cn=admin,dc=company,dc=com"
  admin_password: xxxx
  search_dn_base: "dc=company,dc=com"
  search_dn_scope: sub
  search_dn_filter_prefix: (uid=
  search_dn_filter_suffix: )
  attribute_mapping:
    dn: "uid=[username],ou=users,dc=company,dc=com"
    cn: "[first_name] [last_name]"
    sn: "[last_name]"
    mail: "[email]"
    userPassword: "[password]"
```

## Configuring a Local User Registry

---

A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.

### About this task

---

Local User Registries (LURs) are the default user registries included in API Connect. LURs are local databases included with API Connect. Two default LURs are installed and configured during installation of API Connect. They cannot be deleted. The default Admin user account is stored in the Provider LUR.

You can create and configure a new LUR. After you create it, you must set it as active in Settings > User Registries. See [Selecting user registries for Cloud Manager and API Manager](#).

One of the following roles is required to configure user registries:

- Administrator
- Owner
- Topology Administrator
- Custom role with the Settings: Manage permissions

## Procedure

---

Follow these steps to configure a new LUR:

1. In the Cloud Manager, click  .

- Click Create in the User Registries section.
- Select Local User Registry as the type for the user registry and enter the following information:

| Field                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)        | Enter a descriptive name for use on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Name (required)         | The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see <a href="#">apic user-registries</a> .                                                                                                                                                                                                                                                                                                                                                                         |
| Display Name (required) | The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see <a href="#">Accessing the Cloud Manager user interface</a> , <a href="#">Accessing the API Manager user interface</a> , and <a href="#">Activating your API Manager user account</a> .<br>Note: The Developer Portal uses the <b>Title</b> of the User Registries when rendering them at the login page, rather than the <b>Display Name</b> . |
| Summary (optional)      | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Case sensitive          | Select this setting if user names are case-sensitive.<br>Note:<br>The Developer Portal does not support case sensitive usernames.<br>Note: After at least one user has been onboarded into the registry, you cannot change this setting.                                                                                                                                                                                                                                                                                                            |

- Click Save.

## Results

The user registry is saved and is available to be configured for user authentication in Cloud Manager or API Manager by selecting it in Settings > User Registries. See [Selecting user registries for Cloud Manager and API Manager](#).

## Configuring an OIDC user registry

Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.

You can create an OIDC user registry that is specific to a provider organization, or that is shared and available to all the provider organizations in your API Connect environment. An organization-specific OIDC user registry is used for onboarding and authenticating Developer Portal users, while a shared OIDC user registry can be used for onboarding and authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to create a shared registry. For information on how to create an organization-specific registry, see [Creating an OIDC user registry](#).

API Connect provides two methods for creating an OIDC user registry in Cloud Manager, as described in the following sections:

- [Using the UI to configure an OIDC user registry](#)
- [Using the CLI to configure an OIDC user registry](#)

Note: Refresh tokens are not supported for a user in an OIDC user registry when accessing the Cloud Manager or API Manager user interfaces.

## Using the UI to configure an OIDC user registry

Use the Cloud Manager application's user interface to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

- In the Cloud Manager navigation pane, click  Resources.
- Click User Registries.
- Click Create and select OIDC User Registry.
- On the Create OIDC User Registry page, use the fields in each of the following sections to configure the registry settings, and then click Create. Many of the registry settings are preconfigured to simplify the configuration steps.

### Provider Type

Use the settings in Table 1 to define the provider type.

Table 1. Provider Type settings

| Field | Description |
|-------|-------------|
|-------|-------------|

| Field         | Description                                                                                                                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Provider Type | OIDC provider. Select one of the following supported OIDC providers: <ul style="list-style-type: none"> <li>• Facebook</li> <li>• GitHub</li> <li>• Google</li> <li>• LinkedIn</li> <li>• Slack</li> <li>• Twitter</li> <li>• Windows Live</li> <li>• Standard OIDC (default value allows you to specify another provider)</li> </ul> |
| Title         | Provide a descriptive name for display purposes.                                                                                                                                                                                                                                                                                      |
| Name          | Automatically generated. This name is used in CLI commands to reference the registry. For details of the CLI commands for managing user registries, see the <a href="#">apic user-registries</a> topic in the Command Line tool reference section of this documentation.                                                              |
| Summary       | Provide a brief description of the new registry.                                                                                                                                                                                                                                                                                      |

Provider Endpoint

Automatically generated for most supported providers. In the Authorization Endpoint field, type the URL of the provider's authorization endpoint.

Token Endpoint

Fill in the settings as described in Table 2.

Table 2. Token Endpoint settings

| Field | Description                                                                                                                       |
|-------|-----------------------------------------------------------------------------------------------------------------------------------|
| URL   | Preconfigured for most of the supported OIDC providers. Type the URL of the provider's token endpoint.                            |
| TLS   | Select the TLS Client Profile for the token endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile. |

UserInfo Endpoint

Fill in the settings as described in Table 3.

Table 3. UserInfo Endpoint settings

| Field | Description                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------|
| URL   | Preconfigured for most of the supported OIDC providers. Type the URL of the provider's userinfo endpoint.                            |
| TLS   | Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile. |

JWKS Endpoint

Fill in the settings as described in Table 4.

Table 4. JWKS Endpoint settings

| Field | Description                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------|
| URL   | Type the URL of the read-only endpoint that contains the public keys' information in JWKS format.                                    |
| TLS   | Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile. |

Client Information

Fill in the settings as described in Table 5.

Table 5. Client Information settings

| Field                        | Description                                                                                                                                                                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client ID                    | Provide the client ID of the application that is registered with the selected OIDC provider.                                                                                                                                                                    |
| Client Secret                | Provide the client secret of the application that is registered with the selected OIDC provider.                                                                                                                                                                |
| Response Type                | Preconfigured for most of the supported OIDC providers. Specify the data type of the response that will be received from the OIDC provider.                                                                                                                     |
| Scopes                       | Preconfigured for most of the supported OIDC providers. Specify the access scope for the OIDC provider.                                                                                                                                                         |
| Client Authentication Method | Preconfigured for most of the supported OIDC providers. Select the authentication method to be used with the OIDC provider. Options are: <ul style="list-style-type: none"> <li>• Http basic authentication schema</li> <li>• Data encoded form body</li> </ul> |

Additional Support

Optional. Select the additional security parameters described in Table 6.

Table 6. Additional security options

| Security parameter                 | Description                                                                                                            |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| NONCE                              | Enable the NONCE extension to prevent compromised requests from being used again (replayed).                           |
| Proof Key for Code Exchange (PKCE) | Enable the PKCE extension to allow public clients to mitigate the threat of having the authorization code intercepted. |

Advanced Features

Optional. Select the advanced features described in Table 7.

Table 7. Advanced features

| Feature                          | Description                                                                                                                     |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Auto onboard                     | Allow users to execute calls to APIs without logging in first, provided they present a valid token issued by the OIDC provider. |
| Always use the userinfo endpoint | Configures the OIDC user registry to always fetch user data from the userinfo endpoint, if populated.                           |
| Return third-party access token  | Include the third-party OIDC access token in the response.                                                                      |
| Return third-party id_token      | Include the third-party OIDC id_token in the response.                                                                          |

User Mapping

Fill in the settings as described in Table 8.

Note:

The User Mapping fields are preconfigured for most of the supported OIDC providers to minimize potential errors; use care when changing the settings. For the Standard OIDC option, contact your OIDC provider to obtain the details of the fields.

Table 8. User mapping settings

| Field | Description |
|-------|-------------|
|-------|-------------|

| Field      | Description                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username   | The name of the field in the response token that contains the user's user name.<br>Note: The username field must be unique for this OIDC registry, because it identifies the user in the system and cannot be changed. |
| Email      | The name of the field in the response token that contains the user's email address.                                                                                                                                    |
| First name | The name of the field in the response token that contains the user's given name.                                                                                                                                       |
| Last name  | The name of the field in the response token that contains the user's surname.                                                                                                                                          |

## Enabling the OIDC user registry

Complete the following steps to enable the new user registry for Cloud Manager, API Manager, or both.

1. On the navigation pane, click  Settings.
2. Click User Registries, > Edit.
3. Click Edit in the section that corresponds to the application for which you are enabling the new user registry.
4. Select the new OIDC user registry.
5. When you have finished enabling the registry, click Save.

## Using the CLI to configure an OIDC user registry

Use the developer toolkit CLI to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

You configure an OIDC user registry by first defining the registry details in a configuration file. You then use a CLI command to create the registry, passing the configuration file as parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated Catalog.

Note:

- An OIDC registry, in common with a Local User Registry, cannot be used to secure APIs on the gateway.
- Because the interaction with the third party OIDC provider is handled by the Management server, the Management server is the application from the point of view of the third party OIDC provider. Your OIDC redirection endpoint, which is used by authorization server to send the token to the Management server, must be accessible to the OIDC provider through your firewall. When you register your application with the third party OIDC provider, you are required to supply the associated OIDC redirect URI, `https://consumer.mycompany.com/consumer-api/oauth2/redirect` for example. However, this information is not available until you have created your OIDC user registry in API Connect. You must therefore first register your application without this information, then update it later, as detailed in the instructions on this page.

### Logging in to the Management server

Before you can create an OIDC user registry, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

For full details of the `apic login` command, see [Logging in to a management server](#).

### Defining your OIDC registry configuration

You define the configuration of your OIDC user registry in a YAML file. As a minimum, the YAML file must have the following content:

```
title: registry_title
integration_url: oidc_integration_url
case_sensitive: case_sensitivity_setting
configuration:
  client_id: 'app_client_id'
  client_secret: 'my-client-secret'
  provider_type: oidc_provider_type
```

where:

- `registry_title` is your chosen descriptive title for the user registry.
- `oidc_integration_url` is the OIDC integration URL in your API Connect configuration. You can determine the OIDC integration URL by using the following CLI command:

```
apic integrations:list --server mgmt_endpoint_url --subcollection user-registry
```

- `case_sensitivity_setting` determines whether your user registry is case-sensitive. Valid values are:
  - `true`
  - `false`

To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on the backend OIDC provider:

- **Only** set `case_sensitive` to `true` if the backend OIDC provider supports case-sensitivity.
- Set `case_sensitive` to `false` if the backend OIDC provider does not support case-sensitivity.

Note: After at least one user has been onboarded into the registry, you cannot change this setting.

- `app_client_id` is the client ID of the application that is registered with the OIDC server, and must be in string format.
- `my-client-secret` is the client secret of the application that is registered with the OIDC server, and must be in string format.
- `oidc_provider_type` is the type of OIDC provider; specify one of the following values:
  - `facebook`
  - `github`
  - `google`
  - `linkedin`
  - `slack`
  - `twitter`
  - `windows_live`
  - `standard`

Use the `standard` provider type for any OIDC provider that is compliant with the OIDC standard.

Note: If the provider type is `standard`, you must include the following additional properties in the `configuration` section of your YAML file:

```
authorization_endpoint: 'oidc_auth_endpoint'
token_endpoint:
```

```
endpoint: 'oidc_token_endpoint'
```

where:

- `oidc_auth_endpoint` is the authorization endpoint on the OIDC server, and must be in string format.
- `oidc_token_endpoint` is the token endpoint on the OIDC server, and must be in string format.

## Default OIDC configurations

For each OIDC provider type, API Connect assumes a default configuration, but you can override the default configuration properties in your YAML file. The default configurations are as follows:

- Facebook

```
authorization_endpoint: 'https://www.facebook.com/v3.1/dialog/oauth'
token_endpoint:
  endpoint: 'https://graph.facebook.com/v3.1/oauth/access_token'
userinfo_endpoint:
  endpoint: 'https://graph.facebook.com/me'
scope: email public_profile
field_mapping:
  username: email
  email: email
  last_name: last_name
  first_name: first_name
```

- Github

```
authorization_endpoint: 'https://github.com/login/oauth/authorize'
token_endpoint:
  endpoint: 'https://github.com/login/oauth/access_token'
userinfo_endpoint:
  endpoint: 'https://api.github.com/user'
scope: 'read:user user:email'
field_mapping:
  username: login
  email: email
  last_name: name
  first_name: name
```

- Google

```
authorization_endpoint: 'https://accounts.google.com/o/oauth2/v2/auth'
token_endpoint:
  endpoint: 'https://www.googleapis.com/oauth2/v4/token'
scope: openid profile email
field_mapping:
  username: email
  email: email
  last_name: family_name
  first_name: given_name
```

- LinkedIn

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
token_endpoint:
  endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
userinfo_endpoint:
  endpoint: 'https://api.linkedin.com/v1/people/~:(id,first-name,last-name,picture-url,public-profile-url,email-address)?
format=json'
scope: r_basicprofile r_emailaddress
field_mapping:
  username: emailAddress
  email: emailAddress

  first_name: given_name
credential_location: auth_header
```

Although this is the default configuration for the **standard** provider type, you should contact your OIDC provider to obtain the details of the fields that you need to define.

## Creating your OIDC user registry

To create your OIDC user registry, use the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin oidc_config_file
```

where:

- *mgmt\_endpoint\_url* is the platform API endpoint URL.
- *organization\_name* is the value of the **name** property of your provider organization.
- *oidc\_config\_file* is the name of the YAML file that defines the configuration of your OIDC user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

By default, the *registry\_name* is derived from the **title** property in the configuration YAML file but you can override this by including a **name** property in the file. The *registry\_url* is an internal URL that API Connect assigns to the registry.

After you have created your OIDC user registry, you must update your application registration with the third party OIDC provider to include the OIDC redirect URI; you can obtain this information by using the following command, which displays the details of the registry in the command window:

```
apic user-registries:get --server mgmt_endpoint_url --org organization_name registry_name --output -
```

The required **oidc\_redirect\_uri** value is in the **consumer:** section; for example:

```
consumer:
  oidc_redirect_uri: https://consumer.mycompany.com/consumer-api/oauth2/redirect
```

## Enabling your OIDC registry in a Catalog

If you want to make your OIDC registry available for onboarding and authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your OIDC user registry by using the following command:

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

2. Log in to the Management server as a member of a provider organization; enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

For full details of the **apic login** command, see [Logging in to a management server](#).

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
```

where *catalog\_name* is the value of the **name** property of the required Catalog. The command returns

```
Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
```

4. Enter the following data, followed by a new line:

```
user_registry_url: oidc_registry_url
```

where *oidc\_registry\_url* is the URL of your OIDC registry, obtained in step [1](#).

5. Press **CTRL D** to terminate the input.

For details of all the **apic user-registries** and **apic configured-catalog-user-registries** commands, see [apic user-registries](#) and [apic configured-catalog-user-registries](#).

You can also complete the operations described in this topic by using the API Connect REST APIs; see the [API Connect REST API documentation](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Setting visibility for a user registry

The visibility setting determines which provider organizations can access a resource, for example, user registries.

### Before you begin

---

You must complete the following tasks:

- [Creating an Availability Zone](#)
- [Registering a gateway service](#)

### About this task

---

The user registry visibility setting controls which provider organizations are able to use that registry for authenticating Developer Portal users, or for securing APIs. For details on how to specify the user registries that can be used for authenticating users of the Cloud Manager and API Manager user interfaces, see [Selecting user registries for Cloud Manager and API Manager](#).

### Procedure

---

Follow these steps to set the visibility for the resources (user registries) in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select User Registries as the resource to view.
3. From the list of user registries, choose Edit visibility from the actions menu next to the name of the user registry you are working with.
4. Select the visibility setting for the user registry. The options are:
  - Private - the user registry is not visible and cannot be used by any provider organization
  - Public - the user registry is visible and can be used by all provider organizations
  - Custom - the user registry is visible only to the provider organizations designated by you
5. For Custom visibility, select the provider organizations that you want to have access to the user registry.
6. Click Make visible to complete the operation.

### Results

---

For Private, the user registry cannot be used by any provider organizations. For Public, the user registry can be used by all provider organizations. For Custom, the user registry can be used by the provider organizations that you designate.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Deleting a user registry

As the Cloud Manager administrator, you can delete user registries.

### About this task

---

Complete the following steps to delete a user registry. All users within the user registry will be deleted. The pre-configured user registries (API Manager Local User Registry and Cloud Manager Local User Registry) may not be deleted. Any user registry marked as the Default in Settings > User Registries also may not be deleted.

One of the following roles is required to delete a user registry:

- Administrator
- Owner

### Procedure

---

1. In the Cloud Manager, click .
2. Select User Registries to see the list of current user registries in your cloud.
3. Choose Delete from the overflow menu that is adjacent to the user registry you want to delete.
4. Optionally, you can delete multiple user registries by marking the checkboxes and selecting Delete Selected User Registries from the overflow menu for the list.
5. Confirm the deletion.

### Results

---

The user registry is deleted and removed from the User Registries list in Cloud Manager. All user accounts contained in the user registry are deleted.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Removing a user from a user registry

As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

For details on how to remove a user from a user registry, see the following subtopics:

- [Removing yourself from a user registry](#)  
As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.
- [Removing another user from a user registry](#)  
You can remove a user from an API Connect user registry by using the developer toolkit CLI.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Removing yourself from a user registry

As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.

---

### Before you begin

You cannot remove yourself from a user registry if you are a member of a provider organization. Before removing yourself from a user registry, ensure that you have been deleted from any provider organizations. For more information, see [Removing a user from an organization](#).

---

### Procedure

1. Log in to the management server as the user that you want to remove.  
The format of the login command depends on whether you are a user in the Cloud Manager admin organization, or you are a user in a provider organization.

If you are a Cloud Manager admin user, enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

If you are a provider organization user, enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

For full details of the `apic login` command, see [Logging in to a management server](#).

Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and you have access to both, when you remove yourself from the user registry you will lose access to both user interfaces regardless of which organization you log in to.

2. Remove yourself from the user registry. Enter the following command:

```
apic me:delete --server mgmt_endpoint_url
```

For example:

```
apic me:delete --server platform-api.myserver.com.com
```

The command confirms successful removal by returning the details of the deleted user; for example:

```
user1 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Removing another user from a user registry

You can remove a user from an API Connect user registry by using the developer toolkit CLI.

---

### Before you begin

To complete this task, you must have Administrator access to your API Connect cloud.

You cannot remove a user from a user registry if that user is a member of a provider organization. Before removing a user from a user registry, ensure that they have been deleted from any provider organizations. For more information, see [Removing a user from an organization](#).

## Procedure

1. Log in to the management server as a member of the Cloud Manager admin organization. Enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

For full details of the `apic login` command, see [Logging in to a management server](#).

Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and the user has access to both, when you remove them from the user registry they will lose access to both even though you are logging in to the admin organization.

2. Identify the name of the user registry from which you want to remove the user. Enter the following command:

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

For example:

```
apic user-registries:list --server platform-api.myserver.com.com --org admin
```

The command returns a list of all user registries, with the registry name displayed first; for example:

```
api-manager-lur      https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245
cloud-manager-lur   https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/3adbf524-cd74-4051-99c0-89ce5ffcc9c0
my-ldap             https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/29eae413-cd74-4051-99c0-89ce5ffcc9c0
```

3. Identify the name of the user, from the required user registry, that you want to remove. Enter the following command:

```
apic users:list --server mgmt_endpoint_url --org admin --user-registry user_registry_name
```

For example:

```
apic users:list --server platform-api.myserver.com.com --org admin --user-registry my-ldap
```

The command returns a list of all users in the user registry, with the user name displayed first; for example:

```
user1 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
user2 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/12f1aa82-d9f0-4670-99f1-7500d1fb6583
```

4. Remove the required user from the user registry. Enter the following command:

```
apic users:delete user_name --server mgmt_endpoint_url --org admin --user-registry user_registry_name
```

For example:

```
apic users:delete user1 --server platform-api.myserver.com.com --org admin --user-registry my-ldap
```

The command confirms successful removal by returning the details of the deleted user; for example:

```
user1 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## TLS profiles overview

API Connect supports TLS Profiles for securing data transmission over HTTPS.

### Introduction to TLS profiles

Important: API Connect includes several default TLS profiles to help you get started working with the application. The default profiles should not be used in a production environment. It is important to create your own profiles to ensure a secure network.

API Connect may need to transmit data across an untrusted network, for example, when accessing the Gateway, email server, or LDAP server. TLS provides secure network layer transportation of data between two parties.

There are two types of TLS Profiles: a TLS Server Profile and a TLS Client Profile. A TLS Server Profile is used by the Gateway to configure its endpoint for use during API execution. A TLS Client profile is used whenever the system needs to communicate with another endpoint over TLS.

The components of a TLS Profile are:

- TLS Protocol version indicates the versions of the Transport Layer Security Protocol required for the profile. TLS Protocol versions 1.0, 1.1, and 1.2 are supported.
- Optional support for mutual authentication and renegotiation for Server Profiles.
- Optional support for weak server connections and Server Name Indication for Client Profiles.

- Cipher suites to secure HTTPs communication within the API Connect ecosystem.
- Keystores containing public and private key pairs.
- Truststores containing public keys for trusted third party services, such as Google, Facebook, or Verisign.
- [Viewing TLS Profiles, Keystores, and Truststores](#)  
The current list of TLS profiles, Keystores, and Truststores can be viewed on the main TLS screen.
- [Creating a TLS Server Profile](#)  
In Cloud Manager, you can configure the profile that is used on the gateway when it acts as a TLS server.
- [Creating a TLS Client Profile](#)  
In Cloud Manager, TLS profiles are configured as a Resource to provide secure transmission of data over HTTPs.
- [Creating a Keystore](#)  
Each keystore contain a matched pair of a public certificates and its private keys. These artifacts provide identity information during a TLS handshake.
- [Creating a Truststore](#)  
A truststore contains a list of certificates. The certificates are used to verify the peer during a TLS handshake.
- [Viewing certificate details and adding certificates to a keystore or truststore](#)  
You can view details for the certificates in an existing keystore or truststore and add additional certificates.
- [Generating a self-signed certificate using OpenSSL](#)  
OpenSSL is an open source implementation of the SSL and TLS protocols. It provides the transport layer security over the normal communications layer, allowing it to be intertwined with many network applications and services.
- [Generating a PKCS#12 file for Certificate Authority](#)  
PKCS#12 (P12) files define an archive file format for storing cryptographic objects as a single file. API Connect supports the P12 file format for uploading a keystore and truststore. The keystore should contain both a private and public key along with intermediate CA certificates.
- [Binding a TLS server profile to a gateway service](#)  
You can bind the SSL certificate of a TLS profile to a gateway service to establish an HTTPS binding. This enables you to access the service by using the HTTPS communication protocol.
- [Updating the PKCS#12 certificate for a TLS server profile](#)  
A server certificate bound to a gateway service can be invalidated if the host name in the digital certificate of the server does not match the URL specified by the client, or because it has expired. When this happens, you must update the TLS profile with a new CA certificate or PKCS#12 (P12) file.

## Related tasks

## Viewing TLS Profiles, Keystores, and Truststores

The current list of TLS profiles, Keystores, and Truststores can be viewed on the main TLS screen.

## Before you begin

---

Important: API Connect includes several default TLS profiles to help you get started working with the application. The default profiles should not be used in a production environment. It is important to create your own profiles to ensure a secure network.

One of the following roles is required to view TLS Server Profiles:

- Administrator
- Owner
- Topology Administrator
- Viewer
- Custom role with the `Settings: Manage or Settings: view` permissions

## About this task

---

The TLS list screen provides a list of TLS Profiles, Keystores and Truststores configured for your cloud. Users with view permissions can use this screen as a reference for the TLS Profiles.

Users with manage permissions can create new Profiles, Keystores, and Truststores; edit existing ones; and delete items that are no longer needed. Users can view the Keystores and Truststores assigned to the profiles.

Users can view and set the visibility for Client Profiles. For more information on visibility, see [Setting visibility for a TLS Client Profile](#)

## Procedure

---

Following are the tasks you can perform using the list screen as a base:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Complete your management task:

- To create a new item, click Create next to the table for the type of item you want to create.
- To edit an existing item, either click the Title of the item, or click the options menu  and then click Edit.
- To set the visibility of a TLS Client Profile, click the options menu  for the profile, and then click Edit Visibility.
- To delete an existing item, click the options menu  for the profile, and then click Delete.

# Creating a TLS Server Profile

In Cloud Manager, you can configure the profile that is used on the gateway when it acts as a TLS server.

## Before you begin

Important: API Connect includes several default TLS profiles to help you get started. The default profiles should not be used in a production environment. It is important to create your own profiles to secure your network.

One of the following roles is required to configure TLS Server Profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage permissions`

## About this task

The Server profile is for the gateway when it is acting as the TLS server.

## Procedure

Perform the following steps to create a TLS Server profile:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click Create in the TLS Server Profile table.
4. Enter the fields to configure the TLS Server Profile:

| Field                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)                 | Enter a Title for the profile. The title is displayed on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Name (required)                  | The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage TLS Server Profiles, see <a href="#">apic tls-server-profiles</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Version (required)               | Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, <i>MyProfile 1.0</i> and <i>MyProfile 1.1</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Summary (optional)               | Enter a description of the profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Protocols (required)             | Select one or more supported TLS protocol versions. The default is 1.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Mutual Authentication (required) | Determines the level of two-way authentication for the server profile. In two-way authentication, the server responds to a client by sending a request for the client certificate. <ul style="list-style-type: none"> <li>• None (default) No support for mutual authentication.</li> <li>• Request Enable this option to request client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the certificate is not checked on the gateway.</li> <li>• Require Enable this option to require client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the TLS handshake fails and the request is blocked.</li> </ul> |
| Limit Renegotiation (optional)   | Client-initiated renegotiation allows the connection to be retried. The default is to prevent renegotiation. Remove the checkmark to allow renegotiation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Field                 | Description                                                                                                                                                                                                                                                                                                               |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Keystore (required)   | A keystore is a repository containing a public and private key pair. The Server Profile requires a keystore in order to securely identify the system. When an application sends an API request, the keystore is used to verify a matching certificate.                                                                    |
| Truststore (optional) | A truststore is a repository containing certificates. The certificates are used to verify the peer during a TLS handshake. If, in addition to a keystore, a truststore is specified, the certificate is further checked for validity by ensuring that is signed by the root certificate, which must be in the truststore. |
| Ciphers (required)    | Select the ciphers for the profile.                                                                                                                                                                                                                                                                                       |

5. Click Save.

## Creating a TLS Client Profile

In Cloud Manager, TLS profiles are configured as a Resource to provide secure transmission of data over HTTPs.

### Before you begin

One of the following roles is required to configure TLS Profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

### About this task

API Connect uses both TLS Server and TLS Client profiles. A TLS Server profile is presented when a communication request is received. The Server profile validates the request against the Keystore and protocol version to determine whether the connection is secure. The Client profile is presented to initiate communication with another system. Client Profiles may be made visible for use by provider organizations in policies in API Manager. See [Setting visibility for a TLS Client Profile](#).

### Procedure

Perform the following steps to create a TLS Client profile:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click Create in the TLS Client Profile table.
4. Enter the fields to configure the TLS Client Profile:

| Field                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)             | Enter a Title for the profile. The title is displayed on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Name (required)              | The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage a TLS Client Profile, see <a href="#">apic tls-client-profiles</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Version (required)           | Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, <i>MyProfile 1.0</i> and <i>MyProfile 1.1</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Summary (optional)           | Enter a description of the profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Protocols (required)         | Select one or more supported TLS protocol versions. The default is 1.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Server Connection (optional) | Specify whether to support weak or insecure credentials. <ul style="list-style-type: none"> <li>• Allow insecure server connections - Insecure server connections may result from self-signed certificates, expired or corrupted certificates, or certificates from an unknown or untrusted source. Check this box to allow the connection to proceed with an insecure connection. The default is to not allow insecure server connections.</li> <li>• Support Server Name Indication (SNI) - Check this box to enable SNI. SNI allows support for multiple certificates presented on the same IP address using different host names. The client profile sends the name of a virtual domain as part of the TLS negotiation. The default is to enable SNI.</li> </ul> |

| Field                 | Description                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Keystore (optional)   | A Keystore is a repository containing public and private key pairs. Select the keystore where you will store the certificates for the profile. Default keystores are provided, and you can also create your own.                                                                                                                                                            |
| Truststore (optional) | A Truststore is a repository containing verified public keys, which are usually obtained from a third-party certificate authority. Truststores provide secure identification for peer systems. A truststore is usually used when mutual authentication is enabled. Select a truststore for the profile. Default truststores are provided, and you can also create your own. |
| Ciphers (required)    | Cipher suites are encryption/decryption algorithms used to secure HTTPs communication within the API Connect ecosystem. All ciphers are enabled by default. You can unselect one or more ciphers if they are not needed for the profile.                                                                                                                                    |

## Setting visibility for a TLS Client Profile

The visibility setting determines which provider organizations can access a resource.

### Before you begin

You must complete the following task:

- [Creating a TLS Client Profile](#)

### About this task

The visibility setting gives you control over the resources that are available to provider organizations.

### Procedure

Follow these steps to set the visibility for the resources in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select TLS as the resource to view.
3. From the table of TLS Client Profiles, choose Edit visibility from the  options menu next to the name of the profile you are managing.
4. Select the visibility setting for the profile. The options are:
  - Private - the profile is visible only in Cloud Manager and cannot be used by any provider organization
  - Public - the profile is visible and can be used by all provider organizations
  - Custom - the profile is visible only to the provider organizations designated by you
5. For Custom visibility, select the provider organizations that you want to have access to the profile.
6. Click Save to complete the operation.

### Results

For Private, the profile cannot be used by any provider organizations. For Public, the profile can be used by all provider organizations. For Custom, the profile can be used by the provider organizations that you designate. If visible, the profiles will be available in API Manager.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

# Defining elliptic curve cryptographic schemes for a TLS client profile

You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

## About this task

To define elliptic curve cryptographic schemes for a TLS client profile, you include `elliptic_curve_auto_negotiation` and `elliptic_curve` properties in a YAML file definition for the TLS client profile. The `elliptic_curve` property lists the required elliptic curve cryptographic schemes. For example:

```
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - secp521r1
  - secp384r1
  - prime256v1
```

You then use the developer toolkit CLI to create the TLS client profile in API Connect.

When `elliptic_curve_auto_negotiation` is set to `true`, the system negotiates the Elliptic-curve Diffie-Hellman (ECDH) key agreement automatically with its peer, and any `elliptic_curve` property settings are ignored.

The following example shows a complete YAML file for a TLS client profile:

```
type: tls_client_profile
name: my-tls-client-profile
version: 1.0.0
title: My TLS client profile
protocols:
  - tls_v1.2
ciphers:
  - ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - sect163k1
insecure_server_connections: false
server_name_indication: true
```

Note:

- The `elliptic_curve_auto_negotiation` option is not supported by any of the API Connect gateway types. If the TLS client profile is targeted for an API Connect gateway; this setting is ignored by the gateway.
- The elliptic curve cryptographic schemes shown in each row of the following table are equivalent. However, API Connect recognizes only one or the other depending on how the TLS profile is used, as indicated in the table.

Table 1.

| API enforcement on the gateway | API Connect server access security |
|--------------------------------|------------------------------------|
| secp192r1                      | prime192v1                         |
| secp256r1                      | prime256v1                         |

Therefore, if you want to use either of these schemes and are unsure whether you are targeting the TLS client profile to the API Connect gateway for API enforcement, whether you are using it to secure user access to the API Connect servers, or whether it will be used for both purposes, specify both equivalent schemes; API Connect will simply ignore the non-relevant scheme. For example:

```
elliptic_curve:
  .
  .
  .
  - secp256r1
  - prime256v1
  .
  .
  .
```

## Procedure

To create a TLS client profile with elliptic curve cryptographic schemes defined, complete the following steps:

- Create a YAML file definition for your TLS client profile, with the required `elliptic_curve` property.
- Log in to the management server from the developer toolkit CLI. Log in either as a member of the cloud administration organization or as a member of a provider organization, depending on where you want to create the TLS client profile. For details, see [Logging in to a management server](#).
- Create the TLS client profile by using the following command:

```
apic tls-client-profiles:create --server mgmt_endpoint_url --org organization_name tls_client_profile_yaml_file
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL, and is the same as that which was used when you logged in at step 2.
- `organization_name` is either `admin`, for the cloud administration organization, or the name of your provider organization, and is the same as that which was used when you logged in at step 2.
- `tls_client_profile_yaml_file` is the name of the YAML file that contains the definition for your TLS client profile.

Note: When you install IBM® API Connect, the API Connect gateway has a pre-supplied default TLS client profile that is used for API enforcement if you do not configure a TLS client profile; you cannot configure this default TLS client profile on the gateway.

For reference details of all the `apic tls-client-profiles` commands, see [apic tls-client-profiles](#).

You can also complete the operations described in this topic by using the API Connect REST APIs; see the [API Connect REST API documentation](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Creating a Keystore

Each keystore contains a matched pair of a public certificate and its private keys. These artifacts provide identity information during a TLS handshake.

### Before you begin

Cloud Manager and API Manager both support and use TLS certificates, but they do not themselves produce strong encryption keys or manage your encryption keys. Encryption keys are generated and managed according to your own procedures. For more information, see [Generating a PKCS#12 file for Certificate Authority](#) and [Generating a self-signed certificate using OpenSSL](#).

One of the following roles is required to configure Keystores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

### About this task

API Connect includes pre-configured Keystores which may be used for testing purposes. For production environments, we suggest creating a new, secure Keystore.

### Procedure

Perform the following steps to create a TLS Client profile:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click Create in the Keystore table.

| Field                                                   | Description                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)                                        | Enter a Title for the Keystore. The title is displayed on the screen.                                                                                                                                                                                                                       |
| Name (required)                                         | The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage keystores, see <a href="#">apic keystores</a> .                                                                           |
| Summary (optional)                                      | Enter a brief description.                                                                                                                                                                                                                                                                  |
| Private Key & Public Key:<br>Step 1: Upload private key | Upload the file containing the private key certificate. If necessary, you can click Browse to locate the file. If the file contains both the private and public keys, upload it in Step 1. Private and public keys are always uploaded in pairs, either in a single file or separate files. |
| Private key password (optional)                         | Enter the password for the private key if it has a password.                                                                                                                                                                                                                                |
| Private Key & Public Key:<br>Step 2: Upload public key  | If the public key is contained in a separate file, upload it in Step 2. Private and Public keys are always uploaded in pairs, either in a single file or separate files.                                                                                                                    |

4. Click Save.

Note: After they have been uploaded, private keys cannot be downloaded from API Connect.

---

## Creating a Truststore

A truststore contains a list of certificates. The certificates are used to verify the peer during a TLS handshake.

## Before you begin

---

One of the following roles is required to configure Truststores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

## About this task

---

Cloud Manager and API Manager both support and use TLS certificates, but they do not themselves produce strong encryption keys or manage your encryption keys. Encryption keys are generated and managed according to your own procedures. For more information, see [Generating a PKCS#12 file for Certificate Authority](#) and [Generating a self-signed certificate using OpenSSL](#).

API Connect includes pre-configured Truststores which may be used for testing purposes. For production environments, we suggest creating a new, secure Truststore.

## Procedure

---

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click Create in the Truststore table.

| Field              |                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)   | Enter a Title for the Truststore. The title is displayed on the screen.                                                                                                                                               |
| Name (required)    | The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage truststores, see <a href="#">apic truststores</a> . |
| Summary (optional) | Enter a brief description.                                                                                                                                                                                            |
| Public Keys        | Upload the file containing the public key certificate. If necessary you can click Browse to locate the file.                                                                                                          |

4. Click Save.

---

# Viewing certificate details and adding certificates to a keystore or truststore

You can view details for the certificates in an existing keystore or truststore and add additional certificates.

## Before you begin

---

One of the following roles is required to edit Keystores and Truststores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

## About this task

---

API Connect includes pre-configured Keystores and Truststores which you can use for testing purposes. For production environments, we suggest creating a new, secure Keystore or Truststore. From an existing Keystore or Truststore, you can edit the title, view the details of the certificates, and add new certificates.

## Procedure

---

To work with existing keystores and truststores:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click the name of the keystore or truststore.

4. Edit the name and summary if needed.
5. The Subject, Finger Print, and Expiration date is shown for each certificate in the keystore or truststore. Click > to view the certificate details.
6. Add additional private and/or public keys if needed.
7. Click Save.

Note: After they have been uploaded, private keys cannot be downloaded from API Connect.

# Generating a self-signed certificate using OpenSSL

OpenSSL is an open source implementation of the SSL and TLS protocols. It provides the transport layer security over the normal communications layer, allowing it to be intertwined with many network applications and services.

## Before you begin

---

One of the following roles is required to complete this task:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

## About this task

---

This topic tells you how to generate a self-signed SSL certificate request using the OpenSSL toolkit to enable HTTPS connections.

## Procedure

---

To generate a self-signed SSL certificate using the OpenSSL, complete the following steps:

1. Write down the Common Name (CN) for your SSL Certificate. The CN is the fully qualified name for the system that uses the certificate. For static DNS, use the hostname or IP address set in your Gateway Cluster (for example, `192.16.183.131` or `dp1.acme.com`).
2. Run the following OpenSSL command to generate your private key and public certificate. Answer the questions and enter the Common Name when prompted.

```
openssl req -newkey rsa:2048 -nodes -keyout key.pem -x509 -days 365 -out certificate.pem
```

3. Review the created certificate:

```
openssl x509 -text -noout -in certificate.pem
```

4. Combine your key and certificate in a PKCS#12 (P12) bundle:

```
openssl pkcs12 -inkey key.pem -in certificate.pem -export -out certificate.p12
```

5. Validate your P2 file.

```
openssl pkcs12 -in certificate.p12 -noout -info
```

Once the certificate file is created, it can be uploaded to a keystore.

6. In the Cloud Manager, click  Resources.
7. Select TLS.
8. Click Create in the Keystore table.
9. Create a Keystore and upload the certificate file following the instructions at [Creating a Keystore](#).

Note:

- API Connect supports only the P12 (PKCS12) format file for the present certificate.
- Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
- Your P12 file can contain a maximum of 10 intermediate certificates.

10. Click Save.

## Generating a PKCS#12 file for Certificate Authority

PKCS#12 (P12) files define an archive file format for storing cryptographic objects as a single file. API Connect supports the P12 file format for uploading a keystore and truststore. The keystore should contain both a private and public key along with intermediate CA certificates.

### Before you begin

One of the following roles is required to add a key to a keystore or truststore:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

Before you can generate a P12 file, you must have a private key (for example: `key.pem`), a signed certificate by a Certificate Authority (for example `certificate.pem`) and one or more certificates from the CA authority.

Note: If your certificate file contains more than one certificate, you must manually split the file and create a single file for each entry. Each entry must be bound by the following markers:

```
-----BEGIN CERTIFICATE-----  
-----END CERTIFICATE-----
```

### Procedure

1. If you have intermediate certificates from your CA, concatenate them into a single `.pem` file to build your `caChain`. Be sure to enter a new line following each certificate's data.

```
cat ca1.pem ca2.pem ca3.pem > caChain.pem  
cat caChain.pem  
-----BEGIN CERTIFICATE-----  
MIIEPjCCA46gAwIBAgIQEod26KZabjd+BQMG1Dw16jANBgkqhkiG9w0BAQUFADCB  
...  
lQX7CkTJn61AJUsyEa8H/gjVQnHp4VOLFR/dKgeVcCRvZF7Tt5AuiyHY  
-----END CERTIFICATE-----  
-----BEGIN CERTIFICATE-----  
MIIEPDCCAYsGawIBAgIQSEus8arH1xND0aJ0NumXJTANBgkqhkiG9w0BAQUFADBv  
...  
-----END CERTIFICATE-----  
-----BEGIN CERTIFICATE-----  
MIIEjCCAyx6gAwIBAgIBATANBgkqhkiG9w0BAQUFADBvMQswCQYDVQQGEWJTRTEU  
...  
-----END CERTIFICATE-----
```

2. Create the P12 file including the private key, the signed certificate and the CA file you created in step 1, if applicable. Omit the `-CAfile` option if you don't have CA certificates to include.

The following command uses OpenSSL, an open source implementation of the SSL and TLS protocols.

```
openssl pkcs12 -inkey key.pem -in certificate.pem -export -out certificate.p12 -CAfile caChain.pem -chain
```

Once the certificate file is created, it can be uploaded to a keystore.

3. In the Cloud Manager, click  Resources.

4. Select TLS.

5. Click Create in the Keystore table.

6. Create a Keystore and upload the certificate file following the instructions at [Creating a Keystore](#).

Note:

- API Connect supports only the P12 (PKCS12) format file for the present certificate.
- Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
- Your P12 file can contain a maximum of 10 intermediate certificates.

7. Click Save.

## Binding a TLS server profile to a gateway service

You can bind the SSL certificate of a TLS profile to a gateway service to establish an HTTPS binding. This enables you to access the service by using the HTTPS communication protocol.

### Before you begin

---

One of the following roles is required:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Topology: Manage permissions`

For more information on which user roles have access, see [Adding members to the admin organization](#).

### About this task

---

Perform the following steps to bind a TLS profile to a gateway service.

### Procedure

---

1. In the Cloud Manager user interface, click  Topology, then select the gateway service that you want to work with.
2. Scroll down to the API Invocation Endpoint section, and under Server Name Indication (SNI) select the required TLS server profile.  
You can also bind a TLS server profile during the initial registration of a gateway service; see [Registering a gateway service](#).
3. Click Save when done.

### Results

---

The TLS profile binds to the gateway service.

### What to do next

---

If you want to change the TLS Profile from Cloud Manager, for SNI Mapping of API Invocation endpoint, it is automatically changed in the associated Gateway. You do not need to do a removal or re-registration of the Gateway service.

### Related tasks

---

---

---

## Updating the PKCS#12 certificate for a TLS server profile

A server certificate bound to a gateway service can be invalidated if the host name in the digital certificate of the server does not match the URL specified by the client, or because it has expired. When this happens, you must update the TLS profile with a new CA certificate or PKCS#12 (P12) file.

## Before you begin

---

One of the following roles is required:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

## About this task

---

If the expiration date of a certificate or a P12 file is approaching, or if a certificate is invalidated, use the steps in this topic to update a TLS profile bound to a gateway service. CA certificate and P12 file expiration dates are displayed in the details of the containing keystore; see step 3.

You update the certificate for a TLS server profile by replacing the certificate in the keystore that is associated with the TLS server profile.

Complete the following steps to update a TLS profile that has an invalidated or expired certificate or P12 file. After you have uploaded the new certificate, you must remove and re-add the associated gateway service.

## Procedure

---

1. In the Cloud Manager user interface, click  Resources, then click TLS.
2. To identify the keystore that is associated with the TLS server profile, complete the following steps:
  - a. In the TLS Server Profile section, select the required profile.
  - b. In the Keystore/Truststore section, note the selected keystore, then click Cancel to close the TLS server profile details page.
3. In the Keystore section, select the required keystore.  
The Certificates section displays the expiration date of a certificate. You can expand a certificate to see further details.
4. Click Browse and select the required P12 file.  
Note:
  - API Connect supports only the P12 (PKCS12) format file for the present certificate.
  - Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
  - Your P12 file can contain a maximum of 10 intermediate certificates.
5. Click Save when done.

---

## OAuth Provider overview

API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

## Introduction to OAuth

---

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information. In API Connect, you can secure an API with OAuth.

In Cloud Manager, you configure both Native and Third party OAuth providers that can be made visible to selected Provider organizations. The OAuth Provider configuration is based on the OAuth 2.0 Specification, which is available at <https://tools.ietf.org/html/rfc6749>. Knowledge of the OAuth 2.0 specification is required to implement an OAuth Provider in API Connect.

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage permissions`

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- [Configuring a native OAuth provider](#)  
Native OAuth providers are configured and managed by you within your cloud.
- [Configuring a third-party OAuth provider](#)  
Enter the secure endpoints to provide OAuth authentication from a third party.
- [Setting the visibility for OAuth providers](#)  
The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.
- [OAuth concepts for API Connect](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring a native OAuth provider

Native OAuth providers are configured and managed by you within your cloud.

### About this task

A native OAuth provider object provides settings for OAuth processing operations such as generating and validating OAuth tokens. An OAuth provider object is referenced by an OAuth security definition to protect an API. When a native OAuth provider is used, the OAuth operations are performed natively by API Connect.

Every OAuth provider object has a backing API. Your configuration here automatically updates the OpenAPI document of the API. You can edit the OpenAPI document directly by navigating to the  Resources > OAuth Providers page, selecting your OAuth provider, then clicking API Editor.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

When a published API references an OAuth provider object, the backing API is automatically made available in the gateway.

One of the following roles is required to configure a native OAuth provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:

- The OAuth provider logs Analytics data for failure cases, but does not log successful cases. Activity log policies that call for logging of Analytics data upon success do not apply for the OAuth provider.
- You must ensure the OAuth Provider is configured in the Sandbox Catalog before using the OAuth Provider in a non-Sandbox Catalog.

### Procedure

OAuth provider configuration uses a series of screens. The first set of screens controls a basic OAuth provider configuration. Perform the following steps to configure a native OAuth Provider for your cloud:

1. In the Cloud Manager, click  Resources.
2. Click OAuth Providers > Add > Native OAuth provider.
  - a. Complete the following parameters for the first screen, then click Next.

| Field                  | Description                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title                  | Enter a title for the native OAuth provider.                                                                                                                                                                                                                                                                                                        |
| Name                   | This field is auto-populated by the system.                                                                                                                                                                                                                                                                                                         |
| Description (optional) | Enter a brief description.                                                                                                                                                                                                                                                                                                                          |
| Base path (optional)   | The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path must be unique for a given catalog. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty. |
| Gateway Type           | Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see <a href="#">API Connect gateway types</a> .<br><br>OAuth Providers apply to one gateway type.                                                                                                             |

- b. In the next screen, enter the following additional configuration parameters, then click Next.

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Authorize Path         | <code>/oauth2/authorize/</code> is the standard OAuth endpoint to login to account                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Token Path             | <code>/oauth2/token/</code> is the standard OAuth endpoint to exchange code for access token.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Supported grant types  | <ul style="list-style-type: none"> <li>• Implicit - An access token is returned immediately without an extra authorization code exchange step.</li> <li>• Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security.</li> <li>• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."</li> <li>• Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.</li> <li>•  Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.</li> </ul> |
| Supported client types | <ul style="list-style-type: none"> <li>• Confidential - Client can maintain secure credentials on a secure server</li> <li>• Public - Client credentials are not secure. (Public is not available for DataPower API Gateway at this time.)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

- c. Enter the scopes in the next screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

| Field             | Description     |
|-------------------|-----------------|
| sample_scope_1    | Scope for token |
| additional scopes | Scope for token |

- d. Enter the parameters for User Security in the next screen. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application grant type. Click Next when done.

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Identity Extraction | <p>Determines how the user credential is extracted:</p> <ul style="list-style-type: none"> <li>Basic Authentication - HTTP basic authentication (requires no additional configuration)</li> <li>Default HTML Form - Use default login form for user name and password</li> <li><input type="checkbox"/> API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here <a href="#">API Connect context variables</a><br/>Note: DataPower API Gateway only. Not available for DataPower Gateway (v5 compatible).</li> <li>Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see <a href="#">Creating a custom HTML login form for user security</a>.</li> <li>Redirect - Enter an endpoint to redirect to a third-party identity provider. For more information, see <a href="#">Authenticating and authorizing through a redirect URL</a>.</li> <li><input type="checkbox"/> API Gateway only Disabled - do not collect the user credential</li> </ul> <p>Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint <b>must</b> maintain the order of the query parameters before the <b>state_nonce</b> query parameter, otherwise the authorization fails.</p> |
| Authentication      | <p>Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry. For a DataPower API Gateway, you have the option to disable authentication with a user registry.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Authorization       | <p>The following methods for extracting the user credential are available:</p> <ul style="list-style-type: none"> <li>Authenticated - Authorize authenticated users automatically.</li> <li>Default HTML Form - Use default HTML form to authorize.</li> <li>Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see <a href="#">Creating a custom HTML authorization form for user security</a>.</li> <li><input type="checkbox"/> API Gateway only Disabled - Disable authorization.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

- Review the Summary for the native OAuth provider configuration.
- Click Back to make changes.
- Click Finish to save the basic configurations and to proceed to the Advanced Parameters for a native OAuth Provider.

## Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

- [Configuring basic settings for a native OAuth provider](#)  
You can update the identification details and basic configuration settings for a native OAuth provider.
- [Configuring scopes for a native OAuth provider](#)  
Access tokens contain authorization for specific scopes.
- [Configuring user security for a native OAuth provider](#)  
Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.
- [Configuring tokens for a native OAuth provider](#)  
Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.
- [Configuring token management and revocation for a native OAuth provider](#)  
Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.
- [Configuring introspection for a native OAuth provider](#)  
Define an introspection path to allow the metadata for an access token to be examined.
- [Configuring metadata for a native OAuth provider](#)  
Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- [Configuring the OIDC parameters for a native OAuth provider](#)  
Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.
- [Editing a native OAuth provider by using the API Editor](#)  
You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring basic settings for a native OAuth provider

You can update the identification details and basic configuration settings for a native OAuth provider.

### About this task

One of the following roles is required to configure the basic settings for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator

- Custom role with the `Settings:Manage` permissions

You can select the basis settings pages for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the basic settings for an existing native OAuth provider. If you want to update the basic settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, > OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

1. To modify the identification details, click Info in the sidebar menu, then update the following fields as required:

| Field                  | Description                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title                  | Enter a title for the native OAuth provider.                                                                                                                                                                                                                                                                                                        |
| Name                   | This field is auto-populated by the system.                                                                                                                                                                                                                                                                                                         |
| Description (optional) | Enter a brief description.                                                                                                                                                                                                                                                                                                                          |
| Base path (optional)   | The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path must be unique for a given catalog. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty. |

2. To modify the basic configuration settings, click Configuration in the sidebar menu, then update the following fields as required:

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Authorize Path         | <code>/oauth2/authorize/</code> is the standard OAuth endpoint to login to account                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Token Path             | <code>/oauth2/token/</code> is the standard OAuth endpoint to exchange code for access token.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Supported grant types  | <ul style="list-style-type: none"> <li>• Implicit - An access token is returned immediately without an extra authorization code exchange step.</li> <li>• Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security.</li> <li>• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."</li> <li>• Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.</li> <li>• <span style="border: 1px solid green; padding: 2px;">API Gateway only</span> Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.</li> </ul> <p>Note: If you plan to configure OpenID Connect (OIDC) for a native OAuth provider, you must include at least one of the following grant types: Implicit, Access code.</p> |
| Supported client types | <ul style="list-style-type: none"> <li>• Confidential - Client can maintain secure credentials on a secure server</li> <li>• Public - Client credentials are not secure. (Public is not available for DataPower® API Gateway at this time.)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

DataPower Gateway (v5 compatible) only Note: If the gateway type is DataPower Gateway (v5 compatible) and, when the native OAuth provider was created, only the Application grant type was selected, you cannot add further grant types until you configure the user security settings. In particular, you must specify the user registry for authenticating application users. To configure the user security settings, complete the following steps:

- a. Click User Security in the sidebar menu, then click Edit.
- b. Update the user security settings as required; for more details, see [Configuring user security for a native OAuth provider](#).
- c. Click Save when done.

3. Click Save when done.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring scopes for a native OAuth provider

Access tokens contain authorization for specific scopes.

### About this task

Client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth protected API is invoked, the gateway checks the scopes carried in the access tokens against the list of allowed scopes in the security definition for the API to determine whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The final scope permission that is granted by the access token is the result of all scope checks.

Per IETF RFC 6749, the value of the scope parameter is a list of space-delimited, case-sensitive strings. For more information, see [The OAuth 2.0 Authorization Framework](#).

One of the following roles is required to configure scopes for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the scope settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the scope settings for an existing native OAuth provider. If you want to update the scope settings for an existing native OAuth provider, complete the

following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

Perform the following steps to configure the scopes for the access token:

1. Click **Scopes** in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.

| Field             | Description     |
|-------------------|-----------------|
| sample_scope_1    | Scope for token |
| additional scopes | Scope for token |

In the **Default scopes** section, select the default scopes to be used if the API request doesn't contain any scopes.

If the user authorization method is set to **Default HTML Form** in the **User Security** settings, all scopes specified here are added automatically to the authorization consent form.

2. **Advanced scope check before token generation.** This setting specifies the scope check endpoint where additional scope verification is performed in addition to the basic scopes. The advanced scope check URLs are invoked after application authentication or after owner authentication based on which URLs are configured. The scopes are included in the token and will overwrite any previous scopes.

| Field                   | Description                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application scope check | Allow extra verification by running a scope check from an endpoint. Enter the endpoint and an optional TLS Profile to use for an application scope check. |
| Owner scope check       | Further refine the scope with an additional check. Enter the endpoint and an optional TLS Profile to use for an owner scope check.                        |

For more information about scope, see [Scope](#)

3. **Advanced scope check after token generation.** This setting specifies an additional scope check at the API consumer level to verify compliance with the scope requirements of the API.

| Field                 | Description                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Enabled               | Select the check box to enable the advanced scope check after token validation. Enter an optional default validator endpoint. |
| Use endpoint from API | Select the check box to use the endpoint from the API, or clear the check box to override the endpoint from the API.          |

For more information about scope, see [Scope](#)

4. Click **Save when done**.

## Results

Depending upon the visibility setting, the OAuth Provider with the specified scopes can be used to secure the APIs in catalog.

## Configuring user security for a native OAuth provider

Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.

### About this task

User security authenticates the user. It is required for the **Implicit Access Code (Authorization code)**, and **Resource owner password grant** types. It is not used for an **Application grant** type.

One of the following roles is required to configure user security for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the user security settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the user security settings for an existing native OAuth provider. If you want to update the user security settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

Perform the following steps to configure the user security settings for the OAuth Provider:

1. Click User Security in the sidebar menu.
2. Specify the following parameters for User Security. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Client Credentials (Application) grant type. Click Next when done.

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Identity Extraction | <p>Determines how the user credential is extracted:</p> <ul style="list-style-type: none"> <li>• Basic Authentication - HTTP basic authentication (requires no additional configuration)</li> <li>• Default HTML Form - Use default login form for user name and password</li> <li>•  Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here <a href="#">API Connect context variables</a></li> <li>• Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see <a href="#">Creating a custom HTML login form for user security</a>.</li> <li>• Redirect - Enter an endpoint to redirect to a third-party identity provider. For more information, see <a href="#">Authenticating and authorizing through a redirect URL</a>.</li> <li>•  Disabled - do not collect the user credential</li> </ul> <p>Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint <b>must</b> maintain the order of the query parameters before the <code>state_nonce</code> query parameter, otherwise the authorization fails.</p> |
| Authentication      | <p>Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Authorization       | <p>Various methods may be used to authorize application users. For a DataPower® API Gateway, the following methods for extracting the user credential are available:</p> <ul style="list-style-type: none"> <li>• Authenticated - Authorize authenticated users automatically.</li> <li>• Default HTML Form - Use default HTML form to authorize. If you select the Default HTML Form method, all scopes that are specified in the Scopes settings are added automatically to the authorization consent form.</li> <li>• Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form.</li> <li>•  Disabled - Disable authorization.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

3. Click Save when done.

## Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

## Configuring tokens for a native OAuth provider

Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.

## About this task

Access tokens are granted to the client application to allow the application to access resources on behalf of the application user. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or more narrow scope. You can also specify how long the consent given by the combination of any number of access and refresh token remains valid.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the token settings for an existing native OAuth provider. If you want to update the token settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

Perform the following steps to configure tokens for the native OAuth provider:

1. Click Tokens in the sidebar menu.

2. Define the settings to configure tokens.

| Field                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Access tokens time to live                                               | Enter the expiration time period in seconds for access tokens.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <input type="checkbox"/> API Gateway only<br>One time use access token   | Click the check box to enable one time use for the access token. Access tokens are multiple use by default which allows them to be used for multiple requests. When one time use is enabled, the access token will be consumed after one use. The OAuth flow will need to be repeated to obtain another access token.<br>Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: <ul style="list-style-type: none"><li><a href="#">Configuring token management and revocation for a native OAuth provider</a> (Cloud Manager)</li><li><a href="#">Configuring token management and revocation for a native OAuth provider</a> (API Manager)</li></ul>                                                                                                                                                                                                      |
| Refresh tokens                                                           | Click the check box to enable Refresh tokens. Set the Count to limit the number of times a refresh token can be issued. Set the Refresh Token Time to Live value to determine the time to live, or expiration time period, for each refresh token in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| One time use refresh token                                               | Clear the check box to disable one time use for the refresh tokens. Refresh tokens are one time use by default which allows them to be used one time only to generate an access token and a new refresh token. When refresh token one time use is disabled then the refresh token count is limited to one and the refresh token can be used multiple times to generate new access tokens, however, another refresh token will not be generated unless the initial OAuth flow (Authorization Code or Password) is repeated.<br>Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: <ul style="list-style-type: none"><li><a href="#">Configuring token management and revocation for a native OAuth provider</a> (Cloud Manager)</li><li><a href="#">Configuring token management and revocation for a native OAuth provider</a> (API Manager)</li></ul> |
| Maximum consent                                                          | Click the check box to enable Maximum consent and enter the Maximum Consent Time to Live value in seconds. This is the time to live, or expiration time period, for all tokens, both access and refresh.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <input type="checkbox"/> API Gateway only<br>Token secret                | Click the check box to select the Shared Secret which was configured for the gateway. If no Shared Secret was entered in the Gateway Configuration, then enter an key name and key value to use as the token secret.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <input type="checkbox"/> API Gateway only<br>Proof Key for Code Exchange | Proof Key for Code Exchange (PKCE) is a method to protect OAuth 2.0 public clients from an authorization code interception attack when they use Authorization Code grant requests. 3. Click Save when done.

## Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

## Related information

- [Refresh tokens](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring token management and revocation for a native OAuth provider

Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.

## About this task

Token management enables you to prevent replay attacks by configuring token revocation. API Connect supports token revocation using a native gateway (DataPower) or a third party endpoint. For a native gateway, quota enforcement is used to manage tokens. For a third party endpoint, a URL to an external service is used to manage tokens.

For more information, see the IETF RFC 7009 [OAuth 2.0 Token Revocation](#).

One of the following roles is required to configure token management and revocation for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token management settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the token management settings for an existing native OAuth provider. If you want to update the token management settings for an

existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

---

Perform the following steps to configure revocation settings for tokens:

1. Select Token Management in the sidebar menu.
2. Enable Token Management by selecting the check box.
3. From the Type dropdown menu, select either Native or Third party. Native points to DataPower as the token storage location; Third party points to a revocation URL for token storage. For DataPower® API Gateway, only Native is supported.
4. For Native, select one or both of the Resource owner revocation path and Client revocation path.
  - Resource owner revocation path - Uses the standard OAuth revocation path to allow the resource owner (end user) to revoke the application permission.
  - Client revocation path - Uses the standard OAuth revocation path to allow the client (application) to revoke a single token when the application closes.For more information about managing tokens with the Native DataPower Gateway, see [Token management with the native DataPower Gateway](#).
5. For Third party, specify the Endpoint and TLS Client Profile.
  - Endpoint - Enter the URL to an external web server that contains information about access or refresh tokens. API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blacklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing. For more information see [Token revocation](#).
  - TLS Client Profile - Select a TLS profile to verify the external endpoint.
6. Click Save when done.

## Results

---

Depending on the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring introspection for a native OAuth provider

Define an introspection path to allow the metadata for an access token to be examined.

### About this task

---

Token introspection allows an authorized holder of an access token to examine the contents of tokens using an introspection path. The access token to introspect must be obtained through the native OAuth provider. Introspection provides context for the token by allowing an authorized protected resource to query the authorization server to determine the set of metadata for a given token. The metadata includes whether or not the token is currently active, the scopes assigned to the token, and the authorization context in which the token was granted (including who authorized the token and which client it was issued to). API Connect token introspection conforms to IETF RFC 7662. See [OAuth 2.0 Token Introspection](#).

One of the following roles is required to enable introspection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the introspection settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the introspection settings for an existing native OAuth provider. If you want to update the introspection settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

---

Perform the following steps to enable introspection:

1. Click Introspection in the sidebar menu.
2. Select the check box to enable Introspection. The OAuth standard path for introspection, `/oauth2/introspect` is automatically entered. This path will be used when another entity inspects the token contents.
3. Click Save when done.

## Results

---

Tokens will be queried using the `/oauth2/introspect` path. Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Configuring metadata for a native OAuth provider

Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

### About this task

---

Configure an Authentication URL or an External URL from which custom metadata is collected for inclusion in the token. The metadata is either stored inside the access token or it is sent along with the access token to the client application. For more information about how the metadata is collected, see [OAuth external URL and authentication URL](#).

Following are examples of metadata that can be included with the access token:

- Metadata about the authenticated resource owner
- Grant type that was used to obtain the token
- A confirmation code to be provided to the client application

One of the following roles is required to configure metadata collection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the metadata settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the metadata settings for an existing native OAuth provider. If you want to update the metadata settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

### Procedure

---

Perform the following steps to configure metadata collection:

1. Click Metadata in the sidebar menu.
2. Select Collect metadata to enable metadata collection.
3. The Authentication URL user registry is selected by default and is required. For more information about the Authentication URL, see [Authentication URL user registry](#).
4. Select the External URL to collect metadata from an external URL. Enter the endpoint and an option TLS Client Profile.
5.  If required, override the default Header name token value. The value of this header, if returned in the response from the OAuth endpoint, is placed in the response payload and indicated as `metadata`.
6.  If required, override the default Header name payload value. The value of this header, if returned in the response from the OAuth endpoint, is placed within the access token and indicated as `miscinfo`.
7. Save the OAuth Provider.
8. Click Save when done.

### Results

---

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring the OIDC parameters for a native OAuth provider

Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.

### About this task

---

When you enable OpenID connect, a template is provided for generating ID tokens along with access tokens and the required assembly policies are automatically created. You can customize the policies to suit your needs in the API Editor. The sample key provided is for test purposes only and is used to sign the JWT token.

One of the following roles is required to configure an OIDC template for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator

- Custom role with the `Settings:Manage` permissions

Note: You can configure OIDC parameters only if the selected grant types for the native OAuth provider include at least one of the Implicit or Access code grant types; see [Configuring basic settings for a native OAuth provider](#).

You can select the OIDC settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the OIDC settings for an existing native OAuth provider. If you want to update the OIDC settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, > OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

Perform the following steps to configure an OIDC template:

1. Click OpenID Connect in the sidebar menu.
2. Select the initial check box to configure an OIDC Template. Enter the following parameters:

| Field                                                                                                                      | Description                                                                                                                                                                                      |
|----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  Support hybrid response types (optional) | Select the response types for the OpenID Connect hybrid flow to be supported by this OAuth provider.                                                                                             |
|  Auto Generate OIDC API Assembly          | Select this option to generate the full OIDC assembly. Leave this option unselected to simply enable OIDC support in the OAuth provider and allow the developer to implement their own assembly. |
|  ID token issuer                          | Descriptive text to indicate the source of the key.                                                                                                                                              |
|  ID token signing key                     | Specify the JSON Web Key (JWK) to be used to sign the ID token.                                                                                                                                  |
|  ID token signing algorithm               | Select the algorithm used to sign the token.                                                                                                                                                     |

3. Click Save when done. You can edit the policies by using the API Editor.

## Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Editing a native OAuth provider by using the API Editor

You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

### About this task

If you have configured an OIDC template, you can customize it in API Editor. In the API Editor, the Source tab allows you to edit the code for the configuration using a text editor. The API Assemble tab provides a graphical drag-and-drop editor (identical to the one in API Manager) that allows you to add additional elements to the assembly for the OAuth Provider.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can modify the native OAuth provider configuration by selecting the API Editor page immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the configuration for an existing native OAuth provider. If you want to update the configuration for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, > OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

Perform the following steps to edit the OAuth configuration:

1. Click API Editor in the sidebar menu.
2. In the Source tab, view and edit the policies to customize the behavior for the OAuth provider.
3. In the API Assemble tab, use the drag and drop editor to add additional policies to the OIDC behavior.  
 Note: If you add a policy that references a TLS profile, an **invoke** policy for example, then when you publish an API that uses this OAuth provider, you must ensure that the TLS profile is enabled for the Catalog to which you publish the API. For details on how to enable a TLS profile in a Catalog, see [Creating and configuring Catalogs](#).
4. Click Save when done.

## Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring a third-party OAuth provider

Enter the secure endpoints to provide OAuth authentication from a third party.

### About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

### Procedure

Perform the following steps to configure a third party OAuth provider:

1. In the Cloud Manager, click  Resources.
2. Select OAuth Providers > Add > Third party OAuth Provider.
  - a. Complete the following parameters for the first screen and click Next.

| Field                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title                 | Enter a descriptive title for the gateway service. This title will be displayed on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Name                  | This field is auto-populated by the system and used as the internal field name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Supported grant types | <ul style="list-style-type: none"> <li>• Implicit - An access token is returned immediately without an extra authorization code exchange step.</li> <li>• Application - Application to application. Corresponds to the OAuth grant type Client Credentials. Does not require User Security.</li> <li>• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type Authorization Code.</li> <li>• Resource owner password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.</li> </ul> |
| Gateway type          | Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway.<br>For information about types of gateways, see <a href="#">API Connect gateway types</a> .<br><br>OAuth Providers apply to one gateway type.                                                                                                                                                                                                                                                                                                                                                                                            |

- b. Specify configuration settings for the endpoints.

| Field                                                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Authorization URL                                                                                                                       | An authorization URL where the resource owner grants authorization to the client application to access a protected resource. Example:<br><br><b><code>https://example.com/oauth2/authorize</code></b>                                                                                                                                                                 |
| Token URL                                                                                                                               | A token request URL where the client application exchanges an authorization grant for an access token. Example:<br><br><b><code>https://example.com/oauth2/token</code></b>                                                                                                                                                                                           |
| Introspect URL                                                                                                                          | The introspection URL is where the API gateway validates the access tokens that are issued by the third party provider. Example:<br><br><b><code>https://example.com/oauth2/introspect</code></b><br><br>For more information on integrating third party OAuth providers for introspection, see <a href="#">OAuth introspection for third-party OAuth providers</a> . |
| TLS Profile (optional)                                                                                                                  | Select an optional TLS profile for communicating with the third party provider.                                                                                                                                                                                                                                                                                       |
| Security                                                                                                                                | Default is Basic Authentication.                                                                                                                                                                                                                                                                                                                                      |
|  Basic authentication request header name            | The <code>x-introspect-basic-authorization-header</code> is available to provide a user-configured HTTP Basic authorization header.                                                                                                                                                                                                                                   |
|  Basic authentication request header name (optional) | The name of the header that will provide a user-configured HTTP Basic authorization. The default value is <code>x-introspect-basic-authorization-header</code> .                                                                                                                                                                                                      |

| Field                                                           | Description                                                                                                             |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| API Gateway only<br>Basic authentication<br>username (optional) | The default user name for HTTP Basic authentication.                                                                    |
| API Gateway only<br>Basic authentication<br>password (optional) | The default password for HTTP Basic authentication.                                                                     |
| API Gateway only<br>Custom header pattern<br>(optional)         | A regular expression for request headers that are to be passed to the third-party provider; for example, x-Introspect-* |

c. Enter the scopes in the third screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

| Field             | Description     |
|-------------------|-----------------|
| sample_scope_1    | Scope for token |
| sample_scope_2    | Scope for token |
| additional scopes | Scope for token |

d. Review the settings on the Summary panel.

3. Click Save and Edit to complete the configuration.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Setting the visibility for OAuth providers

The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.

### About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

### Procedure

Follow these steps to set the visibility for the OAuth providers in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select OAuth Providers.
3. Choose Edit visibility from the actions menu next to the name of the OAuth provider that requires a visibility setting.
4. Select the visibility setting for the OAuth provider. The options are:
  - Private - the OAuth provider is not visible and cannot be used by any provider organization. It is accessible only to the admin organization in Cloud Manager.
  - Public - the OAuth provider is visible and can be used by all provider organizations
  - Custom - the OAuth provider is visible only to the provider organizations that you designate
5. For Custom visibility, select the provider organizations that you want to have access to the OAuth provider.
6. Click Save to complete the operation.

### Results

For Private, the OAuth provider is not visible and cannot be used by any provider organizations. For Public, the OAuth provider is visible and can be used by all provider organizations. For Custom, the OAuth provider is visible only to the provider organizations designated by you.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## OAuth concepts for API Connect

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- [OAuth user scenario](#)  
Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available

options.

- [OAuth introspection for third-party OAuth providers](#)  
OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by IBM API Connect. IBM API Connect can use this feature along with the mentioned provider to protect access to the API.
- [OAuth external URL and authentication URL](#)  
You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- [Scope](#)  
Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.
- [Tokens](#)  
Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.
- [Authentication URL user registry](#)  
You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.
- [Custom forms for user security](#)  
You can create custom forms for the authorization and identity extraction phase of OAuth.
- [Securing an API with a JSON Web Token](#)  
There are two methods to secure your API with a JSON Web Token. You can use the `jwt-generate` command, or you can use a token that has been generated external to IBM API Connect.
- [Troubleshooting OAuth](#)  
You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on Youtube.

---

## OAuth user scenario

Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.

---

### Scenario overview

In this scenario, Alice is a user of an application. Alice can grant permission for an application to access specific information about Alice in a third-party system that is using OAuth. Depending on the type of OAuth that is supported by the target service, Alice does not enter her user name and password into the application. Instead, the application receives an access token that represents her credentials (user name and password). The application can now access the information about Alice in the target system.

For example, Alice maintains a list of books that she reads on a service that is provided by mybooks.com. Following the purchase of a smartphone, Alice installs an application on her new phone to display the book details. The phone application wants to call an API provided by mybooks.com, which can access the information. The mybooks.com API is secured by using the OAuth protocol.

To access the book details, the application must complete a two-step process:

1. The application must first obtain permission from Alice.
2. The application then uses that permission to call the target service and obtain the list of books.

In the first step, the application typically directs Alice to the provider of the target service, mybooks.com. Alice provides her user name and password, and gives permission for the application to access her information. It is important that Alice trusts that she is providing her credentials to the provider of the target service and not to an untrusted proxy application. For example, by checking that the security certificate of the website where Alice enters her credentials matches what Alice expects from the provider of the target service.

The result of this step is the access token that the application can use to call the API. The application then generates the appropriately formatted OAuth request. For example, the Authorization header, or HTTP query parameters, which includes the access token, consumer key, and signature method that are required by OAuth. This OAuth request is used to invoke the API proxy operation.

---

### Scenario within API Connect

No changes to the definition of your API operation are required to support this scenario.

1. Alice grants permission for the application to access her information *before* the invocation of the API.
2. When the application provides the Authorization header, or query parameters, containing the OAuth details about the call to the operation endpoint, the header is automatically passed through to the target service without any additional configuration.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

## OAuth introspection for third-party OAuth providers

OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by IBM API Connect. IBM® API Connect can use this feature along with the mentioned provider to protect access to the API.

You can use API Connect to protect an API that is secured by using the third-party OAuth access token in accordance with Introspection specification as defined in [RFC 7662](#). In addition to the specification, the `x-Introspect-` header is provided to pass other content to the third party as you require.

Authentication information can be carried in the request by configuring a basic authentication request header.

The following sequence diagram depicts the overall flow of request and response. The purpose of this diagram is only to provide a general visualization of the nature of the flow; for the precise details, refer to the explanatory information after the diagram.

The Introspect URL is configured in the Third Party OAuth provider configuration. See [Configuring a third-party OAuth provider](#).

When an API is protected by a third-party OAuth provider, API Connect will extract the bearer token and issue an HTTP POST request to the endpoint specified in the Introspect URL field.

The GET request is protected by API Connect with this feature.

You can use a header prefix to pass information to the third-party provider. The header prefix can include a regular expression and specifies the name pattern of the headers to use for sending additional information, such as `x-introspect-*`.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
Authorization: Bearer tGzv3JOkF0XG5Qx2T1KWIA
x-IBM-Client-Id: xxx-xxx
```

However, if you want to use a different header prefix, specify the required value in the Custom header pattern field in the third party OAuth provider configuration. For third-party OAuth provider configuration details, see [Configuring a third-party OAuth provider](#). The Custom header pattern feature is available only with the DataPower® API Gateway, if you are using the DataPower Gateway (v5 compatible) the header prefix must be `x-Introspect-`.

API Connect will issue this POST request to the introspection endpoint specified in `x-tokenIntrospect`, as illustrated in the code sample:

```
POST /oauth/introspectURL HTTP/1.1
Host: apiconnect.ibm.com
Content-Type: application/x-www-form-urlencoded
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123

token_type_hint=access_token&token=tGzv3JOkF0XG5Qx2T1KWIA
```

The third party OAuth/OIDC provider will respond with HTTP 200 indicating the request was successful and that payload contains the token information. API Connect honors the active claim as defined in the RFC specification.

If the value of the active claim is `true`, the token is treated as valid.

```
HTTP/1.1 200 OK
Content-Type: application/json; charset=UTF-8
Cache-Control: no-store
```

```
Pragma: no-cache
```

```
{ "active": true,  
  "token_type": "bearer",  
  "client_id": "xxx-xxx",  
  "username": "John Smith",  
  ...  
}
```

If the value of the active claim is `false`, the token is treated as invalid.

```
HTTP/1.1 200 OK  
Content-Type: application/json; charset=UTF-8  
Cache-Control: no-store  
Pragma: no-cache
```

```
{  
  "active": false  
}
```

A response code other than `HTTP 200` indicates failure to process the request.

When the OAuth token is valid and active, context variables are populated with information from the introspect JSON response. For more information, see [API Connect context variables](#).

When contacting the introspection endpoint, API Connect uses `client_id/appId` and `client_secret/appSecret` to construct the HTTP Basic authorization header.

By default, if `x-introspect-basic-authorization-header` exists in the request, the value is used for the HTTP Basic authentication header when the introspection endpoint is contacted. API Connect verifies that the HTTP Basic authentication header value is Base64 encoded before it is sent, and encodes it if necessary as shown in the following example. If the header is already encoded, it is sent without modification.

```
GET /petstore/pet/123 HTTP/1.1  
Host: apiconnect.com  
x-introspect-basic-authorization-header: user:password
```

API Connect issues the following:

```
POST ..  
Authorization: Basic M3JkLXBhcncR5LWNsaWVudF9pZDozcmQtcGFydH1fY2xpZW50X3NlY3JldA==token_type_hint=access_token&token= ..
```

If you are using the DataPower API Gateway, you can specify your own value for the HTTP Basic authentication header by providing the required value in the Basic authentication request header name field in the third party OAuth provider configuration. The following rules determine what authentication data is passed to the introspection endpoint:

- If there is a basic authentication header in the request, the specified credentials are used. The value must be either a string in the format `user:password`, or the Base64 encoded equivalent; API Connect will Base64 encode the value if necessary before sending the request to the introspection endpoint.
- If there is no basic authentication header in the request but there are values specified in the Basic authentication username and Basic authentication password fields in the third party OAuth provider configuration, those values are used.
- If there is no basic authentication header in the request, and user name and password details are not supplied in the third party OAuth provider configuration, but `client_id` and `client_secret` values are supplied in the body of the request, these are used.
- Otherwise, an error is returned.

For third-party OAuth provider configuration details, see [Configuring a third-party OAuth provider](#).

If either, or both, of `scope` and `scope validate url` are configured, and if the response is an active token with a scope claim from the third-party OAuth Provider introspection endpoint, API Connect would further enforce the scope validation in the following order:

1. If `scope` is configured for the OAuth API protection, verify the third-party scope against the scope that is configured.
2. If `scope validation url` is configured, verify the third-party scope against the scope validation url.

For more information, see [Scope](#).

**DataPower Gateway (v5 compatible) only** By default the API Connect client ID and scope are sent to the third party OAuth provider. You can suppress this behavior in either of the following ways:

- Supply a `suppress-parameters` header as follows:

```
suppress-parameters: client_id
```

```
suppress-parameters: scope
```

or

```
suppress-parameters: client_id scope
```

depending on which parameters you want to suppress.

- Define an API property called `suppress-parameters` in the API definition itself, with one of the following string values:

```
client_id
```

```
scope
```

or

```
client_id scope
```

depending on which parameters you want to suppress. For information on how to define API properties, see [Setting API properties](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## OAuth external URL and authentication URL

You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

---

### Including custom metadata in a token

In many scenarios, custom metadata needs to be included during the access token generation process. The metadata is either stored inside the access token or it is sent along with the access token to the client application. The client application can then send that access token, or the metadata in the payload, in a subsequent request to IBM® API Connect where the metadata is retrieved, validated, or sent to the downstream systems as required.

Examples include, but are not limited to:

- When resource owners are authenticated, metadata about the authenticated resource owner needs to be stored within the access token.
- The grant type that was used to obtain the token is another example of metadata stored within the access token.
- A confirmation code that needs to be sent to the client application along with access token is stored as metadata within the access token.

---

### Configuring External URL or Authentication URL in API Connect to obtain metadata

Metadata can be set by using either or both of the following URLs:

- External URL - When you call the External URL, an HTTP GET request is sent and API Connect expects an HTTP 200 OK along with an optional set of the specified response headers.
- Authentication URL - When you call the Authentication URL, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.  
See: [Authentication URL](#).

The External URL endpoint is entered in the Metadata section when you configure an OAuth Provider in the Cloud Manager or API Manager UI.

Use the following HTTP headers in the response, depending on the type of gateway you are using:

- DataPower® API Gateway:

`X-API-OAUTH-METADATA-FOR-PAYLOAD`

`X-API-OAUTH-METADATA-FOR-ACCESSTOKEN`

Note: These are the default header names for the DataPower API Gateway but you can override them; see [Configuring metadata for a native OAuth provider](#).

- DataPower Gateway (v5 compatible):

`API-OAUTH-METADATA-FOR-PAYLOAD`

`API-OAUTH-METADATA-FOR-ACCESSTOKEN`

The response header value from `X-API-OAUTH-METADATA-FOR-PAYLOAD` or `API-OAUTH-METADATA-FOR-PAYLOAD` is placed in the response payload and indicated as `metadata`.

The response header value from `X-API-OAUTH-METADATA-FOR-ACCESSTOKEN` or `API-OAUTH-METADATA-FOR-ACCESSTOKEN` is placed within the access token and indicated as `miscinfo`.

The two metadata response headers are case insensitive and you must escape any special characters in the string value content.

An example response payload that contains metadata along with the access token:

```
{
  "token_type": "bearer",
  "access_token": "AAEkNzhjDHYyyYy...cL0Mv6ct137w7ZU",
  "metadata": "m:metadata-for-payload_content",
  "expires_in": 3600,
  "scope": "read",
  "refresh_token": "AAEnj5SynCMybF...oEZ6JjxYax_HdNg",
}
```

This example output from the token introspection endpoint shows the contents of the access token with `"miscinfo"` containing the metadata information.

```
{
  "active": true,
  "token_type": "bearer",
  "client_id": "78c2f10f-799a-4e1f-8e0a-098634997a35",
  "username": "Fred Smith",
  "sub": "fred",
  "exp": 1479850049,
  "expstr": "2016-11-22T21:27:29Z",
  "iat": 1479846449,
  "nbf": 1479846449,
  "nbfstr": "2016-11-22T20:27:29Z",
  "scope": "read",
  "miscinfo": "m:metadata-for-access token_content",
  "client_name": "MobileApp"
}
```

## Input to the External URL

The following request headers are sent to the External URL.

Note: Any existing metadata values that were previously sent from the Authentication URL are also sent in the two request headers **x-existing-metadata-for-payload** and **x-existing-metadata-for-access-token**. The Metadata URL can make use of this information to create a new set of metadata values. The two request headers that are sent to the Metadata URL are displayed in bold text.

```
X-existing-metadata-for-payload    payload-from-auth-url
X-existing-metadata-for-access-token    token-from-auth-url
X-URI-in    /org/env/miscinfo/oauth2/token (the URL that was sent to APIConnect for this particular token request)
X-METHOD-in    POST
X-POST-Body-in    client_id=client_id&grant_type=password&scope=read&username=name&password=password
X-X-Client-IP    IP_address
X-X-Global-Transaction-ID    ID_number
...
```

Note: If you are using the DataPower API Gateway rather than the DataPower Gateway (v5 compatible), the **X-POST-Body-in** header is not supported.

## Retrieving Metadata in API Connect

As described in the previous example scenarios, the metadata can be retrieved from the access token in the Application API and sent to the downstream systems. Retrieval can be done in the API assembly, which is secured to accept tokens in the security definitions.

In the resource API that accepts an access token, the **miscinfo** field can be accessed in the Assembly with the **oauth.miscinfo** context variable, as in the example.

```
apim.setvariable('message.body', apim.getvariable('oauth.miscinfo'));
```

You can also use token introspection to look at the contents of the access token.

## Refresh tokens and metadata

The Authentication URL (if configured for authentication) is invoked first, during authentication of the resource owner. The External URL is invoked as the last step, just before the generation of the access token. The only exception is when access tokens are generated from a refresh token. In cases where refresh tokens are used to generate new access tokens, the External URL is not invoked. The metadata from the refresh token is retained and then copied into the newly generated access token.

## Identifying the source of the metadata

The metadata is prefixed with keywords to indicate whether it originated from the External URL or the Authentication URL.

- Metadata from the External URL is prefixed with **m**:
- Metadata from the Authentication URL is prefixed with **a**:

Note: When revocation is enabled, some internal details are also stored in the **miscinfo** field, in square-brackets within the access token as shown in the following example:

```
"miscinfo": "[tlsprofile@https://api-revoke-url:443/server/revocation-url]m:metadata-for-accesstoken_content"
```

## Maximum size of the metadata

Metadata for the access token cannot exceed 512 bytes.

Metadata for the payload does not have a specific size restriction, except for when you use the Authorization code grant type. These restrictions are described in following sections.

## Characters are not allowed in metadata in certain scenarios

When you use the Authorization code grant type, or when a consent form is used for implicit grant type, there is a temporary state or code where the metadata from the authentication URL is stored. API Connect internally uses two prefixes - **!ma** and **!mp** to differentiate between payload and token metadata received from the Authentication URL and store them internally in the temporary state/code. Hence these specific character sequences - **!ma** and **!mp** should not be used as the metadata itself.

## Grant types and metadata

The OAuth grant types described in the following sections include **authorization code (access code)**, **implicit**, and **client credentials (application)**.

Authorization code grant type

- When metadata is included from an Authentication URL for an Authorization code grant type, as it is a three legged flow, both the content and the payload are stored within the **dp-state** and carried on to the authorization code and to the access token. Note that around 10 characters are used internally to differentiate between the metadata for payload and metadata for the access token when stored in the **dp-state**. In addition, if revocation is enabled, that will also be part of the token metadata. Hence the combined size of the token metadata, the payload metadata (including the 10 characters of internal data), and internal revocation details, cannot exceed 512 bytes in total.

If the overall size of the metadata exceeds 512 bytes, then the access token generation succeeds, but the metadata fields contain an error message of "metadata too large" as shown in the example.

```
"metadata": "m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-payload]"
"miscinfo": "[r:gateway]m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-token]"
```

This size restriction can be overcome when the metadata is sent from the Metadata URL and not from the Authentication URL, because the metadata is not stored in `dp-state` or in the authorization code.

Example of the `authorization code (access code)` grant type:

```
$ curl -k -d
"grant_type=authorization_code&code=$mycode&client_id=$myid&scope=scope_introspect&redirect_uri="
https://9.70.153.90/fei/sb/introspectpl/oauth2/token
{ "token_type": "bearer",
  "access_token": "AAEkOTh1ZDhhNjYtYtQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ2OZn5T1_TqYFeIfB7BFf6HFgibEoOjWXXEA84oFsWuE4NY-
RRZVdnGSaXAIYJz7s5vczfk5EV-BIb_6P_1YKm3ahrfr5kI3sPO0uADEoseIP5-09anUpEM5yhsayXvZbJ_6VDYz-hyXSJHTNqVj-
PHBialoRkBD5qca6k00fV2M", "metadata": "a:[Authorization Code-Test-auth-url-payload]", "expires_in": 3600,
  "scope": "scope_introspect", "refresh_token": "AAFAg1EVmBwicr_L0FTZ4q6HZ-
RcQygniXFC9zbSKO4wd3hcniC4KQX21X0fL2c8cnmzCZgws8xxLzNyfjQhUJNG15C1GbIe3dwhXJdiWA0Go-
dudhVtCbG26sJRRXyYrMeRwXWnJsy1BETPI8HQEN4a_D7fmxKcTVRZBvq86byg95qe1ZKyERi0Lhxdd_O4Nvss" }

$ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
"token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectpl/oauth2/introspect
{ "active": true, "token_type": "bearer", "client_id": "98ed8a66-a45e-4a33-a47d-fa68fd344746", "username": "anyuser",
  "sub": "anyuser", "exp": 1484766368, "expstr": "2017-01-18T19:06:08Z", "iat": 1484762768, "nbf": 1484762768,
  "nbfstr": "2017-01-18T18:06:08Z", "scope": "scope_introspect", "miscinfo": "[r:gateway]a:[Authorization Code-Test-auth-
url-token]", "client_name": "oauth_app" }
```

Implicit grant type

- When implicit grant type is used, the access token and the metadata are returned in the `Location` header as a fragment, as you see in the example.

```
< Location:
https://localhost#access_token=AAEkOTh1ZDhhNjYtYtQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ2buS2KfWdq-
nYBJSi4nmPxQBtLae17kKBPRMzwP5BC386n1xpoOTE1G748ZVH6Mq_TJL3GeV3PtXTVIkWOLBji_7tljiQfnpVfrNkovvZkhUexYmFkcDsmLSdaWxZ6Pc
IMPAC4ojT8qVlsYV-
ChTk36yqOx_NiKimZaDikDk7WTg&expires_in=3600&scope=scope_introspect&token_type=bearer&metadata=a%3A[Implicit-Test-
auth-url-payload]

$ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
"token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectpl/oauth2/introspect
{ "active": true, "token_type": "bearer", "client_id": "98ed8a66-a45e-4a33-a47d-fa68fd344746",
  "username": "anyuser", "sub": "anyuser", "exp": 1484768365, "expstr": "2017-01-18T19:39:25Z", "iat": 1484764765,
  "nbf": 1484764765, "nbfstr": "2017-01-18T18:39:25Z", "scope": "scope_introspect", "miscinfo": "[r:gateway]a:[Implicit-
Test-auth-url-token]", "client_name": "oauth_app" }
```

Client credentials grant type

Authentication URL will not be invoked when using client credentials grant type, as there is no resource owner. The metadata from Authentication URL is not available for this grant type. However, content returned from Metadata URL will be included as metadata.

## Behavior when retrieving metadata with both an External URL and an Authentication URL

If an External URL is configured and a connection to the external server is successful, the response headers overwrite any existing metadata obtained from the Authentication URL to become the final value. Therefore, you must carefully examine the incoming request headers and create appropriate response headers from the External URL.

If an External URL is configured, but the connection to the External URL fails, then a failure message of `"error on metadata url"` is written for metadata in both the payload and the access token.

If an External URL is configured and the connection is successful, but the remote server does not send any of the specified HTTP response headers, a blank value is written for metadata in both the payload and the access token.

Attention: An External URL overwrites existing values from Authentication URL. This includes blank values.

If no External URL is configured, the metadata that is obtained from the Authorization URL is retained as the final value.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Scope

Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.

In IBM® API Connect, scopes have no inherent meaning. Instead, scopes are defined in the OAuth Provider so that an application can request an access token that is valid for one or more of the scopes. In the secured API, scopes are listed as requirements for an access token to be considered valid. All scopes that are listed by the security definition for the API must be granted by the access token.

## OAuth provider

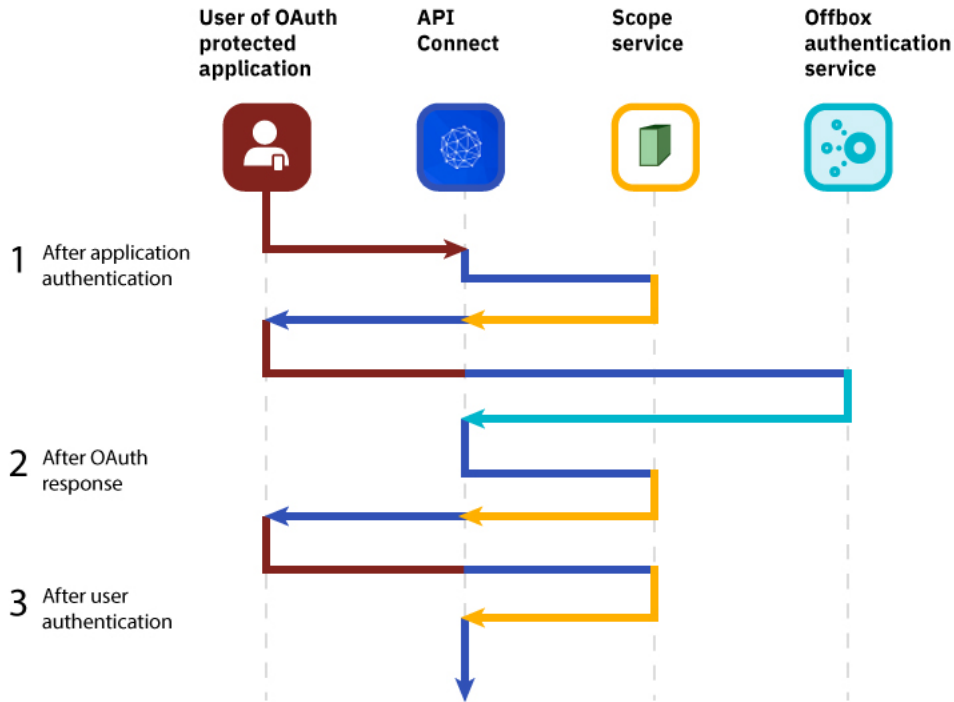

To provide more refined support for the OAuth scope handling, API Connect allows the [Authentication URL user registry](#) extension to modify the scope value.

When you define an [OAuth provider](#), the Advanced scope check extensions provide the flexibility to check and override allowed scopes. The optional extensions are Application scope check and Owner scope check.

The scope that is eventually received by the application is determined by the interactions that are described in the three following paragraphs. Scope processing follows the sequence of paragraphs 1, 2, and 3 in order, offering three opportunities to override the scope value. Figure 1 provides an overview of the process.

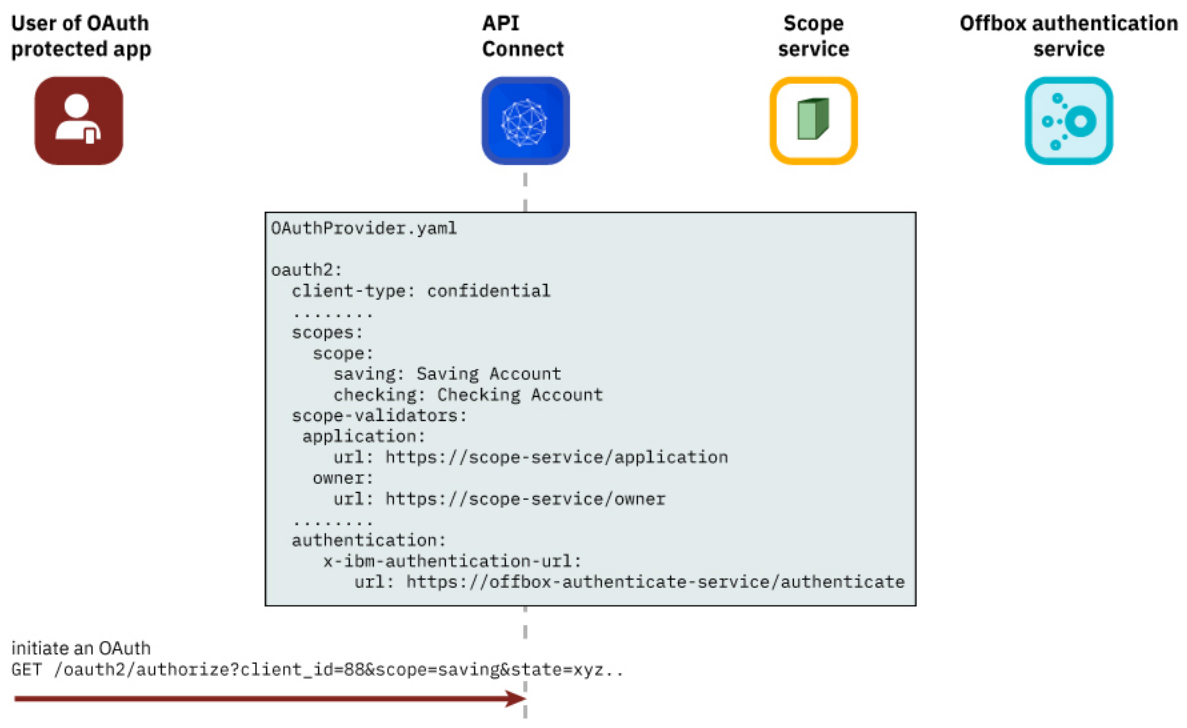

1. After the application successfully authenticates, and if OAuth Native provider `>Advanced scope check>` `>Application scope check` is configured, API Connect makes a call to allow extra verification and uses the contents of `x-selected-scope` to override the scope value that was initially requested by the application. When Application scope check is enabled, the HTTP response header `x-selected-scope` must be present, or the call fails.
2. If OAuth Native provider `>User Security>` `>Authentication` is configured to authenticate application users using an Authentication URL, then API Connect makes a call, as documented in [Authentication URL user registry](#). When the response code is `HTTP 200`, and the response header `x-selected-scope` is present, the value that is configured in `x-selected-scope` is used as the new scope value, overriding both what the application already requested and what was provided in the Application scope check described in paragraph 1. In the response header, `x-selected-scope` is an optional element.
3. After the user successfully authenticates, and if OAuth Native provider `>Advanced scope check>` `>Owner scope check` is enabled and configured with a valid URL, API Connect makes a call to allow the content of `x-selected-scope` to refine the scope value. When Owner scope check is enabled, the HTTP response header `x-selected-scope` must be present, or the call fails.

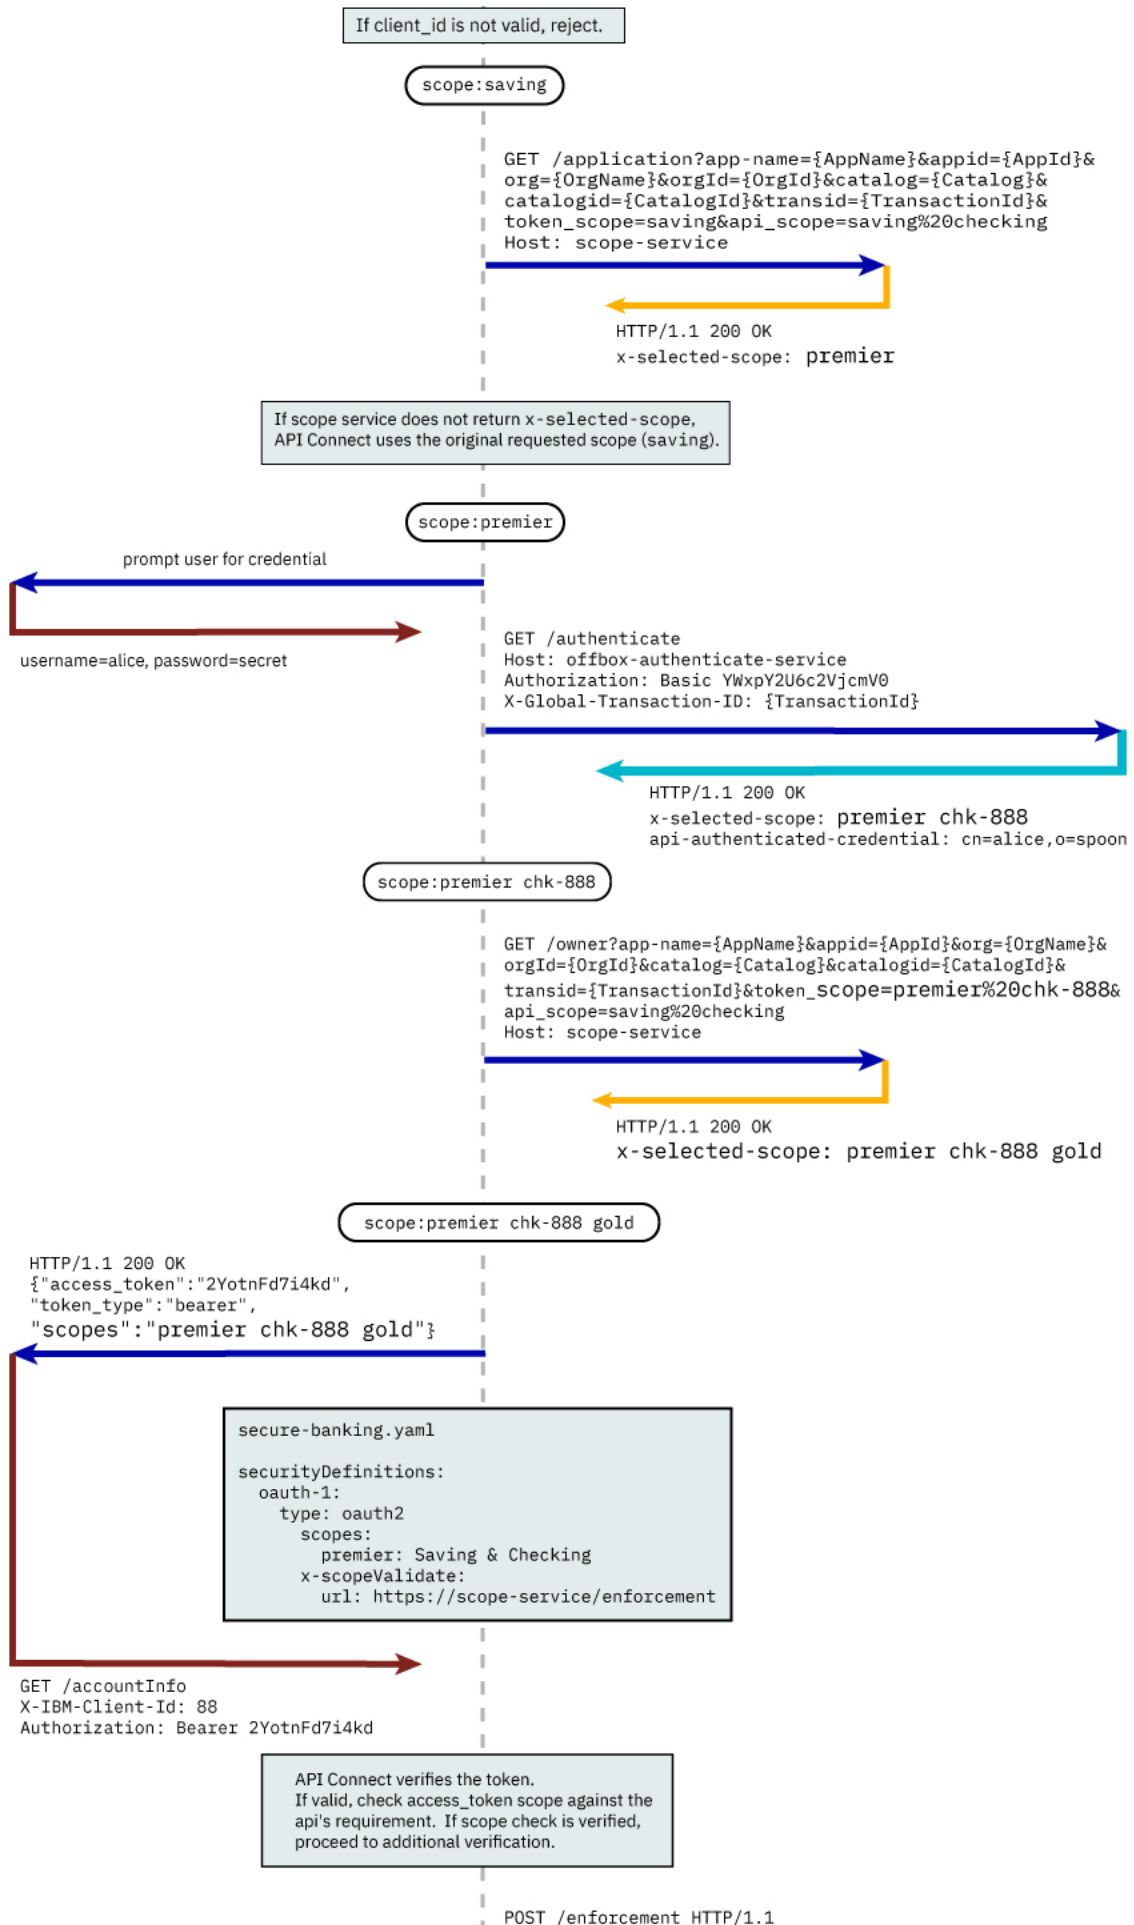

Figure 1. OAuth advanced scope overview

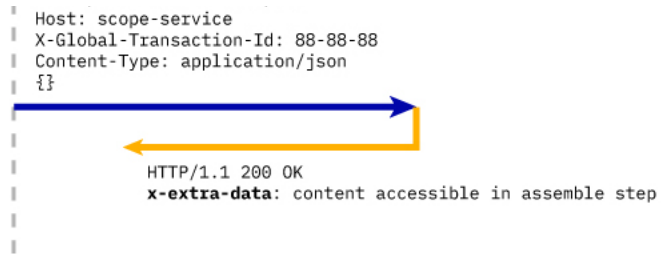

The final scope permission that is granted by the access token is the result of the flow described in paragraphs 1, 2, and 3. [Figure 2](#) shows a more detailed view of the transaction flow with examples that show when `x-selected-scope` provides a new scope value.

Figure 2. OAuth advanced scope detail

If API Connect receives HTTP 200, any HTTP headers in the response that start with "x-" will be accessible at `oauth.advanced-consent.<value>`  
 For the above example, `x-extra-data` is accessible at `oauth.advanced-consent.x-extra-data`.  
 If other than HTTP 200 is returned, it has the same effect as if the access token does not contain necessary permissions to access the resource.

## Consumer API enforcement

Standard scope validation

To access the API `/getaccount` the application must send a `GET` request with an access token that contains the scope, or scopes, defined in the OAuth provider.

```
GET /getaccount
HTTP/1.1
Host: server.example.com
X-IBM-Client-Id: 8888-8888-8888
Authorization: Bearer AAEkNjVkcWlYyJgtOWY5ZS00YWQwLWlYyZktZ
```

The following application OpenAPI file `secure-banking.yaml` defines the scope, or scopes, that must exist in the token to be granted access to the API `/getaccount`.

```
secure-banking.yaml
securityDefinitions:
  scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
security:
  - scope-only:
    - checking
  - scope-only:
    - saving
    - mutual
```

In the examples, the access token `AAEkNjVkcWlYyJgtOWY5ZS00YWQwLWlYyZktZ` is able to access the API because it contains one, or a combination of `scope-only` that is defined in `secure-banking.yaml` such as:

- `checking`
- `saving mutual`
- `checking saving mutual`

Advanced Scope Check

Administrators can enable an additional scope check by configuring the consumer API property Advanced Scope Check URL that becomes `x-scopeValidate` as shown in the following OpenAPI file example.

```
securityDefinitions:
  advanced-scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
  x-scopeValidate:
    url: 'https://advanced-scope-check.bk.com/validate-scope'
    tls-profile: 'ssl-client'
```

After API Connect successfully verifies the access token against any scope requirement, API Connect will make an `HTTP POST` request to the `x-scopeValidate` endpoint similar to the following example. Response code `HTTP 200` from the endpoint indicates a success. Any other response code, or a connection error, is treated as a permission error for the token.

```
POST /validate-scope?app-name=..&appid=..&org=..&orgid=..&catalog=..&catalogid=..&transid=..
HTTP/1.1
Host: advanced-scope-check.bk.com
Content-Type: application/json

{"context-root" : checking,
 "resource" : accountinfo,
 "method" : GET,
```

```

"api-scope-required" : [jointaccount],
"access_token" : {"client_id" : "2cd71759-1003-4a1e-becb-0474d73455f3",
  "not_after" : 174364070,
  "not_after_text" : "2017-07-11T02:27:50Z",
  "not_before" : 174360470,
  "not_before_text" : "2017-07-11T01:27:50Z",
  "grant_type" : "code",
  "consented_on" : 1499736470,
  "consented_on_text" : "2059-07-11T01:27:50Z",
  "resource_owner" : "cn=spoon,email=spoon@poon.com",
  "scope" : "jointaccount mutual",
  "miscinfo" : "[r:gateway]"
}
}

```

An example of successful response follows.

```

HTTP/1.1 200 OK
Cache-Control: no-store
Pragma: no-cache
X-Custom-For-Assemble-Process: audit

```

Any HTTP response header that begins with "x-" is kept as the context variable `oauth.advanced-consent`. Based on the example successful response, `X-Custom-For-Assemble-Process: audit` becomes `oauth.advanced-consent.x-custom-for-assemble-process`, and can be accessed in the assemble step.

Additional validation options

You can optionally use additional fields for validation:

Request Header

Defines the regular expression to match against **request** headers. Matching headers are included in the request to the advanced scope validation endpoint.

Response Context Variable

Defines the regular expression to match against **response** headers. Matching headers are saved as context variables in the format `oauth.advanced-consent.*`.

- [IETF RFC 6749](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Tokens

Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.

This section contains information regarding token management, including refreshing and revoking tokens, redirecting, and managing tokens with the DataPower Gateway.

- [Refresh tokens](#)  
If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.
- [Token revocation](#)  
In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.
- [Authenticating and authorizing through a redirect URL](#)  
You can use a service that is hosted externally from IBM API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.
- [Token management with the DataPower Gateway \(v5 compatible\)](#)  
API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.
- [Token management with the DataPower API Gateway](#)  
API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Refresh tokens

If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.

When you are using OAuth authentication, API requests must include a valid access token, by using the Authorization HTTP header. Access tokens that are issued by the IBM® API Connect Token Endpoint are valid for 3600 seconds (1 hour) by default, as indicated by the `expires_in` property that is returned on the token request. The following code block shows an example API request with an Authorization header:

```
GET /bankingApi/accountSummary?client_id=32427ce5-bb7c-48a7-9de3-4bb629091103
HTTP/1.1
Accept: application/json
Host: api.ibm.com
Authorization: Bearer AAEFYy1hbGx1hdS5nVX4x6iTL2sb3ymBivQb...
```

After an access token expires, if the option is enabled in the OAuth provider configuration Tokens<sub>2</sub>.Refresh tokens screen, the application uses refresh tokens. Each refresh token is valid for approximately 31 days after it is issued (or for the Time to Live time period specified) and can be used only once to request a new access token. Along with the new access token, a new refresh token is also returned. For details on how to enable refresh tokens, see [Configuring a native OAuth provider](#).

If the access token is expired and the application does not have a refresh token, it must restart the OAuth exchange by using the choice of Grant Type(s) allowed by the OAuth provider.

Note: Refresh tokens are not supported for a user in an OIDC user registry when accessing the Cloud Manager or API Manager user interfaces.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Token revocation

In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.

---

## Token revocation using an external third party service

This topic describes token revocation using a third party, external service. This option is configured in the Native OAuth provider, using the Token Management<sub>2</sub>.Type = Third party screen. The revocation URL is an endpoint that links to an external service which contains information about access or refresh tokens. API Connect is involved in the initial creation and validation of tokens. When an OAuth revocation URL is present, API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blacklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing.

---

## Examples

A number of revocation examples follow. The first shows a sample fetch request and the response from a remote revocation URL.

---

## GET request and response

In this example, an API Gateway server issues a GET request to the Revocation URL and receives a result. It shows that different resource owners (Laura and Emily) can revoke all tokens when using the same application (client ID).

Request:

```
<?xml version="1.0" encoding="UTF-8"?>
GET <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Accept: application/xml; text/xml
```

Response:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>

<!--
Access Tokens and/or Refresh Tokens that are revoked can be individually listed.
To keep this list small, please only include access tokens and refresh tokens that are valid.
For access tokens, any token older than 20 minutes is no longer valid.
For refresh tokens, any token older than 44700 minutes is no longer valid.
-->

<token type="access">AAETb2F1dGgtcmV2b2t1LLWN1c3RvbfZaRlVbnPSc1...</token>
<token type="refresh">fZaRlVbnPSc1UGTjCRdq4mPbOosD2+aZIKbJ6bTeW...</token>

<!--
If a resource owner has revoked all tokens issued to a given application, please
list them as shown here.
-->

<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">laura</resource-owner>
<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">emily</resource-owner>

</oauth-revocation>
```

---

## POST request and response

The next example shows a post request and response.

Request:

```
POST <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Content-Type: application/xml
```

```
<?xmlversion="1.0" encoding="UTF-8"?>
<token>
  <token_type>bearer</token_type>
  <access_token>AAENYy1hbGwtcmVmcmVzaOfNeQKX8ZeojsBY9v0FI7/OerQvzKHq...</access_token>
  <expires_in>3600</expires_in>
  <scope>3600</scope>
  <resource-owner>alice</resource-owner>
  <client_id>83d9cdcd-ba72-4d00-abae-005da8da5fb1</client_id>
</token>
```

Response:

```
HTTP/1.1 200 OK
```

## Provide token information on revocation request

---

In this example, the application calls an API and passes a bearer token. In response, the Gateway fetches the revocation URL and provides information on the token being verified.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Alternatively, the same process occurs when using a refresh token to issue a new access token. The application sends a refresh request to the token service. The Gateway then fetches the revocation URL, providing information on the refresh token being verified.

Gateway:

```
GET <revocationURL>GET HTTP/1.1
refresh-token: AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Note: If you are using a third party OAuth provider then, for API Calls with bearer tokens, when Introspect URL is enabled on the API, the revocation URL is not applicable. Instead, the third party endpoint must validate the token and also check for revocation before returning a 200 OK response to the Gateway.

## Revoking tokens issued to Alice up to and including a specific date

---

On May 1st, Alice loses her phone and needs to reset her password. As a result, the token provider wants to revoke every token issued before Alice lost her phone. In this example, the Gateway sends a GET request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-05-01T09:30:10Z">alice</resource-owner>
</oauth-revocation>
```

## Revoking all tokens issued up to and including a specific date

---

Under certain catastrophic conditions, you may need to revoke all tokens issued up to and including a specific date, for example, May 1st. In this example, the Gateway sends a GET request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <everytoken before="2015-05-01T09:30:10Z" />
</oauth-revocation>
```

## Putting it all together

---

The following shows the examples contained in this topic executed in a single action:

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1
```

client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398  
resource-owner: alice

Revocation Service:

HTTP/1.1 200 OK  
Content-Type: application/xml  
Cache-Control: public, max-age=120  
Date: Fri, 08 May 2015 21:49:03 GMT

```
<?xml version="1.0" encoding="UTF-8"?>  
<oauth-revocation>  
  <resource-owner before="2015-04-08T09:30:10Z">mary</resource-owner>  
  <resource-owner before="2015-04-12T09:30:10Z">john</resource-owner>  
  <resource-owner before="2015-04-13T09:30:10Z">kevin</resource-owner>  
  <resource-owner before="2015-04-01T09:30:10Z">alice</resource-owner>  
</oauth-revocation>
```

Notes:

- In the previous example, there are no entries older than one month in the response (the maximum life of a refresh token).
- Each response is cached for up to two minutes according to response's directive.
- The `before` attribute uses the `xs:dateTime` syntax.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Authenticating and authorizing through a redirect URL

You can use a service that is hosted externally from IBM® API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.

### Before you begin

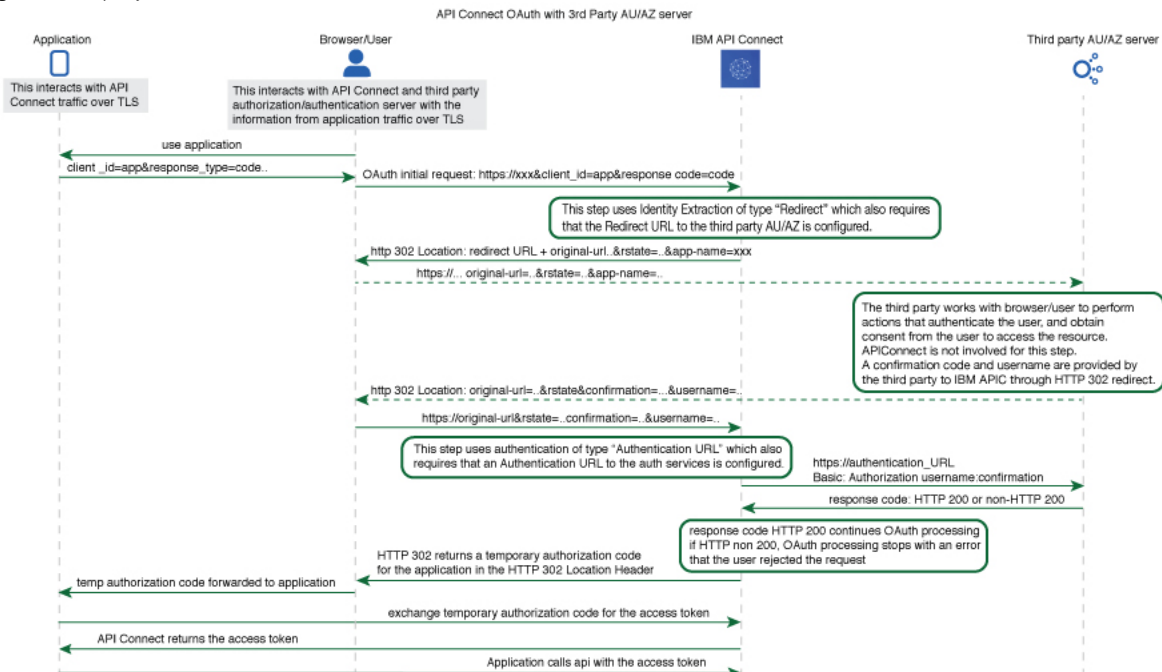

To complete this task, you will need to either create or have created an OAuth security definition that uses Implicit grant type or Access Code (Authorization Code) grant type. For more information, see [Creating an OAuth security definition](#).

### About this task

If you use methods for authentication that are not supported by API Connect, you can redirect users to a suitable URL at which they can authenticate. The user is then returned to the OAuth process after authentication and authorization have been confirmed.

The following illustration indicates the transaction flow for third party authentication.

Figure 1. Third party authentication (AU) and authorization (AZ) transaction flow

1. The application initiates a request to access an API protected with a third-party entity. API Connect redirects the application with an **HTTP 302** redirect based on **identity extraction** ->

- redirect** -> **redirect-url**, for user authentication (and optional authorization).
- The application communicates directly with the third-party entity to gather user identity. API Connect is not involved in this communication. After the third-party entity finishes processing authentication (and optional authorization), it returns an **HTTP 302** redirect that uses the **original-url** from the request, with the username and confirmation code appended.
  - API Connect receives the request that includes the username and confirmation code, and communicates with the authentication URL, based on **authentication** -> **x-ibm-authentication-url**, to confirm user identity before the request is completed.
  - An **HTTP 200** response from the third-party entity allows API Connect to continue the OAuth 2.0 request process as if the owner is authenticated. The request is then processed according to the **grants** type.
    - **accessCode** returns a temporary code to the application.
    - **implicit** returns the access token to the application.
- For any response other than HTTP 200, the request fails with a statement added to the error log.

## Procedure

To create an external form, and to indicate the URL to which API Connect will redirect users, complete the following instructions:

- Create your service for authentication and authorization. You will use the URL of the landing page of this service as your redirect URL.
  - To include elements in your form that are provided by API Connect, use the query parameters from the URL that your user is redirected to. When the user is redirected to your page, the URL they are sent to contains the following query parameters:

**app-name**  
The name of the application requesting access, as provided through the Developer Portal.

**appid**  
The id of the application requesting access.

**catalog**  
The name of the catalog where the product is being used by the application.

**catalogid**  
The id of the catalog where the product is being used by the application.

**catalogtitle**  
User-friendly display name for the catalog.

**org**  
The name of the consumer organization that hosts the application.

**orgid**  
The id of the consumer organization that hosts the application.

**orgtitle**  
User-friendly display name for the organization.

**original-url**  
The original URL that the user was directed to by the application, including query parameters from the original URL that are necessary for standard OAuth 2.0 requests. You can include these parameters in your service to provide information to the user. Additionally the **state\_nonce** is appended. The **state\_nonce** is a hash code generated by API Connect for verification purposes. The URL is URL-encoded and should be decoded before further use, the **state\_nonce** should remain unchanged.

**provider**  
The name of the API provider organization.

**providerid**  
The id of the API provider organization.

**providertitle**  
User-friendly display name for the provider organization.

**requested-scope**  
[optional] If [Application Scope check](#) is enabled and replaces the **scope** from the initial application request, this field holds the **scope** value from the initial application request, and the new replacement scope value is put into **original-url**.

**transid**  
transaction id used in the GW for the transaction which trigger this call

The URL to which the user is sent to when they are redirected to your page has the following form:

**Redirect\_URL?original-url=Original\_URL&state\_nonce=R\_State&app-name=Application\_Name**

where all variables are as described previously. The Redirect URL does not have a size limit enforced by API Connect.

- Create the stages of authentication, authorization, and any intermediate stages that you require to take place before you allow access to the application. Upon completion of these stages, redirect the user to the *Original\_URL* and append a user name, their confirmation code, and the application name to be evaluated for access grant or denial by API Connect. The confirmation code does not have a size limit enforced by API Connect. Original URL requires the following form:

**Original\_URL&username=User\_Name&confirmation=Confirmation\_Code**

where all variables are as described previously.

For example:

**https://your\_gateway.com/your\_org/your\_catalog/your\_api/oauth/authorize?response\_type=code&redirect\_uri=https://example.com/redirect&scope=/your\_api&client\_id=5af57a4a-6db9-4141-ad08-5709432af66e&state\_nonce=HoIbRG+6bZtq1B7LDkq4gj1D3SHKq1CbnYdHs/bMz2Y=&username=spoon&confirmation=12345678**

- To send your own error responses after the authentication and authorization service, redirect the user to the *Original\_URL* and append an error code. You can also append a user name. Use the following form:

**Original\_URL&username=User\_Name&error=Error\_Response**

where *Error\_Response* is the message you wish to send and all other variables are described as previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtq1B7LDkq4gj1D3SHKglCbnYdHs/bMz2Y=&username=User&error=access_denied
```

2. Create a service to validate the confirmation code and user name. API Connect makes a GET call to your authentication URL after the user is redirected back to the authorization URL. When the call is made, it includes in its authorization header the user name and confirmation code you supplied previously. Confirm that these are correct and respond with an HTTP success code such as 200 OK if you want to allow access, or non-200 HTTP response code, such as 401 Unauthorized to deny access.
3. In your OAuth provider configuration, supply the redirect URL that is used in Step 1 and the authentication URL that is used in Step 2.  
For more information on configuring an OAuth Provider, see [Configuring a native OAuth provider](#) when using API Manager or [Configuring a native OAuth provider](#) when using Cloud Manager.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Token management with the DataPower Gateway (v5 compatible)

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

In order to manage tokens with the DataPower® Gateway (v5 compatible), you must set the Token Management Type to Native in your Native OAuth provider configuration. See [Configuring token management and revocation for a native OAuth provider](#) when using Cloud Manager or [Configuring token management and revocation for a native OAuth provider](#) when using API Manager.

Also, the DataPower quota enforcement server must be enabled on the DataPower Gateway to use the distributed cache to manage tokens. See [Quota enforcement](#).

When distributed cache support is enabled, replay protection is provided across the gateway cluster through the quota enforcement server. This support ensures that the same token cannot be reused across the members of the quota enforcement peer group.

Important:

If you have a cluster of DataPower Gateway servers, the OAuth data synchronization behavior across the servers depends on whether or not you enable revocation:

- If you enable revocation, API Connect uses the DataPower quota enforcement server, and OAuth data is synchronized across the servers. If an access token is obtained from one server, the OAuth data synchronization ensures that the same authorization code cannot be used to obtain an access code from another server. You must ensure that the DataPower quota enforcement server is configured.
- If you disable revocation, API Connect does **not** use the DataPower quota enforcement server and OAuth data does not synchronize across the cluster of DataPower Gateway servers. Therefore, to prevent the same authorization code being used to obtain an access code from more than one server you must configure DataPower to synchronize OAuth data across the servers, by using the DataPower Gateway console.

To configure DataPower to synchronize OAuth data, ensure that the DataPower quota enforcement server is configured. For more information, see [Configuring the quota enforcement server](#).

---

## Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user `cn=spoon,o=ibm` with username `spoon` and password `spoon` using a registered administration application of `5287fe53-8747-438a-8262-681ec75b79c5`.

- Request:

```
GET /oauth2/issued
HTTP/1.1
Host: apic.ibm.com
x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache
[
  {
    "clientId": "7369ad66-5674-b7d3-4567-de35283421aca",
    "owner": "cn=spoon,o=ibm",
    "clientName": "PetStore Application",
    "scope": "listpet",
    "issuedAt": 1503327054,
    "consentedOn": 1503327054,
    "expiredAt": 1503330654,
    "refreshTokenIssued": false,
    "appId": "d2031f0f27339315333734ab9",
```

```

    "org": "PetStoreOrg",
    "orgTitle": "Katie Pet Grooming Inc",
    "orgId": "5887803de4b06e6998c4b2c7",
    "provider": "SuperStore",
    "providerTitle": "Simon SuperStore",
    "providerId": "5887803de4b06e6998c4b2c7",
    "catalog": "publicapi",
    "catalogTitle": "For public",
    "catalogId": "5887803de4b06e6998c4b2d3"
  },
  {
    "clientId": "a8746323-9825-a842-8736-abd8202356ac8",
    "owner": "cn=spoon,o=ibm",
    ...
  }
]

```

#### Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```

DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8
HTTP/1.1
Host: apic.ibm.com
x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bt5cV4dN7nW5kM5uP8vL3uF3cT7
Authorization: Basic c3Bvb246c3Bvb24=

```

- Response

```

HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

{ "status": "success" }

```

## Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to `/oauth2/revoke`, which supports OAuth 2.0 [IETF RFC 7009](#). An HTTP POST operation that an application can send to this API to revoke either an `access_token`, or `refresh_token` with `token_type_hint` as shown in the following examples:

#### Revoke `access_token`

- Request:

```

POST /oauth2/revoke
HTTP/1.1
Host: apic.ibm.com

x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bt5cV4dN7nW5kM5uP8vL3uF3cT7
Content-Type: application/x-www-form-urlencoded

token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR...

```

- Response:

```

HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

{ "status": "success" }

```

#### Revoke `refresh_token`

- Request:

```

POST /oauth2/revoke
HTTP/1.1
Host: apic.ibm.com

x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bt5cV4dN7nW5kM5uP8vL3uF3cT7
Content-Type: application/x-www-form-urlencoded

token_type_hint=refresh_token&token=.....

```

- Response:

```

HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

{ "status": "success" }

```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Token management with the DataPower API Gateway

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

In order to manage tokens with the DataPower® API Gateway, you must set the Token Management Type to Native in your Native OAuth provider configuration. See [Configuring token management and revocation for a native OAuth provider](#) when using Cloud Manager or [Configuring token management and revocation for a native OAuth provider](#) when using API Manager.

For token management with the DataPower API Gateway, you must configure the API Security Token Manager on the gateway. Complete the following steps:

1. Log in to the DataPower administration console, selecting apiconnect for the domain, and WebGUI for the Graphical Interface.
2. In the search box, enter API Security Token Manager, then click on the API Security Token Manager link that displays in the search results.
3. For the Administrative state, select enabled.
4. Click the + icon alongside the Gateway Peering field to create a new gateway peering object.
5. Provide a Name and a Local address.
6. In the Local port and Monitor port fields, provide values that aren't already in use by services for the Local address.
7. Ensure that Peer group mode is selected.
8. Alongside the Peers field, use the add button and accompanying field to add at least two peers, to ensure that quorum is achieved.
9. If the Enable SSL option is selected, select a value for the Identification credentials.
10. For Persistence location, select a setting other than memory.
11. When done, click Apply.
12. Repeat steps 1 to 11 for each DataPower API Gateway in the peer group.
13. When done, click Apply, then click Save Configuration to save your changes.

For more information, see [Defining the API security token manager](#) and [Creating a gateway peering instance](#).

## Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user `cn=spoon,o=ibm` with username `spoon` and password `spoon` using a registered administration application of `5287fe53-8747-438a-8262-681ec75b79c5`.

- Request:

```
GET /oauth2/issued
HTTP/1.1
Host: apic.ibm.com
x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bt5cV4dn7nW5km5uP8vL3uF3cT7
Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache
[
  {
    "clientId": "7369ad66-5674-b7d3-4567-de35283421aca",
    "owner": "cn=spoon,o=ibm",
    "clientName": "PetStore Application",
    "scope": "listpet",
    "issuedAt": 1503327054,
    "consentedOn": 1503327054,
    "expiredAt": 1503330654,
    "refreshTokenIssued": false,
    "appId": "d2031f0f27339315333734ab9",
    "org": "PetStoreOrg",
    "orgTitle": "Katie Pet Grooming Inc",
    "orgId": "5887803de4b06e6998c4b2c7",
    "provider": "SuperStore",
    "providerTitle": "Simon SuperStore",
    "providerId": "5887803de4b06e6998c4b2c7",
    "catalog": "publicapi",
    "catalogTitle": "For public",
    "catalogId": "5887803de4b06e6998c4b2d3"
  },
  {
    "clientId": "a8746323-9825-a842-8736-abd8202356ac8",
    "owner": "cn=spoon,o=ibm",
```

```
    ...
  }
]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8
HTTP/1.1
Host: apic.ibm.com
x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

{ "status": "success" }
```

## Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to `/oauth2/revoke`, which supports OAuth 2.0 [IETF RFC 7009](#). An HTTP POST operation that an application can send to this API to revoke either an `access_token`, or `refresh_token` with `token_type_hint` as shown in the following examples:

Revoke `access_token`

- Request:

```
POST /oauth2/revoke
HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
Content-Type: application/x-www-form-urlencoded

token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn941SWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

{ "status": "success" }
```

Revoke `refresh_token`

- Request:

```
POST /oauth2/revoke
HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
Content-Type: application/x-www-form-urlencoded

token_type_hint=refresh_token&token=.....
```

- Response:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

{ "status": "success" }
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs-in with user name: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes `cn=spoon,o=eatery`. The credential is kept in the OAuth `access_token` to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the `access_token`.
- Overriding the `scope` that the application receives after a successful OAuth protocol processing. By responding with a specific header, the Authentication URL endpoint can replace the `scope` value that the application receives. For example, you can provide a specific resource owner an account number within the `scope` header response for use in future processing steps.

When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect will use `cn=spoon,o=eatery` as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see [User Security policy](#).

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see [Example - using multiple OAuth policies in an OAuth provider assembly](#).

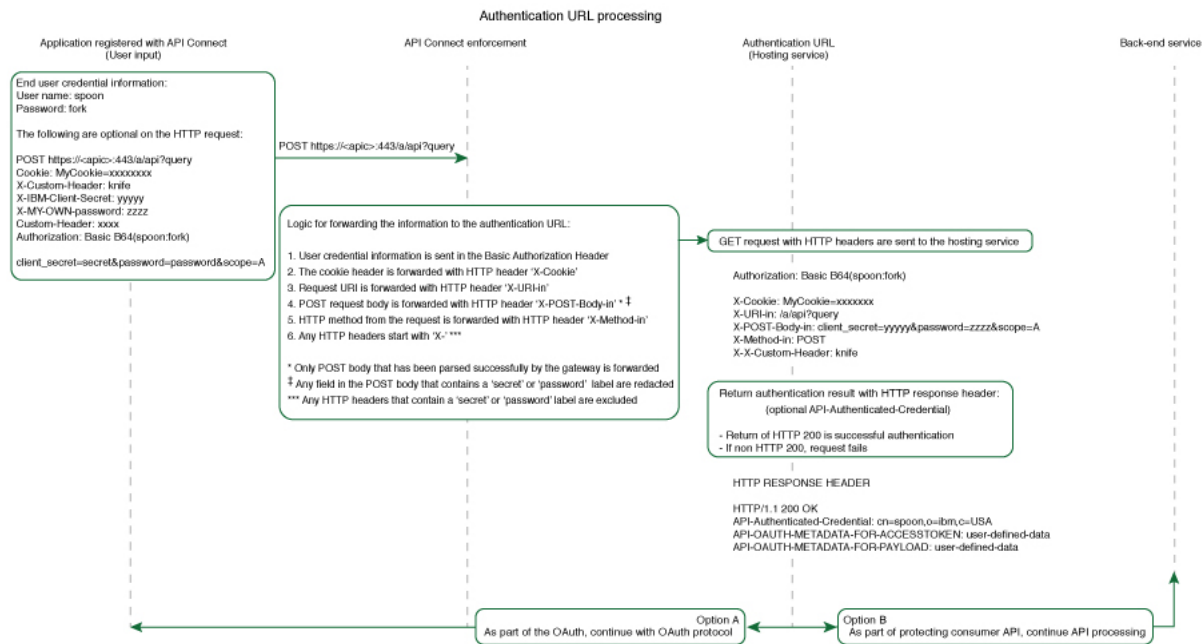

API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see [OAuth external URL and authentication URL](#). The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested `scope` from the application. For more information, see [Scope](#). The response header is:

```
x-selected-scope
```

If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Custom forms for user security

You can create custom forms for the authorization and identity extraction phase of OAuth.

## About this task

The Native OAuth provider configuration provides the capability for requiring additional authentication and authorization steps for user security. Custom HTML forms may be created to extract the identity of the user and to authorize the user. This capability applies to Implicit, Resource owner password, and Access code grant types.

- [Creating a custom HTML login form for user security](#)  
Custom HTML forms can be created for user security during the identity extraction stage in OAuth.
- [Creating a custom HTML authorization form for user security](#)  
Custom HTML forms can be created for user security during the authorization stage in OAuth.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Creating a custom HTML login form for user security

Custom HTML forms can be created for user security during the identity extraction stage in OAuth.

---

### Before you begin

The Native OAuth provider configuration includes Identity Extraction when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to extract the user credential and one of the choices is Custom HTML Form. For more information, see [Configuring a native OAuth provider](#) when using API Manager or [Configuring a native OAuth provider](#) when using Cloud Manager. For more information, see [Configuring a native OAuth provider](#). This topic describes how to create the Custom HTML form for identity extraction.

---

### About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form for signing in to the service provided by the API. You can present a custom form or a default form. Your custom form must fulfill certain requirements.

Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

---

### Procedure

To create a custom sign-in form for your Native OAuth provider, complete the following steps:

1. Create a well formed XHTML document that will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as POST, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.  
For example:

```
<form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
```

3. Create a text input field that is named `username` and create a password input field named `password`.
4. Add the line `<EI-INJECT-HIDDEN-INPUT-FIELDS>`. This third element is a placeholder that API Connect replaces with input fields to complement the user-submitted data.
5. Create a button to initiate the sign-in process.  
For example:

```
<button  
id=" _home_markdown_jenkins_workspace_Transform_in_SSMNED_2018_com.ibm.apic.apionprem.doc_oauth_custom_login_form_login_but  
ton" type="submit" name="login" value="true">Log in</button>
```

6. Optional: Add text that is displayed the first time that the user visits the sign-in page. Use the tag `<EI-LOGINFIRSTTIME>` for the text that you want to display.
7. Optional: Add text that appears when the user is returned to the sign-in page if they fail to authenticate. Use the tag `<EI-LOGINFAILED>` for the text that you want to display.
8. Optional: Have an error message displayed when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<EI-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
9. Optional: You can add elements that are loaded from external sources, such as images or JavaScript.
10. Insert spacing and other features as you require. Completing Steps [1](#) through to [8](#) results in a form similar to the following example:

```
<html lang="en" xml:lang="en">  
<head><meta http-equiv="Content-Type" content="text/html; charset=UTF-8"/></head>  
<body>  
<form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">  
<h1>Please sign in</h1>  
<p>Username </p>  
<p ><input type="text" name="username" required="required" /> </p>  
<p>Password </p>  
<p ><input type="password" name="password" required="required" /> </p>  
<EI-INJECT-HIDDEN-INPUT-FIELDS/>  
<p > <button  
id=" _home_markdown_jenkins_workspace_Transform_in_SSMNED_2018_com.ibm.apic.apionprem.doc_oauth_custom_login_form_login_but  
ton" type="submit" name="login" value="true">Log in</button> </p>  
  
<EI-LOGINFIRSTTIME>  
<p>If you have forgotten your user name or password, contact your system administrator.</p>  
</EI-LOGINFIRSTTIME>  
  
<EI-LOGINFAILED>
```

```

    <p>At least one of your entries does not match our records.
      If you have forgotten your user name or password, contact your system administrator.</p>
  </EI-LOGINFAILED>

  <EI-INTERNAL-CUSTOM-FORM-ERROR/>

</form>
</body>
</html>

```

- Make your form available at a URL of your choice.
- If you have not already done so, configure your Native OAuth provider to use a Custom HTML form for identity extraction and provide the URL at which your form is available. For more information, see [Configuring a native OAuth provider](#) when using API Manager or [Configuring a native OAuth provider](#) when using Cloud Manager.

## Related tasks

## Related information

- [Configuring API security](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

# Creating a custom HTML authorization form for user security

Custom HTML forms can be created for user security during the authorization stage in OAuth.

## Before you begin

The Native OAuth provider configuration includes user authorization when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to authorize application users and one of the choices is Custom HTML Form. For more information, see [Configuring a native OAuth provider](#) when using API Manager or [Configuring a native OAuth provider](#) when using Cloud Manager. This topic describes how to create the Custom HTML form for authorization.

## About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form through which they grant permission to an application to access their data through the API on their behalf. You can present a custom form or a default form. Your custom form must fulfill certain requirements.

Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

## Procedure

To create a custom authorization form for your Native OAuth provider, complete the following steps:

- Create a well-formed XHTML document. This will be parsed and transformed by API Connect to inject hidden fields.
- For your XHTML form, set the method as POST, the encoding type as application/x-www-form-urlencoded, and the action as authorize. Add any other parameters that you require.

For example:

```
<form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
```

- Add the line <AZ-INJECT-HIDDEN-INPUT-FIELDS/>. This line is a placeholder that API Connect will replace with input fields necessary for the completion of the OAuth process.
- Create two buttons with the following code so that the user can grant or deny permission. Edit the text to suit your preferences.

```
<button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
<button class="submit" type="submit" name="approve" value="true">Allow Access</button>
```

- Optional: Display an error message when an error in the custom form prevents it from being displayed to the user correctly. Use the tag <AZ-INTERNAL-CUSTOM-FORM-ERROR/>; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
- Optional: You can add to the form HTML elements that will load features from external sources, such as images or JavaScript. For example, <script src="http://www.example.com/example.js" />
- Insert spacing and additional elements as you require. Completing Steps 1 through to 6 results in a form similar to the following example:

```
<html lang="en" xml:lang="en">
  <head><title>Request for permission</title></head>
  <body class="customconsent">
    <div>
      <div>
        <form method="post" enctype="application/x-www-form-urlencoded" action="authorize">
          <AZ-INJECT-HIDDEN-INPUT-FIELDS/>
          <p>Greeting...</p><DISPLAY-RESOURCE-OWNER/>
        </form>
      </div>
    </div>
  </body>
</html>
```

```
<p>This app </p><OAUTH-APPLICATION-NAME/><p> would like to access your data.</p>
<div>
  <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
  <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
</div>
</form>
</div>
<AZ-INTERNAL-CUSTOM-FORM-ERROR/>
</div>
</body>
</html>
```

8. Make your form available at a URL of your choice.
9. If you have not already done so, configure your Native OAuth provider to use a Custom HTML Form for authorization for User Security. Provide the URL as the endpoint at which your form is available. For more information, see [Configuring a native OAuth provider](#) when using API Manager or [Configuring a native OAuth provider](#) when using Cloud Manager.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Securing an API with a JSON Web Token

There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM® API Connect.

### About this task

---

JSON Web Token (JWT) is an OAuth 2.0 compliant method of authentication that can be useful to secure your API in API Connect.

You can secure your API with a JSON Web Token by using either of the following methods:

- Generate a token through the **jwt-generate** command, and then augment the response payload with your generated token replacing the **id** token.
- Use a token that was generated outside of API Connect and include it into the response payload, by using the metadata URL.

### Procedure

---

Create a **jwt-generate** policy in the assembly.

- a. In API Manager, open the Assembly tab.
- b. Add a **jwt-generate** policy to the assembly for the API.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Troubleshooting OAuth

You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on Youtube.

You can use the following links to go to the topics:

- [Enable an extended error description](#)
- [OAuth 2.0 support in the developer portal test tool](#)
- [OAuth requires quorum in a multi-node cluster](#)

### Enable an extended error description

---

The [OAuth 2.0 Authorization Framework](#) governs how IBM® API Connect is defined. According to the specification, OAuth 2.0 error conditions trigger a payload with error, and an optional field `error_description`. To prevent information leakage, the IBM DataPower® Gateway default setting returns the error only. However, during the development and testing phase of an application, it is useful to find out why an OAuth 2.0 request is being rejected. To enable this behavior, the caller can pass an HTTP request header in the OAuth request:

```
APIm-Debug: true
```

The presence of the header enables the 'just-in-time' debugging for that OAuth transaction, and `error_description` is returned as part of the error condition. The output helps the caller to determine why an OAuth request is rejected by API Connect as shown in the examples. Example error output without 'just-in-time' debugging:

```
{ "error": "invalid_request" }
```

Example error output with 'just-in-time' debugging:

```
{ "error": "invalid_request", "error_description": "Multiple OAuth client credentials are provided" }
```

## OAuth 2.0 support in the developer portal test tool

OAuth 2.0 support is exposed as an API through the provider OpenAPI definition. You can use the test tool that is included with API Connect to test the OAuth 2.0 configuration. For more information, see [Testing an API using the Developer Portal test tool](#).

## OAuth requires quorum in a multi-node cluster

In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring the cloud settings

Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.

The cloud settings let you define basic configuration for your deployment. To view the current settings, log in to Cloud Manager and click  in the navigation pane.

Tip: When you are familiar with the cloud settings, you can modify them using the [Toolkit command-line interface](#) instead of the user interface. Visit the following pages to configure settings:

### Overview

Provide a title and description for your cloud administrator organization. For more information, see [Change the name of your cloud](#).

### Onboarding

Specify time-out settings for onboarding invitations and password resets. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.

For more information on setting timeouts, see the following topics:

- [Configuring invitation timeouts](#)
- [Configuring the password-reset notification and timeout](#)

### User Registries

Configure one or more user registries to authenticate users of Cloud Manager or API Manager. The user credentials for all users who login to each applications must be stored in the specified registries. For more information on configuring user registries, see [Selecting user registries for Cloud Manager and API Manager](#).

### Roles

Create roles and assign them to members of the Admin organization to specify which tasks members are authorized to perform. For more information on assigning roles, see [Administering members and roles](#).

### Role Defaults

The Role Defaults for the Admin organization are not configurable, but you can customize the base roles for provider organizations and consumer organizations. For more information on customizing base roles, see [Role Defaults overview](#).

### Endpoints

View the list of endpoints configured for API Manager, provider APIs, and consumer APIs during the installation process.

### Notifications

Select the email server for your on-premises cloud notifications, configure notification settings, and specify the sender name and email address to be included in the emails. You can also preview and customize email templates used for notifications. Be sure to configure the email server, because it is needed for sending invitations and other notifications to users. For more information on setting up notifications, see [Setting up notifications](#).

Note: Before you can set up notifications, you must [configure an email server](#) for your deployment.

### Catalog Defaults

Specify one or more gateway services to be provided to every Catalog by default, so that Products (which contain APIs) can be made available to users. When a new Catalog is created in a provider organization, it is assigned to the default gateway service. Any changes you make to these settings do not affect existing Catalogs. For more information on selecting gateway services, see [Configuring the default gateway services for Catalogs](#).

Use the following list to locate instructions for using specific cloud settings:

- [Using the CLI to modify cloud settings](#)  
Use the toolkit CLI to edit the cloud settings.
- [Change the name of your cloud](#)  
You can change the name of your cloud.
- [Configuring an email server for notifications](#)  
Connect to an email server in your API Connect on-premises cloud. The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service. Otherwise, the owner of the organization will not receive the email with the details that they require to access the API Manager.

- [Setting up notifications](#)  
To configure email notifications, configure an email server, sender information, and email templates.
- [Configuring invitation timeouts](#)  
You can set the time period for when registration invitations for Cloud Settings access and the Admin organization expire.
- [Configuring the password-reset notification and timeout](#)  
Configure the time allowed for a user to reset a password, and customize the notification that the user receives.
- [Selecting user registries for Cloud Manager and API Manager](#)  
Select the user registries to authenticate users for Cloud Manager and API Manager.
- [Configuring timeouts for access tokens and refresh tokens](#)  
Configure timeout values for the access tokens and refresh tokens for user registries.
- [Viewing platform and UI endpoints](#)  
A view-only list of platform and UI endpoints is provided.
- [Configuring the default gateway services for Catalogs](#)  
Configure the list of default gateway services that are available to new Catalogs.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Using the CLI to modify cloud settings

Use the toolkit CLI to edit the cloud settings.

### About this task

Some cloud settings can be modified in the Cloud Manager UI, but all settings can be modified with the toolkit CLI. You can modify the cloud settings configuration file and upload the changes, or issue commands to modify individual settings directly. If multiple people modify the cloud settings, any newer settings overwrite older settings regardless of the method used to update the settings.

For more information about working with the toolkit CLI, see the following topics:

- For details on using `apic` to modify cloud settings, see [apic cloud-settings:update](#).
- For details on all the cloud settings commands, see [apic cloud-settings](#)

### Procedure

1. Run the following command to log in to a management server as a member of the cloud administration organization:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm realm
```

Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI. For more information on logging in, see [Logging in to a management server](#).

2. Optionally retrieve the current list of cloud settings with the following command:

```
apic cloud-settings:get --server mgmt_endpoint_url --output -
```

where `mgmt_endpoint_url` is the URL of the server where the cloud settings are stored.

3. Add or modify settings using one of the following methods:

- Issue each setting from the command line.  
For simple changes, you can issue commands to modify settings without editing the configuration file.

- Issue the following command to start the update process:

```
apic cloud-settings:update --server mgmt_endpoint_url -
```

where `mgmt_endpoint_url` is the URL of the server where the cloud settings are stored. Include the hyphen at the end of the command to indicate that input follows on the next command line.

- Type the information for a single setting on one line, and press ENTER to submit it.  
Specify each setting on a single line and use the following format to specify the setting's name and value:

```
setting_name: setting_value
```

For example, the following command updates a single setting:

```
apic cloud-settings:update --server mgmt_endpoint_url -
refresh_expires_in: expiration time
Ctrl+D
```

- Type Ctrl+D to indicate that the data entry is complete, as shown in the example.
- Upload a file containing the settings.  
If you have multiple settings or lengthy values to add or modify, you might prefer to make all of the changes at once by creating or modifying the configuration file and then uploading it.
- Create a .yaml file with your settings.  
You can choose the file name but must use YAML format. The file can contain as few or as many settings as needed.

Settings use the following format; notice that the setting's name must be enclosed in quotation marks as shown in the example. The last setting in the file does not end with a comma.

```
"setting_name": setting_value,
```

- Upload the file with the following command:

```
apic cloud-settings:update --server mgmt_endpoint_url my_cloud_settings.yaml
```

For information on using input files with the toolkit CLI, see [./com.ibm.apic.toolkit.doc/rapic\\_cli\\_command\\_line\\_input.html](#).

4. When you are ready to log out of the management server, use the following command:

```
apic logout --server mgmt_endpoint_url
```

## Results

---

The settings are cached for a maximum of five minutes, so you might experience a delay before your changes take effect.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Change the name of your cloud

You can change the name of your cloud.

### About this task

---

You can change the name of your cloud using the Overview page.

One of the following roles is required to change the name of your cloud:

- Administrator
- Owner
- A custom role with the `cloud settings:manage`

### Procedure

---

Follow these steps to change the name of your cloud:

1. In the Cloud Manager, click  Settings.
2. Select Overview..
3. Click Edit to change the name of your cloud.
4. Enter a Title and the name is auto-generated. Enter a brief Summary and click Save.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Configuring an email server for notifications

Connect to an email server in your API Connect on-premises cloud. The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service. Otherwise, the owner of the organization will not receive the email with the details that they require to access the API Manager.

### Before you begin

---

You must complete the tasks in the following section:

1. [Defining your topology](#).

### About this task

---

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator
- Topology Administrator
- Custom role with `Settings:Manage` permission

The email server sends invitation emails with activation links and other system messages. More than one email server may be configured in Cloud Manager, but only one email server may be selected as the active server to send notifications at any one time. For instructions on how to select the active email server and to view a list of the email messages that are sent, see [Setting up notifications](#).

Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

## Procedure

To configure one or more email servers to use for email notifications in Cloud Manager, complete the following steps:

1. In the Cloud Manager, click  Resources.
2. Choose Notifications.
3. Enter the values to configure the email server.

Field	Description
Title (required)	Enter a descriptive title for the availability zone. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Address (required)	IP address for the email server
Port (required)	Port that the email server runs on
Authenticate User	Enter a user name to use for authorization with the SMTP server. The user name is required if the SMTP server requires authentication.
Authenticate Password	Enter the password for the Authenticate User. This password is used for authorization with the SMTP server. The password is required if the SMTP server requires authentication.
TLS Client Profile (optional)	Select an optional TLS Client Profile that will be used to communicate with the email server if the Secure Connection option is selected.
Secure Connection	Select this option to specify that TLS security is used. The following conditions apply: <ul style="list-style-type: none"><li>• If this option is not selected then TLS security is not used even if the email server is configured to use the STARTTLS protocol.</li><li>• If this option is selected and a TLS Client Profile is selected, that profile is used and the STARTTLS protocol configuration on the email server is honored.</li><li>• If this option is selected and no TLS Client Profile is selected, the Default TLS client profile is used and the STARTTLS protocol configuration on the email server is honored.</li></ul>

4. You can send a test email to confirm that the email server is properly configured. Click Test email in the Test Connection panel to open a dialog window. Enter one or more valid email addresses in the Recipients field. Separate multiple recipients with commas. Click Send test email. Check that the test email was received by the recipients.
5. If the test email is successful, click Save to save the email server configuration. If the test is unsuccessful, check the configuration values and update as needed.  
Note: In order to send emails, you must select an email server as your active server in Settings > Notifications.

## Results

The email server is configured. It must be selected in Cloud Settings > Notifications as the active email server. See [Setting up notifications](#)

## What to do next

Select the email server to use for your cloud, enter the sender information, and customize the email templates. See [Setting up notifications](#).

Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

## Related tasks

- [Setting up notifications](#)
- [Editing an email server](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Setting up notifications

To configure email notifications, configure an email server, sender information, and email templates.

### About this task

In Settings > Notifications, you select the email server you want to use as the active server to send notification emails in Resources > Notifications. An active email server is required to send email notifications. More than one email server may be configured in Cloud Manager, but only one email server may be selected to send notifications at any one time. The email server must be configured and selected for notifications before adding a Portal Service to your cloud.

You also configure the sender information to be included on all the emails and optionally, edit the standard text for the email templates.

One of the following roles is required to add roles to select the email server, enter the sender information, and edit the email templates:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` permission

Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

## Procedure

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click Notifications.
3. To configure the active email server:
  - a. Click Edit in the Sender & Email Server section.
  - b. Select an email server in the list; a check mark is displayed next to the currently selected server.
  - c. Click Save.
4. To delete an email server from the list, click the options menu next to the server name and select Delete.
5. To change the sender name and email address for notifications:
  - a. Click Edit in the Sender & Email Server section.
  - b. Fill in the Name and Email address that notifications will be sent from.
  - c. Click Save.
6. To preview and edit the notification email templates, see [Customizing email notification templates](#)

## What to do next

You can now [create a provider organization](#).

- [Customizing email notification templates](#)  
API Connect includes a set of email templates for invitations and other notification emails. You can preview the templates and customize the text if needed.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Customizing email notification templates

API Connect includes a set of email templates for invitations and other notification emails. You can preview the templates and customize the text if needed.

## About this task

The API Connect emails are sent automatically when certain system events occur. The email templates are organized by scope, as explained in Table 1.

Table 1. Notification scopes

Scope	Events that trigger the notification
admin	Admin organization activities such as invitations, portal sign up, and password reset.
catalog	Activities related to Catalogs; for example: such as application life cycle events, invitations to catalogs, product approvals, and subscription approvals.
consumer	Activities to consumer applications and subscription requests in the Developer Portal, invitations to Consumer organizations, and password reset requests for Developer Portal accounts.
provider	Invitations
space	Invitations

One of the following roles is required to configure email notifications:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` permission

## Procedure

1. In the Cloud Manager, click  Settings.
  2. In the Settings navigation list, click Notifications.  
On the Notifications page, templates display in a list, sorted by scope. When selecting a template to modify, be sure to select the version that applies to the appropriate scope.
  3. To preview the text for a template, select Preview from the actions menu next to the template name.
  4. To edit the text for the template, either click the template name, or select Edit Template in the action menu.  
The text includes variables; for example, `{{activationLink}}`.
- To obtain the complete list of variables that are available for a particular notification template, complete the following steps:
- a. Log in to the management server from the command line as a member of the cloud administration organization; for details, see [Logging in to a management server](#). You can use the same management server URL, user name, and password in the login command that you use to log in to the Cloud Manager user interface.
  - b. Enter the following command:

```
apic notification-templates:get template_name --server mgmt_endpoint_url --scope cloud --subcollection template_scope
--fields variables --output -
```

where *template\_name* is the name of the required notification template, as displayed in the Template column in the user interface, and *template\_scope* is the scope name displayed in the Scope column alongside that template.

For example:

```
apic notification-templates:get member-invitation --server https://myserver.com --scope cloud --subcollection catalog
--fields variables --output -
```

The variables that are available for the template are displayed; for example:

```
variables:
- org
- catalog
- activationLink
- expiresAt
```

The `--output -` parameter causes the command output to be written to the command line. You can specify `--output filepath` to have the output written to a .yaml file at the specified location, or omit it altogether to have a file written to the current folder.

5. Click Save when done.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Configuring invitation timeouts

You can set the time period for when registration invitations for Cloud Settings access and the Admin organization expire.

### About this task

---

One of the following roles is required to change the name of your cloud:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

### Procedure

---

Follow these steps to set the invitation timeout:

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the invitation timeout setting that you want to change:
  - Cloud settings invitation timeout
  - Admin organization invitation timeout
4. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
5. Click Save.

### Results

---

Invitations contain a link, which expires after the specified the timeout. If the user does not register before the expiration, you can send a new invitation.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Configuring the password-reset notification and timeout

Configure the time allowed for a user to reset a password, and customize the notification that the user receives.

### Before you begin

---

Configure an email server that can be used for mailing notifications to users. If you do not configure an email server, a link cannot be send to a user who wants to reset a password. For information on configuring the email server, see [Setting up notifications](#).

### About this task

---

When a user clicks **Forgot Password?** and provides an email address on the sign-in page, an email is generated with a link where the user can reset the password. When you deploy API Connect, the password-reset settings are configured with default values. You can optionally modify the time-out setting to set a new expiration for resets as well as the notification that is emailed to users.

## Procedure

---

1. Click  in the navigation pane.
2. In the Settings navigation list, click **Onboarding**.
3. Configure the password reset timeout:
  - a. In the Settings navigation list, click **Onboarding**.
  - b. Click **Edit** next to **Reset Password Time to Live**.
  - c. To specify a timeout value, select or type an integer value in the **Number** field and then choose a unit of time (**Seconds**, **Minutes**, or **Hours**) in the **Unit** field.
  - d. Click **Save**.
4. Customize the notification template for password resets:
  - a. In the Settings navigation list, click **Notifications**.
  - b. In the **Notifications Templates** list, select the appropriate version of the "password-reset" template by clicking the name.  
You can create different versions of the template for different user roles.
  - c. Customize the template as explained in [Customizing email notification templates](#).
  - d. Click **Save**.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Selecting user registries for Cloud Manager and API Manager

Select the user registries to authenticate users for Cloud Manager and API Manager.

### About this task

---

In **Settings > User registries**, you select one or more user registries to authenticate users of Cloud Manager and API Manager. The user credentials for all users who login to the applications must be stored in the selected registries.

One of the following roles is required to select the user registries for Cloud Manager and API Manager:

- Administrator
- Owner
- A custom role with the `cloud.settings:manage` permission

For details on how to control which user registries can be used by provider organizations for authenticating Developer Portal users, or for securing APIs, see [Setting visibility for a user registry](#).

## Procedure

---

To select the user registries for Cloud Manager and API Manager, follow these steps:

1. In the Cloud Manager, click  **Settings**.
2. In the Settings navigation list, click **User Registries**.
3. The current list of user registries is displayed for Cloud Manager and for API Manager. To add user registries, click **Edit** in either the Cloud Manager or API Manager panel.  
**Note:** The list of user registries is derived from the user registries that were previously configured as a Resource in **Resources > User Registries**. For more information, see [User registries overview](#).
4. Select the user registry by placing a check mark next to the name in the list. Remove a user registry by removing the check mark.
5. Click **Save**.

## Results

---

The user registry list is updated to reflect the selected user registries available for authenticating users.

## What to do next

---

To set a user registry as the default, click the options menu next to the registry name in the list, and select **Set as default**.

- [Setting a default user registry for Cloud Manager and API Manager](#)  
You can select a default user registry for Cloud Manager and for API Manager.

## Related tasks

---

- [Configuring an LDAP user registry in the Cloud Manager](#)
- [Configuring an Authentication URL user registry](#)

- [Configuring a Local User Registry](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Setting a default user registry for Cloud Manager and API Manager

You can select a default user registry for Cloud Manager and and for API Manager.

### About this task

---

In Settings > User registries, you can set a user registry as the default user registry.

One of the following roles is required to select the user registries for Cloud Manager and API Manager:

- Administrator
- Owner
- A custom role with the `cloud_settings:manage` permission

### Procedure

---

To set a default user registry for Cloud Manager and API Manager, follow these steps:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click User Registries.
3. To set a user registry as the default, click the options menu next to the registry name in the list, and select Set as default.

Note: The list of user registries is derived from the user registries that were previously configured as resources in Resources > User Registries. For more information, see [User registries overview](#)

### Results

---

The user registry list is updated to reflect the default user registry.

### Related tasks

---

- [Configuring an LDAP user registry in the Cloud Manager](#)
- [Configuring an Authentication URL user registry](#)
- [Configuring a Local User Registry](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Configuring timeouts for access tokens and refresh tokens

Configure timeout values for the access tokens and refresh tokens for user registries.

IBM® API Connect supports refresh tokens for user registries that authenticate users of the Cloud Manager, the API Manager, and the Developer Portal. Refresh tokens, when enabled, are generated every time an access token is created. Refresh tokens can be used to obtain a new access token without having to prompt a user to re-login. If you enable the use of refresh tokens, then when the token expires it is refreshed automatically in the background so that the user can continue working without interruption. When the user logs out, the refresh token is revoked and the application can no longer use it.

Note: If users log in with non-OIDC user registries, the use of refresh tokens is supported in API Manager, API Designer, the Developer Portal, and the CLI Toolkit. When the refresh token expires, the user is always redirected to the login page.

If users log in with OIDC user registries:

- The use of refresh tokens is supported only in the Developer Portal.
- If the OIDC providers do not support refresh tokens, API Connect will not issue a `refresh_token`, regardless of the setting of `refresh_token_enabled` in the cloud settings.
- For more information about OIDC configuration, see [Configuring an OIDC user registry](#).

Use the following properties to specify refresh tokens for cloud settings:

- `refresh_expires_in`  
Integer. Represents the expiration time, in seconds, for refresh tokens issued by API Connect. Must be greater than `access_token_expires_in`.
- `refresh_token_enabled`  
Boolean. Disabled by default. To enable, set to `true`. When enabled, generates a `refresh_token` field in the response to the `/token` API call.

The following extract from a cloud settings file shows example settings for these properties:

```
"type": "cloud_setting",
"api_version": "2.0.0",
"name": "cloud-setting",
"access_token_expires_in": 28800,
.
.
.
"refresh_expires_in": 57600,
"refresh_token_enabled": false,
.
.
.
```

Use the toolkit CLI (`apic`) to update the cloud settings with new values for the properties. You can either specify values as command line arguments, or enter them manually in a configuration file as explained in [Using the CLI to modify cloud settings](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Viewing platform and UI endpoints

A view-only list of platform and UI endpoints is provided.

### About this task

---

You can view the list of endpoints configured during the installation process. Included in this view-only list are the following endpoints:

- API Manager URL - the URL for opening the API Manager UI
- Platform REST API endpoint for the Admin and Provider REST APIs - this endpoint handles the REST APIs for Admin and Provider functions.
- Platform REST API endpoint for consumer REST APIs - this endpoint handles the REST APIs for consumer (Portal) functions.

One of the following roles is required to view endpoints:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` or `cloud-settings: view` permissions

### Procedure

---

To view the endpoints, follow these steps:

1. In the Cloud Manager, click  Settings.
2. Select Endpoints.
3. View the list of endpoints.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring the default gateway services for Catalogs

Configure the list of default gateway services that are available to new Catalogs.

### About this task

---

One of the following roles is required to configure Catalog Defaults:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

You publish APIs by adding them to a Product and then publishing the Product to a Catalog. To be able to publish Products to a Catalog, the Catalog must be assigned at least one gateway service so that the APIs in the Product are available to be called at a gateway service endpoint. You can assign more than one gateway service to a Catalog, and they can be of mixed types, DataPower® API Gateway and DataPower Gateway (v5 compatible).

A Product is gateway type specific, either DataPower API Gateway or DataPower Gateway (v5 compatible). By default, when you publish a Product to a Catalog, it is published to all the assigned gateway services of the same gateway type as the Product, but you can choose to publish the Product only to selected gateway services, of that type, at publish time; see [Publishing a draft Product](#) for more information. The APIs in the Product will be available to be called at all the specified gateway service endpoints.

The procedure described in this topic specifies the gateway services that are assigned by default to newly created Catalogs, but you can change the assigned gateway services for a specific Catalog; see [Creating and configuring Catalogs](#).

## Procedure

---

To configure the gateway services that are assigned to new Catalogs by default, complete the following steps:

- 
1. In the Cloud Manager, click [Settings](#).
  2. In the Settings navigation list, click [Catalog Defaults](#).
  3. Click [Edit](#) to change the list of default gateway services.
  4. Select the required gateway services, then click [Save](#).

## Results

---

When a new Catalog is created in a provider organization, the default gateway services are automatically assigned to it. Any changes you make to the list of default services affects only the Catalogs that are created after you save your changes. Existing Catalogs are not affected.

## Related information

---

- [Working with Catalogs](#)
- [API Connect gateway types](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Administering provider organizations

Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.

### About this task

---

Perform these tasks to manage your provider organizations:

- [Creating a provider organization](#)  
For developers to publish APIs, they must be a member of a provider organization. The first step is to create a provider organization and specify an organization owner. Then members can be added to the provider organization and can start publishing APIs.
- [Editing a provider organization](#)  
You can edit the title of a provider organization.
- [Deleting a provider organization](#)  
You can delete a provider organization. All Catalogs and Spaces are also removed.
- [Viewing current provider organizations](#)  
View the list of current provider organizations for your cloud, including organization title, owner's name and email address, and status. From the list screen, you can add new provider organizations and owners, edit and delete provider organizations, send messages, and change owners.

### Related tasks

---

- [Creating a provider organization](#)
- [Editing a provider organization](#)
- [Deleting a provider organization](#)
- [Viewing current provider organizations](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Creating a provider organization

For developers to publish APIs, they must be a member of a provider organization. The first step is to create a provider organization and specify an organization owner. Then members can be added to the provider organization and can start publishing APIs.

### Before you begin

---

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator

- Organization Manager
- Custom role with the `Provider-org:Manage` permission

You must also complete the following tasks before beginning:

- [Configuring an email server for notifications](#)
- [Setting up notifications](#)

## About this task

Note that an email server must be configured and an active email server must be selected before a provider organization account can be created.

There are two options for creating a provider organization account, as follows:

- Option 1: Create a provider organization and send an email invitation to a new user to register and become the organization owner. Choose the Add > Invite organization owner option.
- Option 2: Create a provider organization and specify the user who will be the organization owner. Choose the Add > Create organization option.

## Procedure

- **Option 1:** To create a provider organization and invite a new user to register as the owner, complete the following steps:

1. In the Cloud Manager, click  Provider Organizations.
2. Click Add > Invite organization owner
3. Enter a valid email address and click Invite. An email containing an activation link is sent to the email address inviting the person to register. The link opens the registration form. Alternately, you can copy and paste the activation link into an email; click Get Activation Link and click Copy in the pop up window. Note that the email server requires the Authenticate User and Authenticate Password values in order to send invitations. See [Configuring an email server for notifications](#).

The new provider organization is placed in Pending status, and is changed to Enabled status after the owner completes the registration form to activate their account. The owner can then log in to the API Manager user interface with the API Connect user name that they specified during account activation.

Note: If you use this option with a Local User Registry, and the user already exists in the registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. This stipulation includes users that were previously provider organization owners but whose organization was deleted.

- **Option 2:** To create a provider organization and specify the user who will be the organization owner, complete the following steps:

1. In the Cloud Manager, click  Provider Organizations.
2. Click Add > Create organization.
3. In the Title field, enter a title for the provider organization. If desired, the title can be edited after the provider organization is created.
4. The internal Name is automatically generated for you by the system. The Name field contains the string that is included in the organization segment of the URL for API calls. For more information, see [Calling an API](#).  
Tip: The Name field is auto-generated to ensure its validity in the URL.  
The value in the Name field is also used to identify the provider organization in developer toolkit CLI commands. To view the CLI commands to manage provider organizations, see [apic orgs](#).

5. Select the user registry for the provider organization owner.

The remaining procedure varies according to the type of the selected user registry, as follows:

- Local User Registry
  - Select whether the user is an Existing user or a New User.
    - For an existing user, complete the following steps:
      - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
      - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.
    - For a new user, complete the following steps:
      - Enter a unique user name for the new user.
      - Supply an email address, name details, and a password.
      - Click Create. The user account is created, and the provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface with the specified user name and password; the user interface open in the new provider organization.
- LDAP
  - Enter the name of a user that exists in the selected user registry.
  - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface with their LDAP user name. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.
- Authentication URL and OIDC
  - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must use the invitation mechanism described in [Option 1](#).
  - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Editing a provider organization

You can edit the title of a provider organization.

### Before you begin

---

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

### Procedure

---

To update a provider organization, complete the following tasks:

1. In the Cloud Manager, click  Provider Organizations.
2. Navigate to the provider organization that you want to update, select Edit from the Actions menu.
3. Enter a new Title for the organization.
4. Click Save.

### Results

---

The provider organization title is updated.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Deleting a provider organization

You can delete a provider organization. All Catalogs and Spaces are also removed.

### Before you begin

---

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

### About this task

---

The user account for the owner of the deleted provider organization remains in the associated API Connect user registry. The user can still log in to the API Manager user interface; if they are a member of one or more other provider organizations then those organizations are accessible, otherwise only information links are available, with no access to view or manage any resources.

The user can be added again as a provider organization owner at a later time; see [Creating a provider organization](#).

### Procedure

---

To delete a provider organization, complete the following tasks:

1. In the Cloud Manager, click  Provider Organizations.
2. Navigate to the provider organization that you want to delete in the list and select Delete from the Actions menu.
3. Confirm that you want to delete the provider organization.  
The provider organization is deleted and removed from the Provider Organizations list.

### Results

---

The provider organization, and its Catalogs and Spaces, are deleted.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Viewing current provider organizations

View the list of current provider organizations for your cloud, including organization title, owner's name and email address, and status. From the list screen, you can add new provider organizations and owners, edit and delete provider organizations, send messages, and change owners.

---

### Before you begin

You must also complete the following tasks before beginning:

- [Configuring an email server for notifications](#)
- [Setting up notifications](#)
- [Creating a provider organization](#)

This task can be completed by users who are assigned one of the following roles:

- All roles
- Custom role with the `Provider-org:Manage` or the `Provider-org:View` permissions

---

### About this task

All roles can view the list of provider organizations. Use the provider organization list screen to manage your provider organizations.

---

### Procedure

1. In the Cloud Manager, click  Provider Organizations.
2. View the list of provider organizations and their status. The statuses are as follows:
  - **Pending:** A provider organization is in `Pending` status until the invited owner successfully completes the registration form.
  - **Active:** A provider organization is in `Active` status if the owner is an existing user with an account in a user registry.
3. The Actions menu performs different functions depending on the organization's status. Use the Actions menu to edit or delete an Active organization. For Pending organizations, use the Actions menu to delete the organization and to resend the invitation to the owner.
  - For an Enabled organization, you can Edit or Delete the organization.
  - For a Pending organization, you can Resend the Invitation, or Delete the request.
4. Add new provider organizations using the Add menu. See [Creating a provider organization](#)

---

### Related tasks

- [Creating a provider organization](#)
- [Editing a provider organization](#)
- [Deleting a provider organization](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#), for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Administering members and roles

Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.

---

### About this task

To manage roles, add members, and assign roles to member, perform the following tasks:

- [Creating roles in the admin organization](#)  
Cloud Manager ships with a set of pre-configured roles. As the Cloud Manager administrator, you can create custom roles, add permissions, and assign the roles to members of the Admin organization.
- [Editing roles in the admin organization](#)  
As the Cloud Manager administrator, you can edit the roles in the Admin Organization. Both pre-configured roles and custom roles may be edited, except for the Owner, Viewer, and Member roles. The Owner, Viewer, and Member roles may not be edited or deleted.
- [Deleting roles in the admin organization](#)  
Roles can be deleted (except for the Owner, Viewer, and Member roles) from the Admin organization. If there are members assigned to a role that has been deleted, they will be assigned the Viewer role.
- [Viewing members and roles](#)  
Use the Members page to view the current members of the Admin organization and manage the role assignments.
- [Adding members to the admin organization](#)  
As the Cloud Manager administrator, you can add and remove members of the Admin organization and assign roles to them. Once removed, a user can no longer access the Cloud Manager.
- [Assigning roles to members](#)  
As the Cloud Manager administrator, you manage the roles that are assigned to members. A member's role determines the tasks they are authorized to perform in Cloud Manager.

- [Deleting a member](#)

As the Cloud Manager administrator, you can delete members of the API Connect cloud administration organization. Once deleted, the user and associated roles are removed, however the user's account still remains in API Connect.

- [Role Defaults overview](#)

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Creating roles in the admin organization

Cloud Manager ships with a set of pre-configured roles. As the Cloud Manager administrator, you can create custom roles, add permissions, and assign the roles to members of the Admin organization.

### About this task

---

If you are assigned a role that has the `Settings: manage` permission, you can create custom roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.

One of the following roles is required to add custom roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

### Procedure

---

Perform the following steps to add custom roles to the Admin Organization:

1. In the Cloud Manager, click  Settings.
2. Select Roles.
3. Click Add to add a new role.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see [User roles and permissions in the Cloud Manager UI](#).
6. Save the custom role.

### Results

---

The custom role appears in the list of roles and can be assigned to members.

### What to do next

---

Assign the role to a member in the Members list. See [Assigning roles to members](#)

### Related tasks

---

- [Editing roles in the admin organization](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Editing roles in the admin organization

As the Cloud Manager administrator, you can edit the roles in the Admin Organization. Both pre-configured roles and custom roles may be edited, except for the Owner, Viewer, and Member roles. The Owner, Viewer, and Member roles may not be edited or deleted.

### About this task

---

You can customize the per-configured roles (except for the Owner, Viewer, and Member roles) to reflect your business needs.

If you are assigned a role that has the `Settings: manage` permission, you can edit the roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage permissions`

Following are the edits you can perform for a role:

- Change the title
- Add or delete permissions

## Procedure

---

Perform the following steps to edit roles in the Admin organization:

1. In the Cloud Manager, click  Settings.
2. Select Roles.
3. Locate the Role you want to edit, and select Edit from the overflow menu.
4. Enter the desired Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see [User roles and permissions in the Cloud Manager UI](#).
6. Save the updated role.

## Results

---

The Role will be updated with a new name and/or permissions. An updated role will affect the members who are assigned the role. If you change the name of a role, you will have to assign it to the members. If you change the permissions for a role, the way that members use the product may change.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Deleting roles in the admin organization

---

Roles can be deleted (except for the Owner, Viewer, and Member roles) from the Admin organization. If there are members assigned to a role that has been deleted, they will be assigned the Viewer role.

## About this task

---

All custom roles may be deleted. Pre-configured roles can also be deleted, except for the Owner, Viewer, and Member roles. Owner, viewer, and Member role cannot be deleted or edited. Members who are assigned a deleted role are given the most limited role, Viewer, with View-only privileges. These members will need to be assigned a new role if they require any other privileges.

If you are assigned a role that has the `Settings: manage` permission, you can delete roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.

One of the following roles is required to delete custom roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage permissions`

## Procedure

---

Perform the following steps to delete roles in the Admin organization:

1. In the Cloud Manager, click  Settings.
2. Select Roles.
3. Locate the Role you want to delete, and select Delete from the overflow menu.
4. Confirm that you want to proceed with deleting the role.

## Results

---

The Role will be deleted. Members who had been assigned the role are given the Viewer role.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Viewing members and roles

Use the Members page to view the current members of the Admin organization and manage the role assignments.

### Procedure

---

To view the members of the Admin organization and their roles in Cloud Manager, follow these steps:

1. In the Cloud Manager, click  Members.
  2. From the Members list, you can scroll through the list of users to see their current roles and their status.
    - **Pending** - The invitation with the activation link has been sent to the user, but they have not yet completed the registration form.
    - **Enabled** - The user has completed the registration form and is now able to login and access the features associated with their role.
- Note: If your role has the proper permissions, you can assign roles, add, and delete members from this list.

### What to do next

---

- To add members, see [Adding members to the admin organization](#)
- To change the roles assigned to members see [Assigning roles to members](#)
- To delete a member, see [Deleting a member](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Adding members to the admin organization

As the Cloud Manager administrator, you can add and remove members of the Admin organization and assign roles to them. Once removed, a user can no longer access the Cloud Manager.

### About this task

---

Membership in the Admin organization is required to use Cloud Manager to view and manage the topology of the API Connect cloud, to set up and manage provider organizations, and to manage other features of the cloud. There are two ways to add a member:

- Invite member - send an email invitation to a new user to register as a member of the Admin organization.
- Add member - specify the user and add them as a member of the Admin organization immediately.

One of the following roles is required to add members:

- Administrator
- Owner

### Procedure

---

- To send an email invitation to a new user to register as a member of the Admin organization, complete the following steps:

1. In the Cloud Manager, click  Members.  
The list of current members for the Admin organization is displayed. You can view the owner of the Admin Organization by expanding View Owners.
2. Click Add > Invite member.
3. Enter a valid email address.
4. Select the roles that you want to assign to the user.
5. Click Invite. An email containing an activation link is sent to the email address inviting the person to register. The link opens the registration form. Alternately, you can copy and paste the activation link into an email; click Get Activation Link and click Copy in the pop up window.  
Note that the email server requires the Authenticate User and Authenticate Password values in order to send invitations. See [Configuring an email server for notifications](#).

The user is placed in Pending status, and is changed to Enabled status after they complete the registration form to activate their account. They can then log in to the Cloud Manager user interface with the API Connect user name that they specified during account activation.

Note: If you use this option with a Local User Registry, and the user already exists in the registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. This stipulation includes users that were previously members but were deleted from the admin organization.

- To specify the user and add them as a member of the Admin organization immediately, complete the following steps:

1. In the Cloud Manager, click  Members.  
The list of current members for the Admin organization is displayed. You can view the owner of the Admin Organization by expanding View Owners.
2. Click Add > Add member.
3. Select the required user registry  
The remaining procedure varies according to the type of the selected user registry, as follows:
  - Local User Registry
    - Select whether the user is an Existing user or a New User.

- For an existing user, complete the following steps:
  - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
  - Select the roles that you want to assign to the user, then click Create. The user is added and their membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.
- For a new user, complete the following steps:
  - Enter a unique user name for the new user.
  - Supply an email address, name details, and a password.
  - Select the roles that you want to assign to the user, then click Create. The user account is created, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.
- LDAP
  - Enter the name of a user that exists in the selected user registry.
  - Select the roles that you want to assign to the user, then click Create. The user is added, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface with their LDAP user name.
- Authentication URL and OIDC
  - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
  - Select the roles that you want to assign to the user, then click Create. The user is added, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.

## What to do next

The new member can log in and work in Cloud Manager. The member's authorization is defined by the roles assigned to them.

For instructions on assigning roles, see [Assigning roles to members](#). The list of roles and permissions can be viewed at [User roles and permissions in the Cloud Manager UI](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Assigning roles to members

As the Cloud Manager administrator, you manage the roles that are assigned to members. A member's role determines the tasks they are authorized to perform in Cloud Manager.

### About this task

Members in the Admin organization use Cloud Manager to view and manage the topology of the Cloud, to set up and manage provider organizations, and to work with other features of the API Connect Cloud. The member's role determines what tasks they are authorized to perform.

When assigning roles, you need to be aware that all members always have a basic set of permissions, which are contained in the **Member** role. The Member role is automatically granted to all members and cannot be removed. For this reason, you do not explicitly assign the Member role. You can grant additional permissions by selecting one or more roles. If additional roles are not assigned, then the user will have only the basic Member role.

One of the following roles is required to assign roles to members:

- Administrator
- Owner

## Procedure

Perform the following steps to assign one or more roles to a member:

1. In the Cloud Manager, click  Members.
2. The list of current members for the Admin organization is displayed.
3. To change the roles assigned to a member, select the roles by marking the check boxes next to their name. The roles will be updated instantly. The list of roles and permissions can be viewed at [User roles and permissions in the Cloud Manager UI](#)

## Results

The member will be assigned the permissions for the role(s).

## What to do next

The new member can work in Cloud Manager. The member's authorization is defined by the roles assigned to them.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Deleting a member

As the Cloud Manager administrator, you can delete members of the API Connect cloud administration organization. Once deleted, the user and associated roles are removed, however the user's account still remains in API Connect.

## About this task

---

One of the following roles is required to delete a member:

- Administrator
- Owner

Note: The user account of the deleted user remains in the associated API Connect user registry. The user can still log in to the Cloud Manager user interface but only information links are available; there is no access to view or manage any resources.

The user can be added again as a member at a later time; see [Adding members to the admin organization](#).

## Procedure

---

To delete a member of the cloud administration organization, complete the following steps:

1. In the Cloud Manager, click  Members.
2. Choose Delete from the overflow menu that is adjacent to the member you want to delete.
3. Confirm the deletion.

## Results

---

The member is deleted and removed from the Members list in Cloud Manager.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Role Defaults overview

---

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

## Role Defaults concepts

---

Role Defaults determine the base roles applied to either Provider or Consumer Organizations. The Role Defaults for the Admin organization are not configurable. Role Defaults help to standardize base roles for all organizations. Roles and permissions may be added or modified in the Role Defaults to customize the base roles as needed. Role Defaults are a "point-in-time" configuration, which effects only new organizations. You can add, delete, or modify roles (except for the Owner, Member, and Viewer roles) in the organization to customize the permissions for each organization.

Rules for editing Role Defaults:

- Edits to Role Defaults are not applied retroactively to existing organizations. Edits apply only to new organizations created after the changes are made.
- Role Defaults apply to all new organizations; roles can then be edited at the organization, catalog, and space level.
- Edits made to roles in an organization do not affect the Role Defaults. Role Defaults are the "parent" and organization roles are the "child". The child inherits from the parent, but changes do not filter up from the organization to the Role Default.
- [Managing role defaults for provider organizations](#)  
Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.
- [Managing role defaults for consumer organizations](#)

## Managing role defaults for provider organizations

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

### About this task

---

If you are assigned a role that has permissions to manage Cloud Settings, you can create manage the Role Defaults for the provider organizations. One of the following roles is required to add roles to the role defaults:

- Administrator
- Topology Administrator
- Owner

Perform the following steps to add or edit roles to the Roles Defaults for provider organizations:

### Procedure

---

1. In the Cloud Manager, click  Settings.
2. Select Role Defaults.
3. Click Add to add a new role.
  - a. To edit a role, select Edit from the overflow menu for the role.
  - b. To delete a role from the Role Default, select Delete from overflow menu and confirm the deletion. Owner, Member, and Viewer roles cannot be deleted.  
Note: Role deletions apply to new members added after the deletion. If a current member is assigned the role, they will continue to have the permissions connected with the role. You need to manage the deletions for each member in the Members screen.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see [User roles and permissions in the Cloud Manager UI](#).
6. Save the role.

### Results

---

The role appears in the list of roles for the provider organization Role Defaults. It will be included in the roles that can be assigned to members for all new provider organizations. The roles can be edited for individual organizations.

### Related concepts

---

---

---

## Managing role defaults for consumer organizations

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

### About this task

---

If you are assigned a role that has permissions to manage Cloud Settings, you can create and manage the Role Defaults for consumer organizations. One of the following roles is required to add roles to the role defaults:

- Administrator
- Topology Administrator
- Owner

Perform the following steps to add or edit roles to the roles defaults for consumer organization:

### Procedure

---

1. In the Cloud Manager, click  Settings.

2. Select Role Defaults.
3. Click Add to add a new role.
  - a. To edit a role, select Edit from the overflow menu for the role.
  - b. To delete a role from the Role Default, select Delete from overflow menu and confirm the deletion. Owner, Member, and Viewer roles cannot be deleted.  
Note: Role deletions apply to new members added after the deletion. If a current member is assigned the role, they will continue to have the permissions connected with the role. You need to manage the deletions for each member in the Members screen.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see [User roles and permissions in the Cloud Manager UI](#).
6. Save the role.

---

## Results

The role appears in the list of roles for the consumer organization Role Defaults. It will be included in the roles that can be assigned to members for new consumer organizations. The roles can be edited for catalogs, but permissions inherited from the Role Default cannot be deleted. Permissions can be added at the catalog level, but not deleted.

## Monitoring the cloud

API Connect generates events to monitor the status of your cloud.

---

## About this task

You can monitor your API Connect cloud and configure destination targets for your analytics data by using the following tasks:

- [Counting total API calls for your Analytics service](#)  
Count the API calls for the IBM API Connect Analytics subsystem and return the total categorized by response status.
- [Customizing Analytics data with filters](#)  
Define filters to refine the Analytics data that you want to store. Using filters, you can add fields, remove fields, or modify field contents.
- [Configuring data retention and index rollover time periods](#)  
You can set a time period for data retention and index rollover using the Advanced Analytics Configuration option for an analytics service.
- [Configuring analytics offload for API Connect](#)  
The event data that is generated and collected in your API Connect on-premises cloud can be forwarded to different destination targets for display and analysis. Destination targets include the API Connect user interfaces, and third-party systems that are external to API Connect.
- [Configuring the audit log to track API calls](#)  
Configure auditing in IBM API Connect to monitor user operations such as who published which product and when.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Counting total API calls for your Analytics service

Count the API calls for the IBM® API Connect Analytics subsystem and return the total categorized by response status.

---

## Before you begin

This procedure requires you to deploy the Analytics subsystem and store data in IBM API Connect. If your organization did not deploy the Analytics subsystem, then you cannot use this process to track usage. If you deployed Analytics but offload all of your data and do not store it in IBM API Connect, then you must capture usage information from the third-party application where you offload data.

---

## About this task

If your IBM API Connect bases costs on usage, you can use the following procedure to track this information so that you can accurately report it.

## Procedure

1. Find an analytics-storage pod (for example, coordinating, data, master, or basic) by running the following command.

```
kubect1 get pods
```

2. Build a query for your request to the analytics datastore.

- a. Set the `size` to 0 to disable the return of raw data.

The following example shows how to specify the `size`.

```
{
  "size": 0
}
```

Tip: If you want to return some raw data to verify that the range query in the next step works, set the `size` to 1 instead.

- b. Add a `range` query for date filtering.

The following example shows how to specify the time range in your query:

```
{
  "size": 0,
  "query": {
    "range": {
      "datetime": {
        "gte": "YYYY-MM-DD",
        "lt": "YYYY-MM-DD"
      }
    }
  }
}
```

This setting filters the query by specifying a time range that begins on or after (is greater than or equal to) the `gte` date, and ends before (is less than) the `lt`.

Note:

When specifying the time range, note the following considerations about the value that you specify for the date:

- Format: The value must use the ISO-8601 format (`YYYY-MM-DDThh:mm:ss.yyyZ`) or a shortened version of that format (for example, `YYYY-MM-DD`).
- Timezone: The value must follow UTC time (Coordinated Universal Time) because the query will be executed by the analytics-storage pod (which runs on UTC time), so it's important to allow for any time difference when you run a query.

- c. Build the aggregation.

The aggregation code uses regular expressions to match the patterns for response codes (for example all of the responses with a code that begins with "1").

The query counts the documents within the specified time range that match each set of response codes, and then calculates the total number of documents.

The following example shows the complete query. The `aggs` section contains the code to count the total number of API calls.

```
{
  "size": 0,
  "query": {
    "range": {
      "datetime": {
        "gte": "YYYY-MM-DD",
        "lt": "YYYY-MM-DD"
      }
    }
  },
  "aggs": {
    "status_codes": {
      "filters": {
        "filters": {
          "1xx": {
            "regexp": {
              "status_code": "1.*"
            }
          },
          "2xx": {
            "regexp": {
              "status_code": "2.*"
            }
          },
          "3xx": {
            "regexp": {
              "status_code": "3.*"
            }
          },
          "4xx": {
            "regexp": {
              "status_code": "4.*"
            }
          },
          "5xx": {
            "regexp": {
              "status_code": "5.*"
            }
          }
        }
      }
    }
  }
}
```

3. Submit a request with your query to the analytics-storage pod that you located in step 1.

Run the following command, where:

- `analytics-storage-pod` represents the name of the analytics-storage pod that you identified in step 1.
- `analytics_query` is the content of the query, as shown in step 2c.

```
kubectl exec -it analytics-storage-pod -- \
curl_es /apic-api-r/_search?pretty \
-d 'analytics_query' \
-H 'Content-Type: application/json'
```

#### 4. Review the response.

Most of the information in the response can be ignored because it doesn't apply to your use case. Locate the `aggregations.status_codes.buckets` field, which contains the individual fields that represent the status codes.

The status code fields are labeled as `1xx`, `2xx`, `3xx`, `4xx`, and `5xx`. Each of the status code fields has an object as its value with a field called `doc_count`.

In each status code field, locate the `doc_count` field and note its value, which represents the total number of API calls for the current status code within the specified time range.

The following example shows a sample response with an aggregated total of 100,000 API calls.

```
{
  "took" : 19,
  "timed_out" : false,
  "_shards" : {
    "total" : 2500,
    "successful" : 2500,
    "skipped" : 0,
    "failed" : 0
  },
  "hits" : {
    "total" : 100000,
    "max_score" : 0.0,
    "hits" : [ ]
  },
  "aggregations" : {
    "status_codes" : {
      "buckets" : {
        "1xx" : {
          "doc_count" : 10000
        },
        "2xx" : {
          "doc_count" : 60000
        },
        "3xx" : {
          "doc_count" : 5000
        },
        "4xx" : {
          "doc_count" : 15000
        },
        "5xx" : {
          "doc_count" : 10000
        }
      }
    }
  }
}
```

## What to do next

To ensure you correctly track the API calls, you should run the query on a daily basis and store the accumulated daily totals where you can make sure they are backed up. You can create a script based on the query and schedule it to run daily. For more information about creating the script, see [Creating a script to count API calls](#).

- [Creating a script to count API calls](#)  
Optionally create a script containing a query that counts the API calls for the IBM API Connect Analytics subsystem.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Creating a script to count API calls

Optionally create a script containing a query that counts the API calls for the IBM® API Connect Analytics subsystem.

## Before you begin

Create a query to count the total number of API calls in the Analytics subsystem as explained in [Counting total API calls for your Analytics service](#).

## About this task

If you need to count your API calls to track the totals for your contract, then you must run the query to count API calls on a periodic basis. You can automate the process by creating a script that contains the query. To ensure you correctly track the API calls, schedule the script to run on a daily basis and store the accumulated daily totals where you can make sure they are backed up.

The example script includes the following changes to the original query. The changes make it easier to run the script repeatedly without editing it each time.

- Accept the namespace and release name of the analytics service as input.  
If you only deployed one release in the namespace, then you can leave the release name blank. For appliance deployments, use `default` as the value of the namespace, and leave the release name blank.
- Identify the analytics-storage pod automatically and saves it in the `POD` variable to be used by your query.
- Change the query's time range variables from ISO format to date math syntax so that you can run the script again without editing the time range.  
You should run the script at the same time every day to ensure consistent counts. Using date math, you can use variables to calculate yesterday's date and today's date. Then, your script can use those dates to retrieve the total number of calls for the 24 hours that elapsed between the beginning of yesterday and the beginning of today.
  - Set the start date (`gte`) to the value `now-1d/d`, which represents the beginning of yesterday.
  - Set the end date (`lt`) to `now/d`, which represents the beginning of today.

Note: Remember, the values for the time range variables are calculated from the current system time of the analytics-storage pod, which follows UTC time (Coordinated Universal Time). It's important to allow for any time difference when you run a query because your timing might cause an inadvertent date change for the results.

For example, if today is January 2 in EST and your current time is 5:00 AM (2019-01-02T05:00:00), then the system time on the analytics-storage pod (in UTC) is 10:00 AM on January 2 (2019-01-02T10:00:00). The date math calculation for yesterday (`now-1d/d`) is equal to 2019-01-01T00:00:00, and the date math calculation for today (`now/d`) is equal to 2019-01-02T00:00:00. The query captures the API call counts for "yesterday", which is the 24 hours of the date 2019-01-01T00:00:00. But if your current time in EST is 8:00 PM on January 2, the time on the system time on the analytics-storage pod is 1:00 AM on January 3. "Yesterday" is now January 2 and "today" is now January 3, so the query returns the call count for January 2 instead of January 1.

## Procedure

1. Create the script.

The following example shows the completed script. In the script, the `kubectl exec` statement must be on a single line.

```
#!/bin/bash

NAMESPACE=$1
RELEASE_NAME=$2

POD=$(kubectl get po -n $NAMESPACE -o custom-columns=NAME:metadata.name | grep -e "storage-master-0" | head -n 1 |
grep -e "$RELEASE_NAME-analytics-storage" | \

kubectl exec -it $POD -n $NAMESPACE -- curl -s /apic-api-r/_search?pretty -H 'Content-Type: application/json' -d '{
"size": 0, "query": { "range": { "datetime": { "gte": "now-1d/d", "lt": "now/d" } } }, "aggs": { "status_codes": {
"filters": { "filters": { "1xx": { "regexp": { "status_code": "1." } }, "2xx": { "regexp": { "status_code": "2." } },
"3xx": { "regexp": { "status_code": "3." } }, "4xx": { "regexp": { "status_code": "4." } }, "5xx": { "regexp": {
"status_code": "5.*" } } } } } } } } }
```

2. Save the file and make it executable, as shown in the following example.

```
chmod +x path/to/my-script-filename.sh
```

3. Run the script.

Invoke it with your namespace and release name as shown in the following example:

```
./my-script-filename.sh namespace release_name
```

Remember, you can omit the release name if it's not needed, as shown in the following example:

```
./my-script-filename.sh namespace
```

For appliance deployments, you can use `default` as the namespace and omit the release name as shown in the following example:

```
./my-script-filename.sh default
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Customizing Analytics data with filters

Define filters to refine the Analytics data that you want to store. Using filters, you can add fields, remove fields, or modify field contents.

### About this task

Use filters to add or remove fields before storing Analytics data. Using an Analytics filter is the only supported way to add top-level Analytics fields.

Tip: If you want to search or visualize data that is stored in request and response headers, you can add fields to a filter to include that information in your Analytics data. For more information on including header fields in your Analytics data, see the example for adding a field to the filter in the topic, [Sample filters for customizing Analytics data](#).

You can filter data for both storing in API Connect and offloading to third-party systems. Before configuring filters, note the following considerations:

- Filters are defined in configuration files, which you modify using the Cloud Manager. You cannot edit the files directly.

- The following filters might cause problems if used incorrectly, so you should only use them when instructed to do so by API Connect Support: `19_filter.conf`, `39_filter.conf`, and `49_filter.conf`.
- Typically you will edit the `69_apic_filter.conf` file. If [analytics message queue](#) is enabled, that filter only applies to data that is stored in API Connect. If you enable message queue and you want to filter data for offloading, you must also modify the `69_offload_filter.conf` file.
- The following fields cannot be modified because they are used by the Analytics service: `org_id`, `catalog_id`, `space_id`, and `developer_org_id`.

See [Sample filters for customizing Analytics data](#) to review filtering examples.

## Procedure

Complete the following steps to define the filter for every Analytics service.

1. Use the Cloud Manager to add your filter:

- a. In the Cloud Manager, click  Topology.
- b. Locate the Analytics service where you want to filter data and click its title to edit the service.
- c. On the Edit Analytics Service page, click Advanced Analytics Configuration to load Kibana.
- d. In Kibana, click Ingestion in the "API Connect" section to open the configuration files selection page.
- e. Select the filter that you want to edit by clicking its tab (all filter files include the word "filter" in the name).  
Remember: Typically you will edit the `69_apic_filter.conf` file. You should only use the other files with guidance from API Connect Support.
- f. Click Save to update the file.

2. If you added or removed a field with the filter, confirm the new field list:

- a. In Kibana, click Index Patterns in the "API Connect" section.
- b. On the Index Patterns page, click Refresh field list and confirm that your new field shows (or that a field you removed no longer shows) in the list.

3. Invoke an API that generates data that your new filter will modify.

4. Use API Manager to view Analytics data for the API that you just invoked:

- a. Log on to the API Manager that contains the Catalog for which you want to view the analytics.
- b. Select Manage  in the navigation.
- c. From the list of available Catalogs in the API Manager Dashboard, select the appropriate Catalog.

If you want to view analytics for a particular Space, click Spaces  in the navigation and then select the Space.

- d. Select Analytics  in the navigation.  
The default analytics dashboard for the Catalog or Space is displayed.
- e. Click Discover.
- f. On the Discover tab, select the All Events saved search.

Verify that the event data for your API reflects the changes imposed by the filter. For example, if you added a field, make sure the new field is included in the event data. If you removed a field, make sure that field is not included. You can use the search filters and time period settings on the page to refine your search.

If you don't see your filtering change reflected in the data, then your filter might be coded incorrectly. Repeat the procedure to verify your coding in the filter and test it again.

- [Sample filters for customizing Analytics data](#)

Review sample filters to see how to code your own filters for refining Analytics data by adding fields, removing fields, or modifying field contents.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Sample filters for customizing Analytics data

Review sample filters to see how to code your own filters for refining Analytics data by adding fields, removing fields, or modifying field contents.

Follow the examples to create filters and add them to the appropriate configuration files as explained in [Customizing Analytics data with filters](#). The sample filters use Ruby code to customize data. For information on using Ruby with Logstash filters plugins, see [Ruby filter plugin](#) in the Logstash documentation.

Typically you will edit the `69_apic_filter.conf` file. If [analytics message queue](#) is enabled, that filter only applies to data that is stored in API Connect. If you enable message queue and you want to filter data for offloading, you must also modify the `69_offload_filter.conf` file.

Remember: You should only use the `19_filter.conf`, `39_filter.conf`, and `49_filter.conf` files with guidance from API Connect Support.

## Adding a new field

You can add custom data to API event data by adding a field to the logging document. For example, if you want to search or visualize data that is stored in request and response headers, you can add fields to a filter to include that information in the top level of your analytics' data.

To avoid naming conflicts with future or current analytics fields, include a prefix that ensures your new field name is unique. For example, instead of naming the field `employee_num` you might name it `x_mycompany_employee_num`.

The following example copies the contents of the `X-Employee-Num` field from the request header and adds it to the `x_mycompany_employee_num` field in the event data. Adding the field to the event data enables you to use the information in visualizations.

```
# Here you should specify any filters that you want to take affect after
# the second stage of APIC Analytics filter processing.
#
# At this point the data has been modified by APIC Analytics, and is in the
# expected documented format. This is where you should feel free to modify
```

```

# the data prior to it being stored in APIC Analytics Storage.
#
# In message queue deployments, this will only affect data that will
# ultimately be stored in APIC Analytics Storage, and will not affect data
# that will be offloaded.
filter {
  if "apicapievent" in [tags] {
    if [request_http_headers] {
      ruby {
        code => "event.get('[request_http_headers]').collect {|i| event.set('[x_mycompany_employee_Num]', i['X-Employee-Num'])}
if i.has_key?('X-Employee-Num')}"
      }
    }
  }
}

```

## Modifying an existing field

Sometimes you don't want to remove a field entirely from your data, you just want to redact sensitive information such as IDs to prevent them from being exposed in visualizations. You can modify the contents of a field and replace information with a symbols or a message.

Note: The following fields should not be modified if the data is being written to internal analytics storage: `org_id`, `catalog_id`, `space_id`, `developer_org_id`, `datetime`, and `@timestamp`.

The following example replaces sensitive information in the "Employee-Name" and "Employee-ID" header fields with the string "\*\*\*\*\*sanitized\*\*\*\*\*".

```

# Here you should specify any filters that you want to take effect after
# the second stage of APIC Analytics filter processing.
#
# At this point the data has been modified by APIC Analytics, and is in the
# expected documented format. This is where you should feel free to modify
# the data prior to it being stored in APIC Analytics Storage.
#
# In message queue deployments, this will only affect data that will
# ultimately be stored in APIC Analytics Storage, and will not affect data
# that will be offloaded.
filter {
  if "apicapievent" in [tags] {
    if [request_http_headers] {
      ruby {
        code => "headers=['X-Employee-Name','X-Employee-ID']; newHeaders = event.get('[request_http_headers]').collect {|i|
headers.each {|header| i[header] = '*****sanitized*****' if i.has_key?(header)}; i}; event.set('[request_http_headers]',
newHeaders)"
      }
    }
  }
}

```

## Removing an existing field

Use the mutate `remove_field` operation to delete a field from the Analytics data. To remove multiple fields, delimit the field names with commas.

The following example removes the following fields from the Analytics data: `request_http_headers`, `response_http_headers`, `request_body`, `response_body`, and `query_string`.

```

# Here you should specify any filters that you want to take effect after
# the second stage of APIC Analytics filter processing.
#
# At this point the data has been modified by APIC Analytics, and is in the
# expected documented format. This is where you should feel free to modify
# the data prior to it being stored in APIC Analytics Storage.
#
# In message queue deployments, this will only affect data that will
# ultimately be stored in APIC Analytics Storage, and will not affect data
# that will be offloaded.
filter {
  if "apicapievent" in [tags] {
    mutate {
      remove_field => ["request_http_headers", "response_http_headers", "request_body", "response_body", "query_string"]
    }
  }
}

```

## Filter and output plugin for splunk

When you create a filter for use with splunk, you must also create an output plugin for it.

Filter:

```

# Here you should specify any filters that you want to take effect after
# the second stage of APIC Analytics filter processing.
#
# At this point the data has been modified by APIC Analytics, and is in the
# expected documented format. This is where you should feel free to modify
# the data prior to it being stored in APIC Analytics Storage.
#
# In message queue deployments, this will only affect data that will
# ultimately be stored in APIC Analytics Storage, and will not affect data
# that will be offloaded.
filter {
  if "apicapievent" in [tags] {

```

```

ruby {
  code => "event.set('@metadata[newevent]', event.to_json)"
}
}
}

```

Output plugin:

```

apicapievent" in [tags] {
  http {
    url => "http://your-domain/services/collector/event"
    http_method => "post"
    codec => "json"
    content_type => "application/json"
    id => "offload_http"
    format => "message"
    message => '{"event": "%{[@metadata][newevent]}", "index": "applications-int-ms", "sourcetype": "json:apimlogs"}'
    headers => ["Authorization", "Splunk XXXX"]
  }
}
}

```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring data retention and index rollover time periods

You can set a time period for data retention and index rollover using the Advanced Analytics Configuration option for an analytics service.

### Before you begin

This task assumes you have registered an analytics service and associated it with a gateway service. See [Registering an analytics service](#) and [Associating an analytics service with a gateway service](#).

One of the following roles is required to set the Data Retention and Index Rollover values:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `topology:manage` permission

### About this task

Each API call is recorded as a document in a shared index. Periodically, a new index is created and the previous index is stored. You can specify Index Rollover and Data Retention settings that control how often new indexes are created, and how long indexes are stored.

The Index Rollover settings determine how long an index accumulates data before it "rolls over" into storage and a new index is created. You can control the duration of an index two ways: by setting a maximum age for the index (default is 1 day), and by setting a maximum number of documents that can be recorded in the index (default is 25 million documents). When the rollover occurs, a new index is created and documents are recorded there, while the previous index is stored until its age exceeds the Data Retention setting. If you change the rollover settings, consider both the amount of data being stored within each index as well as the number of indexes being stored. Allowing indexes to grow too large, or storing too many indexes at once, might cause issues.

The Data Retention setting determines how long the stored indexes (and the data they contain) are retained. Once every day, all indexes that are older than the specified retention period are purged. Retention is based on the index's age, not the age of the data within that index. When the index's own creation date exceeds the retention period, the index and all its data is deleted even if some of the data stored in that index is younger than the retention period. Data is purged by deleting entire records so you cannot choose to delete only certain fields.

The default retention period is 90 days. Reasons for changing this setting include storage constraints, and data retention requirements for your organization. You might want to set this value to be less than the default if a large number of API events are stored, especially if payload logging is enabled on the APIs. If you modify the retention value, you should modify the index rollover setting as well to ensure that they remain in sync.

The most recently created index (the index that is currently being written to) is not deleted, even if you set the retention period as small as 1 hour. If you regularly need to delete data quickly, adjust the Index Rollover setting so that a new index is rolled over to sooner, and the old index can be deleted.

To change the data retention and index rollover settings, you must configure you settings in the Cloud Manager, and then edit the schedule in the related cronjob as explained in the following procedure.

## Procedure

1. Modify the Cloud Manager properties that specify the data retention and index rollover settings:

- a. In the Cloud Manager, click  Topology.
- b. Locate the Analytics service that requires data retention and index rollover settings, then click the title to open the Edit Analytics Service page.
- c. Click the Advanced Analytics Configuration link to load Kibana.
- d. In Kibana, click Storage in the API Connect section.
- e. For Data Retention, select a number and a unit of time, and then click Save.
- f. Enter the desired value for Index Rollover and click Save.

## 2. Modify the schedule for the cronjob that manages data retention and index rollovers.

If you want to set the data retention or index rollover frequency to more than once per day, then you must also edit the schedule that determines when the related cronjob runs.

On all platforms, the retention and rollover actions are triggered using a [Kubernetes cronjob](#), which runs once per day by default. If you want the cronjob to run more frequently, modify its schedule by completing the following steps:

### a. View the current cronjob schedule by running the following command:

- Kubernetes:

```
kubectl -n <apic-analytics-namespace> get cronjob
```

- OpenShift and Cloud Pak for Integration:

```
oc -n <apic-analytics-namespace> get cronjob
```

- VMware:

- Run the following command to connect as the API Connect administrator, replacing `<ip_address>` with the appropriate IP address:

```
ssh <ip_address> -l apicadm
```

- When prompted, select Yes to continue connecting.
- When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

- View the current cronjob schedule by running the following command:

```
kubectl -n <apic-analytics-namespace> get cronjob
```

The response displays the current **SCHEDULE**, as in the following example:

NAME	SCHEDULE	SUSPEND	ACTIVE	LAST SCHEDULE	AGE
analytics-cj-retention	30 1 * * *	False	0	8h	266d
analytics-cj-rollover	15,45 * * * * *	False	0	19m	266d

### b. Run the following command to edit the cronjob so you can modify the schedules:

- Kubernetes:

```
kubectl -n <apic-analytics-namespace> edit cronjob <cronjob_name>
```

- OpenShift:

```
oc -n <apic-analytics-namespace> edit cronjob <cronjob_name>
```

- VMware:

```
kubectl -n <apic-analytics-namespace> edit cronjob <cronjob_name>
```

### c. Adjust the cronjob's rollover and retention schedules, and then save your changes.

Important: Do not make any other changes to the cronjob. Other changes might result in the retention and rollover actions failing to complete successfully. To configure the job to run more than once a day, modify the schedule and update the minutes and hour values as needed (the values in positions 1 and 2).

The format for the schedule consists of 5 fields, separated with spaces. Each field is represented with a \* and based on its position, controls the value shown in the following list:

- \* \* \* \* \* schedule includes 5 fields
- \* \* \* \* +----- position 5: day of week (0 - 6 where 0=Sunday)
- \* \* \* +----- position 4: month (1 - 12)
- \* \* +----- position 3: day of month (1 - 31)
- \* +----- position 2: hour (0 - 23)
- +----- position 1: minutes (0 - 59)

For example, the following schedule runs a job at 30 minutes (position 1) past the first hour (position 2) every day: 30 1 \* \* \*

If you want a job to run more than once an hour, you can specify multiple minutes values by separating them with a comma. The following schedule runs a job at 15 minutes and 45 minutes past the every hour of every day: 15,45 \* \* \* \*

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring analytics offload for API Connect

The event data that is generated and collected in your API Connect on-premises cloud can be forwarded to different destination targets for display and analysis. Destination targets include the API Connect user interfaces, and third-party systems that are external to API Connect.

### About this task

API event data can be forwarded to a third-party system for data consolidation within data warehouse systems, enhanced monitoring, and richer analytical data processing. The data offload capability in API Connect enables users to form correlations with other data sources on a single platform, and helps to reduce the time between analysis, decision, and action. When you offload event data to a third party system, the data is streamed in real time to the target system as the events occur. Multiple target systems are supported for the data offload.

You can configure a combination of destination systems to which data is forwarded for analysis and display. You can choose one of the following options:

- Enable access to analytics data in the API Manager user interface. This is the default setting.
- Disable access to analytics data in API Connect and instead re-route the data streams to one or more third-party systems. When you select this method, the data is not written to the API Connect analytics management server.
- Enable access to analytics data in API Connect and simultaneously stream the data to one or more third-party systems.
- Enable the Analytics Message Queue. The Analytics Message Queue acts as a broker between the ingestion pipelines to ensure data collection continued uninterrupted if the offline endpoint becomes nonfunctional. See
- Completely disable access to analytics data.

Use the following information to configure destination targets for your analytics data:

- [Supported event types for analytics offload](#)  
API Connect generates API event data. The captured event data can be viewed in the API Manager or offloaded to third-party systems.
- [Supported third-party systems for analytics offload](#)  
You can offload the analytics data for API events to several third-party systems. The supported systems include HTTP servers, Elasticsearch clusters, Kafka clusters, and Syslog servers.
- [Providing a custom certificate for analytics offload](#)  
Optionally configure a private or self-signed certificate to secure the connections between IBM® API Connect Analytics and your external offload endpoint.
- [Configuring output plugins for analytics offload](#)  
In API Connect version 2018.3.7, and later, you can configure output plugins for third-party systems by editing the `outputs.yml` and `offload_output.conf` files. In earlier versions, you can configure output plugins for third-party systems in the `logstash.conf` file to offload the analytics data for API Connect. The output plugins point to one of the following target systems: HTTP, Elasticsearch, Kafka, and Syslog servers. The output plugin for displaying analytics data in the API Manager is included by default.
- [Configuring the analytics message queue](#)  
The analytics message queue is embedded in the data ingestion pipeline. It is most useful when offloading data from the analytics subsystem to a third-party system. It ensures that data collection continues in the event of a failure.
- [Configuration files for analytics offload customization](#)  
Beginning with API Connect version 2018.3.7, settings for analytics offload customization are maintained in the `offload_output.conf`, `19_filter.conf`, `39_filter.conf`, `49_apic_filter.conf`, and `69_apic_filter.conf` files.
- [Disabling access to analytics event data in API Connect](#)  
If you configured the IBM API Connect Analytics subsystem to offload data to a third-party product, you might not want to store a copy of the data in API Connect. You can disable the storage of analytics data in API Connect by modifying the `outputs.yml` file.
- [Troubleshooting your analytics offload](#)  
Perform these checks if the offload fails. Common causes for an offload failure are connection or security-related issues.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Supported event types for analytics offload

API Connect generates API event data. The captured event data can be viewed in the API Manager or offloaded to third-party systems.

### API events

---

An API event is logged each time an API operation is invoked, and an event record is generated for each API event on the Gateway server. The API event record contains information about the API call. When an analytics service is associated with a gateway, it will capture API events.

The content of the record depends on the logging policy that is set for the operation. For information about how to configure your logging preferences for API events, see [activity-log policy](#) and [Including components in your assembly](#).

By default, API providers can view API event data in a number of ways:

- In the analytics dashboard for a catalog in API Manager. See `Manage > Catalog_name > Analytics`. These dashboards group together a set of related *visualizations* that depict analytics data as a graphical or metric representation. Default dashboards are provided for viewing and customizing analytics data for APIs, Plans, Products, and Catalogs (including Spaces if enabled). Custom dashboards can also be created. For more information about accessing and working with the API event data shown in API, Plan, and Product dashboards, see [Managing your Products](#).
- By using the debug function for the integrated test tool that is provided in the API Manager user interface. The debug function is typically used to view information about the API configuration in order to identify possible causes for an API invocation failure.

API consumers who are members of a consumer organization can also view analytics data within dashboard views in the Developer Portal user interface. The dashboard views depict API invocation metrics about the APIs used either by a single application or within the entire consumer organization. For more information about accessing the analytics data for APIs that are invoked by developer applications, see [Analytics in the Developer Portal](#).

Effect of switching off IBM API Connect Analytics for API events:

For information on disabling access to the analytics data, see [Disabling access to analytics event data in API Connect](#). Following are the effects of disabling access to analytics data within API Connect:

- Data streaming from the Gateway to the UIs is immediately terminated. Dashboards will still be visible, but may contain no data, or they might show data for a time period in the past, depending on when Analytics was disabled.
- No API data will be displayed when API developers use the debug function while testing their APIs locally in the API Manager user interface.

---

## Related concepts

- [Supported third-party systems for analytics offload](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Supported third-party systems for analytics offload

You can offload the analytics data for API events to several third-party systems. The supported systems include HTTP servers, Elasticsearch clusters, Kafka clusters, and Syslog servers.

For details about how to set up the data offload to these systems, see [Configuring output plugins for analytics offload](#). Following are descriptions of the third-party systems:

- [HTTP](#)
- [Elasticsearch \(Version 6 or 7\)](#)
- [Apache Kafka \(Version 1.0.0\)](#)
- [Syslog](#)

Attention: When you set up data offloading, the third-party endpoint must be available at all times to prevent the loss of analytics data.

### HTTP

---

You can offload API Connect analytics data to a web server that processes requests by using HTTP. Note that if the offload HTTP target is unreachable, the events will be lost.

To configure data offload to an HTTP server, you must provide the server URL. You can optionally add standardized or custom HTTP headers to define additional operating parameters.

You can also configure your data offload to forward the real-time event stream to other systems that provide enhanced search, analytics, and visualization capabilities. For example, you can forward your API Connect event data to a Splunk deployment. Or, you can forward your API Connect event data to an in-memory data structure store like Redis.

Refer to the Elasticsearch documentation for configuring HTTP plugins at <https://www.elastic.co/guide/en/logstash/6.8/plugins-outputs-http.html>

### Elasticsearch (Version 6 or 7)

---

You can offload API Connect analytics data to an Elasticsearch cluster, either a single node or a collection of nodes.

To configure data offload to an Elasticsearch cluster, you must provide one or more server URLs, define how indices should be created by specifying a dynamically configured name, specify the number of primary shards for storing the indexed documents, and specify a number of replica shards for redundancy.

The naming syntax that you specify for your indices determines how many indices are created and how they are characterized. For example, you can define indices that are created based on a date pattern (for example, daily or weekly), or indices that are created to store data by provider organization or by API name.

Refer to the Elasticsearch documentation for configuring plugins at <https://www.elastic.co/guide/en/logstash/6.8/plugins-outputs-elasticsearch.html>

### Apache Kafka (Version 1.0.0)

---

You can offload API Connect analytics data to an Apache Kafka target system that provides a stream processing platform for handling real-time data feeds. In this scenario, API Connect acts as a *producer* of data for a Kafka system that runs as a cluster on one or more servers (known as Kafka brokers).

The data that you offload to Kafka will be published to a *topic*, which is divided into a number of *partitions* that are implemented as structured commit logs and spread across the Kafka brokers. The data is written to the tail of these logs and can subsequently be distributed to the *consumers* that are configured in Kafka to process published feeds.

To configure data offload to a Kafka cluster, you must provide host and port connection details for one or more servers, and the name of the Kafka topic to which you want to publish the offloaded data. For logging and monitoring purposes within Kafka, you can optionally specify a string identifier by which API Connect can be uniquely identified.

Refer to the Elasticsearch documentation for configuring plugins at <https://www.elastic.co/guide/en/logstash/6.8/plugins-outputs-kafka.html>. Note that the Logstash plugin is based on `kafka-client version 2.3.1` and not `v2.1.0` as specified in the logstash doc.

### Syslog

---

You can offload API Connect analytics data to a Syslog server (or collector) that is configured to accept the event data for data consolidation, analysis, or review. The implementation supports both User Datagram Protocol (UDP) and Transmission Control Protocol (TCP). The Syslog server can optionally be configured to forward the API Connect data to an external datastore for further processing or archiving.

Restriction: Syslog does not support the use of chained client certificates for TLS profiles.  
To configure data offload to Syslog, you must provide host and port connection details for the server.

Attention: Due to a third-party issue with Logstash, most of the facility values are not set correctly on the offload server. As a temporary workaround, set the facility to "user-level" to ensure that the corresponding value is correctly sent to the offload server. When Logstash corrects this problem, you must update the offload configuration to change the value to a more appropriate setting.

Refer to the Elasticsearch documentation for configuring plugins at <https://www.elastic.co/guide/en/logstash/6.8/plugins-outputs-syslog.html>.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Providing a custom certificate for analytics offload

Optionally configure a private or self-signed certificate to secure the connections between IBM® API Connect Analytics and your external offload endpoint.

### About this task

If you configure Analytics for offloading and your endpoint requires a particular certificate, you can configure the certificate now and then reference it in the offload plugin when you complete the next task.

### Procedure

1. Create a Kubernetes secret to contain the certificates, and then apply it to the cluster where the Analytics subsystem runs.
  - a. Log in to a server that has kubectl access to the Kubernetes cluster where API Connect Analytics is deployed.  
For OVA deployments, you must log in to one of the running Analytics VMs as a user with kubectl access.
  - b. Encode the certificates file in base64.  
For offload certificates, you only need to provide the certificates that your endpoint requires. Some offload plugins require certificates as JKS files and others accept text-based files such as PEM files; use the format that is appropriate for your plugin.

Attention: If you use a JKS file for certificates, then this step is required because the non-text JKS file must be encoded in advance. If you use a text-based file such as PEM, then you can choose between encoding the file now or skipping this step and adding the keys to the secret in the next step.  
There are several ways to encode the file. If `cat` and `base64` are available, then you can run the following command to encode the file:

```
cat keystore.jks | base64
```

Copy the output so that you can paste it into the secret in the next step.

- c. Create a Kubernetes secret and add the certificate.
  - i. Create a YAML file to contain the secret; for example, you can call the file `offload_certs.yaml`. The secret's name that you specify in the file does not have to match the file name. In this example, the secret's name is `offload-certificates`.  
Add as many keys as you want, using any field names that you want. For each key, a file based on the corresponding field name is created in the container at `$(OFFLOAD_CERTS_DIR)`, and you can use it in your offload plugin's configuration. For example, if you paste a certificate in the `cacert` field as shown in the following example, then a file named `cacert` is stored in the `$(OFFLOAD_CERTS_DIR)` location.

```
apiVersion: v1
kind: Secret
metadata:
  # Change value of name to be whatever you wish secret to be called
  name: offload-certificates
  # Only base64 encoded data should be placed in data section; JKS keys would go here
data:
  keystore.jks: "output_of_base64_encoded_jks"
stringData:
  cacert: |-
    -----BEGIN CERTIFICATE-----

    70+sB3c4
    -----END CERTIFICATE-----
```

- ii. Paste the certificate into the file.  
The method for adding the certificate to the secret depends on whether you encoded the file in the previous step:

- Base64-encoded file: In the **data** section of the secret, type a name for the field (you can choose the name). Paste the encoded output from the previous step (enclosed in "") as the value.
  - Plain text file: In the **stringData** section of the secret, type a name for the key or certificate (you can choose the name), and paste the value.
- iii. Save the file.
- d. Update the cluster with the new certificate.  
Run the following command to update the cluster:

```
kubectl apply -f offload_certs.yaml -n your_namespace
```

where:

- **offload\_certs.yaml** is the secret's file name (not the name of the secret).
- **your\_namespace** is the name of your deployment's namespace. The namespace is only needed for Kubernetes deployments. For OVA deployments, you can omit the entire **-n your\_namespace** parameter from the command. By default, kubectl is already configured to match the namespace where your Analytics resources are deployed.

- e. Optionally create another Kubernetes secret, which can be used in environment variables.

If you have sensitive data such as a certificate passphrase that must be available in text format, you can store it in another secret.

If your passphrase is not sensitive (such as the JKS default passphrase), then you can supply it directly in the logstash configuration, and skip this step.

- Create a new YAML file; for example, call the file **offload\_env\_var.yaml**. The secret's name that you specify in the file does not have to match the file name. In this example, the secret's name is **offload-environment**.
- Paste the environment variable name and the passphrase (in plain text) into the **stringData** section of the file as shown in the following code example:

```
apiVersion: v1
kind: Secret
metadata:
  name: offload-environment
stringData:
  # Example environment variable names, you'll reference these from within logstash
  OFFLOAD_JKS_PASSWORD: password123
```

- Run the following command to update the cluster:

```
kubectl apply -f offload_env_var.yaml -n your_namespace
```

where **offload\_env\_var.yaml** is the secret's file name.

2. Update the Analytics subsystem so that it can use the new secrets.

- Create an **extra-values.yaml** file that specifies the names of your certificate and environment variables secret files.

Include the following lines in the **extra-values.yaml** file, making sure to use the names of your Kubernetes secrets (value the of the **name** field in the **metadata** section of the secret, which might not match the file's name):

```
apic-analytics-ingestion:
# offloadSecretEnv will mount all objects in specified secret name provided as environment variables
offloadSecretEnv: offload-environment
# offloadSecretCerts will mount all objects in specified secret as files on containers, using key as file name
offloadSecretCerts: offload-certificates
```

where:

- The **offloadSecretEnv** setting provides the name of the secret that is used by environment variables (to contain the certificate passphrase, for example). Keys provided in this file are made available as environment variables. The sample **offload\_env\_var.yaml** file in step 1 uses **offload-environment** as the secret's name.
- The **offloadSecretCerts** setting provides the name of the secret that contains the certificates needed for connecting to the offload endpoint. Keys provided in this file are stored as files in the **\$(OFFLOAD\_CERTS\_DIR)** directory. The sample **offload\_certs.yaml** file in step 1 uses **offload-certificates** as the certificates secret's name.

- Update the Analytics subsystem.

- Log in to the server where you run **apicup**, and navigate to the project directory.  
In Kubernetes deployments this is probably the same server that you used for step 1, but for OVA deployments it is a different server.
- Run the following **apicup** commands to reinstall the Analytics subsystem using the configuration settings in the **extra-values.yaml** file.

```
apicup subsys set analytics extra-values-file=~ /extra-values.yaml
apicup subsys install analytics
```

3. Update the logstash configuration to use the new secret.

Modify the logstash configuration and replace the references to the certificate file with references to the new secret:

- Items specified in the secret provided to **offloadSecretEnv** are available to use in logstash config files as environment variables; for example: **\$(OFFLOAD\_JKS\_PASSWORD)**.
- Keys from **offloadSecretCerts** are stored as files in **\$(OFFLOAD\_CERTS\_DIR)**. The path and file name can be referenced in the logstash configuration; for example, **\$(OFFLOAD\_CERTS\_DIR)/keystore.jks** for a JKS file or **\$(OFFLOAD\_CERTS\_DIR)/cacert** for a PEM file.
- For information on configuring the logstash plugins, see [Configuring output plugins for analytics offload](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring output plugins for analytics offload

In API Connect version 2018.3.7, and later, you can configure output plugins for third-party systems by editing the `outputs.yml` and `offload_output.conf` files. In earlier versions, you can configure output plugins for third-party systems in the `logstash.conf` file to offload the analytics data for API Connect. The output plugins point to one of the following target systems: HTTP, Elasticsearch, Kafka, and Syslog servers. The output plugin for displaying analytics data in the API Manager is included by default.

## About this task

Important: After you upgrade from a version of API Connect that is earlier than 2018.3.7 to version 2018.3.7, or later, you must reconfigure any customizations that you made in your `logstash.conf` file. Beginning with version 2018.3.7, the sections of the `logstash.conf` file are separated into smaller files to make them easier to use. Use the following chart to recreate the customizations:

Location of customization within <code>logstash.conf</code> file	Type of customization	Customization with new configuration files
input	Any customizations	This was unsupported in the previous versions and remains unsupported.
filter	Enable <code>geoip</code>	In the <code>install/upgrade</code> section of the <code>extra_values.yml</code> file, set the <code>apic-analytics-ingestion.geoIpEnabled</code> value to <code>true</code> .
filter	Additions to the pipeline (pre-apiconnect changes)	Add these to the <code>49_apic_filter.conf</code> file.
filter	Additions to the pipeline (post-apiconnect changes)	Add these to the <code>69_apic_filter.conf</code> file.
output	Disable the API Connect native analytics storage.	Set <code>apic_output_enabled</code> to the value of <code>false</code> in the <code>outputs.yml</code> or set <code>apic-analytics-ingestion.outputApicEnabled</code> to <code>false</code> in the <code>install/upgrade</code> section of the <code>extra_values.yml</code> file.
output	Add offload configuration	<p>Complete one of the following procedures to add the offload configuration:</p> <ul style="list-style-type: none"> <li>Set <code>offload_output_enabled</code> to <code>true</code> in the <code>outputs.yml</code> file</li> <li>In the <code>install/upgrade</code> section of the <code>extra_values.yml</code> file, set the value of <code>apic-analytics-ingestion.outputOffloadEnabled</code> to <code>true</code>.</li> </ul> <p>After you complete either of these steps, you must add your offload configuration to the <code>offload_output.conf</code> file.</p>

If you need to review the previous changes to your `logstash.conf` file, they are stored in the `analytics-ingestion-pipeline` configuration map in the Kubernetes instance. One of the following roles is required to configure the output plugins for analytics offload:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `topology:manage` permission

Output plugins control the analytics data offload to both the API Manager or to a third-party system. The data will be offloaded to the output plugins that are configured in the `offload_output.conf` file.

If you are using SSL to secure the communications between API Connect and your offload endpoint, then you will need to include a path to a file containing a list of trusted certificates. Both KeyStore and PEM bundles are available.

Note: The example uses default certificates. If you want to provide private or self-signed certificates instead, configure them as explained in [Providing a custom certificate for analytics offload](#) and then reference them in your `logstash` configuration.

Keystore:

```
Keystore: ` /usr/lib/jvm/jre/lib/security/cacerts `
passphrase: ` changeit `
type: ` JKS `
```

PEM:

```
cacert: ` /etc/pki/tls/cert.pem `
```

Important: When you configure the offload of analytics data, or enable or disable access to analytics data in API Connect, the configuration is applied across all provider and consumer organizations in the cloud infrastructure.

## Procedure

Complete the following steps to configure analytics offload for your cloud:

- In the Cloud Manager, click  Topology.
- Locate the Analytics service that is associated with the Gateway service, then click the title to open the Edit Analytics Service page.
- Click the Advanced Analytics Configuration link to load Kibana.
- In Kibana, click Ingestion in the API Connect section to open the configuration files selection page in the editor.
- Open the `outputs.yml` file by selecting its tab.
- Change the value of `offload_output_enabled`: to `true`.
- Save the values.
- Open the `offload_output.conf` file by selecting its tab.
- Add your new offload configuration within the `if` statement. The following content is an example of this file:

```
output {
  if "apicapievent" in [tags] {
    kafka {
      topic_id => "test"
      bootstrap_servers => "example.com:9093"
      codec => "json"
      id => "kafka_offload"
      ssl_truststore_location => "/usr/share/logstash/jdk/lib/security/cacerts"
      ssl_truststore_password => "changeit"
      ssl_truststore_type => "JKS"
    }
  }
}
```

```

    security_protocol => SSL
  }
}
}

```

Note: To disable storing the data in API Manager, change the `apic_output_enabled` setting in the `outputs.yml` file to `disabled` as shown in: [Disabling access to analytics event data in API Connect](#).

- The following examples show how to configure output plugins in `offload_output.conf` for each supported offload type. These examples use SSL with a public SSL certificate mounted at the endpoint. For a complete list of configuration options, refer to the logstash documentation.

#### HTTP

The following example configures an HTTP output plugin. For more options, refer to the Logstash documentation: [Http output plugin](#).

```

http {
  url => "example.com"
  http_method => "post"
  codec => "json"
  content_type => "application/json"
  id => "offload_http"
  truststore => "/usr/lib/jvm/jre/lib/security/cacerts"
  truststore_password => "changeit"
  truststore_type => "JKS"
}

```

The following example configures an HTTP output plugin using a custom certificate. For more information on using a custom certificate for your offload endpoint, see [Providing a custom certificate for analytics offload](#).

```

http {
  url => "https://example.com:443"
  http_method => "post"
  codec => "json"
  content_type => "application/json"
  id => "offload_http"
  cacert => "${OFFLOAD_CERTS_DIR}/cacert.pem"
  client_cert => "${OFFLOAD_CERTS_DIR}/client.pem"
  client_key => "${OFFLOAD_CERTS_DIR}/client.key"
}

```

#### Elasticsearch

The following example configures an Elasticsearch output plugin. For more options, refer to the Logstash documentation: [Elasticsearch output plugin](#).

```

elasticsearch {
  hosts => "https://example.com:443"
  index => "apiconnect"
  ssl => true
  cacert => "/etc/pki/tls/cert.pem"
}

```

#### Kafka

The following example configures a Kafka output plugin. For more options, refer to the Logstash documentation: [Kafka output plugin](#).

```

kafka {
  topic_id => "test"
  bootstrap_servers => "example.com:9093"
  codec => "json"
  id => "kafka_offload"
  ssl_truststore_location => "/usr/share/logstash/jdk/lib/security/cacerts"
  ssl_truststore_password => "changeit"
  ssl_truststore_type => "JKS"
  security_protocol => SSL
}

```

#### Syslog

The following example configures a Kafka output plugin. For more options, refer to the Logstash documentation: [Syslog output plugin](#).

Restriction: Syslog does not support the use of chained client certificates for TLS profiles.

```

syslog {
  host => "example.com"
  port => 601
  protocol => "ssl-tcp"
  id => "offload_syslog"
  appname => "apiconnect"
  msgid => "%{org_id}"
  facility => "log_audit"
  severity => "informational"
  codec => "json"
  ssl_cacert => "/etc/pki/tls/cert.pem"
}

```

- Click Save.

Important: It might take a few minutes for the new configuration to be applied to all your pods. Check the logs on the pods to ensure that there are no Logstash errors.

- If you want to include the `client_geoip` and `gateway_geoip` fields in your Analytics data, configure your Kubernetes ingresses/cluster to include the `X-Forwarded-For` header in the data that is collected by the DataPower gateway and passed to APIC Analytics.

This step is only required if you want to include the fields in your Analytics data. For information on the configuration task, see the following Kubernetes documentation:

- [NGINX Configuration "use-forwarded-headers"](#)
- [Troubleshooting NGINX Ingress](#)

## What to do next

Log in to the target system and verify that you can see the data stream for API Connect events.  
Attention: The third-party endpoint must be available at all times to prevent the loss of analytics data.  
**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuring the analytics message queue

The analytics message queue is embedded in the data ingestion pipeline. It is most useful when offloading data from the analytics subsystem to a third-party system. It ensures that data collection continues in the event of a failure.

### About this task

The analytics message queue is an optional service that provides a reliable ingestion pipeline, especially when offloading analytics to a third party system. The message queue ensures that the analytics pipeline will not be blocked when either analytics storage or the offload endpoint becomes unavailable. Data collection will continue internally in the analytics subsystem, and will be buffered if analytics offload has been configured. With the message queue enabled, data storage will continue even if the offload endpoint is unresponsive. Additional benefits include better handling of traffic spikes and a larger buffer to handle Elasticsearch issues such as red indices, mapping issues, etc.

### Procedure

Complete the following steps to configure an analytics message queue:

1. Enable the message queue using the APICUP installer and install the analytics subsystem. The command is `apicup subsys set analytics enable-message-queue=true`.
2. Set an optional `mq-storage-class`, or use the `storageClass` object.  
This parameter is used in Kubernetes installations only. It is not used in VMware environments (OVA files).
3. Install the Analytics subsystem to activate the message queue.
4. Optionally, configure analytics third-party offload if required. See [Configuring analytics offload](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Configuration files for analytics offload customization

Beginning with API Connect version 2018.3.7, settings for analytics offload customization are maintained in the `offload_output.conf`, `19_filter.conf`, `39_filter.conf`, `49_apic_filter.conf`, and `69_apic_filter.conf` files.

The settings for configuring the offload of analytics data are contained in multiple files to make it easier to customize the content. Each of these files is displayed as a tab in the Cloud Manager Console. The files can be opened and changed in the Cloud Manager Console by following the instructions in [Configuring output plugins for analytics offload](#).

### outputs.yml file

The `outputs.yml` file is where you set the values for enabling and disabling the settings for where your analytics events are maintained. You can offload the data to a third-party collection repository, maintain the data on the API Connect internal collection repository, enable both methods to collect the data internally and externally, or disable them both to collect no analytics data. To enable the offloading of data, the value for the `offload_output_enabled` setting must be set to `true`. If the `offload_output_enabled` is set to `false`, no data is offloaded to an external repository. To maintain the data in the internal API Connect analytics data collection repository, the `apic_output_enabled` setting must be set to `true`.

When the value of the `apic_output_enabled` parameter is set to `false`, the internal API Connect analytics data collection is disabled. There is no analytics data captured internally when this is set to `false`.

Important: When the values of the `offload_output_enabled` and the `apic_output_enabled` parameters are both set to `false`, no analytics data is being collected. The following example shows sample contents of the `outputs.yml` file:

```
apic_output_enabled: true
offload_output_enabled: false
```

### offload\_output.conf file

You can specify outputs in the `offload_output.conf` file to identify which API events that you want to offload. The API events that are not offloaded are either collected in the API Connect if internal analytics data collection is enabled, or discarded if it is not enabled.

The following example shows sample contents of the `offload_output.conf` file:

```
output {
  if "apicapievent" in [tags] {
```

```
}  
}
```

---

## 19\_filter.conf

You can specify filters in the 19\_filter.conf file to apply filters to the data immediately after it enters the pipeline from the gateway.

Note: Do not filter using this file unless you are instructed to do so by the API Connect support team.

The following example shows sample contents of the 19\_filter.conf file:

```
filter {  
  if "apicapievent" in [tags] {  
  }  
}
```

---

## 39\_filter.conf

You can specify filters in the 39\_filter.conf file to that apply to the data after it is filtered according to the settings in the 19\_filter.conf file.

Note: Do not filter using this file unless you are instructed to do so by the API Connect support team.

The following example shows sample contents of the 39\_filter.conf file:

```
filter {  
  if "apicapievent" in [tags] {  
  }  
}
```

---

## 49\_apic\_filter.conf

You can specify filters in the 49\_apic\_filter.conf file to that apply to the data after it is filtered according to the settings in the 19\_filter.conf file and the 39\_filter.conf file.

Note: Do not filter using this file unless you are instructed to do so by the API Connect support team.

The following example shows sample contents of the 49\_apic\_filter.conf file:

```
filter {  
  if "apicapievent" in [tags] {  
  }  
}
```

---

## 69\_apic\_filter.conf

You can specify filters in the 69\_apic\_filter.conf file to that apply to the data after it is filtered according to the settings in the 19\_filter.conf file, the 39\_filter file, and the 49\_apic\_filter.conf file. The filter settings in this file only affect the analytics data that is stored on the internal API Connect analytics data collection. It cannot be used to filter offloaded data.

You can filter the events in this file based on the event record fields that are described in [API event record fields](#).

The following example shows sample contents of the 69\_apic\_filter.conf file:

```
filter {  
  if "apicapievent" in [tags] {  
  }  
}
```

---

## Related concepts

- [Supported third-party systems for analytics offload](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Disabling access to analytics event data in API Connect

If you configured the IBM® API Connect Analytics subsystem to offload data to a third-party product, you might not want to store a copy of the data in API Connect. You can disable the storage of analytics data in API Connect by modifying the outputs.yml file.

---

## Before you begin

One of the following roles is required to perform this task:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `topology:manage` permission

---

## About this task

The Gateway reports all API events to the API Connect analytics engine, for real-time and historical reporting. By default, the analytics data is stored in API Connect and can be viewed from the dashboards in API Manager.

Important: When you enable or disable the storage of analytics data in API Connect, that change is applied across all provider and consumer organizations in the cloud infrastructure.

There are two ways to disable (or enable) the storage of analytics data in API Connect:

- Disable all analytics collection by unassociating the analytics service from the gateway service. If you disable all analytics collection, there will be no data in either the API Manager Dashboards or third-party offloads. See [Associating an analytics service with a gateway service](#) for how to unassociate an analytics service.
- Disable analytics storage in API Connect by setting the `apic_output_enabled` to `false` in the `outputs.yml` file. This approach lets you retain the third-party offload capability. Do this if you want to [configure third-party output plugins](#) and don't want to view the analytics in API Manager.

## Procedure

---

Complete the following steps to disable the storage of analytics data in API Connect.

1. In the Cloud Manager, click  Topology.
2. Locate the Analytics service that has been associated with the Gateway service, then click the title to open the Edit Analytics Service page.
3. Click the Advanced Analytics Configuration link to load Kibana.
4. In Kibana, click Ingestion in the API Connect section to open configuration file selection page.
5. Open the `outputs.yml` file by selecting its tab.
6. In the `outputs.yml` file, set the value of `apic_output_enabled` to `false`.

The `outputs.yml` file contains some comments plus two settings by default:

```
# Here you should specify whether certain functionalities are enabled or
# disabled. Specifically, the apic_output_enabled flag indicates whether
# data should be stored in APIC Analytics Storage, while the
# offload_output_enabled flag indicates whether data should be offloaded
# to the configured offload output in offload_output.conf.
apic_output_enabled: true
offload_output_enabled: false
```

To disable the Analytics user interface, set `apic_output_enabled` to `false` as in the following example:

```
# Here you should specify whether certain functionalities are enabled or
# disabled. Specifically, the apic_output_enabled flag indicates whether
# data should be stored in APIC Analytics Storage, while the
# offload_output_enabled flag indicates whether data should be offloaded
# to the configured offload output in offload_output.conf.
apic_output_enabled: false
offload_output_enabled: false
```

7. Click Save.

## Results

---

Analytics data will not be stored in API Connect, and will not be available for viewing in the API Manager analytics dashboards. If you configured data offloading, that will not be affected.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Troubleshooting your analytics offload

Perform these checks if the offload fails. Common causes for an offload failure are connection or security-related issues.

When you save the configuration files, their syntax is first validated to verify that it can be applied. However, this does not confirm that other parts of your analytics collection ecosystem are trouble-free, for example, that your endpoints are running, or that the TLS certificates are validated. Errors in these areas may also result in no data output.

To verify issues you will need to examine the logs for one of your Kubernetes analytics ingestion pods. (Note that it may take a few minutes for the pods to pick up changes in the configuration files after edits are applied.)

For information on obtaining logs, refer to [Configuring remote logging for a VMware deployment](#) and [Configuring logging for a Kubernetes deployment](#).

Following are some common checks you can make to troubleshoot the offload:

- Verify that the specified URL or the host and port values for the target system are accurate.
- Verify that the server or cluster of servers in the target system are running and reachable. If applicable, also verify that the connection problems are not caused by firewall settings.
- If you are using Transport Layer Security (TLS) to establish a private and secure communication channel to the target system, investigate whether the issue is caused by SSL certificate errors; for example, untrusted server certificates, certificates that have expired or are not yet valid, or missing intermediate (or chain) certificates.
- If offloading to an Elasticsearch or Kafka target, verify that your configuration settings are valid; for example, the user credentials for authenticating to Elasticsearch or the Kafka topic name.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring the audit log to track API calls

Configure auditing in IBM® API Connect to monitor user operations such as who published which product and when.

Audit logging is useful when you want to monitor the create, update, and delete activity in your deployment; for example, who made changes, when, and what they changed.

## What events are audited?

The audit focuses on "who" did "what" and "when", including the request payload and the result of the operation. All create, update, and delete operations are audited. Generally, read operations are only audited if the calling user logged in with an OIDC Provider user registry.

Internal calls and calls between system components are not audited because they are part of the product functionality and not executed by users.

## How are audit events logged?

Audit events are logged by sending the information about API calls (the requests) to one or more endpoints. Audit logging messages are sent as HTTP/HTTPS requests and use the payload format defined by the Cloud Auditing Data Federation (CADF). If the endpoint requires authentication, you can configure a header that will be included in the audit logging request. Audit logging requests are issued once only, on the assumption that every endpoint is available to receive the requests. There is no error checking to ensure that requests are received and stored by the endpoints, and failed requests are not re-sent. If you suspect that audit logging requests are not successfully reaching an endpoint, you can check the server logs on the console, where any error messages are recorded.

There are two modes that control how the auditing is sent to an endpoint: blocking and non-blocking. In non-blocking mode (the default), an audit event is sent to the endpoint and the system does not wait for a response from the endpoint. Non-blocking mode provides the best performance. Blocking mode should be used with caution: when an audit event is sent, the system pauses and waits for a response from the endpoint. Blocking mode has a negative impact on performance.

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

## What's included in the audit logging request?

When an API call is made, the system injects a request header to capture information, including the request URL and the payload (with sensitive information redacted), plus a subset of the data returned in the response to that call. The system injects additional information to describe the "who", "what", and "when" of the call.

The payload containing the audit logging record includes information about the user who issued the API call, the date and time of the call, the resource affected by the call, the operation performed, and the payload. To see the most recent set of fields that are included in the payload, refer to the OpenAPI schema for the audit logging request in the Provider API, which you can download at [https://us-south.functions.cloud.ibm.com/api/v1/web/API%20Connect%20Native\\_apic-on-prem/default/index.http](https://us-south.functions.cloud.ibm.com/api/v1/web/API%20Connect%20Native_apic-on-prem/default/index.http).

The following code example shows a sample payload for an audit logging message (IDs and users are not real):

```
{

      }
    }
  ]
}

```

## Verifying that the endpoint is receiving audit logging messages

By default, auditing operates in `non_block` mode to ensure best performance. In `non_block` mode, each audit logging message is sent immediately without waiting to ensure that the previous message was received. If you suspect that audit logging messages are not being received by the endpoint, download the server logs from the Kubernetes console and examine the `apim_microservices` file for messages related to the connection state. Review the messages to validate that the connection was successful or to further diagnose issues.

You can test the connection to a particular endpoint by issuing a "test-connection" call using either the toolkit or a REST API. A response status of `204` indicates that the call was successful and the endpoint is available. The following example contains the payload from a connection test (IDs and users are not real):

```

{
  "id": "8d8eaaa2-1b46-4dcb-cadf-639d7d1f7f20",
  "typeURI": "http://schemas.dmtf.org/cloud/audit/1.0/event",
  "action": "create",
  "outcome": "success",
  "eventType": "activity",
  "reason": {
    "reasonCode": "200",
    "reasonType": "HTTP"
  },
  "eventTime": "2020-01-30T15:51:18.254Z",
  "initiator": {
    "name": "admin:default-idp-1/tjwatson",
    "typeURI": "service/security/account/user"
  },
  "target": {
    "id": "test-connection",
    "typeURI": "cloud_setting"
  },

    "type": "toolkit"
  }
}
]
}

```

Tip: To ensure that audit logging messages are not lost due to an unavailable endpoint, verify each endpoint periodically.

- [Configure the audit settings](#)  
Use either the IBM API Connect Cloud Manager UI or the Toolkit CLI to enable auditing of API calls.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configure the audit settings

Use either the IBM® API Connect Cloud Manager UI or the Toolkit CLI to enable auditing of API calls.

### Before you begin

Configure one or more audit endpoints where logging data can be directed, and validate that every endpoint is available by testing the connection as explained in [Configuring the audit log to track API calls](#).

### About this task

You can configure audit settings using the [Cloud Manager UI](#) or the [Toolkit CLI](#).

By default, auditing is disabled. If you enable auditing, the API Connect management node emits audit events as messages and sends them to the endpoint for storage.

### Using the UI to configure audit settings

Use the Cloud Manager user interface to enable auditing of customer API calls.

#### Procedure

1. In the Cloud Manager, click  Settings > Audit Setting > Edit.
2. Click Enable to enable the audit feature, or Disable to disable it.
3. Select an audit mode:
  - Non-blocking - Default value, offers the best performance. Each request is passed immediately without waiting for a response to the previous request. This is susceptible to errors if a request is dependent on the results of an earlier request whose response is not received before the new request is sent.
  - Blocking - If you select this mode, expect a degradation in performance. Each request is allowed to finish execution before the next request is sent. This mode results in fewer errors when requests are dependent on the responses of earlier operations, but the delayed requests slow the network.
4. Add the values to describe an endpoint (you must specify at least one endpoint):
  - URL - Required, must not be empty. The URL of the server where audit logging messages will be sent. The URL must use either HTTP or HTTPS; TCP is not supported.  
If you previously saved the audit settings with an empty URL and experienced problems, you can edit the URL to correct it.
  - TLS client profile - Optional. The URL of the server where the endpoint's TLS client profile is stored.
  - Header name and Header value - Optional. Multiple headers are allowed (click Add to add another header. For each header, specify the header name and the header value.
5. Optional. To specify another endpoint, click Add at the beginning of the "Endpoints" section.
6. Optional. Verify that you can reach the endpoint by clicking Test.
7. Click Save to save your settings.

#### Results

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

#### What to do next

If you suspect that audit logging messages are not being received by the endpoint, see [Verifying that the endpoint is receiving audit logging messages](#) for information on validating the connection.

### Using the CLI to configure audit settings

Use the IBM API Connect toolkit CLI to enable auditing of API calls.

#### About this task

Use the following settings to configure auditing with the CLI toolkit:

- **enable** - Boolean, defaults to **false** (no audit). Set to **true** if you want to enable auditing.
- **mode** - Enumerated, defaults to **non\_block**. The audit mode determines how audit requests are timed when they are sent to the endpoint:
  - **non\_block** - Default value, offers the best performance. Each request is passed immediately without waiting for a response to the previous request. This is susceptible to errors if a request is dependent on the results of an earlier request whose response is not received before the new request is sent.
  - **block** - If you select this mode, expect a degradation in performance. Each request is allowed to finish execution before the next request is sent. This mode results in fewer errors when requests are dependent on the responses of earlier operations, but the delayed requests slow the network.
- **endpoints** - Array of strings. You must specify at least one endpoint where the audit logging messages are sent. For each endpoint, you can optionally include a TLS client profile URL and one or more headers. For example, if the endpoint requires an authorization header, you can include it in the endpoint setting.
  - **endpoint\_url** - String. Required, must not be empty. The URL of the server where audit logging messages will be sent. The URL must use either HTTP or HTTPS; TCP is not supported.  
If you previously saved the audit settings with an empty URL and experienced problems, you can edit the URL to correct it.
  - **tls\_client\_profile\_url** - String. Optional. The URL of the server where the endpoint's TLS client profile is stored.
  - **headers** - String. Optional. Multiple headers are allowed. For each header, specify the header name and the header value using the format shown in the example.

The endpoint setting can be lengthy, so uploading the settings in a file helps to avoid errors. Format the settings as a .yaml file (you can choose the file name) and upload the file using the toolkit CLI. The following example enables auditing in non-blocking mode with three endpoints. The first endpoint setting omits both the TLS client profile and the headers, the second endpoint setting includes a TLS client profile and one header, and the third endpoint setting omits the TLS profile but includes two headers.

```
audit_setting:
  enabled: true
  mode: non_block
  endpoints:
    - endpoint:
      endpoint: >-
      https://mutt-audit-endpoint.example_1.com/auditing
    - endpoint:
      endpoint: >-
      https://auditing-endpoint.example_1.com/inputs/64e38c02-acd9-6530-76f8-dd0f336d7b11
      tls_client_profile_url: >-
      https://security.tls_example.com/api/orgs/d8eac736-b4e2-3aa6-c7ff-978a4cd19d0b/tls-client-profiles/19d0f087-b4e2-3aa6-926b-9f6d51d028c3
      headers:
        authorization: Basic c3Bvb246c21tb25rYXRpZXVtYQ==
    - endpoint:
      endpoint: >-
      https://auditing-endpoint.example_2.com/inputs/64e38c02-acd9-6530-76f8-dd0f336d7b11
      headers:
        authorization: Basic c3Bvb246c21tb24=
        x-header: ForYourEyeOnly
```

## Procedure

1. Create a YAML file with the audit settings as shown in the example.  
For information on using input files with the toolkit CLI, see [Reading input from the command line](#).
2. Run the following command to log in to a management server as a member of the cloud administration organization:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm realm
```

Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI. For more information on logging in, see [Logging in to a management server](#).

3. Upload the YAML file with the auditing settings by running the following command:

```
apic cloud-settings:update --server mgmt_endpoint_url my_audit_settings.yaml
```

4. Run the following command to log out of the management server:

```
apic logout --server mgmt_endpoint_url
```

## Results

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

## What to do next

If you suspect that audit logging messages are not being received by the endpoint, see [Verifying that the endpoint is receiving audit logging messages](#) for information on validating the connection.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

# Changing your Cloud Manager password and profile information

You can change your Cloud Manager password and update your profile information.

## Procedure

---

To change your password or profile information, follow these steps:

1. Log in to the Cloud Manager user interface.
2. Click the User icon , and then select My Account.
3. In the Profile section, enter a new email address and First Name and Last Name for the account owner.
4. Click Save.
5. In the Change password section, enter your current password and your new password, and confirm the new password.  
The password must contain six characters at a minimum. It must contain at least three of the following types of characters:
  - Lowercase letters
  - Uppercase letters
  - Numbers
  - Characters from the following list of allowed punctuation and special characters:

```
!
\"
#
$
%
&
\
(
)
*
+
, (comma)
- (dash/hyphen)
. (period)
/
: (colon)
; (semi-colon)
<
=
>
?
@
[
\\
]
^
_ (underscore)
` (back quote/grave accent)
{
| (pipe)
}
~ (tilde)
```

The password cannot contain more than two consecutive repeating characters.

6. Click Save.

## Results

---

Your profile information and password are changed.

## Related concepts

---

## Resolving login problems by increasing HTTP header size

You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.

### About this task

---

Login attempts to the user interface might fail with error 502 (**Bad Gateway**). This error can occur when logging in from a browser that has a large number of cookies. The error occurs because size of the login request exceeds the maximum HTTP client header size.

The maximum HTTP client header size is limited for security reasons. To workaroud this issue, you can clear the browser cache and cookies, or open an incognito window from the browser, and then retry the login.

Alternatively, you can increase the maximum HTTP client header size. Use caution when increasing the maximum size because larger headers can raise a security risk to your system.

## Procedure

---

1. SSH to your management system or appliance.
2. Enter the following commands:

```
kubectl get deployment -n namespace | grep apim-v2
kubectl edit deployment -n namespace apiconnect-apim-v2-deployment
```

3. In the `env` section of the deployment configuration, change `--max-http-header-size=12000` to a larger value that works for your environment. For example:

```
- name: NODE_OPTIONS
  value: --max-old-space-size=8094 --max-http-header-size=16000
```

4. Save the updated configuration.
5. Run `kubectl get pod -n namespace` a few times until the new `apiconnect-apim-v2` pod is up and running.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Extending the Gateway server behavior

To support your enterprise requirements, you can extend the Gateway servers within IBM® API Connect to provide extra enforcement behavior.

### Before you begin

---

Before you develop your extensions, consider the guidelines in the following topics depending on which type of gateway you are using:

- [Gateway extension guidelines - DataPower Gateway \(v5 compatible\)](#)
- [Gateway extension guidelines - DataPower API Gateway](#)

For information on the different types of gateway, see [API Connect gateway types](#).

### About this task

---

API Connect Gateway servers uses a subset of DataPower® enforcement capabilities. You can supply DataPower Extensions to customize these enforcement capabilities further.

The DataPower extensibility function can be used to perform actions that include schema validation, antivirus scanning, message filtering, authentication, and authorization, token translation, message enrichment, encryption & decryption, digital signing, and validation and message transformation. For more information, see [IBM DataPower Version 7.5 documentation](#).

## Procedure

---

To extend the default enforcement capabilities that are provided in API Connect for the Gateway server, complete the following steps.

1. In your IBM DataPower environment, develop the configuration that you want to add to your Gateway server.
2. Test your enforcement configuration before you add the configuration to the Gateway server.
3. When you complete the IBM DataPower configuration, save the enforcement objects and files as a DataPower exported .zip file.  
The package file is ready to be uploaded to the Gateway server.
4. Copy your exported configuration .zip file to a centralized file system ready for upload to the Gateway server.

### What to do next

---

Upload your extension to the Gateway server; see [Configuring your Gateway server extensions](#).

- [Gateway extension guidelines - DataPower Gateway \(v5 compatible\)](#)  
Before you develop your extensions to the DataPower Gateway (v5 compatible), consider these guidelines.
- [Gateway extension guidelines - DataPower API Gateway](#)  
Before you develop your extensions to the DataPower API Gateway, consider these guidelines.
- [Configuring your Gateway server extensions](#)  
You can add extra IBM DataPower enforcement capabilities to a Gateway service by using API Connect CLI commands to upload a .zip file that defines the required extension behavior, and then enabling the extension in IBM DataPower.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

DataPower Gateway (v5 compatible)

---

## Gateway extension guidelines - DataPower Gateway (v5 compatible)

Before you develop your extensions to the DataPower® Gateway (v5 compatible), consider these guidelines.

Note: These guidelines apply to the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see [Gateway extension guidelines - DataPower API Gateway](#).

For information on the different types of gateway, see [API Connect gateway types](#).

You can download sample gateway extensions from <https://github.com/ibm-apiconnect/dp-extensions>.

You can create DataPower Processing Rules that can extend the enforcement behavior of the IBM® API Connect Gateway server at the following locations:

- **pre-request** extension:
  - Before the Gateway server begins to use the policies in the assembly to process the request.
- **post-request** extension:
  - After the Gateway server processes all of the policies in the assembly up to the proxy policy, if a proxy policy is used.
  - After the Gateway server processes all policies in the assembly, but before any catch logic is processed, if a proxy policy is not used.
- **post-response** extension:
  - After the Gateway server processes all of the remaining policies in the assembly after the proxy policy (including catch logic), but before the response is returned to the client application, if a proxy policy is used.
  - After the Gateway server processes the catch logic, but before the response is returned to the client application, if a proxy policy is not used.
- **post-error** extension:
  - If an error occurs, then before the Gateway server returns the error response to the client application.

To configure the Gateway server to call your extension Processing Rule, you must create an XML file that indicates the extension location and Processing Rule name. For example,

```
<extensions>
<extension location="pre-request">CustomRule1</extension>
<extension location="post-request">CustomRule2</extension>
<extension location="post-response">CustomRule3</extension>
<extension location="post-error">CustomRule4</extension>
</extensions>
```

The `<extension>` element entries are optional for any of the locations. Refer to the Gateway server Extension schema for the XML file syntax.

An extension Processing Rule can be applied to a specific organization or to all of the organizations and Catalogs. If the `<extension>` element does not have a tenant attribute, then the `<extension>` element is applied to all of the organizations. The following example shows an `<extension>` element without a tenant attribute.

```
<extension location="post-error">gen_error_handling</extension>
```

To apply an extension Processing Rule to a specific organization, enter the organization name as the value for the tenant attribute in the `<extension>` element. The following example shows an `<extension>` element with a tenant attribute value of `organization1`.

```
<extension location="post-error" tenant="organization1">organization1_error_handling</extension>
```

If you want to exclude a specific organization in an extension Processing Rule, enter the organization name as the value for the tenant attribute in an empty `<extension>` element. Add the empty `<extension>` element immediately after the custom rule `<extension>` element that you want to exclude the organization from. The following example shows an empty `<extension>` element with a tenant attribute value of `organization1`.

```
<extension location="pre-request">a_specified_CustomRule</extension>
<extension location="pre-request" tenant="organization1"></extension>
```

Important: An extension Processing Rule with a specified tenant attribute takes precedence over an `<extension>` element that applies to all of the organizations. Also, only one extension Processing Rule is applied to each extension location.

This XML file must be saved to the following location and included in your DataPower exported configuration .zip file:

```
local:///ext/extensions.xml
```

There can be only one DataPower exported configuration .zip file added to a Gateway server in API Connect.

## DataPower configuration restrictions

All Processing Rules have read access to the INPUT context.

Processing Rules must not rely on context variables that are created by the IBM Gateway server enforcement configuration, because those configuration variables might change in the future.

All Processing Rules except Before Request can transform or alter the message flowing through the Gateway server. Ensure that the Processing Rule returns the desired message output context back to the Gateway server at the end of processing.

To avoid name conflicts, all DataPower configuration object names prefixed with `webapi` are reserved for IBM use.

The following folders cannot be modified:

- `local:///isp/*`
- `local:///gwapi/*`

As a best practice, avoid adding asynchronous actions in your custom Processing Rules because they increase the use of memory per transaction.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Gateway extension guidelines - DataPower API Gateway

Before you develop your extensions to the DataPower® API Gateway, consider these guidelines.

Note: These guidelines apply to the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see [Gateway extension guidelines - DataPower Gateway \(v5 compatible\)](#).

For information on the different types of gateway, see [API Connect gateway types](#).

---

### Introduction

You apply an extension to a DataPower API Gateway by uploading one or more .cfg files that define the required extension behavior. These .cfg files contain DataPower API Gateway CLI commands. For details of the full set of CLI commands that are available, see the [DataPower API Gateway CLI command documentation](#).

You package the .cfg files in a .zip file, together with any additional required files that are referenced from CLI commands; for example, a .json file that contains the OpenAPI definition for an API. The .cfg files are processed in alphanumeric order by file name.

You upload the extension .zip file to an API Connect Gateway service, and enable the extension, as described in [Configuring your Gateway server extensions](#).

---

### Using CLI commands in a Gateway extension

Although you can use any DataPower API Gateway CLI commands in your extension .cfg files, typically you use commands that modify API Connect objects that have previously been deployed to the DataPower API Gateway.

When API Connect objects are deployed to a DataPower API Gateway, .cfg are created on the Gateway that define the configuration of those objects. By examining those .cfg on the Gateway, you can determine the precise names of API Connect objects that you want to modify, and the current values of the properties of those objects. You can access these .cfg files by completing the following steps:

1. Log in to the DataPower administrative user interface; for the Graphical Interface, select WebGUI rather than Blueprint Console.
2. Switch to the DataPower application domain for API Connect if necessary.
3. Under Files and Administration, click File Management.
4. Expand the temporary: folder to locate the .cfg files. The files for API Connect objects are named according to their containing provider organization and Catalog, as follows:

```
20.provider-org-name_catalog-name_collection.cfg
```

The prefix 20 controls the position of the file in the overall processing sequence, which is in alphanumeric order by file name.

CAUTION:

- Do not modify these files directly in the DataPower API Gateway file system, use the gateway extension mechanism described on this page.
- Do not apply gateway extension modifications to configuration in the local:/config-sequence.cfg file.

---

### Example 1 - change the scope of the rate limit for a Plan

Suppose the DataPower API Gateway configuration for a Plan has the following CLI command:

```
api-plan myorg_sandbox_financial-services_1.0.0_basic
```

The **api-plan** command has the following syntax:

```
api-plan plan_name
```

and creates a Plan of the specified name, or modifies a Plan of the same name if it already exists. By using the specified name, you can add **api-plan** commands in your Gateway extension .cfg files to modify the Plan.

Note: The names of API Connect objects in the DataPower API Gateway configuration are derived from their configuration in API Connect. For example, a Plan name has the following structure:

```
provider-org-name_catalog-name_product-name_product-version_plan-name
```

where:

- *provider-org-name* is the name of the provider organization.
- *catalog-name* is the name of the Catalog in that provider organization.
- *product-name* is the name of the Product that contains the Plan.
- *product-version* is the version of the Product.
- *plan-name* is the name of the Plan.

The default scope to which a Plan rate limit applies is per application. To change this setting on the Plan in this example, so that the rate limit scope is per client ID, add the following command to a .cfg in your Gateway extension:

```
api-plan myorg_sandbox_financial-services_1.0.0_basic
rate-limit-scope per-client-id
exit
```

For more information on configuring Plans by using DataPower API Gateway CLI commands, see [API Plan commands](#).

---

### Example 2 - add a path to an API definition

The .cfg file in this example performs the following actions:

1. Uses the **top** and **configure terminal** commands to reset CLI processing.
2. Uses the **api-operation** command as follows:

- a. Creates a new operation called `bank_branches_get_operation`.
- b. Uses the `reset` command to set all properties to their default values.
- c. Sets the operation method to `GET`.
3. Uses the `api-path` command as follows:
  - a. Creates a new path called `bank_branches_path`.
  - b. Uses the `reset` command to set all properties to their default values.
  - c. Sets the path URL segment to `/details`.
  - d. Adds the previously created operation `bank_branches_get_operation` to the path.
4. Uses the `api-definition` command as follows:
  - a. Modifies the existing API definition called `myorg_sandbox_myapi_1.0.0`.  
 Note: The name of the API definition was derived from its configuration in API Connect when it was published to the DataPower API Gateway, and has the following structure:

```
provider-org-name_catalog-name_api-name_api-version
```

where:

- `provider-org-name` is the name of the provider organization.
- `catalog-name` is the name of the Catalog in that provider organization.
- `api-name` is the name of the API definition in API Connect.
- `api-version` is the version of the API.

- b. Adds the previously created path `bank_branches_path` to the API definition.

Note: The `reset` command is not used here because that would reset all the current settings on the `myorg_sandbox_myapi_1.0.0` API definition, whereas the requirement is to add a new path to the existing configuration of the API definition.

The `.cfg` file is as follows:

```
top; configure terminal

api-operation bank_branches_get_operation
  reset
  method GET
exit

api-path bank_branches_path
  reset
  path "/details"
  operation bank_branches_get_operation
exit

api-definition myorg_sandbox_myapi_1.0.0
  path bank_branches_path
exit
```

For more information on the DataPower API Gateway CLI commands used in this example, see the following pages:

- [Initial login and common commands](#)
- [API Operation commands](#)
- [API Path commands](#)
- [API Definition commands](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Configuring your Gateway server extensions

You can add extra IBM® DataPower® enforcement capabilities to a Gateway service by using API Connect CLI commands to upload a `.zip` file that defines the required extension behavior, and then enabling the extension in IBM DataPower.

### About this task

You upload Gateway server extensions by using the developer toolkit CLI.

### Procedure

1. Log in to your API Connect Management server as an administrator, by using the following command:

```
apic login --server mgmt_endpoint_url --username admin_user_ID --password admin_password --realm admin/identity_provider
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL.
- `admin_user_ID` is the user ID of your administrator account, and is the same as the user ID that you use to log in to the Cloud Manager user interface.
- `admin_password` is the password for your administrator account.
- `identity_provider` is the identity provider that is used to authenticate administrative users.

For example:

```
apic login --server platform-api.myserver.com --username admin --password password --realm admin/myldap
```

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

2. Upload the Gateway extension .zip file by using the following command:

```
apic gateway-extensions:create extension_zip_file --scope org --org admin --gateway-service gateway_service --availability-zone availability-zone --server mgmt_endpoint_url
```

where:

- `extension_zip_file` is the Gateway extension .zip file that you want to upload.
- `gateway_service` is the name of the Gateway service that you want add the extension to.
- `availability-zone` is the name of the availability zone that contains the Gateway service.
- `mgmt_endpoint_url` is the platform API endpoint URL.

For example:

```
apic gateway-extensions:create myextension.zip --scope org --org admin --gateway-service mygatewayservice --availability-zone availability-zone-default --server platform-api.myserver.com
```

This example uses the default supplied availability zone name of `availability-zone-default`, which will be the required value if you have not configured your own availability zones. To check the names of the currently configured availability zones, use the following command:

```
apic availability-zones:list --org admin --server mgmt_endpoint_url
```

For details on configuring availability zones, see [Creating an Availability Zone](#).

To check the names of the currently configured gateway services, use the following command:

```
apic gateway-services:list --org admin --availability-zone availability-zone --server mgmt_endpoint_url
```

You can confirm that the extension has been added to the Gateway service by using the `gateway-extensions:get` command; for example:

```
apic gateway-extensions:get --scope org --org admin --gateway-service mygatewayservice --availability-zone myavailabilityzone --server platform-api.myserver.com --output -
```

(the parameter setting `--output -` writes the details of the Gateway extension object to the command window. You can specify the name of an existing folder to have the details written to a `.yaml` file in that folder.)

For reference details of the `apic`

`gateway-extensions` commands, see [apic gateway-extensions](#).

Note: You cannot upload more than one Gateway extension .zip file to the same Gateway service. If you want add further extensions later, update the original .zip file, then use the `apic`

`gateway-extensions:update` command to replace the previous gateway extensions file with the revised one; for example:

```
apic gateway-extensions:update mynewextension.zip --scope org --org admin --gateway-service mygatewayservice --availability-zone myavailabilityzone --server platform-api.myserver.com
```

3. Apply the extension to each server by restarting the API Connect gateway service object; complete the following steps on **each** Gateway server in the Gateway service:

Note: In Kubernetes environments, the following steps can be accomplished by issuing `kubect1`

`delete pod` on **each** gateway pod. Be sure to wait until each pod gets back to the ready state before deleting the next gateway pod.

- Remove the Gateway server from the load balancing group.
- Disable, then enable the API Connect gateway service object. You can do this by using either the DataPower administrative user interface in a web browser, or by using the DataPower CLI.
  - By using the administrative user interface:
    - Log in to the DataPower administrative user interface; for the Graphical Interface, select WebGUI rather than Blueprint Console.
    - Switch to the DataPower application domain for API Connect if necessary.
    - Search for `API Connect Gateway Service`.
    - Set the Administrative State to disabled.
    - Apply the changes.
    - Set the Administrative State to enabled.
    - Apply the changes.
  - By using the CLI:
    - Enter configuration mode by entering the command `configure`.
    - Navigate to the DataPower application domain for API Connect by entering the command `switch api_connect_domain_name`, where `api_connect_domain_name` is the name of your API Connect application domain.
    - Disable the API Connect gateway service object by entering the following command:

```
apic-gw-service; admin-state disabled; exit
```
    - Enable the API Connect gateway service object by entering the following command:

```
apic-gw-service; admin-state enabled; exit
```
- Ensure that the gateway service object initialization has completed.
- Re-add the Gateway server to the load balancing group.

## Results

The extension is uploaded and applied to each of the servers in the Gateway service, and the associated enforcement capabilities are applied to all incoming API resource requests.

Warning: DataPower Gateway (v5 compatible) only If you upload an extension to the DataPower Gateway (v5 compatible), a status file called `extension_import_response.xml` is written to the `local:/ext` folder in the gateway file system. Do not remove this file, otherwise if your gateway extension is subsequently removed then the referenced objects cannot be reverted to their original state automatically, and you will therefore have to either complete these clean up tasks manually, or re-add the gateway extension to regenerate the `extension_import_response.xml` file and then remove the gateway extension again. If the `extension_import_response.xml` exists and there is a cleanup failure for any object, a failure file is written to the `local:/ext` folder, with the failure details.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

# Cloud Manager Tutorials

Tutorials for using the Cloud Manager user interface in IBM® API Connect.

## Prerequisites

---

To complete the following tutorials you must be the Cloud Administrator or Cloud Owner of an API Connect instance.

## Overview

---

These tutorials guide you through common tasks performed to set up and maintain the configuration of a cloud.

- [Tutorial: Configuring the Cloud](#)  
This tutorial shows you how to create a basic cloud configuration, with available gateway, analytics and developer portal services.
- [Tutorial: Creating a Provider Organization](#)  
This tutorial shows you how to create a Provider Organization.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Tutorial: Configuring the Cloud

This tutorial shows you how to create a basic cloud configuration, with available gateway, analytics and developer portal services.

### Before You Begin

---

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator

You must run the Install Assist installation program to configure the Default Availability Zone that contains the Management service. See [Installing API Connect into a Kubernetes environment](#) and [Deploying the Management OVA file](#).

You will need the following information to complete this tutorial.

- The IP address or FQDN of the gateway, and the port assigned to accept API requests from clients.
- The IP address or FQDN of the gateway, and the port assigned to communicate with the API Management server. This cannot be the same as the port for API requests.
- The FQDN of the Developer Portal service to accept requests from clients. This value was set using the InstallAssist command:

```
apicup subsys set ptl portal-www <portal>.<hostname>.<domainname>
```

- The FQDN of the Developer Portal to communicate with the API Management server. This value was set using the InstallAssist command:

```
apicup subsys set ptl portal-admin <admin>.<hostname>.<domainname>
```

- The FQDN of the Analytics service to accept requests from clients. This value was set using the InstallAssist command:

```
apicup subsys set analyt analytics-client <ac>.<hostname>.<domainname>
```

- The address, port and optional login credentials for an SMTP email server.

Note: The port for the `portal-www`, `portal-admin`, and `analytics-client` services is **443**, and isn't configurable.

---

### About this tutorial

In this tutorial you are going to complete the following lessons:

- [Initial Cloud Manager Console login](#)
- [Configure an Email Server](#)
- [Register a Gateway Service](#)
- [Register a Portal Service](#)
- [Register an Analytics Service](#)
- [Configure a Default Gateway Service](#)

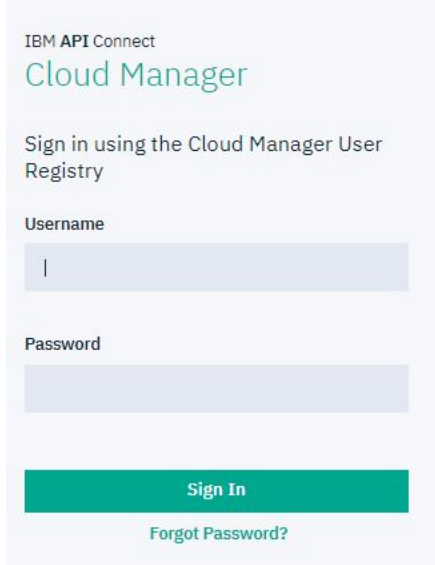

## Initial Cloud Manager Console login

---

Take the following steps to log in to the Cloud Manager user interface for the first time.

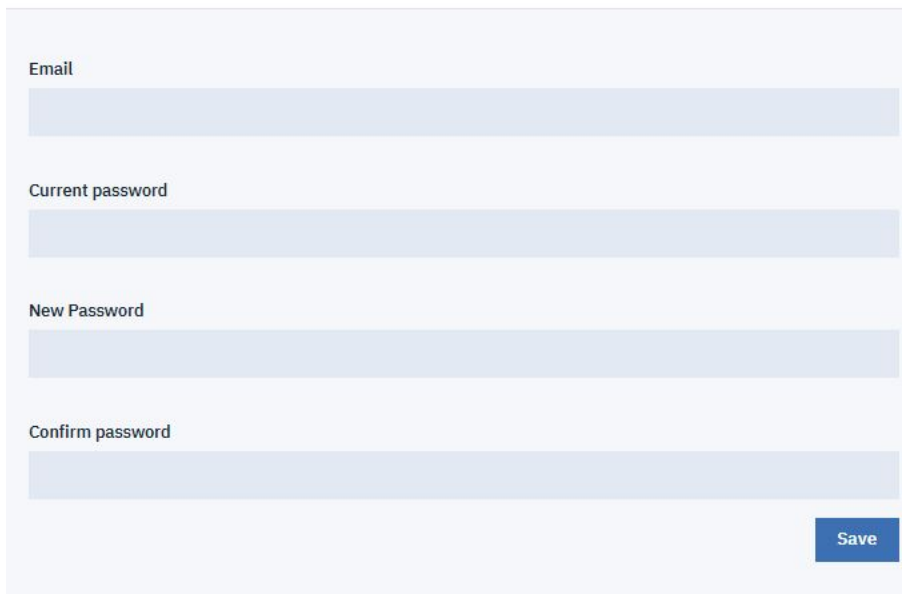

1. In a web browser, enter the management service URL. For example, `https://ManagementService.domain/admin` where `ManagementService.domain` is the fully qualified host name or IP address of the Management service.

The screenshot shows the login page for IBM API Connect Cloud Manager. At the top, it says "IBM API Connect" and "Cloud Manager" in a large green font. Below that, it says "Sign in using the Cloud Manager User Registry". There are two input fields: "Username" and "Password". Below the password field is a green "Sign In" button and a link for "Forgot Password?".

2. Enter the Cloud Administrator user name and password. The default values are `admin` for the user name and `7iron-hide` for the password.
3. You are immediately required to change the admin password, as well as provide an email address for the cloud administrator. Enter the necessary information.  
Note: If you forget your password and request a password reset, the notification email is sent to this email address. This action will use the email server set in the Notifications section of the cloud Settings. This tutorial shows you how to set this configuration.

### Change Password

The screenshot shows the "Change Password" form. It has four input fields: "Email", "Current password", "New Password", and "Confirm password". At the bottom right, there is a blue "Save" button.

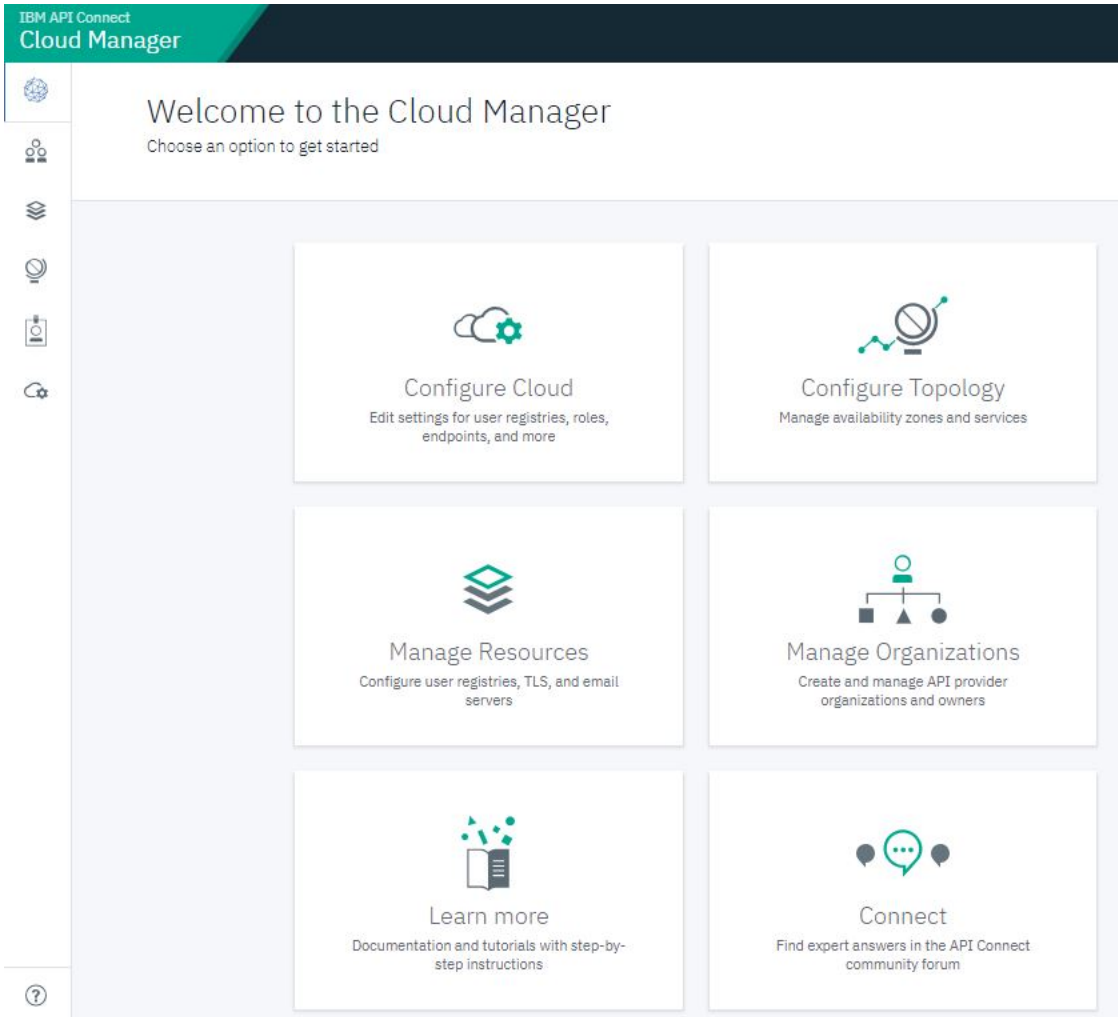

4. Click Save.
5. Log in using the new password.

## Configure an Email Server

---

Take the following steps to configure an email server. This configuration allows you to recover the admin password or receive other important notifications.

1. Click  Resources icon or the Manage Resources tile.

2. Click Notifications.

## Resources

User Registries Create

TITLE	TYPE	VISIBLE TO	
API Manager Local User Registry	Local User Registry	Private	⋮
Cloud Manager Local User Registry	Local User Registry	Private	⋮

3. Click Create.

User Registries Create

Notifications

TITLE	MAIL SERVER
 No items found	

- 4. Enter the appropriate values in the fields These values vary depending on your site.
- 5. Click Save.

## Create Email Server

### Email Server Configuration

**Title**  
Sendgrid

**Name**  
sendgrid

**Address**  
smtp.sendgrid.net

**Port**  
587

**Authenticate User (optional)**

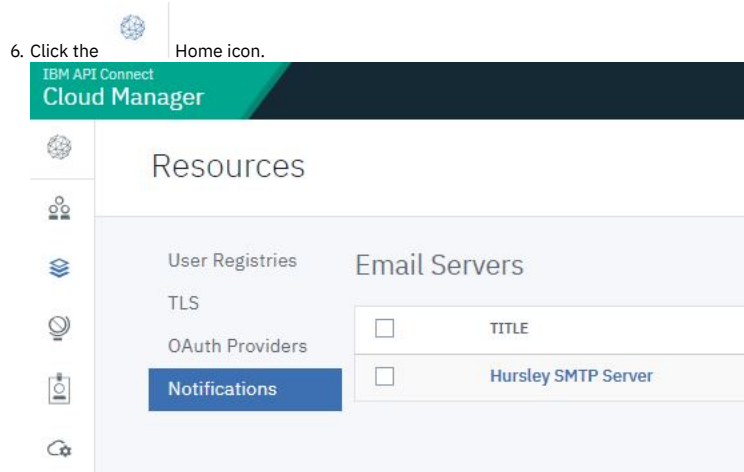

**Authenticate Password (optional)**

**TLS Client Profile (optional)**  
Default TLS client profile

**Test Connection** Test email

Send a test email to confirm that the email server is properly configured.

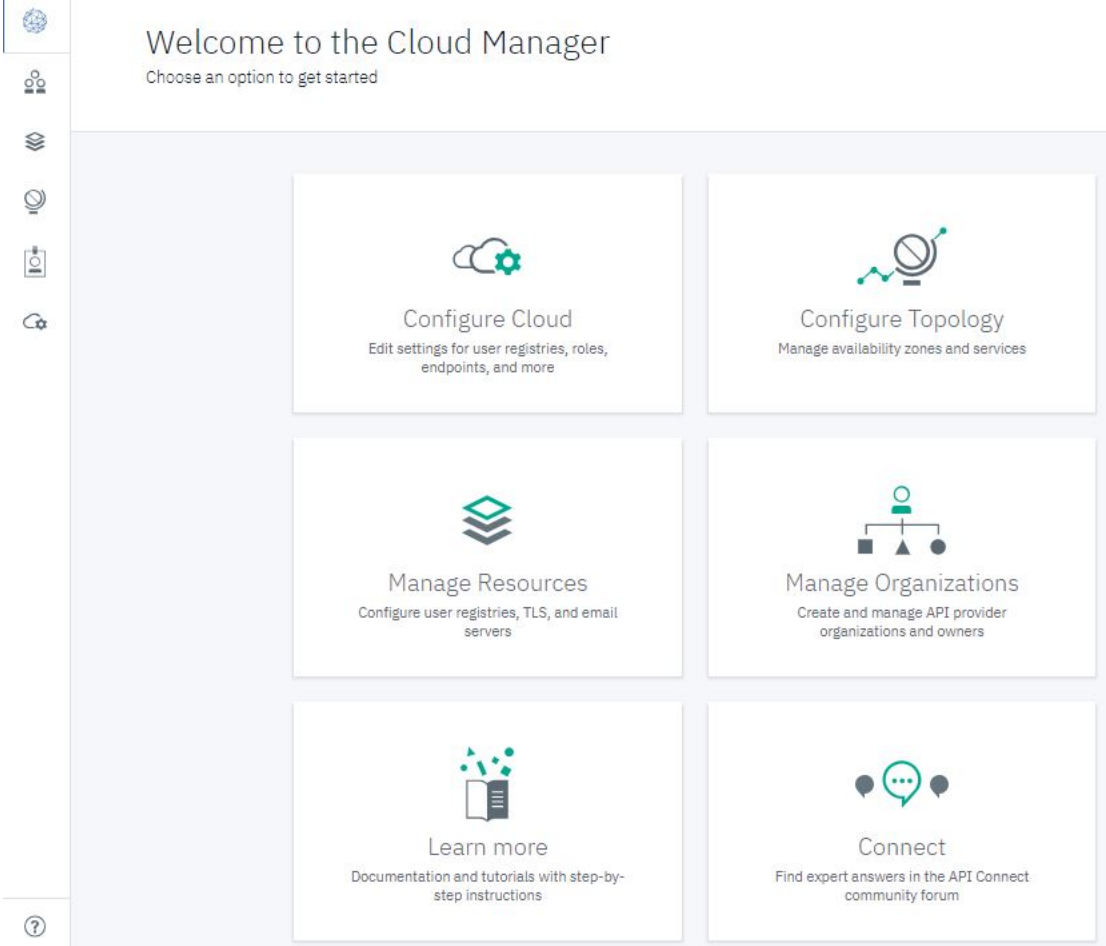

Cancel Save

## Register a Gateway Service

Take the following steps to register a gateway service.

1. Click the Configure Topology tile.

2. Click Register Service.

## Topology

3. Click DataPower Gateway (v5 compatible).

## Select Service Type

**DataPower API Gateway**  
Configure an DataPower API gateway service for securing and enforcing APIs

**DataPower Gateway (Classic)**  
Configure a DataPower gateway service for securing and enforcing APIs

**Portal**  
Configure a developer portal service for API consumers

**Analytics**  
Configure an analytics service to collect API call data

Cancel

#### 4. Take the following steps.

- Enter `gateway_service` in the Title field.
- In the Management Endpoint section, enter the URL of the address and port assigned to the management endpoint in the Endpoint field. This is the port used by the API Management server to connect to the gateway.
- Leave the remaining values as given to set TLS profiles.

## Configure DataPower Gateway Service

**Gateway Details**

**Title**  
gateway\_service

**Name**  
gateway-service

**Summary (optional)**

**Management Endpoint**

**Endpoint**  
https://gateway.example.com:3000

**TLS Client Profile (optional)**  
Default TLS client profile

- In the API Invocation Endpoint section, enter the URL of the gateway address and port assigned to accept API requests from clients in the API Endpoint Base field.
- Do not change the defaults in the Server Name Indication (SNI) fields. Note that your topology may require specific values in these fields.
- Optionally enter a hex value in the OAuth Shared Secret field. This must be a 64-bit hex value that begins with "0x". Providing a shared secret value here enables gateways in a cluster to read the OAuth tokens generated by any member of the cluster using the same secret.
- Click Save.

## API Invocation Endpoint

**API Endpoint Base**

https://gwv5c.example.com:443

**Server Name Indication (SNI)** Add

HOST NAME	TLS SERVER PROFILE	ORDER	DELETE
*	Default TLS server profile		

**OAuth Shared Secret (optional)**

0x

Cancel Save

## Register a Portal Service

---

Take the following steps to register a portal service.

1. Click Register Service.
2. Click Portal.
3. Take the following steps.
  - a. Enter `portal_service` in the Title field.
  - b. In the Management Endpoint section, enter the URL of the portal address and port assigned to communicate with the management server in the Endpoint field.
  - c. Enter the URL of the portal address and port assigned to accept requests from clients in the Portal Website URL field.
  - d. Use the reconfigured profile in the TLS Client Profile field.
  - e. Click Save.

## Configure Portal Service

**Title**  
portal\_service

**Name**  
portal-service

**Summary (optional)**

---

**Management Endpoint**

**Endpoint**  
https://portalsvc.example.com:9443

**TLS Client Profile (optional)**  
Portal Director TLS client profile

---

**Portal Website URL**  
https://portalsvc.example.com:443

## Register an Analytics Service

---

Take the following steps to register an analytics service.

1. Click Register Service
2. Click Analytics.
3. Take the following steps.
  - a. Enter `analytics_service` in the Title field.
  - b. In the Management Endpoint section, enter the URL of the analytics server address and port assigned to accept requests from clients in the Endpoint field.
  - c. Select `Analytics client TLS client profile` in the TLS Client Profile field.
  - d. Click Save.

## Configure Analytics Service

### Analytics Details

**Title**  
analytics\_service

**Name**  
analytics-service

**Summary (optional)**

### Management Endpoint

**Endpoint**  
https://analytics.example.com:9443

**TLS Client Profile (optional)**  
Analytics client TLS client profile

4. Click Associate Analytics Service corresponding to the gateway service listing.

### Default Availability Zone Management

Register new services and manage existing services

SERVICE	ASSOCIATED ANALYTICS SERVICE	VISIBLE TO
gateway_service	<a href="#">Associate Analytics service</a>	Public
analytics_service		Public
portal_service		Public

5. Select analytics\_service\_1. Click Associate.

### Gateway Service

gateway\_service

### Analytics Service

Select the analytics service you would like to associate with the gateway service

ANALYTICS	AVAILABILITY ZONE
<input checked="" type="checkbox"/> analytics_service	Default Availability Zone

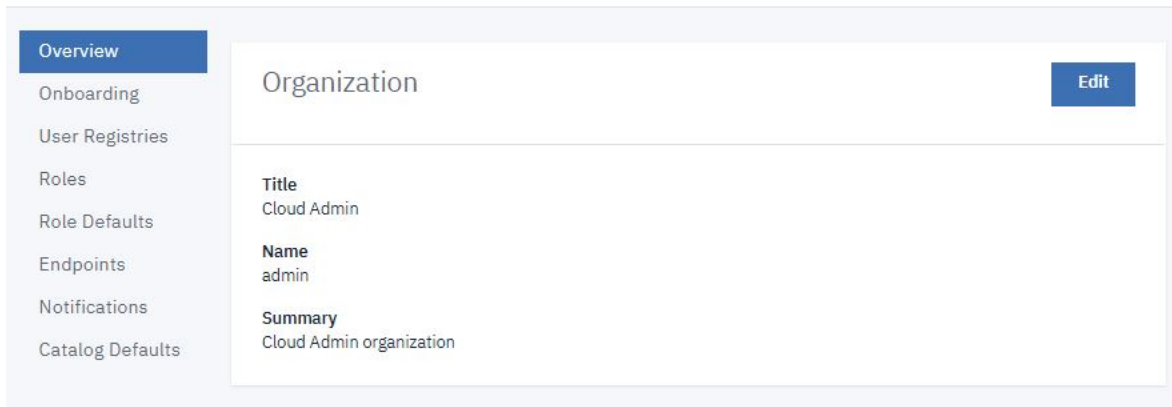

## Configure a Default Gateway Service

Take the following steps to configure a default gateway service for every catalog in the cloud.

1. Click  Settings icon .
2. Click Catalog Defaults.

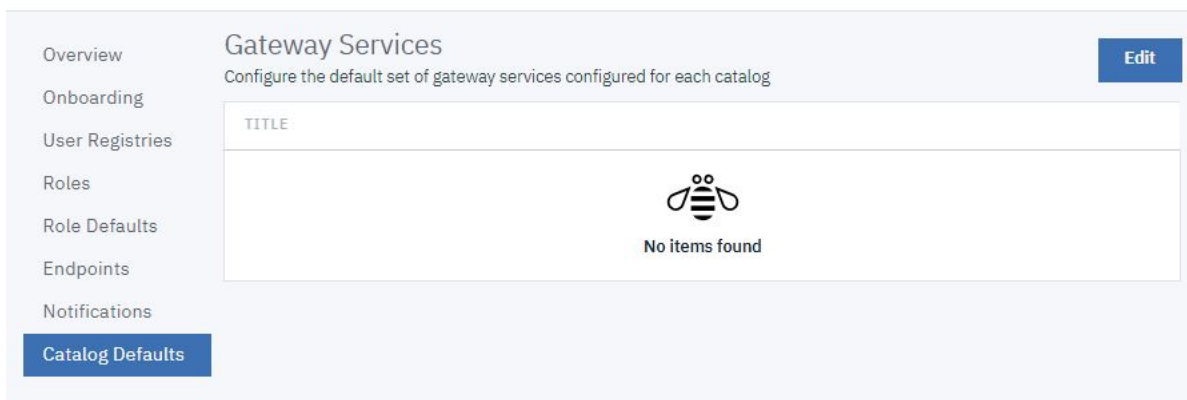

### Settings

The screenshot shows the 'Settings' page with a sidebar on the left containing the following menu items: Overview (selected), Onboarding, User Registries, Roles, Role Defaults, Endpoints, Notifications, and Catalog Defaults. The main content area is titled 'Organization' and includes an 'Edit' button in the top right corner. Below the title, there are three sections: 'Title' with the value 'Cloud Admin', 'Name' with the value 'admin', and 'Summary' with the value 'Cloud Admin organization'.

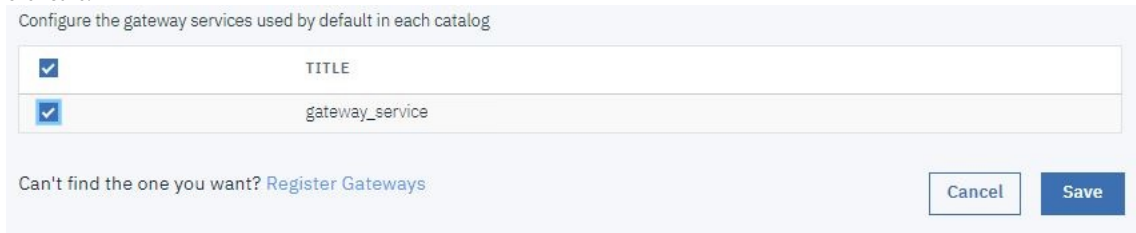

3. Click Edit.

### Settings

The screenshot shows the 'Settings' page with the 'Catalog Defaults' menu item selected in the sidebar. The main content area is titled 'Gateway Services' and includes an 'Edit' button in the top right corner. Below the title, there is a subtitle: 'Configure the default set of gateway services configured for each catalog'. A search bar labeled 'TITLE' is present. Below the search bar, there is a large area with a bee icon and the text 'No items found'.

4. Select an available gateway service.
5. Click Save.

The screenshot shows a dialog box titled 'Configure the gateway services used by default in each catalog'. It contains a table with two rows, each with a checked checkbox and a 'TITLE' column. The first row is empty, and the second row contains the text 'gateway\_service'. Below the table, there is a link: 'Can't find the one you want? [Register Gateways](#)'. At the bottom right, there are two buttons: 'Cancel' and 'Save'.

## What you did in this tutorial

- Set new Cloud Manager Console login password
- Configured a Gateway Service
- Configured a Developer Portal Service
- Configured an Analytics Service
- Configured a Notifications Email Server
- Configured a Catalog Default Gateway Service

## Related information

- [All tutorials](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

# Tutorial: Creating a Provider Organization

This tutorial shows you how to create a Provider Organization.

## Before You Begin

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator

You must also complete the following tasks before beginning:

- [Configuring an email server for notifications](#)
- [Setting up notifications](#)

Note that an email server must be configured and an active email server must be selected before a provider organization account can be created.

## About this tutorial

In this tutorial you are going to complete the following lessons:

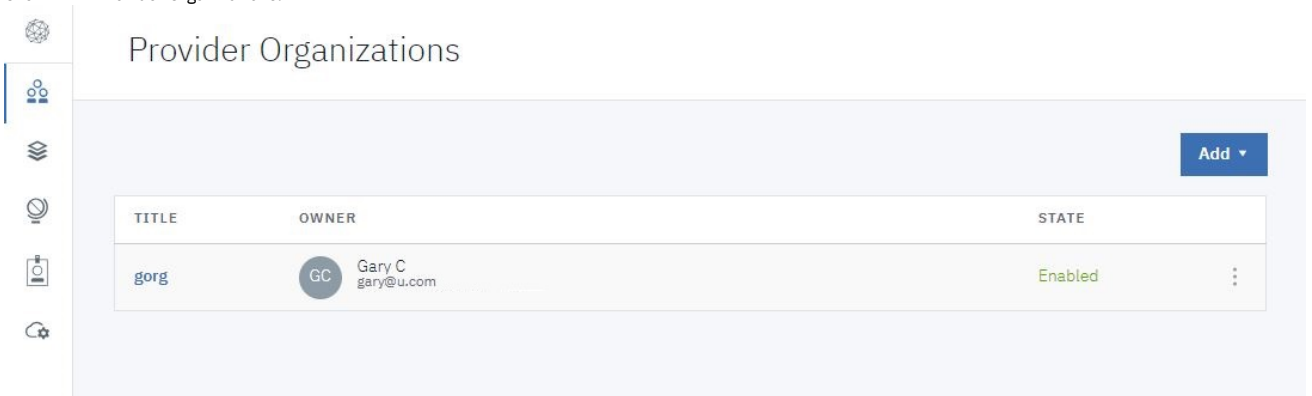

- [Create a Provider Organization](#)

## Create a Provider Organization

Take the following steps to create a new Provider Organization.

1. Log in to the Cloud Manager.

2. Click  Provider Organizations.

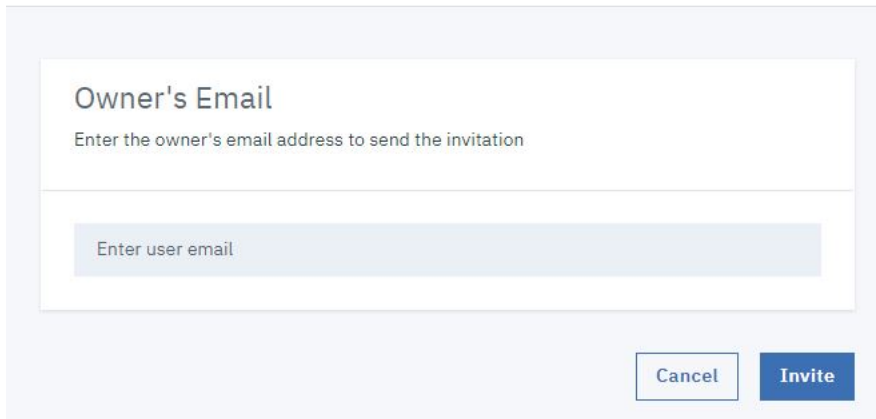

3. Click Add > Invite organization owner.

4. Enter the email address of the organization owner in the Owner's Email field.

## Invite Organization Owner

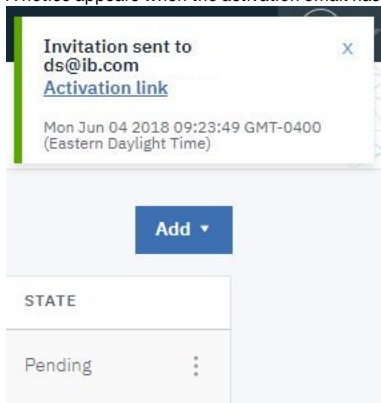

**Owner's Email**  
Enter the owner's email address to send the invitation

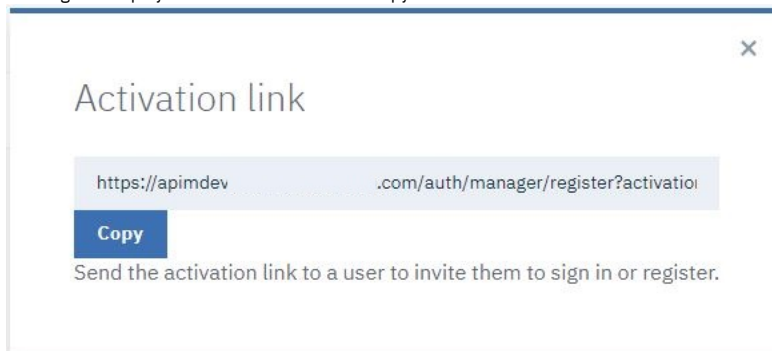

Enter user email

Cancel Invite

5. Click Invite.
6. A notice appears when the activation email has been sent. Click Activation link..

7. A dialog box displays the activation link. Click Copy.

8. Open a new window in your browser. Paste the copied activation link into the Location bar. Optionally, you can click the activation link in the invitation email to open the registration form.
9. Complete fields shown in the form to sign up with the API Manager User Registry. Click Sign up.

**Registration completed successfully**

Congratulations, you are now registered.

**Next step**

Log in with your credentials to work in the API Connect cloud.

- Manage your organization
- Manage members for your organization
- Log in with the credentials you registered with

Click the button below to login

[Sign In](#)

11. Enter the username and password you just created. Click Sign in to begin creating APIs and products.

12. Return to the original window of your browser. Click  Provider Organizations to refresh the list. Your new organization is listed.

## Provider Organizations

TITLE	OWNER	STATE
Tutorial	 DS ds@ib.com	Enabled

## What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a new Provider Organization.

## Related information

- [Importing an API](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Developing your APIs and applications

You develop APIs and LoopBack® applications by using the IBM® API Connect developer toolkit.

The API Connect developer toolkit provides both the API Manager user interface and a command line interface that you can use to develop APIs and LoopBack applications and publish them to API Connect.

You publish APIs by including them in a Product and then publishing the Product. You define your APIs and Products by creating and validating YAML definition files in your local file system. You can then interact with API Connect by using either the API Manager or the toolkit commands.

The developer toolkit is described in detail in the following subsections:

- [Working with the toolkit](#)  
You install the developer toolkit into a Node.js command line environment. You can then use the toolkit commands to interact with IBM API Connect and publish APIs that you have defined in your file system.
- [\[Technical Preview\] Searching for items in API Manager](#)  
Use the search feature in IBM API Connect API Manager to easily locate items such as APIs, Catalogs, applications, and subscriptions.
- [Working with API definitions](#)  
An API definition specifies the complete configuration for an API. You can create and configure your APIs either by using either the API Designer UI application, or by using the browser based API Manager UI.
- [Configuring API security](#)  
You configure security for an API by creating one or more security definitions by using IBM API Connect that specify various aspects of security configuration. You

then select which definitions you want to apply to your API, and to the operations in your API.

- [Working with Products](#)

In IBM API Connect, Plans and APIs are grouped together in Products, with which you can manage the availability and visibility of APIs and Plans.

- [Creating and validating API and Product definitions by using the CLI](#)

The developer toolkit of IBM API Connect provides a command line interface that you can use to create and publish API and Product definitions, and also to validate YAML or JSON definitions.

- [Working with global policies](#)

Use global policies to configure policy assemblies that are called just before, or just after, each of your API assemblies is called. You can upload global policies into each of the gateway services in your Catalogs, and then designate, for each gateway service, which global policy is to be called before an API assembly is called, and which one is to be called after. The designated global policies are applied to all the APIs that are deployed to the associated gateway service.

- [Reference](#)

Reference information for developing your APIs in API Connect, including context variables, and template variables.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Working with the toolkit

You install the developer toolkit into a Node.js command line environment. You can then use the toolkit commands to interact with IBM® API Connect and publish APIs that you have defined in your file system.

The following subsections describe how to install and use the toolkit:

- [Installing the toolkit](#)

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM API Connect.

- [Logging in from API Designer](#)

To log in from the API Designer user interface for IBM API Connect, you will need the host name of the management server and the user name and password associated with your API Manager account.

- [Using the developer toolkit command-line tool](#)

The IBM API Connect developer toolkit provides a command-line tool, `apic`, that you can use to perform all API Connect tasks. You can also use the command-line tool to script tasks such as continuous integration and delivery.

- [Viewing application performance metrics](#)

IBM API Connect provides two ways to view application performance metrics for Node.js applications running locally: the built-in metrics dashboard and sending the data to third-party consoles or log files.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

### About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer user interface.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer user interface.

You can download the toolkit compressed file in either of the following ways:

- From IBM Fix Central.
- From either the Cloud Manager or API Manager user interface.

The following table identifies the name of the compressed file that you need to download, depending on your chosen toolkit option and platform:

Table 1. Toolkit file names, by option and platform

Toolkit option	Mac OS X	Linux®	Windows
CLI	toolkit-mac.zip	toolkit-linux.tgz	toolkit-windows.zip
CLI + LoopBack + Designer	toolkit-loopback-designer-mac.zip	toolkit-loopback-designer-linux.tgz	toolkit-loopback-designer-windows.zip

## Procedure

---

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
  - To download the toolkit from IBM Fix Central, complete the following steps:
    - Open the [IBM Fix Central site](#) in your browser.
    - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
    - Select your installed 2018.x.y version from the Installed Version list, then click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
    - In the Text field, enter `toolkit`, then click Continue.
    - Select the required file, as identified in [Table 1](#).  
Note: When you download from IBM Fix Central, the release number is appended to the file name.
    - Click Continue, then follow the instructions to complete the download operation.
  - To download the toolkit from either the Cloud Manager or API Manager user interface, complete the following steps:
    - Cloud Manager or API Manager user interface.
    - Select Help ( ? ) in the navigation.
    - Select Install API Connect CLI & API Designer.
    - Select CLI or CLI + LoopBack + Designer according to your preferred option.
    - Select your platform to download the toolkit compressed file.
    - Close the Install API Connect CLI & API Designer window.

2. Extract the contents of the toolkit compressed file to a folder of your choice.  
The contents of the file depend on the your chosen toolkit option and platform, as follows:

Table 2. Toolkit compressed file contents, by option and platform

Toolkit option	Mac OS X	Linux	Windows
CLI	apic-slim	apic-slim	apic-slim.exe
CLI + LoopBack + Designer	apic api_designer-mac.zip: contains the API Designer user interface application.	apic api_designer-linux	apic.exe api_designer-win.exe

The `apic-slim` or `apic-slim.exe` file is the CLI for IBM API Connect.

The `apic` or `apic.exe` file is the CLI for IBM API Connect including LoopBack support.

Tip: If you are using the CLI option, then if you rename the `apic-slim` file to `apic`, or the `apic-slim.exe` file to `apic.exe`, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.

The `api_designer-platform` file is the API Designer user interface application for the specified platform.

3. Run the CLI.
  - For the Mac OS X or Linux platforms, complete the following steps:
    - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
    - Make the CLI file an executable file by entering the following command:

```
chmod +x download_name
```

Where `download_name` is the name of the toolkit file that you downloaded, either `apic` or `apic-slim`.

- Run CLI commands as follows:

```
./apic command_name_and_parameters
```

or

```
./apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

- For the Windows platform, complete the following steps:
  - Open a terminal window and navigate to the folder where you extracted the contents of the toolkit compressed file.
  - Run CLI commands as follows:

```
apic command_name_and_parameters
```

or

```
apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.

4. Launch the API Designer user interface by running the application from the location to which you extracted the contents of the toolkit compressed file.

Note:

- To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
  - In Windows File Explorer, navigate to the `USER_HOME\AppData\Local\Programs\api-designer` folder.
  - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
- To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

## Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see [Developing your APIs and applications](#).

For information on using the toolkit CLI, see [Using the developer toolkit command-line tool](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Logging in from API Designer

To log in from the API Designer user interface for IBM® API Connect, you will need the host name of the management server and the user name and password associated with your API Manager account.

---

### About this task

API Designer provides a secure login to a management server for staging and publishing APIs and Products. You log in to the same host that was configured for API Manager and use your API Manager user name and password. You will need an account on API Manager and membership in a provider organization to access the API Designer.

You can also use the **Explorer** tab to see how your APIs look to a consumer. You can check the descriptions of the different artifacts, and refine any schemas or examples.

Note:

- Configuration changes that are made in API Manager are not available in API Designer concurrently. You will need to log out of API Designer and log back in to access any updates.
- Set `SKIP_IBMID_LOGIN=true` as an environment variable to bypass the IBM ID login screen for API Designer. This applies to users who are working on an internal network, without access to external networks.
- API Designer supports the following OIDC user registries:
  - IBM ID User Registry
  - Google
  - Keycloak
  - Slack
  - Twitter

---

### Procedure

To log in to API Designer, complete the following steps:

1. Download and extract API Designer, as described in [Installing the toolkit](#).
2. Launch the API Designer user interface by running the application from the location where you extracted the contents of the toolkit compressed file.
3. Optional: If you receive the Accept License page, click the URL read the license agreement, then click the button to accept the license. This prompt appears only one time. It does not appear once you have accepted the license on the current system.
4. Optional: If you receive the IBM ID login page, enter your IBM customer ID.  
Note: You won't receive the IBM ID page if you are already authorized, or if you have set the `SKIP_IBMID_LOGIN` environment variable to `true`.
5. Open a directory on your local file system to store the API and Product specifications that you create in API Designer. The system defaults to a previously-accessed directory.  
Note: If you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, don't copy the file into your API Designer directory.  
Such an API will **not** be visible in the API Designer user interface if it doesn't contain the API Connect specific sections that are required by API Designer.  
  
Instead, copy the OpenAPI definition file to another folder, then import it into API Designer; the import operation adds the necessary API Connect specific sections; see [Adding a REST API by importing an OpenAPI definition file](#).  
  
For more information on the API Connect specific sections in an OpenAPI definition file, see [IBM extensions to the OpenAPI specification](#).
6. If this is the first time you have logged in, establish a cloud connection for API Connect by following these steps:
  - In the dialog window, enter the valid HOST URL of the management server where your API Manager account exists in the form `https://hostname.domain`
  - Click Next.
  - Enter the user name and password for your API Manager account.
  - Select the User Registry from the list.
  - Click Sign In.
7. For subsequent log ins, select the appropriate cloud where you will be working. You can select from any previous cloud connections.
8. When more than one cloud connection is configured, you can switch clouds when developing APIs and Products. See [Switching clouds from API Designer](#).  
Note: If you are using an OIDC user registry that supports single sign-on (SSO), you cannot switch clouds to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then select the required cloud connection.
9. Click Add Another Cloud to add another cloud connection. Enter the URL, user name and password, and user registry to add the cloud connection.  
Note: If you are using an OIDC user registry that supports single sign-on (SSO), and you are already logged in, you cannot add a new cloud connection to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then add the new cloud connection.
10. Delete a cloud connection by selecting the trash can icon.
11. API Designer will launch with the organization set to your provider organization in the selected cloud. If you have accounts for multiple provider organizations, it will default to the first organization in alphabetical order.
12. To choose another provider organization, select it from the drop-down list.
  - [Switching clouds from API Designer](#)  
You can switch clouds to work in another cloud in API Designer.
  - [Working offline with API Designer](#)  
You can work offline (without a connection to the cloud) with API Designer to create APIs. Some functionality is missing due to the lack of a cloud connection.

---

---

## Switching clouds from API Designer

You can switch clouds to work in another cloud in API Designer.

### About this task

---

API Designer allows the flexibility to connect to multiple clouds. For example, your organization may have separate clouds for testing, development, and demos. You select the cloud connection when you log in, but you can also switch clouds when you are developing APIs and Products. Multiple clouds must be configured in order to switch clouds. You must have a valid API Manager account to connect to a cloud.

**Note:** If you are using an OIDC user registry that supports single sign-on (SSO), you cannot switch clouds to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then select the required cloud connection.

### Procedure

---

To switch clouds for working in API Designer, complete the following steps:

1. Log in to API Designer and select a cloud, or configure a new cloud connection.
2. From the Develop: APIs and Products screen, you can switch to another cloud by selecting it from the Switch Cloud Connection menu.
3. Delete a cloud connection by selecting the trash can icon.

### Related information

---

- [Activating your API Manager user account](#)
- [Creating a provider organization account](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Working offline with API Designer

You can work offline (without a connection to the cloud) with API Designer to create APIs. Some functionality is missing due to the lack of a cloud connection.

### About this task

---

API Designer provides the capability to work in offline mode without a connection to a management server. You can work on APIs with no management server, but some functions will be changed or missing.

The preferred method for working in API Designer is with a Cloud Connection to the management server when logging into API Designer. Working while connected to a management server provides full functionality, with automatic field completion. When working offline, you will need to remember the values to complete the fields that are backfilled from the management server.

Following are the differences when working in offline mode:

- There is no connection to a management server.
- There is no Provider Organization selection.
- Only the Develop APIs and Products tile may be selected. The Learn more and Connect menu tiles are not available.
- When creating an API, the Gateway Type defaults to V5 Gateway and the default policies are loaded.
- Stage and Publish for APIs and Products functions are not available.
- The Sandbox catalog is not available.
- When configuring a Security Definition, there are no selection lists available for the User Registry for a Basic Auth security definition or for the OAuth Provider for an OAuth 2 security definition. You will need to enter the User Registry and OAuth Provider values correctly as text.
- When adding custom Visibility and custom Subscribability values for a product, there is no selection list for the Organization field. You will need to enter the organization name correctly as text.

### Procedure

---

To work in offline mode in API Designer, complete the following steps:

1. Log in to API Designer and open a directory location.
2. To start offline mode, choose Work Offline from the selector in the upper right corner of the Connect to Cloud screen.

3. The Home page appears with the Develop APIs and Products tile. Select Develop APIs and Products to start working in offline mode.
4. To return to online mode, choose Connect to Cloud in the upper right hand corner and select the management server to log in to.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Using the developer toolkit command-line tool

The IBM® API Connect developer toolkit provides a command-line tool, **apic**, that you can use to perform all API Connect tasks. You can also use the command-line tool to script tasks such as continuous integration and delivery.

The command line tool is described in detail in the following subtopics. For summary reference material for each of the available commands for the developer toolkit, see [Command-line tool reference for the developer toolkit](#).

- [Overview of the command-line tool](#)  
The IBM API Connect developer toolkit provides commands for cloud administration and API development and management.
- [Logging in to a management server](#)  
You log in to a management server from the command line by using the **apic login** command. The parameters that you supply determine the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.
- [Cloud administration commands](#)  
A summary of the cloud administration commands in the IBM API Connect developer toolkit.
- [API development and management commands](#)  
A summary of the core commands in the IBM API Connect developer toolkit.
- [Creating APIs and applications](#)  
You can develop API proxies and API implementations by using the developer toolkit. In the documentation, *API* refers to the API proxy and *application* refers to the API implementation.
- [Publishing APIs and applications](#)  
To publish APIs and applications by using the developer toolkit of IBM API Connect, you set configuration variables to define where you want to publish, log in to the target cloud platform, and then use the appropriate publishing commands.
- [Managing API Products](#)  
Use the **apic products** and **apic apis** commands to manage Products and APIs that have been published to IBM API Connect Catalogs. Use the **--scope space** option to manage Products and APIs that have been published to Spaces within Catalogs.
- [Working with Drafts](#)  
Co-locate your APIs and applications in your local source code control systems to support typical development activities such as commits, branching, merges, continuous integration, and so on. The developer toolkit provides the bridge from the developer's environment to the IBM API Connect runtime services.
- [Reading input from the command line](#)  
If a developer toolkit command takes a file as an input parameter, you can direct the command to read the input directly from the command line rather than supplying a separate file; this can be useful when writing scripts to automate command line operations, for example.
- [Scripting with the toolkit commands](#)  
The IBM API Connect developer toolkit provides commands for cloud administration and API development and management.
- [Working with OpenAPI extensions](#)  
Use the developer toolkit CLI **extensions** commands to manage OpenAPI extensions in your Catalogs or Spaces.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Overview of the command-line tool

The IBM® API Connect developer toolkit provides commands for cloud administration and API development and management.

### Command syntax

---

In general, commands have the following syntax:

```
apic command:sub-command [argument] [options]
```

where

- *command* is the command, usually the thing on which you are acting (for example, product, app, API, Catalogs, and so on).
- *sub-command* is the action to perform.
- *argument* is the argument, where applicable (for example, **catalog**).
- *options* are any number of command-line options, which have the form **--option [value]**. Options also have a short form with a single dash instead of a double dash.

For example, **apic apps:publish --server mgmthost.com**.

For some commands, either the command or sub-command portion is optional. For example:

- **apic products:publish** is equivalent to **apic publish**.
- **apic products:list** is equivalent to **apic products**.

The **create** command has a slightly different syntax:

`apic create:type [options]`

Use the `-h` or `--help` option to view command help.

Note: The language in which the CLI help text, and other command response text, is displayed is determined by the locale setting on your local machine.

## Viewing command line tool help

Display general command-line help information by entering the following command: `apic --help` or `apic -h`. Display help information for a specific `apic` command by entering the following command: `apic command_name --help` or `apic command_name -h`.

## Viewing version information

Display the version of the command-line tool by entering the command: `apic --version`.

## Using configuration variables

You can set the values of commonly-used properties in configuration variables. In general, it's easier and more consistent to set configuration variables instead of specifying them using command-line options.

Note:

You can set a configuration variable locally (the default) to affect only the current LoopBack project, or globally (with command-line option `-g`), to affect all projects. The local value supersedes the global value. You can set local configuration variables only for LoopBack projects. When you set configuration variables for OpenAPI projects, they are always global.

The values of local configuration variables are stored in the `project-root/.apiconnect/config` file, where `project-root` is the project root directory. The values of global configuration variables are stored in the `user-home-dir/.apiconnect/config` file, where `user-home-dir` is the user's home directory.

Use the following commands to work with configuration variables:

- `apic config:get varname` - Get a configuration variable. Use `apic config` to display the values of all local configuration variables or `apic config -g` to display the values of all global configuration variables.
- `apic config:set varname` - Set or update the specified configuration variable.
- `apic config:delete varname` - Delete the specified configuration variable.
- `apic config:clear` - Delete all configuration variables.

You set configuration property values by using the `apic config:set` command. By setting configuration properties (for example `catalog` and `app`), you do not need to supply values for these options when you enter a command.

Additionally, you can use `apic properties` commands to work with configuration properties:

- `apic properties:clear` - Clear the configuration properties.
- `apic properties:create` - Augment the configuration properties with additional name/value pairs.
- `apic properties:delete` - Delete the configuration property.
- `apic properties:get` - Get the configuration property.
- `apic properties:list` - List the configuration properties.
- `apic properties:update` - Update the configuration property.

Note:

If you have an environment variable of the same name as a CLI configuration property then, by default, its value will override the value of the corresponding CLI configuration property for any CLI command at that scope.

For example, if you have defined an environment variable called `SPACE` then, by default, that value will be assumed for the value of the `--space` parameter in the following command, regardless of any `space` configuration property setting:

```
apic products:publish my_product.yaml --scope space
```

To prevent environment variables overriding CLI configuration properties, define an environment variable called `APIC_LOAD_FROM_ENV`, set to the value `false`.

The following table describes the configuration variables:

Table 1. Configuration variables

Variable name	Description	Use instead of (or override with) these flags...
catalog	Default Catalog URI for all commands that manage aspects of a Catalog. Form: <code>mgmt-server/api/catalogs/org-name/catalog-name</code> , where <code>mgmt-server</code> is the management server, <code>org-name</code> is the organization name, and <code>catalog-name</code> is the Catalog name.  Note: The Catalog name <code>apic-dev</code> is reserved for local testing.	<code>--catalog</code> , <code>--organization</code> , <code>--server</code>
cloud	Default management server host name for cloud administration commands. Form: <code>mgmt-server/api/</code> .	<code>--server</code>
consumer	Default URI of an API consumer. Form: <code>mgmt-server/api/consumer-orgs/org-name/catalog-name/consumer-org-name</code> , where <code>mgmt-server</code> is the management server, <code>org-name</code> is the organization name, <code>catalog-name</code> is the Catalog name, and <code>consumer-org-name</code> is the consumer organization name.	<code>--server</code> , <code>--organization</code> , <code>--catalog</code> , <code>--consumer</code>
mode	The default value of the <code>--mode</code> parameter for CLI commands. Set the value to <code>apim</code> or <code>consumer</code> depending on whether you want to run commands on a provider organization or a consumer organization. If you do not set this variable, and do not supply a <code>--mode</code> parameter on a command, the value <code>apim</code> is assumed.	<code>--mode</code>

Variable name	Description	Use instead of (or override with) these flags...
org	Default org URI for all commands that manage organizations. Form: <code>mgmt-server/api/orgs/org-name</code> , where <code>mgmt-server</code> is the management server, <code>org-name</code> is the organization name.  The <code>mgmt-server</code> portion sets the default value of the <code>--server</code> option.  You can append the port number to the server name if it is not the default value of 443.	--organization, --server
space	Default Space URI for all commands that manage aspects of a Space. Form: <code>mgmt-server/api/spaces/org-name/catalog-name/space-name</code> , where <code>mgmt-server</code> is the management server, <code>org-name</code> is the organization name, <code>catalog-name</code> is the Catalog name, and <code>space-name</code> is the Space name.  You can append the port number to the server name if it is not the default value of 443.	--server, --organization, --catalog, --space

To set configuration properties, enter the following command:

```
apic config:set name=value
```

where `name` is the name of the configuration property and `value` the value to assign to it.

For example:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
```

## Scripting commands

It's often helpful to automate a series of `apic` commands in a shell script. Since the `apic` tool first requires you to interactively accept the license, you must first use the following command:

```
apic --accept-license
```

Once you do that, your scripts can run non-interactively.

To disable collection of usage analytics, enter this command:

```
apic --live-help
```

## Related information

- [Command-line tool reference for the developer toolkit](#)

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Logging in to a management server

You log in to a management server from the command line by using the `apic login` command.

The parameters that you supply determine the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.

Note: You cannot use the CLI to log in to a management server that uses an OIDC user registry for authentication, because browser access is required for OIDC log in.

To log in to the management server from the command line, enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm realm
```

The parameters for the `apic login` command are as follows:

`mgmt_endpoint_url`

Either the platform API endpoint URL, or the consumer API endpoint URL. Use the platform API endpoint URL if you are logging in as a member of a cloud administration organization or provider organization, and the consumer API endpoint URL if you are logging in as a member of a consumer organization. These endpoint URLs are configured during the installation of API Connect, as described in [Installing the Management subsystem into a Kubernetes environment](#) and [Deploying the Management subsystem in a VMware environment](#). If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in [Viewing platform and UI endpoints](#), ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

`user_id`

The user ID you want to log in with. Depending on the tasks that you want to perform, this user ID might be any of the following:

- A user ID that is a member of the cloud administration organization. This is an ID that you could also use to log in to the Cloud Manager user interface.
- A user ID that is a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
- A user ID that is a member of a consumer organization. This is an ID that you could also use to log in to the Developer Portal.

`password`

The password associated with the supplied user ID.

`realm`

The `realm` parameter specifies the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.

The format of the *realm* depends on the type of user, as follows:

- Member of the cloud administration organization:

```
admin/identity_provider
```

To determine the identity provider, see [How to determine the identity provider](#).

- Member of a provider organization:

```
provider/identity_provider
```

To determine the identity provider, see [How to determine the identity provider](#).

- Member of a consumer organization:

```
consumer:provider_org:catalog/identity_provider
```

where *provider\_org* is the name of your provider organization, and *catalog* is the name of the Catalog in that provider organization.

To determine the identity provider, see [How to determine the identity provider](#).

Important: If you log in to the CLI as a member of a consumer organization, you must supply the `--mode=consumer` parameter to the `apic login` command, and to all consumer commands. To avoid having to type the parameter every time, you can set the `mode` configuration variable, by entering the following command:

```
apic config:set mode=consumer
```

You can also use the command interactively; enter `apic login` and you will be prompted for the values. For example:

```
apic login
Enter your API Connect credentials
Server? platform-api.myserver.com
Realm? provider/default-idp-2
Username? myuser
Password?
Logged into myserver.com successfully
```

## How to determine the identity provider

If you want to log in as a member of the cloud administration organization, or as a member of a provider organization, you can help determine which identity provider to use in the *realm* parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope scope --server mgmt_endpoint_url --fields name,title
```

where *scope* has the value `admin` or `provider` depending on whether you want to log in as a member of the cloud administration organization, or as a member of a provider organization. The output lists the names and titles of all identity providers, for example:

```
apic identity-providers:list --scope admin --server myserver.com --fields name,title
total_results: 2
results:
- name: default-idp-1
  title: Cloud Manager User Registry
- name: corporate-ldap
  title: Corporate LDAP user registry
```

The `title` value should enable you to determine which identity provider to use; the corresponding `name` value is what you specify in the *realm* parameter.

For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time.

By default, API Connect creates a local user registry for user login for every context. The identity providers associated with these default registries are as follows:

Registry	Identity provider name
Cloud Manager Local User Registry (for login as a member of the cloud administration organization)	default-idp-1
API Manager Local User Registry (for login as a member of a provider organization)	default-idp-2
Sandbox Catalog User Registry (for login as a member of a consumer organization)	sandbox-idp

If you want to log in as a member of a consumer organization, and you are not using the default Sandbox Catalog User Registry, ask your administrator for the name of your identity provider.

## Logging out

To log out of a management server, use the following command:

```
apic logout --server mgmt_endpoint_url
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Cloud administration commands

A summary of the cloud administration commands in the IBM® API Connect developer toolkit.

## Authenticating

Use the `apic login` command to authenticate to an API Manager service, and the `apic logout` command to remove your local authentication credentials.

Note: When you authenticate successfully, your credentials are stored, in plain text, in the file `Linux .netrc` or `Windows _netrc`. You should therefore set the file permissions in such a way that your credentials are not accessible by others.

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

## Configuring the command-line tool to use TLS certificates

API Manager uses TLS profiles to secure data transmission. For information on how to create a TLS profile in API Manager, see [TLS profiles](#).

To configure the toolkit command-line tool to use certificates to communicate with an API Manager that has TLS profiles enabled, follow these steps:

For more information about the `NODE_EXTRA_CA_CERTS` environment variable, see [Node.js documentation](#).

Note: When using any CLI command that applies directly to the configuration of your IBM API Connect cloud, you must supply the parameter setting `--org admin` for a command that requires an organization name as a parameter.

## Command summary

The following tables summarize `apic` commands for cloud administration.

Table 1. Summary commands for cloud administrators

Command	Description	Sub-commands
<code>apic analytics-services</code>	Analytics Service commands	<ul style="list-style-type: none"> <li><code>apic analytics-services</code> - Analytics Service collection operations.</li> <li><code>apic analytics-services:clear</code> - Clear the Analytics Services.</li> <li><code>apic analytics-services:create</code> - Create a Analytics Service.</li> <li><code>apic analytics-services:delete</code> - Delete the Analytics Service by name or ID.</li> <li><code>apic analytics-services:get</code> - Get the Analytics Service by name or ID.</li> <li><code>apic analytics-services:list</code> - List the Analytics Services.</li> <li><code>apic analytics-services:update</code> - Update the Analytics Service by name or ID.</li> </ul>
<code>apic associates</code>	Associates commands	<ul style="list-style-type: none"> <li><code>apic associates</code> - Associate collection operations.</li> <li><code>apic associates:get</code> - Get the Associate by name or ID.</li> <li><code>apic associates:list</code> - List the Associates.</li> </ul>
<code>apic availability-zones</code>	Availability Zone commands	<ul style="list-style-type: none"> <li><code>apic availability-zones</code> - Availability Zone collection operations.</li> <li><code>apic availability-zones:clear</code> - Clear the Availability Zones.</li> <li><code>apic availability-zones:create</code> - Create a Availability Zone.</li> <li><code>apic availability-zones:delete</code> - Delete the Availability Zone by name or ID.</li> <li><code>apic availability-zones:get</code> - Get the Availability Zone by name or ID.</li> <li><code>apic availability-zones:list</code> - List the Availability Zones.</li> <li><code>apic availability-zones:update</code> - Update the Availability Zone by name or ID.</li> </ul>
<code>apic cloud-settings</code>	Cloud settings commands	<ul style="list-style-type: none"> <li><code>apic cloud-settings:get</code> - Get the Cloud Setting.</li> <li><code>apic cloud-settings:mail-server-configured</code> - indicates whether a mail server has been configured.</li> <li><code>apic cloud-settings:topology</code> - Returns summary details of the configuration of your cloud topology.</li> <li><code>apic cloud-settings:update</code> - Update the Cloud Setting.</li> </ul>
<code>apic configured-gateway-services</code>	Commands for Configured Gateway Services in a Catalog or Space.	<ul style="list-style-type: none"> <li><code>apic configured-gateway-services</code> - Configured Gateway Services operations.</li> <li><code>apic configured-gateway-services:clear</code> - Delete all Configured Gateway Services from a Catalog or Space.</li> <li><code>apic configured-gateway-services:create</code> - Configure a Gateway Service in a Catalog or Space.</li> <li><code>apic configured-gateway-services:delete</code> - Delete a Configured Gateway Service from a Catalog or Space.</li> <li><code>apic configured-gateway-services:get</code> - Obtain the details of a Configured Gateway Service in a Catalog or Space.</li> <li><code>apic configured-gateway-services:list</code> - List the Configured Gateway Services in a Catalog or Space.</li> </ul>
<code>apic credentials</code>	Credential commands	<ul style="list-style-type: none"> <li><code>apic credentials</code> - Application Credential collection operations.</li> <li><code>apic credentials:clear</code> - Clear the Application Credentials.</li> <li><code>apic credentials:create</code> - Create a Application Credential.</li> <li><code>apic credentials:delete</code> - Delete the Application Credential by name or ID.</li> <li><code>apic credentials:get</code> - Get the Application Credential by name or ID.</li> <li><code>apic credentials:list</code> - List the Application Credentials.</li> <li><code>apic credentials:reset</code> - Reset the client id and client secret.</li> <li><code>apic credentials:reset-client-secret</code> - Reset the client secret.</li> <li><code>apic credentials:update</code> - Update the Application Credential by name or ID.</li> <li><code>apic credentials:verify-client-secret</code> - Verify the client secret.</li> </ul>

Command	Description	Sub-commands
<b>apic extensions</b>	Extension commands	<ul style="list-style-type: none"> <li>• <b>apic extensions</b> - Extension collection operations.</li> <li>• <b>apic extensions:document</b> - Get the document for an extension by id, or by name and version.</li> <li>• <b>apic extensions:get</b> - Get an extension by id, or by name and version.</li> <li>• <b>apic extensions:list</b> - List all versions of an extension given the name.</li> <li>• <b>apic extensions:list-all</b> - List all versions of all extensions.</li> </ul>
<b>apic gateway-services</b>	Gateway service commands	<ul style="list-style-type: none"> <li>• <b>apic gateway-services</b> - Gateway Service collection operations.</li> <li>• <b>apic gateway-services:clear</b> - Clear the Gateway Services.</li> <li>• <b>apic gateway-services:create</b> - Create a Gateway Service.</li> <li>• <b>apic gateway-services:delete</b> - Delete the Gateway Service by name or ID.</li> <li>• <b>apic gateway-services:get</b> - Get the Gateway Service by name or ID.</li> <li>• <b>apic gateway-services:list</b> - List the Gateway Services.</li> <li>• <b>apic gateway-services:reset-oauth-secret</b> - Reset the OAuth cryptographic</li> <li>• <b>apic gateway-services:update</b> - Update the Gateway Service by name or ID.</li> </ul>
<b>apic integrations</b>	Integrations commands	<ul style="list-style-type: none"> <li>• <b>apic integrations</b> - Integration collection operations.</li> <li>• <b>apic integrations:clear</b> - Clear the Integrations.</li> <li>• <b>apic integrations:clear-all</b> - Clear all of the Integrations in all of the collections.</li> <li>• <b>apic integrations:create</b> - Create a Integration.</li> <li>• <b>apic integrations:delete</b> - Delete the Integration by name or ID.</li> <li>• <b>apic integrations:get</b> - Get the Integration by name or ID.</li> <li>• <b>apic integrations:list</b> - List the Integrations.</li> <li>• <b>apic integrations:list-all</b> - List all Integrations in all collections.</li> <li>• <b>apic integrations:update</b> - Update the Integration by name or ID.</li> </ul>
<b>apic keystores</b>	Keystores commands	<ul style="list-style-type: none"> <li>• <b>apic keystores</b> - Keystore collection operations.</li> <li>• <b>apic keystores:clear</b> - Clear the Keystores.</li> <li>• <b>apic keystores:create</b> - Create a Keystore.</li> <li>• <b>apic keystores:delete</b> - Delete the Keystore by name or ID.</li> <li>• <b>apic keystores:get</b> - Get the Keystore by name or ID.</li> <li>• <b>apic keystores:list</b> - List the Keystores.</li> <li>• <b>apic keystores:update</b> - Update the Keystore by name or ID.</li> </ul>
<b>apic mail-servers</b>	Mail server commands	<ul style="list-style-type: none"> <li>• <b>apic mail-servers</b> - Mail Server collection operations.</li> <li>• <b>apic mail-servers:clear</b> - Clear the Mail Servers.</li> <li>• <b>apic mail-servers:create</b> - Create a Mail Server.</li> <li>• <b>apic mail-servers:delete</b> - Delete the Mail Server by name or ID.</li> <li>• <b>apic mail-servers:get</b> - Get the Mail Server by name or ID.</li> <li>• <b>apic mail-servers:list</b> - List the Mail Servers.</li> <li>• <b>apic mail-servers:test-connection</b> - Test a mail server connection.</li> <li>• <b>apic mail-servers:update</b> - Update the Mail Server by name or ID.</li> </ul>
<b>apic notification-templates</b>	Notification template commands	<ul style="list-style-type: none"> <li>• <b>apic notification-templates</b> - Notification Template collection operations.</li> <li>• <b>apic notification-templates:get</b> - Get the Notification Template by name or ID.</li> <li>• <b>apic notification-templates:list</b> - List the Notification Templates.</li> <li>• <b>apic notification-templates:list-all</b> - List all Notification Templates in all collections.</li> <li>• <b>apic notification-templates:update</b> - Update the Notification Template by name or ID.</li> </ul>
<b>apic permissions</b>	Permissions commands	<ul style="list-style-type: none"> <li>• <b>apic permissions</b> - Permission collection operations.</li> <li>• <b>apic permissions:get</b> - Get the Permission by name or ID.</li> <li>• <b>apic permissions:list</b> - List the Permissions.</li> <li>• <b>apic permissions:list-all</b> - List all Permissions in all collections.</li> </ul>
<b>apic portal-services</b>	Portal services commands	<ul style="list-style-type: none"> <li>• <b>apic portal-services</b> - Portal Service collection operations.</li> <li>• <b>apic portal-services:clear</b> - Clear the Portal Services.</li> <li>• <b>apic portal-services:create</b> - Create a Portal Service.</li> <li>• <b>apic portal-services:delete</b> - Delete the Portal Service by name or ID.</li> <li>• <b>apic portal-services:get</b> - Get the Portal Service by name or ID.</li> <li>• <b>apic portal-services:list</b> - List the Portal Services.</li> <li>• <b>apic portal-services:update</b> - Update the Portal Service by name or ID.</li> </ul>
<b>apic services</b>	Services commands	<ul style="list-style-type: none"> <li>• <b>apic services</b> - Service collection operations.</li> <li>• <b>apic services:clear</b> - Clear the Services.</li> <li>• <b>apic services:clear-all</b> - Clear all Services in all collections.</li> <li>• <b>apic services:create</b> - Create a Service.</li> <li>• <b>apic services:delete</b> - Delete a Service.</li> <li>• <b>apic services:get</b> - Get the Service by name and version.</li> <li>• <b>apic services:list</b> - List the Services.</li> <li>• <b>apic services:list-all</b> - List all Services in all collections.</li> <li>• <b>apic services:update</b> - Update the Service by name and version.</li> </ul>

Command	Description	Sub-commands
<code>apic space-settings</code>	Space settings commands	<ul style="list-style-type: none"> <li>• <code>apic space-settings:get</code> - Get the Space Setting.</li> <li>• <code>apic space-settings:update</code> - Update the Space Setting.</li> </ul>
<code>apic spaces</code>	Space commands	<ul style="list-style-type: none"> <li>• <code>apic spaces</code> - Space collection operations.</li> <li>• <code>apic spaces:clear</code> - Clear the Spaces.</li> <li>• <code>apic spaces:create</code> - Create a Space.</li> <li>• <code>apic spaces:delete</code> - Delete the Space by name or ID.</li> <li>• <code>apic spaces:get</code> - Get the Space by name or ID.</li> <li>• <code>apic spaces:list</code> - List the Spaces.</li> <li>• <code>apic spaces:transfer-owner</code> - Transfer owner to a new member.</li> <li>• <code>apic spaces:update</code> - Update the Space by name or ID.</li> </ul>
<code>apic tls-client-profiles</code>	TLS client profile commands	<ul style="list-style-type: none"> <li>• <code>apic tls-client-profiles</code> - TLS Client Profile collection operations.</li> <li>• <code>apic tls-client-profiles:clear</code> - Clear the TLS Client Profiles.</li> <li>• <code>apic tls-client-profiles:clear-all</code> - Clear all of the TLS Client Profiles in the collection.</li> <li>• <code>apic tls-client-profiles:create</code> - Create a TLS Client Profile.</li> <li>• <code>apic tls-client-profiles:delete</code> - Delete the TLS Client Profile by name or ID.</li> <li>• <code>apic tls-client-profiles:get</code> - Get the TLS Client Profile by name or ID.</li> <li>• <code>apic tls-client-profiles:list</code> - List the TLS Client Profiles.</li> <li>• <code>apic tls-client-profiles:list-all</code> - Lists all of the TLS Client Profiles in a collection.</li> <li>• <code>apic tls-client-profiles:update</code> - Update the TLS Client Profile by name or ID.</li> </ul>
<code>apic tls-server-profiles</code>	TLS server profile commands	<ul style="list-style-type: none"> <li>• <code>apic tls-server-profiles</code> - TLS Server Profile collection operations.</li> <li>• <code>apic tls-server-profiles:clear</code> - Clear the TLS Server Profiles.</li> <li>• <code>apic tls-server-profiles:clear-all</code> - Clear all of the TLS Server Profiles in the collection.</li> <li>• <code>apic tls-server-profiles:create</code> - Create a TLS Server Profile.</li> <li>• <code>apic tls-server-profiles:delete</code> - Delete the TLS Server Profile by name or ID.</li> <li>• <code>apic tls-server-profiles:get</code> - Get the TLS Server Profile by name or ID.</li> <li>• <code>apic tls-server-profiles:list</code> - List the TLS Server Profiles.</li> <li>• <code>apic tls-server-profiles:list-all</code> - List all of the TLS Server Profiles in the collection.</li> <li>• <code>apic tls-server-profiles:update</code> - Update the TLS Server Profile by name or ID.</li> </ul>
<code>apic truststores</code>	Truststore commands	<ul style="list-style-type: none"> <li>• <code>apic truststores</code> - Truststore collection operations.</li> <li>• <code>apic truststores:clear</code> - Clear the Truststores.</li> <li>• <code>apic truststores:create</code> - Create a Truststore.</li> <li>• <code>apic truststores:delete</code> - Delete the Truststore by name or ID.</li> <li>• <code>apic truststores:get</code> - Get the Truststore by name or ID.</li> <li>• <code>apic truststores:list</code> - List the Truststores.</li> <li>• <code>apic truststores:update</code> - Update the Truststore by name or ID.</li> </ul>
<code>apic user-registries</code>	User registry commands	<ul style="list-style-type: none"> <li>• <code>apic user-registries</code> - User Registry collection operations.</li> <li>• <code>apic user-registries:clear</code> - Clear the User Registries.</li> <li>• <code>apic user-registries:create</code> - Create a User Registry.</li> <li>• <code>apic user-registries:delete</code> - Delete the User Registry by name or ID.</li> <li>• <code>apic user-registries:execute</code> - Execute a User Registry operation.</li> <li>• <code>apic user-registries:get</code> - Get the User Registry by name or ID.</li> <li>• <code>apic user-registries:list</code> - List the User Registries.</li> <li>• <code>apic user-registries:search</code> - search for users in a user registry.</li> <li>• <code>apic user-registries:test-connection</code> - Test a User Registry connection.</li> <li>• <code>apic user-registries:update</code> - Update the User Registry by name or ID.</li> </ul>
<code>apic user-registry-settings</code>	User registry settings commands	<ul style="list-style-type: none"> <li>• <code>apic user-registry-settings:get</code> - Get the User Registry Setting.</li> <li>• <code>apic user-registry-settings:update</code> - Update the User Registry Setting.</li> </ul>
<code>apic users</code>	Users commands	<ul style="list-style-type: none"> <li>• <code>apic users</code> - User collection operations.</li> <li>• <code>apic users:clear</code> - Clear the Users.</li> <li>• <code>apic users:create</code> - Create a User.</li> <li>• <code>apic users:delete</code> - Delete the User by name or ID.</li> <li>• <code>apic users:get</code> - Get the User by name or ID.</li> <li>• <code>apic users:list</code> - List the Users.</li> <li>• <code>apic users:request-password-reset</code> - send a password reset link.</li> <li>• <code>apic users:search-provider</code> - Search for provider users from an organization.</li> <li>• <code>apic users:update</code> - Update the User by name or ID.</li> </ul>
<code>apic webhooks</code>	Webhooks commands	<ul style="list-style-type: none"> <li>• <code>apic webhooks</code> - Webhooks collection operations.</li> <li>• <code>apic webhooks:get</code> - Get the Webhooks by name or ID.</li> <li>• <code>apic webhooks:list</code> - List the Webhooks.</li> <li>• <code>apic webhooks:update</code> - Update the Webhooks by name or ID.</li> </ul>

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## API development and management commands

A summary of the core commands in the IBM® API Connect developer toolkit.

### Authenticating

Use the `apic login` command to authenticate to an API Manager service, and the `apic logout` command to remove your local authentication credentials.

Note: When you authenticate successfully, your credentials are stored, in plain text, in the file `Linux .netrc` or `Windows _netrc`. You should therefore set the file permissions in such a way that your credentials are not accessible by others.

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

### Configuring the command-line tool to use TLS certificates

API Manager uses TLS profiles to secure data transmission. For information on how to create a TLS profile in API Manager, see [TLS profiles](#).

To configure the toolkit command-line tool to use certificates to communicate with an API Manager that has TLS profiles enabled, follow these steps:

For more information about the `NODE_EXTRA_CA_CERTS` environment variable, see [Node.js documentation](#).

### Creating and managing local files

You create and work with API and Product definition YAML files locally before you stage them to API Manager.

To create a local API definition file, use the `apic create:api` command. To create a local Product definition file, use the `apic create:product` command.

Use the `apic apis` and `apic products` commands to list API Manager artifacts of the specified type.

To validate the syntactical correctness of a local API or Product definition file, use the `apic validate` command.

To create a draft API in API Manager from a local API or Product definition file, use the `apic draft-apis:create` and `apic draft-products:create` commands, respectively.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before an API is validated, created in draft, staged, or published. For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

### Working with Catalogs and Spaces

To create a Catalog, use the `apic catalog:create` command. To view information on a Catalog, use the `apic catalog:get` command; to list all Catalogs contained in organizations that the currently authenticated user is a member of, use the `apic catalogs` command.

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a sub-catalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see [Using syndication in IBM API Connect](#).

To enable Spaces for a Catalog, use the following command:

```
apic catalogs:set catalog_name --spaces enabled
```

Use the toolkit `apic spaces` commands to create and manage Spaces:

- `apic spaces` - List Spaces contained in a Catalog.
- `apic:spaces create` - Create a Space in a Catalog.
- `apic:spaces get` - Get information on a Space in a Catalog.
- `apic:spaces set` - Set information on a Space in a Catalog.
- `apic:spaces delete` - Delete a Space in a Catalog.

### Command summary

The following tables summarize `apic` commands for API development and management.

Table 1. Summary of general-purpose commands

Command	Description	Sub-commands
<code>apic config</code>	List and manage configuration variables. For more information, see <a href="#">Using configuration variables</a> . With no sub-command, lists values of defined configuration variables.	<ul style="list-style-type: none"><li>• <code>apic config</code> - Manage configuration variables</li><li>• <code>apic config:clear</code> - Delete all configuration variables</li><li>• <code>apic config:delete</code> - Delete a configuration variable</li><li>• <code>apic config:get</code> - Get a configuration variable</li><li>• <code>apic config:list</code> - List the application and global configuration variables</li><li>• <code>apic config:set</code> - Set or update configuration variables</li></ul>

Command	Description	Sub-commands
<b>apic create</b>	Create a draft API or Product definition YAML file.	<ul style="list-style-type: none"> <li>• <b>create:api</b> - Create a draft API OpenAPI definition YAML file</li> <li>• <b>create:product</b> - Create a Product definition YAML file</li> </ul>
<b>apic extensions</b>	Manage OpenAPI extensions in a Catalog. With no sub-command, lists the extensions in the production Catalog.	<ul style="list-style-type: none"> <li>• <b>apic extensions</b> - Extension collection operations.</li> <li>• <b>apic extensions:clear</b> - Delete all versions of an extension given the name.</li> <li>• <b>apic extensions:clear-all</b> - Delete all versions of all extensions.</li> <li>• <b>apic extensions:clone</b> - Download all versions of all extensions to your local drive.</li> <li>• <b>apic extensions:create</b> - Create an extension.</li> <li>• <b>apic extensions:delete</b> - Delete an extension by id, or by name and version.</li> <li>• <b>apic extensions:document</b> - Get the document for an extension by id, or by name and version.</li> <li>• <b>apic extensions:get</b> - Get an extension by id, or by name and version.</li> <li>• <b>apic extensions:list</b> - List all versions of an extension given the name.</li> <li>• <b>apic extensions:list-all</b> - List all versions of all extensions.</li> <li>• <b>apic extensions:update</b> - Update an extension by id, or by name and version.</li> </ul>
<b>apic lb</b>	Create LoopBack® project and project artifacts. With no sub-command, creates a new LoopBack project.	<ul style="list-style-type: none"> <li>• <b>acl</b> - Add access control list specification</li> <li>• <b>app</b> - Create a new LoopBack project (default)</li> <li>• <b>boot-script</b> - Add boot script</li> <li>• <b>datasource</b> - Create data source</li> <li>• <b>export-api-def</b> - Generate OpenAPI definitions from models</li> <li>• <b>middleware</b> - Add middleware function</li> <li>• <b>model</b> - Create model.</li> <li>• <b>oracle</b> - Utility to help install LoopBack Oracle connector</li> <li>• <b>property</b> - Add property to existing model</li> <li>• <b>relation</b> - Add relation between models</li> <li>• <b>remote-method</b> - Add remote method</li> <li>• <b>soap</b> - Generate models based on SOAP web service</li> <li>• <b>swagger</b> - Generate LoopBack project from an OpenAPI definition</li> </ul>
<b>apic login</b>	Log in to API Manager.	<p>None. Specify server and credentials with the required flags:</p> <ul style="list-style-type: none"> <li>• <b>-p, --password password</b></li> <li>• <b>-r, --realm realm</b>. Determines the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.</li> <li>• <b>-s, --server mgmt_endpoint_url</b>. Use the value of the platform API endpoint URL for this entry.</li> <li>• <b>-u, --username user_name</b></li> </ul> <p>For full details on how to log in to your management server from the CLI, see <a href="#">Logging in to the management server</a>.</p>
<b>apic logout</b>	Log out from API Manager.	<p>None. Specify server with the required flag:</p> <ul style="list-style-type: none"> <li>• <b>-s, --server mgmt_service</b>.</li> </ul> <p>You can append the port number to the server name if it is not the default value of 443.</p>
<b>apic validate</b>	Validate API or Product definition YAML file.	None

Table 2. Summary of commands to manage APIs, Products, and Catalogs

Command	Description	Sub-commands
<b>apic apis</b>	List and manage APIs that are staged or published to Catalog or Space. Default sub-command is <b>list-all</b> .	<ul style="list-style-type: none"> <li>• <b>apic apis</b> - API collection operations</li> <li>• <b>apic apis:get</b> - Get the OpenAPI definition YAML file for an API by name and version, or by ID</li> <li>• <b>apic apis:list</b> - List an API by name</li> <li>• <b>apic apis:list-all</b> - List all APIs in a Catalog or Space</li> <li>• <b>apic apis:update</b> - Update an API by name</li> </ul>
<b>apic apps</b>	List and manage developer applications that are registered in a consumer organization. Default sub-command is <b>list</b> .	<ul style="list-style-type: none"> <li>• <b>apic apps</b> - Application collection operations</li> <li>• <b>apic apps:clear</b> - Clear all applications</li> <li>• <b>apic apps:create</b> - Create an application</li> <li>• <b>apic apps:delete</b> - Delete an application by name or ID</li> <li>• <b>apic apps:get</b> - Get an application object by name</li> <li>• <b>apic apps:list</b> - List all the applications in a consumer organization</li> <li>• <b>apic apps:update</b> - Update an application by name or ID</li> </ul>
<b>apic catalogs</b>	List and manage Catalogs in a provider organization. Default sub-command is <b>list</b> .	<ul style="list-style-type: none"> <li>• <b>apic catalogs:clear</b> - Clear all Catalogs from provider organization</li> <li>• <b>apic catalogs:create</b> - Create a Catalog</li> <li>• <b>apic catalogs:delete</b> - Delete a Catalog by name or ID</li> <li>• <b>apic catalogs:get</b> - Get a Catalog object by name or ID</li> <li>• <b>apic catalogs:list</b> - List all the Catalogs in a provider organization</li> <li>• <b>apic catalogs:transfer-owner</b> - Transfer the ownership of a Catalog to another user</li> <li>• <b>apic catalogs:update</b> - Update a Catalog by name or ID</li> </ul>

Command	Description	Sub-commands
<b>apic catalog-settings</b>	Manage the configuration settings for a Catalog	<ul style="list-style-type: none"> <li>• <b>apic catalog-settings:get</b> - Get the Catalog settings.</li> <li>• <b>apic catalog-settings:update</b> - Update the Catalog settings.</li> </ul>
<b>apic drafts</b>	List and manage the draft API and Product definitions in a provider organization. Default sub-command is <b>list</b> .	<ul style="list-style-type: none"> <li>• <b>apic drafts</b> - Draft collection operations</li> <li>• <b>apic drafts:clear</b> - Delete all draft APIs and Products in a provider organization</li> <li>• <b>apic drafts:list</b> - List the draft APIs and Products in a provider organization</li> </ul>
<b>apic draft-apis</b>	List and manage the draft API definitions in a provider organization. Default sub-command is <b>list-all</b> .	<ul style="list-style-type: none"> <li>• <b>apic draft-apis</b> - Draft API collection operations</li> <li>• <b>apic draft-apis:clear</b> - Delete all versions of a draft API by name</li> <li>• <b>apic draft-apis:clear-all</b> - Delete all draft APIs in a provider organization</li> <li>• <b>apic draft-apis:create</b> - Create a draft API</li> <li>• <b>apic draft-apis:delete</b> - Delete a Draft API by name and version</li> <li>• <b>apic draft-apis:get</b> - Get the OpenAPI definition YAML file for an API by name and version</li> <li>• <b>apic draft-apis:list</b> - List all versions of a draft API by name</li> <li>• <b>apic draft-apis:list-all</b> - List all draft APIs in a provider organization</li> <li>• <b>apic draft-apis:update</b> - Update a draft API by name and version, supplying the revised OpenAPI definition file</li> <li>• <b>apic draft-apis:validate</b> - Validates a draft API</li> </ul>
<b>apic draft-products</b>	List and manage the draft Product definitions in a provider organization. Default sub-command is <b>list-all</b> .	<ul style="list-style-type: none"> <li>• <b>apic draft-products</b> - Draft Product collection operations</li> <li>• <b>apic draft-products:clear</b> - Delete all versions of a draft Product by name</li> <li>• <b>apic draft-products:clear-all</b> - Delete all draft Products in a provider organization</li> <li>• <b>apic draft-products:create</b> - Create a draft Product</li> <li>• <b>apic draft-products:delete</b> - Delete a draft Product by name and version</li> <li>• <b>apic draft-products:get</b> - Get the Draft Product by name and version</li> <li>• <b>apic draft-products:list</b> - List the Draft Products</li> <li>• <b>apic draft-products:list-all</b> - List all draft Products in a provider organization</li> <li>• <b>apic draft-products:publish-all</b> - Publishes the Draft Product</li> <li>• <b>apic draft-products:update</b> - Update a draft Product by name and version, supplying the revised definition file</li> <li>• <b>apic draft-products:validate</b> - Validates a draft Product</li> </ul>
<b>apic members</b>	List and manage the members of a provider organization, consumer organization, Catalog, or Space. Default sub-command is <b>list</b> .	<ul style="list-style-type: none"> <li>• <b>apic members</b> - Member operations</li> <li>• <b>apic members:clear</b> - Delete all members</li> <li>• <b>apic members:create</b> - Create a member</li> <li>• <b>apic members:delete</b> - Delete a member by name or ID</li> <li>• <b>apic members:get</b> - Get a member object by name or ID</li> <li>• <b>apic members:list</b> - List all members</li> <li>• <b>apic members:update</b> - Update the member by name or ID</li> </ul>
<b>apic member-invitations</b>	List and manage member invitations. A member invitation is created when a user is invited to be a member of a provider organization, consumer organization, Catalog, or Space. Default sub-command is <b>list</b> .	<ul style="list-style-type: none"> <li>• <b>apic member-invitations</b> - Member invitation collection operations.</li> <li>• <b>apic member-invitations:clear</b> - Delete all member invitations.</li> <li>• <b>apic member-invitations:create</b> - Create a member invitation.</li> <li>• <b>apic member-invitations:delete</b> - Delete a member invitation by name or ID.</li> <li>• <b>apic member-invitations:get</b> - Get a member invitation object by name or ID.</li> <li>• <b>apic member-invitations:list</b> - List all member invitations.</li> <li>• <b>apic member-invitations:update</b> - Update a member invitation by name or ID.</li> </ul>

Command	Description	Sub-commands
<b>apic orgs</b>	List and manage provider organizations, and the admin organization. Default sub-command is <b>list</b> .	<ul style="list-style-type: none"> <li>• <b>apic orgs</b> - Organization collection operations</li> <li>• <b>apic orgs:clear</b> - Delete all organizations</li> <li>• <b>apic orgs:create</b> - Create an organization</li> <li>• <b>apic orgs:delete</b> - Delete an organization by name or ID</li> <li>• <b>apic orgs:get</b> - Get an organization object by name or ID</li> <li>• <b>apic orgs:list</b> - List all organizations</li> <li>• <b>apic orgs:transfer-owner</b> - Transfer ownership of an organization</li> <li>• <b>apic orgs:update</b> - Update an organization by name or ID</li> </ul>
<b>apic org-settings</b>	Manage settings for provider organizations, and the admin organization.	<ul style="list-style-type: none"> <li>• <b>apic org-settings:get</b> - Get the settings object for an organization</li> <li>• <b>apic org-settings:update</b> - Update the settings for an organization</li> </ul>
<b>apic policies</b>	List and manage policies in a Catalog. Default sub-command is <b>list</b> .	<ul style="list-style-type: none"> <li>• <b>apic policies</b> - Policy collection operations</li> <li>• <b>apic policies:clear</b> - Clear the Policies</li> <li>• <b>apic policies:clear-all</b> - Clear all Policies in all collections</li> <li>• <b>apic policies:create</b> - Create a Policy</li> <li>• <b>apic policies:delete</b> - Delete a Policy</li> <li>• <b>apic policies:get</b> - Get the Policy by name and version</li> <li>• <b>apic policies:list</b> - List the Policies</li> <li>• <b>apic policies:list-all</b> - List all Policies in all collections</li> <li>• <b>apic policies:update</b> - Update the Policy by name and version</li> </ul>
<b>apic products</b>	List and manage Products that are staged or published to Catalog or Space. Default sub-command is <b>list-all</b> .	<ul style="list-style-type: none"> <li>• <b>apic products</b> - Product collection operations</li> <li>• <b>apic products:clear</b> - Delete all versions of a Product by name</li> <li>• <b>apic products:clear-all</b> - Delete all Products</li> <li>• <b>apic products:delete</b> - Delete a Product by name and version</li> <li>• <b>apic products:execute-migration-target</b> - Products execute migration target operations</li> <li>• <b>apic products:get</b> - Get a Product object by name and version</li> <li>• <b>apic products:list</b> - List all versions of a Product by name</li> <li>• <b>apic products:list-all</b> - List all Products</li> <li>• <b>apic products:publish</b> - Publish a Product to a Catalog or Space, supplying the Product definition YAML file</li> <li>• <b>apic products:replace</b> - Replace a Product with another Product</li> <li>• <b>apic products:set-migration-target</b> - Set the target Product for migrating subscriptions from a Product</li> <li>• <b>apic products:supersede</b> - Supersede a Product with another Product</li> <li>• <b>apic products:update</b> - Update a Product by name and version, supplying the revised Product definition YAML file</li> </ul>
<b>apic identity-providers</b>	View information about identity providers.	<ul style="list-style-type: none"> <li>• <b>apic identity-providers</b> - Identity provider operations</li> <li>• <b>apic identity-providers:list</b> - List the identity providers.</li> </ul>
<b>apic spaces</b>	List and manage Spaces contained in a Catalog. Default sub-command is <b>list</b> .	<ul style="list-style-type: none"> <li>• <b>apic spaces</b> - Space collection operations</li> <li>• <b>apic spaces:clear</b> - Delete all Spaces from a Catalog</li> <li>• <b>apic spaces:create</b> - Create a Space in a Catalog</li> <li>• <b>apic spaces:delete</b> - Delete a Space from a Catalog, by name or ID</li> <li>• <b>apic spaces:get</b> - Get a Space object by name or ID</li> <li>• <b>apic spaces:list</b> - List all the Spaces in a Catalog</li> <li>• <b>apic spaces:transfer-owner</b> - Transfer the ownership of a Space to another user</li> <li>• <b>apic spaces:update</b> - Update a Space by name or ID</li> </ul>
<b>apic subscriptions</b>	List and manage subscriptions in a Product or a Catalog. Default sub-command is <b>list</b> .	<ul style="list-style-type: none"> <li>• <b>apic subscriptions</b> - Subscription collection operations</li> <li>• <b>apic subscriptions:clear</b> - Clear the Subscriptions</li> <li>• <b>apic subscriptions:create</b> - Create a Subscription</li> <li>• <b>apic subscriptions:delete</b> - Delete the Subscription by name or ID</li> <li>• <b>apic subscriptions:get</b> - Get the Subscription by name or ID</li> <li>• <b>apic subscriptions:list</b> - List the Subscriptions</li> <li>• <b>apic subscriptions:update</b> - Update the Subscription by name or ID</li> </ul>

Table 3. Summary of other commands for API developers and managers

Command	Description	Sub-commands
---------	-------------	--------------

Command	Description	Sub-commands
<code>apic consumer-orgs</code>	Manage consumer organizations	<ul style="list-style-type: none"> <li>• <code>apic consumer-orgs</code> - Consumer Organization collection operations.</li> <li>• <code>apic consumer-orgs:clear</code> - Clear the Consumer Organizations.</li> <li>• <code>apic consumer-orgs:create</code> - Create a Consumer Organization.</li> <li>• <code>apic consumer-orgs:delete</code> - Delete the Consumer Organization by name or ID.</li> <li>• <code>apic consumer-orgs:get</code> - Get the Consumer Organization by name or ID.</li> <li>• <code>apic consumer-orgs:list</code> - List the Consumer Organizations.</li> <li>• <code>apic consumer-orgs:transfer-owner</code> - Transfer owner to a new member.</li> <li>• <code>apic consumer-orgs:update</code> - Update the Consumer Organization by name or ID.</li> </ul>
<code>apic consumer-org-settings</code>	Manage consumer organization settings	<ul style="list-style-type: none"> <li>• <code>apic consumer-org-settings:delete</code> - Delete the Consumer Organization Setting.</li> <li>• <code>apic consumer-org-settings:get</code> - Get the Consumer Organization Setting.</li> <li>• <code>apic consumer-org-settings:update</code> - Update the Consumer Organization Setting.</li> </ul>
<code>apic groups</code>	Manage groups	<ul style="list-style-type: none"> <li>• <code>apic groups</code> - Group collection operations.</li> <li>• <code>apic groups:clear</code> - Clear the Groups.</li> <li>• <code>apic groups:create</code> - Create a Group.</li> <li>• <code>apic groups:delete</code> - Delete the Group by name or ID.</li> <li>• <code>apic groups:get</code> - Get the Group by name or ID.</li> <li>• <code>apic groups:list</code> - List the Groups.</li> <li>• <code>apic groups:update</code> - Update the Group by name or ID.</li> </ul>
<code>apic invitations</code>	Manage invitations. An invitation is created when a user is invited to be the owner of a provider organization, consumer organization, Catalog, or Space.	<ul style="list-style-type: none"> <li>• <code>apic invitations</code> - Invitation collection operations.</li> <li>• <code>apic invitations:clear</code> - Delete all invitations.</li> <li>• <code>apic invitations:create</code> - Create an invitation.</li> <li>• <code>apic invitations:delete</code> - Delete an invitation by name or ID.</li> <li>• <code>apic invitations:get</code> - Get the details of an invitation by name or ID.</li> <li>• <code>apic invitations:list</code> - List all invitations.</li> <li>• <code>apic invitations:update</code> - Update an invitation by name or ID.</li> </ul>
<code>apic member-invitations</code>	Manage member invitations. A member invitation is created when a user is invited to be a member of a provider organization, consumer organization, Catalog, or Space.	<ul style="list-style-type: none"> <li>• <code>apic member-invitations</code> - Member invitation collection operations.</li> <li>• <code>apic member-invitations:clear</code> - Delete all member invitations.</li> <li>• <code>apic member-invitations:create</code> - Create a member invitation.</li> <li>• <code>apic member-invitations:delete</code> - Delete a member invitation by name or ID.</li> <li>• <code>apic member-invitations:get</code> - Get the details of a member invitation by name or ID.</li> <li>• <code>apic member-invitations:list</code> - List all member invitations.</li> <li>• <code>apic member-invitations:update</code> - Update a member invitation by name or ID.</li> </ul>
<code>apic members</code>		<ul style="list-style-type: none"> <li>• <code>apic members</code> - Member collection operations.</li> <li>• <code>apic members:clear</code> - Clear the Members.</li> <li>• <code>apic members:create</code> - Create a Member.</li> <li>• <code>apic members:delete</code> - Delete the Member by name or ID.</li> <li>• <code>apic members:get</code> - Get the Member by name or ID.</li> <li>• <code>apic members:list</code> - List the Members.</li> <li>• <code>apic members:update</code> - Update the Member by name or ID.</li> </ul>

Command	Description	Sub-commands
<b>apic registration</b>		<ul style="list-style-type: none"> <li>• <b>apic registrations</b> - Registration collection operations.</li> <li>• <b>apic registrations:clear</b> - Clear the Registrations.</li> <li>• <b>apic registrations:create</b> - Create a Registration.</li> <li>• <b>apic registrations:delete</b> - Delete the Registration by name or ID.</li> <li>• <b>apic registrations:get</b> - Get the Registration by name or ID.</li> <li>• <b>apic registrations:list</b> - List the Registrations.</li> <li>• <b>apic registrations:update</b> - Update the Registration by name or ID.</li> </ul>
<b>apic role-defaults</b>		<ul style="list-style-type: none"> <li>• <b>apic role-defaults</b> - Role Default collection operations.</li> <li>• <b>apic role-defaults:clear</b> - Clear the Role Defaults.</li> <li>• <b>apic role-defaults:create</b> - Create a Role Default.</li> <li>• <b>apic role-defaults:delete</b> - Delete the Role Default by name or ID.</li> <li>• <b>apic role-defaults:get</b> - Get the Role Default by name or ID.</li> <li>• <b>apic role-defaults:list</b> - List the Role Defaults.</li> <li>• <b>apic role-defaults:list-all</b> - List all Role Defaults in all collections.</li> <li>• <b>apic role-defaults:update</b> - Update the Role Default by name or ID.</li> </ul>
<b>apic roles</b>		<ul style="list-style-type: none"> <li>• <b>apic roles</b> - Role collection operations.</li> <li>• <b>apic roles:clear</b> - Clear the Roles.</li> <li>• <b>apic roles:create</b> - Create a Role.</li> <li>• <b>apic roles:delete</b> - Delete the Role by name or ID.</li> <li>• <b>apic roles:get</b> - Get the Role by name or ID.</li> <li>• <b>apic roles:list</b> - List the Roles.</li> <li>• <b>apic roles:update</b> - Update the Role by name or ID.</li> </ul>
<b>apic tasks</b>		<ul style="list-style-type: none"> <li>• <b>apic tasks</b> - Task collection operations.</li> <li>• <b>apic tasks:clear</b> - Clear the Tasks.</li> <li>• <b>apic tasks:create</b> - Create a Task.</li> <li>• <b>apic tasks:delete</b> - Delete the Task by name or ID.</li> <li>• <b>apic tasks:get</b> - Get the Task by name or ID.</li> <li>• <b>apic tasks:list</b> - List the Tasks.</li> <li>• <b>apic tasks:update</b> - Update the Task by name or ID.</li> </ul>
<b>apic user-registries</b>		<ul style="list-style-type: none"> <li>• <b>apic user-registries</b> - User Registry collection operations.</li> <li>• <b>apic user-registries:clear</b> - Clear the User Registries.</li> <li>• <b>apic user-registries:create</b> - Create a User Registry.</li> <li>• <b>apic user-registries:delete</b> - Delete the User Registry by name or ID.</li> <li>• <b>apic user-registries:execute</b> - Execute a User Registry operation.</li> <li>• <b>apic user-registries:get</b> - Get the User Registry by name or ID.</li> <li>• <b>apic user-registries:list</b> - List the User Registries.</li> <li>• <b>apic user-registries:search</b> - search for users in a user registry.</li> <li>• <b>apic user-registries:test-connection</b> - Test a User Registry connection.</li> <li>• <b>apic user-registries:update</b> - Update the User Registry by name or ID.</li> </ul>

Command	Description	Sub-commands
<code>apic user-registry-settings</code>		<ul style="list-style-type: none"> <li>• <code>apic user-registry-settings:delete</code> - Delete the User Registry Setting.</li> <li>• <code>apic user-registry-settings:get</code> - Get the User Registry Setting.</li> <li>• <code>apic user-registry-settings:update</code> - Update the User Registry Setting.</li> </ul>
<code>apic users</code>		<ul style="list-style-type: none"> <li>• <code>apic users</code> - User collection operations.</li> <li>• <code>apic users:clear</code> - Clear the Users.</li> <li>• <code>apic users:create</code> - Create a User.</li> <li>• <code>apic users:delete</code> - Delete the User by name or ID.</li> <li>• <code>apic users:get</code> - Get the User by name or ID.</li> <li>• <code>apic users:list</code> - List the Users.</li> <li>• <code>apic users:request-password-reset</code> - send a password reset link.</li> <li>• <code>apic users:search-provider</code> - Search for provider users from an organization.</li> <li>• <code>apic users:update</code> - Update the User by name or ID.</li> </ul>

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Creating APIs and applications

You can develop API proxies and API implementations by using the developer toolkit. In the documentation, *API* refers to the API proxy and *application* refers to the API implementation.

LoopBack® is a high-performance Node.js interaction-tier framework for APIs and micro-services. The [LoopBack framework](#) can be downloaded and installed using the **CLI + LoopBack + Designer** option for downloading the toolkit. See [Installing the toolkit](#). To create a new LoopBack project, use the command `apic lb`.

You can use the developer toolkit or LoopBack to create language-independent APIs by using [OpenAPI](#) to proxy to an existing backend implementation or to augment applications developed in other languages or frameworks such as [Express®](#), Java™, [Swift](#), Go, and others.

## Creating development artifact definitions

Use the `apic create` command to create development artifacts, by using the following commands:

Command	Description
<code>apic create:api</code>	Create an OpenAPI definition.
<code>apic create:api --wsdl filename</code>	Create a SOAP API definition from a WSDL definition file, or a .zip file that contains the WSDL definition files for a service. The name and version of the generated API are obtained from the WSDL file. If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see <a href="#">Using an options file when importing a WSDL service</a> .
<code>apic create:product</code>	Create an API Product definition.

Note: You can create an API or Product from an OpenAPI template file by using the `--template template-name` option.

You can also create Product and API definitions non-interactively by providing the `--title` option. This option sets several values that you can also customize with additional options; for example:

```
apic create:api --title Routes
apic create:product --title "Climb On"
```

You can also create the API and Product definitions at the same time:

```
apic create:api --title Routes --product "Climb On"
apic create:api --wsdl globalweather.wsdl --product "Weather Forecasting"
```

Alternatively, you can create APIs and then reference them when you create a new Product; for example:

```
apic create:api --title Routes
apic create:api --title Ascents
apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
```

## Validating development artifact definitions

After you edit development artifacts or before you publish artifacts, best practice is to validate them; for example:

```
apic validate routes.yaml # Validate an API
apic validate climb-on.yaml # Validate the Product and its APIs
apic validate climb-on.yaml --product-only # Validate the Product only (do not validate the referenced APIs)
```

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the draft API is created with the `apic drafts:validate` command. For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

## Developing LoopBack applications

After you've created a LoopBack application with the `apic lb app` command, you can add additional functionality to the application with the commands listed in the following table. Run these commands from the project root directory of the application. APIs created with LoopBack can be imported into API Manager.

Command	Description
<code>apic lb acl</code>	Define an <a href="#">access control list</a> for accessing LoopBack models.
<code>apic lb app</code>	Create a LoopBack application with the <a href="#">Application generator</a> .
<code>apic lb bluemix</code>	Add IBM Cloud deployment artifacts to a LoopBack application. See <a href="#">IBM Cloud configuration generator</a> .
<code>apic lb boot-script</code>	Create a new <a href="#">boot script</a> .
<code>apic lb datasource</code>	<a href="#">Data source generator</a>
<code>apic lb export-api-def</code>	Export an OpenAPI and a Product definition from LoopBack models.
<code>apic lb middleware</code>	Define and register <a href="#">Express middleware</a> to define the phase of execution.
<code>apic lb model</code>	Add a new model to a LoopBack application: <a href="#">Model generator</a>
<code>apic lb oracle</code>	Install and troubleshoot the Oracle connector: <a href="#">Oracle installer</a>
<code>apic lb property</code>	Add <a href="#">additional properties</a> to a Loopback model.
<code>apic lb relation</code>	Add <a href="#">relationships</a> between LoopBack models.
<code>apic lb remote-method</code>	Add <a href="#">remote methods</a> to a LoopBack model.
<code>apic lb soap</code>	Generate a model from a SOAP web service:
<code>apic lb swagger</code>	Generate a LoopBack application project from an OpenAPI definition.

Note: These commands are annotated with "Stability: prototype" because IBM® is looking for feedback on them before certifying them for production.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Publishing APIs and applications

To publish APIs and applications by using the developer toolkit of IBM® API Connect, you set configuration variables to define where you want to publish, log in to the target cloud platform, and then use the appropriate publishing commands.

See the following sections for more information:

- [Setting configuration variables](#)
- [Logging in to API Connect](#)
- [Publishing APIs](#)

## Setting configuration variables

The `apic config` command provides global and project-based configuration variables that specify the target Catalog for publishing APIs and applications. The values of these variables are stored in `~/.apiconnect/config` (for global variables) and `project-dir/.apiconnect` (for project variables). For a full list of configuration variables, see [Overview of the command-line tool](#).

Set the `catalog` configuration variable to the URI of an API Connect Catalog to define a default Catalog target for all commands managing Catalogs. The `catalog` URI has the form:

```
https://mgmt_endpoint_url/api/catalogs/org_name/catalog_name
```

where `mgmt_endpoint_url` is the platform API endpoint URL, `org_name` is the provider organization name, and `catalog_name` is the Catalog name. The `mgmt_endpoint_url` portion sets the default value of the `--server` option, the `org_name` portion sets the default value of the `--org` option, and the `catalog_name` portion sets the default value of the `--catalog` option; you can override any of these values by including the corresponding option in a command.

Set the `space` configuration variable to the URI of an API Connect Space, to define a default Space target for all commands that manage Spaces. The `space` URI has the form:

```
https://mgmt_endpoint_url/api/spaces/org_name/catalog_name/space_name
```

where `mgmt_endpoint_url` is the platform API endpoint URL, `org_name` is the provider organization name, `catalog_name` is the Catalog name, and `space_name` is the name of the Space. The `mgmt_endpoint_url` portion sets the default value of the `--server` option, the `org_name` portion sets the default value of the `--org` option, the `catalog_name` portion sets the default value of the `--catalog` option, and the `space_name` sets the default value of the `--space` option; you can override any of these values by including the corresponding option in a command.

Although setting these configuration variables is not required, doing so simplifies commands that interact with API Connect clouds by providing default values for frequently used command-line options.

Here is an example of publishing with and without the `catalog` configuration variable set.

Without the configuration variable set:

```
apic products publish climb-on.yaml --server mgmthost.com --org climbon --catalog sandbox
```

With the configuration variable set:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
catalog: https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic products publish climb-on.yaml
```

You can override default values provided by the `catalog` configuration variable by providing one of the standard options with a different value. For example, use the `--catalog` option with the `apic products publish` command to specify the `qa` Catalog:

```
apic products publish climb-on.yaml --catalog qa
```

Don't forget about global configuration variables. If you use the same Catalog as the default target for multiple projects, set the value globally:

```
apic config:set --global catalog=https://platform-api.myserver.com/api/catalogs/climb-on/sandbox
```

Note:

If you have an environment variable of the same name as a CLI configuration property then, by default, its value will override the value of the corresponding CLI configuration property for any CLI command at that scope.

For example, if you have defined an environment variable called `SPACE` then, by default, that value will be assumed for the value of the `--space` parameter in the following command, regardless of any `space` configuration property setting:

```
apic products:publish my_product.yaml --scope space
```

To prevent environment variables overriding CLI configuration properties, define an environment variable called `APIC_LOAD_FROM_ENV`, set to the value `false`.

## Logging in to API Connect

Use the `apic login` and `apic logout` commands to manage your authentication. For details, see [Logging in to a management server](#).

## Publishing APIs

Publishing APIs to API Catalogs in API Connect clouds enables you to socialize the APIs by using the developer portal and secure them by using the Gateway.

An *API Product* (or simply *Product*) is used to compose APIs for publishing. API Product managers can use it to bundle one or more APIs together, control the visibility of the Product in the developer portal (for example, only allow partners x, y, and z to view and subscribe to the Product), and define Plans to provide consumption options. The Products that reference the APIs and define the consumption Plans are also the primary unit of lifecycle management for APIs.

Use the `apic products publish` command (equivalent to `apic products:publish`) to publish API Products to an API Connect cloud. The following example demonstrates how to create APIs composed by a Product, and publishing the Product and its APIs to a Catalog:

```
apic create:api --title Routes
apic create:api --title Ascents
apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climb-on/sandbox
apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/default-idp-2
apic products publish climb-on.yaml
```

For full details on how to log in to your management server from the CLI, see [Logging in to a management server](#).

Add the `--stage` option to `apic publish` to stage the Product into a Catalog instead of publishing it. Products in a Catalog can be in the following states: staged, published, deprecated, or retired. For example:

```
apic products publish --stage climb-on.yaml
```

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a sub-catalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see [Using syndication in IBM API Connect](#).

If default configuration values have been set for the Space, Catalog, organization and management server, the following publish command could be used:

```
apic products publish --scope space product.yaml
```

where *product* is the name of the product that you want to publish.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the product that contains the API is staged or published with the `apic publish` command. For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Managing API Products

Use the `apic products` and `apic apis` commands to manage Products and APIs that have been published to IBM® API Connect Catalogs. Use the `--scope space` option to manage Products and APIs that have been published to Spaces within Catalogs.

## Product management command summary

The following table summarizes the commands available for managing API Products. Usage examples follow.

Example command	Description
<pre>apic config:set catalog=https://platform- api.myserver.com/api/catalogs/myorg/sandbox</pre>	Set the default Catalog.

Example command	Description
<code>apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/my-identity-provider</code>	Login into the management server. For full details on how to log in to your management server from the CLI, see <a href="#">Logging in to the management server</a> .
<code>apic create:api --title Routes --product "ClimbOn"</code>	Create the Product and API.
<code>apic products:publish climbon.yaml</code>	Publish the Product to the default catalog. Add <code>--stage</code> argument to stage the Product.
<code>apic products:list-all --scope catalog</code>	List the Products in the default catalog.
<code>apic products:get climbon:1.0.0 --output -</code>	Display the Product's properties. Omit the output argument to download to a file.
<code>apic apis:list-all --scope catalog</code>	List the APIs in the Catalog.
<code>apic apis:get routes:1.0.0 --output -</code>	Get the API properties. Omit the output argument to download to a file.
<code>apic products:replace climbon:1.0.0 mapfile.txt</code>	Replace the Product indicated on the command line with the staged or published Product designated in the mapfile. This retires the replaced Product.
<code>apic products:supersede climbon:1.0.0 mapfile.txt</code>	Supersede the Product indicated on the command line with the staged or published Product designated in the mapfile. This deprecates the superseded Product.
<code>apic products:delete climbon:1.0.0</code>	Delete the Product from the Catalog. The Product must be either retired or deprecated.

## Using the products and apis commands through a full lifecycle

This example shows a complex lifecycle where a new version of a Product and API replaces the original version at run time.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the product that contains the API is staged or published with the `apic publish` command. For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

Set the default Catalog and login to the mgmthost.com API Connect cloud

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic login --username some-user --password some-password --server platform-api.myserver.com --realm my-identity-provider
```

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

Create and publish an initial version

```
apic create:api --title Routes --version 1.0.0 --filename routes100.yaml
apic create:product --title "Climb On" --version 1.0.0 --apis routes100.yaml --filename climbon100.yaml
apic products:publish climbon100.yaml
```

Create a new version to fix a bug in the API, stage it to the Catalog

```
apic create:api --title Routes --version 1.0.1 --filename routes101.yaml
apic create:product --title "Climb On" --version 1.0.1 --apis routes101.yaml --filename climbon101.yaml
apic products:publish --stage climbon101.yaml
```

Inspect the Catalog

```
apic products:list-all --scope catalog
```

This produces a list of all Products in the catalog. Copy the ID of the `climbon:1.0.1` Product. The ID resembles the following example.

```
https://server/api/catalogs/3eca6046-3c27-4ad/ab8772bf-0f65-45/products/8f854623-bda1-4f9
```

Create a mapping file

For example, if you are replacing a Product, the mapping file specifies the Product that you want to replace, and the mapping of the Plans from the source Product to the target Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then `product_url` property specifies the URL of `climbon:1.0.0`. This file takes the following form:

```
product_url: https://server/api/catalogs/{id}/products/{id}
plans:
- source: {source_plan_name_1}
  target: {target_plan_name_1}
- source: {source_plan_name_2}
  target: {target_plan_name_2}
  .
  .
  .
```

Note:

- The source and target Plan names can be the same or different.
- Every Plan in the Product you are replacing must be mapped to a Plan in the replacement Product.

"Hot-replace" version 1.0.0 with 1.0.1

```
apic products:replace climbon:1.0.1 PRODUCT_PLAN_MAPPING_FILE
```

After it is replaced in this way, a Product is retired. It is no longer active.

Note: The Product specified on the command line is the replacement Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then the Product specified on the command line is `climbon:1.0.1`.

Supersede version 1.0.0 with 1.0.1

Rather than hot-replacing an existing Product with a new one (usually an updated version), you can supersede the existing Product with a new one. When you replace a Product, all external application subscriptions to that Product are automatically moved to the new Product. When you supersede a Product, the subscriptions are not automatically moved to the new Product, some action must be taken to subscribe external applications to the superseding Product.

The command to supersede a Product uses the same mapping file as the command to replace a Product. The name of the superseding Product is given on the command line.

```
apic products:supersede climbon:1.0.1 PRODUCT_PLAN_MAPPING_FILE
```

Once superseded, a Product is marked deprecated, meaning that no further subscriptions to the Product are allowed, although it is still active and existing subscriptions still work.

Note: The Product specified on the command line is the superseding Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then the Product specified on the command line is `climbon:1.0.1`. The mapping file specifies the URL of the Product you are superseding.

Set a migration target

It is possible to set a migration target for the existing Product. This helps migration.

Use a command like the following to set the migration target.

```
apic products:set-migration-target climbon:1.0.0 PRODUCT_PLAN_MAPPING_FILE
```

Note: The Product specified on the command line is the Product from which you want to migrate subscriptions. The mapping file specifies the target Product for the subscriptions.

Once a migration target is set, external application developers will be able to migrate their application subscriptions through the Developer Portal with ease. It is also possible to execute a subscription migration using the following command.

```
apic products:execute-migration-target climbon:1.0.0
```

Delete a Product

When the replaced or superseded Product is no longer needed, it can be deleted.

```
apic products:delete climbon:1.0.0
```

## Additional Product and API operations

In addition to the lifecycle management capabilities, you can download Products and APIs in a catalog or space using the `clone` sub-command:

Command	Description
<code>apic products:clone</code>	Download all Products and their APIs from the catalog or space.
<code>apic apis:clone</code>	Download all APIs from the catalog or space.

It can also be useful to clear all Products and their APIs from a Catalog, particularly for a development Catalog (you must provide the name of the Catalog as the value of the `--confirm` parameter):

```
apic products:clear --confirm catalog_name
```

where `catalog_name` is the name of the Catalog.

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a sub-catalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see [Using syndication in IBM API Connect](#).

To manage the Products and APIs that have been published to a Space, include the `--scope space` option with the `apic products` and `apic apis` commands. For example, to list the Products that are contained in a Space called `flights`, use the following command:

```
apic products --scope space --space flights --catalog production --org climbonorg --server platform-api.myserver.com
```

## Changing the lifecycle state of a Product in a Catalog or Space

To directly change the lifecycle state of a Product that has previously been staged or published to a Catalog or Space, complete the following steps:

- Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic products:update product_name:version --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space] -
```

where:

- `product_name` is the name of the Product whose lifecycle state you want to change.
- `version` is the version of that Product.
- `mgmt_endpoint_url` is the platform API endpoint URL.
- `organization` is the name of the provider organization in which the Product was previously staged or published.
- `scope` has one of the following values:
  - `catalog` if the Catalog does not have Spaces enabled.
  - `space` if the Catalog has Spaces enabled. If you specify `space` for the `--scope` parameter you must also supply the `--space` parameter.
- `catalog` is the name of the Catalog in which the Product was previously staged or published.
- (optional) `space` is the name of the Space. The `--space` parameter is required if the Catalog has Spaces enabled, in which case you must also include `--scope space` in the command.

The command returns:

```
Reading PRODUCT_FILE arg from stdin
```

- Enter the following data, followed by a new line:

```
state: new_state
```

where `new_state` is the state that you want to change the Product to, and must have one of the following values.

- `staged`
  - `published`
  - `deprecated`
  - `retired`
  - `archived`
- Press **CTRL D** to terminate the input. If the command is successful, the lifecycle state change is confirmed. For example:

```
apic products:update finance:1.0.0 --server https://myserver.com --org development --scope catalog --catalog sandbox -
Reading PRODUCT_FILE arg from stdin
state: published
finance:1.0.0 [state: published] https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-
9e82-427a-abe6-be5b126210f7/products/0f0af980-f505-4f36-b09c-d7b1c9c1a2f2
```

Note:

The command will not succeed if the lifecycle state change you are attempting is not permitted.

For example, the following lifecycle state changes are permitted:

- staged to published
- deprecated to retired

The following lifecycle state changes are not permitted:

- published to staged
- retired to published

For full details, see [The Product lifecycle](#).

To list all Products in a Catalog or Space, together with their lifecycle states, use the following command:

```
apic products:list-all --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space]
```

For example:

```
apic products:list-all --server https://myserver.com --org development --scope catalog --catalog sandbox
graphql-services:1.0.0 [state: staged] https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-
9e82-427a-abe6-be5b126210f7/products/7652d568-b396-4bfa-bf71-2f18cea63737
finance:1.0.0 [state: published] https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-
9e82-427a-abe6-be5b126210f7/products/0f0af980-f505-4f36-b09c-d7b1c9c1a2f2
```

To find out the lifecycle state of a specific Product, use the following command:

```
apic products:get product_name:version --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space
space] --fields state --output -
```

For example:

```
apic products:get finance:1.0.0 --server https://myserver.com --org development --scope catalog --catalog sandbox --fields
state --output -
state: published
```

## Example scripts

A set of example toolkit scripts that demonstrate how to create and manage organizations, users, apps, Products and APIs are available at <https://github.com/ibm-apiconnect/example-toolkit-scripts>.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Working with Drafts

Co-locate your APIs and applications in your local source code control systems to support typical development activities such as commits, branching, merges, continuous integration, and so on. The developer toolkit provides the bridge from the developer's environment to the IBM® API Connect runtime services.

API Connect provides an online development capability called *Drafts* where you can define API and Product definitions. The `apic drafts` commands enable synchronization of Product and API artifacts between local source code control systems and drafts.

You can use `drafts` to clear and list your drafts. For example:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox # set the default Catalog
apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/myldap # login
into the management server

apic create:api --title routes --product ClimbOn
apic drafts # list what is in drafts
apic drafts:clear --confirm drafts # clear drafts collection
apic drafts:list # list the available drafts
```

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.

For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Reading input from the command line

If a developer toolkit command takes a file as an input parameter, you can direct the command to read the input directly from the command line rather than supplying a separate file; this can be useful when writing scripts to automate command line operations, for example.

## Reading input from a file

Many developer toolkit commands that create or update new objects in API Connect take a file as an input parameter. For example:

- Register a new gateway service:  

```
apic gateway-services:create [flags] GATEWAY_SERVICE_FILE
```
- Update a provider organization:  

```
apic orgs:update [flags] ORG_FILE
```
- Create a new Catalog:  

```
apic catalogs:create [flags] CATALOG_FILE
```
- Create a new consumer organization:  

```
apic consumer-orgs:create [flags] CONSUMER_ORG_FILE
```
- Register a new developer application:  

```
apic apps:create [flags] APP_FILE
```
- Create a new email server:  

```
apic mail-servers:create [flags] MAIL_SERVER_FILE
```
- Update the list of applications that subscribe to a Product:  

```
apic subscriptions:update [flags] SUBSCRIPTION_FILE
```

You can format the input file as a YAML file (the default) or as a JSON file. To use a JSON file as input, include the `--format json` parameter.

## Reading input from the command line

As an alternative to supplying an explicit file name to the command, you can supply a hyphen (-) in place of the file name parameter; the command will then read the file content directly from the command line as shown in the following examples.

- Register a new DataPower® Gateway (v5 compatible) gateway service:  

```
apic gateway-services:create --server platform-api.myserver.com --org admin --availability-zone availability-zone-default -
Reading GATEWAY_SERVICE_FILE arg from stdin
name: dpgw-service
title: DataPower gateway service, compatible with v5
gateway_service_type: datapower-gateway
endpoint: 'https://mygwhost.com:3000'
api_endpoint_base: 'https://mygwhost.com:9443'
sni:
  - host: '*'
    tls_server_profile_url: https://platform-api.myserver.com/api/orgs/75203636-f038-4287-a732-24af4bf7059d/tls-server-
profiles/3c0a0e93-6aa4-4288-b09c-eccf4901b104
visibility:
  type: public
```

Note: You can obtain the `tls_server_profile_url` property value for a TLS server profile by using the following command, which lists the URLs for all TLS server profiles:

```
apic tls-server-profiles --org organization_name --server mgmt_endpoint_url
```

- Create a new provider organization:  

```
apic orgs:create --server platform-api.myserver.com -
Reading ORG_FILE arg from stdin
name: development
title: Development organization
owner_url: https://platform-api.myserver.com/api/user-registries/1bbbd414-22f1-47cf-8eac-2050530d29a7/c082d755-866e-4394-
959f-fbb264c6c3a1/users/2db491c7-2d0f-4f60-a8ae-f38d07481f21
```

Note: You can obtain the `owner_url` property value by using the following command, which returns the `url` property for a specific user:

```
apic users:get username --user-registry user_registry_name --server mgmt_endpoint_url --org organization_name --fields url
--output -
```
- Create a new Catalog:  

```
apic catalogs:create --server platform-api.myserver.com --org myorg -
Reading CATALOG_FILE arg from stdin
name: production
title: Production Catalog
summary: Catalog containing APIs in production use
```
- Create a new consumer organization:  

```
apic consumer-orgs:create --server platform-api.myserver.com --catalog sandbox --org myorg -
Reading CONSUMER_ORG_FILE arg from stdin
name: finance-apps
title: Developers of finance applications
```

```
owner_url: https://platform-api.myserver.com/api/user-registries/a1fb8159-fda1-410f-93ab-a0ea5fd04535/70ce7ec3-e83f-4c87-9f3c-4662ad108bbc/users/fddd5df5-c178-4a34-ab92-0a48344d5c9b
```

Note: You can obtain the `owner_url` property value by using the following command, which returns the `url` property for a specific user:

```
apic users:get username --user-registry user_registry_name --server mgmt_endpoint_url --org organization_name --fields url --output -
```

- Register a new developer application:

```
apic apps:create --server consumer-api.myserver.com --org my-consumer-org --mode consumer -
Reading APP_FILE arg from stdin
name: finance
title: Finance application
summary: Mobile app for personal finance management
```

- Create a new email server:

```
apic mail-servers:create --org admin --server platform-api.myserver.com -
Reading MAIL_SERVER_FILE arg from stdin
title: My email server
name: my-email-server
host: smtp.myemail.com
port: 20
credentials:
  username: me@myemail.com
  password: password
```

- Create a new subscription to subscribe an application to a Product:

```
apic subscriptions:create --app myapp --catalog sandbox --org myorg --server platform-api.myserver.com --consumer-org my-consumer-org -
Reading SUBSCRIPTION_FILE arg from stdin
product_url: https://platform-api.myserver.com/api/catalogs/960733c1-d7f7-4b90-9bc7-69dbf4ce31/ca34537d-adf4-4320-8495-a7feaa62d679/products/638015c6-a8b0-452e-841f-2ac441ab6962
plan: default-plan
```

Note: You can obtain the `product_url` property value for a Product by using the following command, which lists the URLs for all versions of a Product given the Product name:

```
apic products:list product_name --scope catalog --catalog catalog_name --org provider_org_name --server mgmt_endpoint_url
```

# Scripting with the toolkit commands

The IBM® API Connect developer toolkit provides commands for cloud administration and API development and management.

---

## Scripting commands

It's often helpful to automate a series of `apic` commands in a shell script. Since the `apic` tool first requires you to interactively accept the license, you must first use the following command:

```
apic --accept-license
```

Once you do that, your scripts can run non-interactively.

Toolkit command scripts allow you to automate many of the tasks required to set up and maintain your API products. A set of example scripts are available at <https://github.com/ibm-apiconnect/example-toolkit-scripts>.

These scripts demonstrate how to perform the following tasks.

- Create a Provider Organization
- Configure a catalog to use one or more gateways
- Create draft APIs and Products
- Publish Products
- Replace an existing published product with a new version
- Delete a product

- Create a Consumer Organization
- Create a new consumer app
- Subscribe the new app to an existing published product
- Stage a new product version
- Supersede the existing published product with the new one
- Migrate existing subscriptions from the old product to the new product

## Related information

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Working with OpenAPI extensions

Use the developer toolkit CLI **extensions** commands to manage OpenAPI extensions in your Catalogs or Spaces.

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API, depending on the version of IBM® API Connect you are using. An extension is imported into a Catalog, or as Space in a Catalog, then added to the API schema.

The commands described here are for importing OpenAPI extensions into a Catalog or Space, and viewing and managing them. After you have imported an OpenAPI extension, you can reference it in your API definitions; for details, see [Referring to an extension in an API definition](#).

Note: If Spaces are enabled in a Catalog, an OpenAPI extension that you import into one Space is imported into **all** Spaces; you cannot import an OpenAPI extension into an individual Space in the Catalog. Any subsequent updates are also applied to all Spaces.

Command name	Action	Syntax
<b>extensions clear</b>	<p>The <b>extensions:clear</b> command deletes all versions of an extension given the extension name.</p> <p>The parameters are as follows:</p> <p><b>--scope</b> Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:</p> <p><b>catalog</b> The command is to be applied to Catalog</p> <p><b>space</b> The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to <b>space</b> and supply the <b>--space</b> parameter.</p> <p><b>--catalog</b> or <b>-c &lt;catalog_name&gt;</b> Specifies a single Catalog with the Catalog name.</p> <p><b>--space</b> Specifies the name of a Space in a Catalog. The <b>--space</b> parameter is required if the Catalog has Spaces enabled, in which case you must also include <b>--scope space</b> in the command.</p> <p><b>--configured-gateway-service &lt;service_name&gt;</b> Specifies the name of the gateway service.</p> <p><b>--confirm &lt;catalog_name&gt;</b> Confirms the clear of the extension.</p> <p><b>&lt;extension_name&gt;</b> Specifies the name of the existing extension. Note: This is the extension name, not the file name.</p> <p><b>--org</b> or <b>-o &lt;organization_name&gt;</b> Specifies a single organization with the organization name.</p> <p><b>--server</b> or <b>-s &lt;management_server_endpoint&gt;</b> Specifies the server endpoint.</p>	<pre>apic extensions:clear --scope catalog space --catalog_  -c catalog_name --server   -s management_server_endpoint --configured-gateway-service gw_service_name --confirm catalog_name --org_  -o org_name [--space space]</pre> <p>Example:</p> <pre>apic extensions:clear --scope catalog --catalog catalog1 extension1 --server endpoint1 --configured-gateway-service gw_service1 --confirm catalog1 --org my_org</pre> <p>This example deletes all versions of the <b>extension1</b> extension that are in <b>catalog1</b> of the <b>my_org</b> organization, and are paired with <b>endpoint1</b>.</p>

Command name	Action	Syntax
<b>extensions clear-all</b>	<p>The <b>extensions:clear-all</b> command deletes all of the extensions in the specified Catalog or Space.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:</p> <p><b>catalog</b> The command is to be applied to Catalog</p> <p><b>space</b> The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to <b>space</b> and supply the <b>--space</b> parameter.</p> <p>--catalog or -c &lt;catalog_name&gt; Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The <b>--space</b> parameter is required if the Catalog has Spaces enabled, in which case you must also include <b>--scope space</b> in the command.</p> <p>--configured-gateway-service &lt;service_name&gt; Specifies the name of the gateway service.</p> <p>--confirm &lt;catalog_name&gt; Confirms the clear of the extension.</p> <p>--org or -o &lt;organization_name&gt; Specifies a single organization with the organization name.</p> <p>--server or -s &lt;management_server_endpoint&gt; Specifies the server endpoint.</p>	<pre>apic extensions:clear-all --scope catalog space --catalog -c catalog_name --server -s management_server_endpoint --configured-gateway-service gw_service_name --confirm catalog_name --org -o org_name [--space space]</pre> <p>Example:</p> <pre>apic extensions:clear-all --scope catalog --catalog catalog1 --server endpoint1 --configured-gateway-service gw_service1 --confirm catalog1 --org my_org</pre> <p>This example deletes all the extensions that are in <b>catalog1</b> of the <b>my_org</b> organization, and are paired with <b>endpoint1</b>.</p>
<b>extensions clone</b>	<p>The <b>extensions:clone</b> command creates a local definition file for each extension.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available:</p> <p><b>catalog</b> The command is to be applied to Catalog</p> <p><b>org</b> Sets the scope to the organization.</p> <p><b>space</b> The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to <b>space</b> and supply the <b>--space</b> parameter.</p> <p>--catalog or -c &lt;catalog_name&gt; Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The <b>--space</b> parameter is required if the Catalog has Spaces enabled, in which case you must also include <b>--scope space</b> in the command.</p> <p>--org or -o &lt;organization_name&gt; Specifies a single organization with the organization name.</p> <p>--server or -s &lt;management_server_endpoint&gt; Specifies the server endpoint.</p> <p>--configured-gateway-service &lt;service_name&gt; Specifies the name of the gateway service.</p>	<pre>apic extensions:clone --scope catalog space --catalog -c catalog_name --org -o org_name [-- space space] --server -s management_server_endpoint --configured- gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:clone --scope catalog --catalog catalog1 --org my_org --server endpoint1 --configured- gateway-service gw_service_1</pre> <p>This example clones the extensions that are in <b>catalog1</b> of the <b>my_org</b> organization, and are paired with <b>endpoint1</b>.</p>

Command name	Action	Syntax
<b>extensions create</b>	<p>The <b>extensions:create</b> command creates an extension in a Catalog or Space, given an extension definition file.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:</p> <p><b>catalog</b> The command is to be applied to Catalog</p> <p><b>space</b> The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to <b>space</b> and supply the <b>--space</b> parameter.</p> <p>&lt;extension_file&gt; Specifies the name of the extension file that contains the new information for your extension.</p> <p>Note: This is the OpenAPI file name, not the name of the extension.</p> <p>--server or -s &lt;management_server_endpoint&gt; Specifies the server endpoint.</p> <p>--catalog or -c &lt;catalog_name&gt; Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The <b>--space</b> parameter is required if the Catalog has Spaces enabled, in which case you must also include <b>--scope space</b> in the command.</p> <p>--org or -o &lt;organization_name&gt; Specifies a single organization with the organization name.</p> <p>--configured-gateway-service &lt;service_name&gt; Specifies the name of the gateway service.</p>	<pre>apic extensions:create --scope catalog space extension_file --server   -s management_server_endpoint --catalog   -c catalog_name [--space space] --org   -o org_name --configured-gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:create --scope catalog filename.yaml -- server endpoint1 --catalog catalog1 --org my_org --configured-gateway-service gw_service_1</pre> <p>This example creates an extension in <b>catalog1</b> of the <b>my_org</b> organization, paired with <b>endpoint1</b>, using the <b>filename.yaml</b> OpenAPI extension definition file.</p>
<b>extensions delete</b>	<p>The <b>extensions:delete</b> command deletes a specific version of an extension.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:</p> <p><b>catalog</b> The command is to be applied to Catalog</p> <p><b>space</b> The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to <b>space</b> and supply the <b>--space</b> parameter.</p> <p>--server or -s &lt;management_server_endpoint&gt; Specifies the server endpoint.</p> <p>--catalog or -c &lt;catalog_name&gt; Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The <b>--space</b> parameter is required if the Catalog has Spaces enabled, in which case you must also include <b>--scope space</b> in the command.</p> <p>&lt;extension_name&gt;:&lt;version_number&gt; Specifies the name and version number of the extension. Note: <i>extension_name</i> is the extension name, not the file name.</p> <p>--org or -o &lt;organization_name&gt; Specifies a single organization with the organization name.</p> <p>--configured-gateway-service &lt;service_name&gt; Specifies the name of the gateway service.</p>	<pre>apic extensions:delete --scope catalog space extension_name:version_number --catalog   -c catalog_name --org   -o org_name [-- space space] --server   -s management_server_endpoint --configured- gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:delete --scope catalog myextension:1.0.0 --catalog catalog1 --org orgmain --server endpoint1 --configured-gateway- service gw_service_1</pre> <p>This example deletes <b>myextension</b> version <b>1.0.0</b> that is in <b>catalog1</b> of the <b>orgmain</b> organization, and is paired with <b>endpoint1</b>.</p>

Command name	Action	Syntax
<b>extensions get</b>	<p>The <b>extensions:get</b> command retrieves the definition file for a specific version of an extension.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available:</p> <p><b>catalog</b> The command is to be applied to Catalog</p> <p><b>org</b> Sets the scope to the organization.</p> <p><b>space</b> The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to <b>space</b> and supply the <b>--space</b> parameter.</p> <p>--server or -s &lt;management_server_endpoint&gt; Specifies the server endpoint.</p> <p>--catalog or -c &lt;catalog_name&gt; Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The <b>--space</b> parameter is required if the Catalog has Spaces enabled, in which case you must also include <b>--scope space</b> in the command.</p> <p>&lt;extension_name&gt;:&lt;version_number&gt; Specifies the name and version number of the extension. Note: <i>extension_name</i> is the extension name, not the file name.</p> <p>--org or -o &lt;organization_name&gt; Specifies a single organization with the organization name.</p> <p>--configured-gateway-service &lt;service_name&gt; Specifies the name of the gateway service.</p>	<pre>apic extensions:get --scope catalog space extension_name:version_number --catalog   -c catalog_name --org   -o org_name [-- space space] --server   -s management_server_endpoint --configured- gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:get --scope catalog myextension:1.0.0 - -catalog catalog1 --org orgmain --server endpoint1 --configured-gateway- service gw_service_1</pre> <p>This example gets <b>myextension</b> version 1.0.0 that is in <b>catalog1</b> of the <b>orgmain</b> organization, and is paired with <b>endpoint1</b>.</p>
<b>extensions list</b>	<p>The <b>extensions:list</b> command lists all versions of an extension given the extension name.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available:</p> <p><b>catalog</b> The command is to be applied to Catalog</p> <p><b>org</b> Sets the scope to the organization.</p> <p><b>space</b> The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to <b>space</b> and supply the <b>--space</b> parameter.</p> <p>--server or -s &lt;management_server_endpoint&gt; Specifies the server endpoint.</p> <p>--catalog or -c &lt;catalog_name&gt; Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The <b>--space</b> parameter is required if the Catalog has Spaces enabled, in which case you must also include <b>--scope space</b> in the command.</p> <p>&lt;extension_name&gt; Specifies the name of the existing extension. Note: This is the extension name, not the file name.</p> <p>--org or -o &lt;organization_name&gt; Specifies a single organization with the organization name.</p> <p>--configured-gateway-service &lt;service_name&gt; Specifies the name of the gateway service.</p>	<pre>apic extensions:list --scope catalog space extension_name --catalog   -c catalog_name --org   -o org_name [-- space space] --server   -s management_server_endpoint --configured- gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:list --scope catalog my_extension -- -catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service_1</pre> <p>This example lists all versions of the extension <b>my_extension</b> that are paired with <b>endpoint1</b>, are in <b>catalog1</b>, and in the <b>my_org</b> organization.</p>

Command name	Action	Syntax
<b>extensions list-all</b>	<p>The <b>extensions:list-all</b> command lists all of the extensions that are available in a Catalog or Space. This is the default command if you enter only <b>apic extensions</b>.</p> <p>The parameters are as follows:</p> <p><b>--scope</b> Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available:</p> <p><b>catalog</b> The command is to be applied to Catalog</p> <p><b>org</b> Sets the scope to the organization.</p> <p><b>space</b> The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to <b>space</b> and supply the <b>--space</b> parameter.</p> <p><b>--server</b> or <b>-s</b> <i>&lt;management_server_endpoint&gt;</i> Specifies the server endpoint.</p> <p><b>--catalog</b> or <b>-c</b> <i>&lt;catalog_name&gt;</i> Specifies a single Catalog with the Catalog name.</p> <p><b>--space</b> Specifies the name of a Space in a Catalog. The <b>--space</b> parameter is required if the Catalog has Spaces enabled, in which case you must also include <b>--scope space</b> in the command.</p> <p><b>--org</b> or <b>-o</b> <i>&lt;organization_name&gt;</i> Specifies a single organization with the organization name.</p> <p><b>--configured-gateway-service</b> <i>&lt;service_name&gt;</i> Specifies the name of the gateway service.</p>	<pre>apic extensions:list-all --scope catalog space --catalog -c catalog_name --org -o org_name [--space space] --server -s management_server_endpoint --configured-gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:list-all --scope catalog --catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service1</pre> <p>This example lists the extensions that are paired with <b>endpoint1</b>, are in <b>catalog1</b>, and in the <b>my_org</b> organization.</p>
<b>extensions update</b>	<p>The <b>extensions:update</b> command replaces the information of an existing version of an extension with the information in an external file.</p> <p>The parameters are as follows:</p> <p><b>--scope</b> Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:</p> <p><b>catalog</b> The command is to be applied to Catalog</p> <p><b>space</b> The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to <b>space</b> and supply the <b>--space</b> parameter.</p> <p><b>--server</b> or <b>-s</b> <i>&lt;management_server_endpoint&gt;</i> Specifies the server endpoint.</p> <p><b>--catalog</b> or <b>-c</b> <i>&lt;catalog_name&gt;</i> Specifies a single Catalog with the Catalog name.</p> <p><b>--space</b> Specifies the name of a Space in a Catalog. The <b>--space</b> parameter is required if the Catalog has Spaces enabled, in which case you must also include <b>--scope space</b> in the command.</p> <p><b>--org</b> or <b>-o</b> <i>&lt;organization_name&gt;</i> Specifies a single organization with the organization name.</p> <p><b>--configured-gateway-service</b> <i>&lt;service_name&gt;</i> Specifies the name of the gateway service.</p> <p><b>&lt;extension_name&gt;:&lt;version_number&gt;</b> Specifies the name and version number of the extension. Note: <i>extension_name</i> is the extension name, not the file name.</p> <p><b>&lt;extension_file&gt;</b> Specifies the name of the extension file that contains the new information for your extension. Note: This is the OpenAPI file name, not the name of the extension.</p>	<pre>apic extensions:update --scope catalog space extension_name:version_number extension_file --catalog -c catalog_name --org -o org_name [--space space] --server -s management_server_endpoint --configured-gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:update --scope catalog extension1:1.0.0 extension2.yaml --catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service1</pre> <p>This example updates <b>extension1</b> version <b>1.0.0</b> that is paired with <b>endpoint1</b>, in <b>catalog1</b>, and in the <b>my_org</b> organization, from the file <b>extension2.yaml</b>.</p>

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

## Viewing application performance metrics

IBM® API Connect provides two ways to view application performance metrics for Node.js applications running locally: the built-in metrics dashboard and sending the data to third-party consoles or log files.

To view application performance metrics, you have to run your app with `apic start`. The metrics dashboard is available automatically. To use third-party consoles, you need to set an environment variable and have the console configured properly.

- [Viewing the application metrics dashboard](#)  
You can view the application performance metrics for a Node application by using IBM API Connect.
- [Viewing application metrics using third-party consoles](#)  
You can monitor your LoopBack® applications by obtaining metrics data. You can send the metrics data to a third-party console, a log file, or syslog.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

---

---

## Viewing the application metrics dashboard

You can view the application performance metrics for a Node application by using IBM® API Connect.

### Before you begin

---

To view application metrics for a Node application, the application project must either have:

- A main script file named `server.js`, `app.js`, or `index.js`.
- Or a `package.json` file that has a `main` property specifying the main application script file, for example:

```
"main": "server/myserver.js",
```

LoopBack application projects created with `apic loopback` automatically meet this requirement.

### About this task

---

When you run an application locally, you can view application performance metrics based on [Node application metrics](#) in the application metrics dashboard.

To view application metrics:

### Procedure

---

1. In the application project root directory, enter this command to run the application:

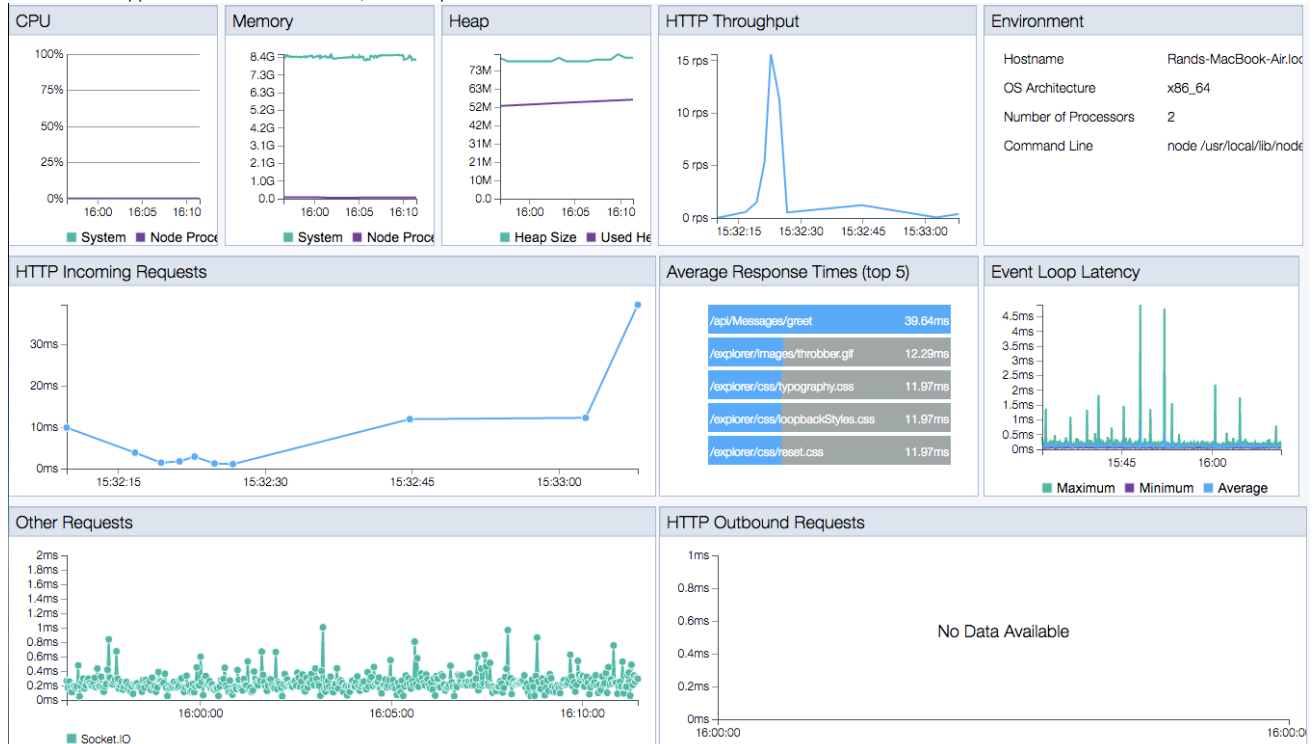

```
$ apic start
```

The console will display the following message:

```
Service <project-name> started on port 4001. Access the application dashboard at http://127.0.0.1:4001/appmetrics-dash  
Service <project-name> started on port 4002.
```

2. Open your browser to <http://127.0.0.1:4001/appmetrics-dash>.

You'll see the application metrics dashboard; for example:

The metrics are:

- **CPU** - Percentage of CPU time spent on the Node process.
- **Memory** - Amount of memory used by the Node process and available in the system.
- **Heap** - Amount of heap memory used and available.
- **HTTP Throughput** (requests per second) versus time.
- **HTTP Incoming Requests** - Response time for HTTP requests versus time.
- **Average Response Time** for the top five routes.
- **Event Loop Latency** (minimum / maximum / average) - Amount of time spent for an event loop "tick."
- **Other Requests**
- **HTTP Outbound Requests**

For more information on these metrics, see [Understanding the Application Metrics for Node.js dashboard](#).

Note: Node Report diagnostics are not currently available. The Node Report button is not operational in this release.

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details. For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## Viewing application metrics using third-party consoles

You can monitor your LoopBack® applications by obtaining metrics data. You can send the metrics data to a third-party console, a log file, or syslog.

You enable monitoring for an application by setting the **STRONGLOOP\_METRICS** environment variable. The value of the environment variable is a metrics URL that specifies the destination for the metrics data.

Enter the following command:

```
apic props:set STRONGLOOP_METRICS=metrics_url --remote --service app_name --organization org_name --server management_cluster_hostname_or_address
```

where:

- *metrics\_url* is the metrics URL that specifies the logging destination.
- *app\_name* is the value of the Name property of the App that references the collective to which the application is published.
- *org\_name* is the provider organization to which the application is published.
- *management\_cluster\_hostname\_or\_address* is the IP address or host name of the Management cluster to which the application is published.

The following sections provide details of the possible logging destinations.

## StatsD

StatsD is a simple protocol for log information together with a simple daemon (server) that aggregates and summarizes application metrics. The client communicates with the StatsD server by using the StatsD protocol, and the daemon then generates aggregate metrics and relays them to a graphing or monitoring backend. For more information on StatsD, see [StatsD, what it is and how it can help you](#).

The [StatsD](#) Node server has the following capabilities:

- Includes a built-in [Graphite](#) backend that can be local or [hosted](#).
- Supports other [backends](#) such [Zabbix](#), [DataDog](#), and so on.
- Supports custom backends.

Other metrics consumers, such as [DataDog](#), have agents that support the StatsD-protocol.

To use StatsD, set a metrics URL of the following form:

```
statsd://[host[:port]][/scope]
```

where:

- *host* is the name of the host where the StatsD server is running; the default value is `localhost`.
- *port* is the TCP port that the StatsD server is using; the default value is `8125`.
- *scope* is a string to scope or identify metrics; for example this might be the name of the application or module.

For example:

```
apic props:set STRONGLOOP_METRICS=statsd://myhost:1234/app1 --remote --service myApp --organization myOrg --server myhost.com
```

Example output:

```
my-app.cpu.user:0.00907|g
my-app.cpu.system:0.01664|g
my-app.cpu.total:0.0257|g
my-app.heap.used:10698193|g
my-app.heap.total:27423366|g
my-app.loop.count:127|c
```

## Hosted Graphite

---

To use Graphite, set a metrics URL of the following form:

```
graphite://[host[:port]]
```

where:

- *host* is the name of the host where the Graphite server is running; the default value is `localhost`.
- *port* is the TCP port the Graphite server is using; the default value is `2003`.

The metrics data is forwarded to hosted Graphite.

For example:

```
apic props:set STRONGLOOP_METRICS=graphite://myhost.com:1234 --remote --service myApp --organization myOrg --server myhost.com
```

## Splunk

---

To use Splunk, set a metrics URL of the following form:

```
splunk://[host]:port
```

where:

- *host* is the name of the host where the Splunk server is running; the default value is `localhost`.
- *port* is the TCP port that the Splunk server is using; you must provide a value because the protocol has no assigned port.

The metrics data is written to Splunk by using a UDP key-value protocol

For example:

```
apic props:set STRONGLOOP_METRICS=splunk://myhost.com:1234 --remote --service myApp --organization myOrg --server myhost.com
```

## Log file

---

To send metrics information to a log file, set a metrics URL of the following form:

```
log:[file]
```

where *file* is the name of the log file that you want to send the metrics information to. If you omit the file name, metrics information is sent to the console (stdout).

For example:

```
apic props:set STRONGLOOP_METRICS=log:myapp.log --remote --service myApp --organization myOrg --server myhost.com
```

## Syslog

---

To write metrics information using syslog, set a metrics URL of the following form:

```
syslog:[?[application=appName] [&priority=level]]
```

where:

- *appName* is any string; the default value is `statsd`.
- *level* is any of the following values:
  - LOG\_DEBUG
  - LOG\_INFO (the default)

- LOG\_NOTICE
- LOG\_WARNING
- LOG\_CRIT

For example:

```
apic props:set STRONGLOOP_METRICS=syslog:?application=myApp&priority=LOG_WARNING --remote --service myApp --organization myOrg --server myhost.com
```

**Note:** IBM API Connect 2018.x was EOS after 30 April 2023. See [support policy](#) for details.  
For a more recent version, see the [IBM API Connect 10.0.5.x and later product documentation](#).

## [Technical Preview] Searching for items in API Manager

Use the search feature in IBM® API Connect API Manager to easily locate items such as APIs, Catalogs, applications, and subscriptions.
